Tenofovir (yes vs. no)	0.96 (0.90-1.03)	0.238	0.97 (0.91-1.03)	0.307
Exposure to PIs (yes vs. no)	0.92 (0.86-1.00)	0.036	0.98 (0.91-1.04)	0.689
Time on PIs (vs. <5 years)				
5-10	0.96 (0.88-1.04)	0.331	0.98 (0.90-1.07)	0.697
10-15	0.95 (0.86-1.05)	0.331	1.00 (0.90-1.11)	0.950
>15	1.03 (0.94-1.14)	0.506	0.97 (0.87-1.08)	0.561

[Table 1. Univariate results for the association of independent variables and telomere length: exponentiated regression coefficients and 95% Confidence Intervals.]

Results: 200 patients included, 72% male, median age 49(IQR 45-54.5). In the univariate analysis, only age was associated with TL with both methods. Assuming results from qPCR, non-caucasian race, longer time of known HIV-infection and longer time on ART were associated with TL. However, with Southern these associations were not statistically significant, but higher CD4 count nadir and tobacco resulted associated, which had been non-significant when analyzed with qPCR. In the multivariate analysis significant predictors of TL, assuming qPCR results, were older age, older parental age at birth, non-caucasian race, and longer time of known HIV-infection. When using Southern, only older age and AIDS stage resulted independently associated to TL.
We compared the assays and we found no correlation between qPCR and Southern (R^2=0.077). The inter-assay coefficient of variation for qPCR was 8.75% and for Southern was 17.1%.
Conclusions: Risk factors for shorter TL in HIV patients were discordant depending on the method used for TL measurement. Southern blot results were less consistent that those obtained by qPCR. Inter-assay variability of Southern blot could play a role in the results we obtained.

WEPEB0533

Risks for COPD in HIV-infected individuals using symptom-based scores and spirometry

M. Hlatshwayo[1], A. Sahagun[2], R. Presti[1], J. Atkinson[3]
[1]Washington University School of Medicine, Infectious Diseases, St. Louis, United States, [2]Washington University, St. Louis, United States, [3]Washington University, Pulmonary and Critical Care Medicine, St. Louis, United States
Presenting author email: mhlatshwayo@wustl.edu

Background: Pulmonary complications are a significant source of morbidity in HIV-infected persons. Due to improved HIV infection treatment and high levels of smoking, chronic non-infectious respiratory co-morbidities have become prevalent among HIV-infected patients. Obstructive lung disease occurs in 7-9% of HIV+ persons, but a third of patients report respiratory symptoms. This project aims to define the relationship between symptom-based scores and pulmonary function tests, chest imaging, tobacco exposure and HIV disease severity.
Methods: HIV-positive and HIV-negative participants over age 30 who are current smokers with at least a 15 pack-year smoking history were enrolled. Pulmonary function tests were performed to assess for obstructive defect. St. George's Respiratory questionnaires (SGRQ) were administered and served as the primary source for symptom-based data. CT scans were performed to evaluate for underlying lung disease. All patients underwent basic demographic data collection as well as HIV disease specific information, including CD4 count and HIV viral load.

Parameter	HIV +	HIV –	p-value
Demographic Characteristics			
N	75	38	
Age, year	49.1 ± 8.0	56.1 ± 7.0	<0.001
Male, (%)	57 (77.3%)	24 (63.2%)	
African American (%)	60 (80%)	29 (76.3%)	
BMI	27.1 ± 6.0	28.8 ± 5.0	0.119
Respiratory Status			
Smoking Pack Year	75 (100%) 27.3 ± 17.9	38 (100%) 46.4 ± 14.4	<0.001
FEV1 % Pred	95.9 ± 15.0	88.3 ± 25.0	0.102
DLCO % Pred	58.3 ± 12.3	56. ±14.4	0.548
FEV1/FVC	0.79 ± 7.5	0.72 ± 13.6	0.008
<0.70 FEV1/FVC	9 (12%)	12 (31.6%)	
SGRQ			
Total	27.1 ± 19.9	28.5 ± 25.4	0.770

[Respiratory status in HIV+ and HIV- individuals]

Results: This study included 75 HIV-infected patients and 38 HIV-negative controls. HIV-infected patients had lower tobacco exposure than HIV-negative patients (27.1 versus 46.4 pack-years), were younger (49.1 ± 8.0 vs 56.1 ± 7.0), and had less obstruction as demonstrated by higher FEV1/FVC ratio. Despite this, symptom-based scores were similar (26.9±20.7 vs 28±25.4, p>0.05), suggesting symptomatology may be a result of complex interactions between smoking, HIV, and COPD. Within the HIV-infected population, SGRQ scores were found to be most associated with pack year smoking history. Decreased FEV1/FVC ratio was associated with age, suggesting that the prevalence of clinical obstruction is likely to increase as overall survival improves.
Conclusions: This study underlines the importance of long-term study in the smoking, HIV-infected population in order obtain a better understanding of the role of HIV, tobacco, and aging in respiratory symptoms and the development of chronic respiratory co-morbidities.

WEPEB0534

HIV-DNA burden in central memory CD4 T cells prior to ART initiation dictates immune recovery

L. Micci[1], E. Ryan[1], A. Pagliuzza[2], S. Aldrete[3], K. Delman[3], J. Estes[4], R. Sekaly[5], N. Chomont[2], M. Paiardini[6,7], V. Marconi[3]
[1]Emory University, Yerkes National Primate Research Center, Atlanta, United States, [2]University of Montreal, CRCHUM, Montreal, United States, [3]Emory University, School of Medicine, Atlanta, United States, [4]Leidos Biomedical Research, Frederick, United States, [5]Case Western Reserve University, Cleveland, United States, [6]Emory University School of Medicine, Department of Medicine, Atlanta, United States, [7]Emory University, Department of Microbiology and Immunology, Yerkes National Primate Research Center, Atlanta, United States
Presenting author email: mirko.paiardini@emory.edu

Background: Despite antiretroviral therapy (ART) fully suppress HIV replication, immune dysfunction - including incomplete recovery of CD4 T-cells - inflammation, and HIV persistence endure for many individuals. Based on a large set of preliminary data, we hypothesized that differential infection of specific CD4 T-cell subsets could further explain divergent CD4 recovery and maintenance of the HIV reservoir during ART.
Methods: 30 HIV-positive individuals were enrolled. Immunologic responders (IR) were defined as having CD4 counts >500 cells/μL ≤2 years after ART initiation; Immunologic non-responders (INR) as having CD4 counts < 350 cells/ μL up to 2 years after ART initiation. Before and during ART, the frequency of total (T) and integrated (I) HIV-DNA was measured in sorted blood naïve, central (CM), transitional (TM), and effector memory CD4 T-cells. T-cell levels, activation/proliferation states, and expression of co-inhibitory receptors (Co-IRs) were analyzed by flow cytometry.
Results: Median age of the cohort was 46; 90% were male and 82.8% were African-American. T and I HIV-DNA content in all CD4 T-cell subsets were significantly higher (P< 0.01) prior to ART and on-ART in INR than IR. The increased HIV-DNA content in INR was associated with higher levels of T-cell proliferation and activation, both at pre- and on-ART (P< 0.05). Expression of Co-IRs such as: PD-1 and TIGIT was significantly increased in memory CD4 T-cells of INR (P< 0.05), with the frequency of these Co-IR-expressing T-cells correlating with levels of I HIV-DNA. HIV-DNA contents in IR were significantly reduced (P< 0.01) on-ART as compared to pre-ART in all CD4 T-cell subsets. Remarkably, INR T and I HIV-DNA levels were significantly more stable in CM and TM CD4 T-cells between pre- and on-ART, and despite INR have been on-ART longer than IR.
Conclusions: When compared to IR, INR demonstrate higher levels of T-cell activation, Co-IRs expression, and viral burden in all memory CD4 T cell subsets, both prior to and on-ART. Furthermore, CM and TM CD4 T-cells harboring HIV-DNA persist longer during ART in INR. These data link levels of inflammation and CD4 T-cell infection prior to ART, particularly in long-lived CD4 T-cell subsets, with immune recovery and HIV persistence.

WEPEB0535

IL-27 is an independent predictor of IRIS: results of a multicenter international prospective study

I. Sereti[1], V. Sheikh[1], D. Shaffer[2,3], B. Agan[3,4], E. Gabriel[1], A. Pau[1], J. Wang[5], A. Rupert[5], N. Phanuphak[6], S. Tansuphaswadikul[7], J. Ananworanich[4,6], F. Sawe[2], IRIS NIAID/IDCRP Team Study Group
[1]National Institutes of Allergy and Infectious Diseases, Bethesda, United States, [2]Kenyan Medical Research Institute (KEMRI)/Walter Reed Program (WRP) Clinical Research Center, Kericho, Kenya, [3]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [4]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [5]Lei, Frederick, United States, [6]University, Bangkok, Thailand, [7]Bamrasnaradura Infectious Diseases Institute, Nonthaburi, Thailand
Presenting author email: isereti@niaid.nih.gov

Background: Immune reconstitution inflammatory syndrome (IRIS) is a complication of antiretroviral therapy (ART) initiation in lymphopenic HIV patients especially those with an opportunistic infection. Better understanding of pathogenesis and identification of predictors of IRIS is needed.

Methods: We enrolled HIV+ persons with CD4 count < 100 cells/μL starting ART in a prospective international multicenter study in US, Kenya and Thailand (NCT00286767), and followed them prospectively for 48 weeks for the development of IRIS or death. IRIS events were adjudicated by an independent committee using the ACTG criteria. Plasma biomarkers of inflammation, coagulation and tissue fibrosis, were measured. Multivariate and univariate logistic regression and competing risk regression, accounting for death prior to IRIS, were used to investigate the association of baseline biomarkers and the occurrence of and time to IRIS events.
Results: A total of 506 participants were enrolled (206 US, 200 Kenya, 100 Thailand) and there were 109 IRIS events observed and 48 deaths. IRIS patients had lower CD4 and CD8 T cell counts at baseline and lower Hg (Table A).

	All participants (N=506)	IRIS (N=97)	Non-IRIS* (N=409)	P-values
Age (years)	37.0 (31.0-45.0)	37.0 (30.0-44.0)	37.0 (32.0-45.0)	0.2938
Gender				0.8181
Female	199 (39.3%)	37 (38.1%)	162 (39.6%)	
Male	307 (60.7%)	60 (61.9%)	247 (60.4%)	
BMI	20.24 (17.90-23.48)	19.73 (17.85-23.37)	20.48 (17.90-23.48)	0.5121
Hgb	10.90 (9.60-12.40)	10.80 (8.90-11.20)	11.20(9.80- 12.70)	<.0001
CD4 T cells/μL	29 (11-56)	22 (7-49)	30 (12-58)	0.0253
CD8 T cells/μL	458 (273-740)	357 (235-656)	478 (281-747)	0.0287
HIV-RNA (log10 copies/mL)	5.30 (4.89-5.70)	5.37 (5.06-5.70)	5.28 (4.87-5.70)	0.0394

* If IRIS is not observed prior to 24 weeks, the subject drops-out prior to 24 weeks or dies before 24 weeks.

[Table A. Median values with IQR or percent are shown]

In logistic regression adjusting for baseline characteristics and all baseline biomarkers, lower Hg, higher L-27, higher BMI, higher HA and lower IL-17 were significantly associated with increased risk of IRIS. In a similarly adjusted competing risk of death model only lower Hg (P=0.003), higher IL-27 (P≤0.001) and higher BMI (p≤0.001) were associated with increased risk of IRIS. Patients with IRIS did not differ with respect to time to death within 48 weeks, after adjustment for other risk factors, however they had significantly higher CD4 increases from baseline to 24 weeks when compared to subjects without IRIS (P=0.01).
Conclusions: This novel strong association of IL-27 with IRIS may represent an important immune check-point between inflammation and immune regulation in treated HIV infection.

Switching from atripla (TDF/FTC/EFV) to eviplera (TDF/FTC/RPV) in virologically suppressed HIV-positive individuals without perceived neuropsychiatric complains improves sleep associated symptoms

J. Vera[1], M. Bracchi[2], J. Alagaratnam[3], J. Lwanga[4], C. Fitzpatrick[5], J. Fox[4], A. Winston[3], M. Nelson[2]
[1]Brighton and Sussex Medical School, Brighton, United Kingdom, [2]St Stephen's AIDS Trust, Chelsea and Westminster Hospital, London, United Kingdom, [3]Imperial College London, St Mary's Hospital, London, United Kingdom, [4]Guy's and St Thomas' NHS Trust, London, United Kingdom, [5]Brighton and Sussex University Hospitals NHS Trust, London, United Kingdom
Presenting author email: mark.nelson@chelwest.nhs.uk

Background: Central nervous system (CNS) toxicity is common with combination antiretroviral therapy and with efavirenz (EFV) use. Concerns exist regarding overt CNS toxicities that are not directly recognized by people with HIV (PWH) on EFV or clinicians, which could have an impact on quality of life. The aim of this study was to determine whether CNS symptoms improve in PWH without overt complains of CNS toxicities when switching off EFV
Methods: PWH receiving Atripla for at least 12 weeks with HIV RNA of < 40 copies /mL, and no self-reported CNS symptoms associated with EFV were enrolled in a prospective study of switching to Eviplera. CNS toxicities were evaluated using CNS and sleep questionnaires. The median CNS score derived from the sum of toxicity of all grades collected in the CNS questionnaires effects (Table), and the median Sleep score were calculated at baseline, and weeks 4 (primary endpoint), and 12 after switching to Eviplera. Cognitive function was assessed at baseline and week 4 using a comprehensive battery
Results: 41 patients (median age 47 y; interquartile range [IQR] 31, 68), predominantly male (92%) and of white ethnicity (80%) were recruited in this 4, and 12 weeks' analysis. A significant reduction in total CNS score was observed at 4 weeks (p=0.028) with a trend towards improvement at 12 weeks (p=0.064). Table summarises the changes in CNS side effects at week 4. Significant improvements in sleep scores at week 4 (p=0.005), and week 12 (p=0.002) were also observed. There were no significant changes in cognitive function at 4 weeks (p=>0.1). HIV-RNA remained undetectable in all patients and there were no clinically significant abnormalities in laboratory parameters throughout the study period
Conclusions: Switching from Atripla to Eviplera in virologically supressed PWH without perceived CNS symptoms, was well tolerated and improved overall CNS score and sleep associated symptoms

CNS side effect n (%)	Baseline n=41	4 weeks n=40	P value
Dizziness	10(24)	2(5)	0.005
Depression	14(34)	14(35)	0.65
Insomnia	23(56)	15(37)	0.05
Anxiety	14(34)	15(37)	0.31
Confusion/ Impaired concentration	14(34)	15(37)	0.52
Somnolence	9(22)	16(40)	0.02
Aggressive mood behaviour	9(22)	7(17)	0.65

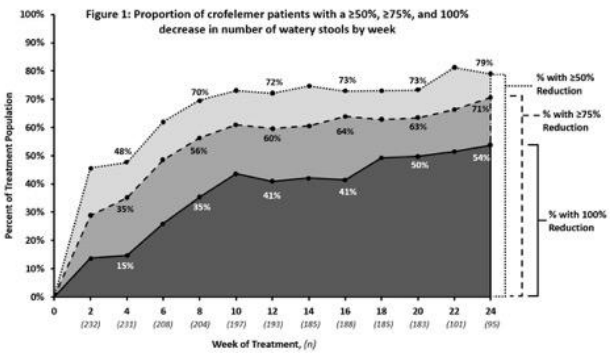
Long-term crofelemer use gives clinically relevant reductions in HIV-related diarrhea

R.D. MacArthur[1], P. Clay[2], G. Blick[3], R. Waltzman[4], M. Bell[5]
[1]Medical College of Georgia at Augusta University, Department of Medicine, Division of Infectious Diseases, Augusta, United States, [2]University of North Texas System, College of Pharmacy, Fort Worth, United States, [3]Health Care Advocates International, LLC, Stratford, United States, [4]Napo Pharmaceuticals, San Francisco, United States, [5]Cli, Biometrics, Fort Collins, United States
Presenting author email: rmacarthur@augusta.edu

Background: Although the incidence of infectious diarrhea has declined in HIV+ persons due to the increased use of antiretroviral therapy (ART), HIV- and ART-associated diarrhea affect millions of individuals. Crofelemer is the only drug approved for treatment of diarrhea in HIV+ persons. The ADVENT study responder definition typically required a 90% reduction in watery stools per week. Substantial clinical benefits may occur from a 50% or greater reduction in the frequency of diarrheal symptoms.
Methods: Daily diary data were analyzed retrospectively from all persons treated with crofelemer 125mg bid for up to 20 weeks. The average reduction in watery stools from baseline was determined by week. Chi-square tests were performed to detect differences based on protease inhibitor (PI) use or etiology of diarrhea (ART vs. HIV disease).
Results: The baseline diarrheal frequency was 20 watery stools per week among the 274 enrolled persons. Comparing week 4 to weeks 12 and 20, a 100% reduction in weekly watery stools occurred in 15%, 41%, and 50%, respectively; a 75% reduction occurred in 35%, 60%, and 63%, respectively; a 50% reduction occurred in 48%, 73%, and 73%, respectively (Figure 1). There were no significant differences at any week in the proportion of individuals with ≥50%, ≥75%, and 100% reductions based on PI use or diarrhea etiology.



[Figure 1. Proportion of crofelemer patients with a ≥50%, ≥75% and 100% decrease in number of watery stools by week]

Conclusions: Crofelemer use resulted in marked reductions of watery diarrhea in the majority of persons. Therapeutic regimens now include less use of PIs. Results were similar regardless of whether individuals were taking PIs, and whether the eti-

ology of the diarrhea was believed to be secondary to ART or HIV disease. The utility of crofelemer may have been underestimated based upon the previously reported responder analysis. Given the 36 million people worldwide with HIV, this analysis suggests that millions of HIV-infected persons may achieve clinically meaningful reductions in diarrhea by using crofelemer.

WEPEB0538

Metabolic complications in virally-suppressed perinatally HIV infected children and adolescents on tenofovir disoproxil fumarate

K. Swaby[1], R. Pierre[2], J. Moore[1], M. Miller[1], T. Evans-Gilbert[3], K. Lewis-O'connor[3], C. Christie-Samuels[2]
[1]*University Hospital of the West Indies, Child and Adolescent Health, Kingston, Jamaica,* [2]*University of the West Indies, Faculty of Medical Sciences, Kingston, Jamaica,* [3]*Ministry of Health, Kingston, Jamaica*
Presenting author email: kathryn.swaby@gmail.com

Background: Tenofovir Disoproxil Fumarate (TDF) can exhibit nephrotoxic effects (renal tubular defects, acute kidney injury, chronic kidney disease, bone mineral density changes) among HIV infected children on combination antiretroviral therapy (cART). Maturing perinatal infected children in Jamaica have been on cART since 2002, when the Jamaica Pediatric and Perinatal HIV/AIDS Program (JaPPAIDS) in collaboration with the Jamaica Ministry of Health implemented antiretroviral management protocols congruent with the WHO HIV treatment guidelines. Currently 30% are on 2nd line cART (protease inhibitor based) and have increased exposure to TDF. We aimed to characterize the metabolic disturbances associated with TDF exposure among this perinatally infected cohort.
Methods: Longitudinal data (demographic variables, HIV characteristics, antiretroviral exposure and duration) for HIV-infected children followed between January 1, 2003 and December 31, 2016 in infectious disease clinics of the JaPPAIDS were collated. Adverse outcomes (clinical, laboratory, radiographic) attributable to TDF were described using univariate analyses.
Results: Fourteen of 123 (11%) perinatally infected children exposed to TDF developed metabolic abnormalities. Of the 14, median age 14.50 years (range 8.68 - 20.62), 57% were male, 62% stunted, 50% underweight, 71% CDC category C. Mean duration on cART and TDF was 11.00 years (S.D. 2.06) and 1.58 years (S.D. 1.37) respectively; 78.5% had viral load < 20 copies/ml. Clinical features at presentation included bone pain (7/50%), associated limp (5/39%), altered gait (5/39%), pathologic fractures (5/36%) and asymptomatic (4/29%). Biochemical abnormalities were hypophostatemia (11/79%), elevated alkaline phosphatase (11/85%), acidosis (9/64%), hypokalemia (7/50%), hyponatremia (7/43%), elevated creatinine (7/58%), decreased GFR (7/58%), and urinary wasting of electrolytes. Outcomes were Fanconi syndrome (9/64%), acute kidney injury (3/21%) and metabolic bone disease (13/93%). Resolution of abnormalities followed optimizing cART (substitution of abacavir for TDF), electrolyte replacement for renal losses and vitamin D supplementation.
Conclusions: The maturing cohort of children and adolescents on cART (and achieving viral suppression) is at increased risk for adverse effects attributable to TDF. In the resource-limited setting screening for hypophosphatemia and other biochemical abnormalities is critical. Access to affordable, safer, and equally efficacious cART alternatives (tenofovir alafenamide) must be advocated for these settings which account for majority of paediatric HIV infection worldwide.

WEPEB0539

Switches due to adverse events from integrase inhibitors to other antiretroviral treatments in a clinical practice setting during a 3-year study

H. Knobel[1], M. de Antonio-Cuscó[2], S. Luque[2], E. González-Colominas[2], R. Guerri[1], E. Lerma[1], A. González[1], J. Villar[1], L. Sorlí[1], M. Montero[1], A. Guelar[1]
[1]*Hospital del Mar, Infectious Diseases, Barcelona, Spain,* [2]*Hospital del Mar, Pharmacy, Barcelona, Spain*
Presenting author email: hknobel@parcdesalutmar.cat

Background: Integrase inhibitors (INSTIs) are recommended as first-line antiretroviral treatment (ART) in HIV patients. However, differences in tolerability have been reported between different INSTIs. The purpose of the study was to assess the frequency and compare switches due to adverse events from the INSTIs in a clinical practice setting.
Methods: Retrospective study including all patients who switched from INSTIs to other ART from our cohort of 1,750 HIV-infected patients from January 2014-September 2016 at a University Hospital in Barcelona, Spain Switches involving other ART than INSTIs were not included. Collected data: demographics, hepatitis C virus-coinfection, previous and new ART. Adverse events were classified as: neuropsychiatric toxicity, dermatologic, gastrointestinal (GI) and others. Chi square test was used to compare proportions.
Results: In total 733 patients were treated with INSTIs during this period: 351 (47.9%) dolutegravir, 223 (30.4%) raltegravir and 159 (21.7%) elvitegravir. The INSTI was switched in 105 patients (14.3%), being in 40/105 (38.1%) due to adverse events, 30(75%) male, age: 49.9 (22-79) years, HCV: 11 (27.5%). Some patients experienced more than one adverse event. The other causes of switching were: Simplification: 42 (40%), low level viremia 18 (17.1%), drug-interactions: 3 (2.9%) and pregnancy 2 (1.9%).

	Raltegravir n=223	Elvitegravir n=159	Dolutegravir n=351	P
Switches due to adverse events (n=40)	8(3.6%)	7(4.4%)	25(7.1%)	<0.001
Adverse events				
Neuropsychiatric	3(1.3%)	1(0.6%)	9(2.6%)	0.002
Dermatologic	0(0%)	0(0%)	5(1.4%)	0.001
Gastro-intestinal	1(0.4%)	2(1.3%)	8(2.3%)	<0.001
Others	4(2.2%)	4(2.5%)	3(0.9%)	<0.001

[Table 1]

Conclusions: Compared with the other integrase inhibitors dolutegravir has a higher proportion of switching due to adverse effects However, only 2.6% of patients treated with dolutegravir had to be discontinued because of central nervous system adverse events, a percentage lower than that reported in other cohorts.

WEPEB0540

An analysis of neurologic and psychiatric adverse events of subjects receiving the investigational HIV-1 maturation inhibitor (MI) GSK3532795/BMS-955176

J. Gan[1], T.P. Dumitrescu[2], B. Shepherd[3], H. Sevinsky[4], J. Coumbis[5], K. Barker[3], S. Min[6], M. Lataillade[7], S.R. Joshi[7]
[1]*GlaxoSmithKline, Upper Providence, United States,* [2]*GlaxoSmithKline, Upper Merion, United States,* [3]*GlaxoSmithKline, Stockley Park, United Kingdom,* [4]*ViiV Healthcare, Upper Providence, United States,* [5]*Bristol-Myers Squibb, Hopewell, United States,* [6]*ViiV Healthcare, Research Triangle Park, United States,* [7]*ViiV Healthcare, Wallingford, United States*
Presenting author email: samit.r.joshi@viivhealthcare.com

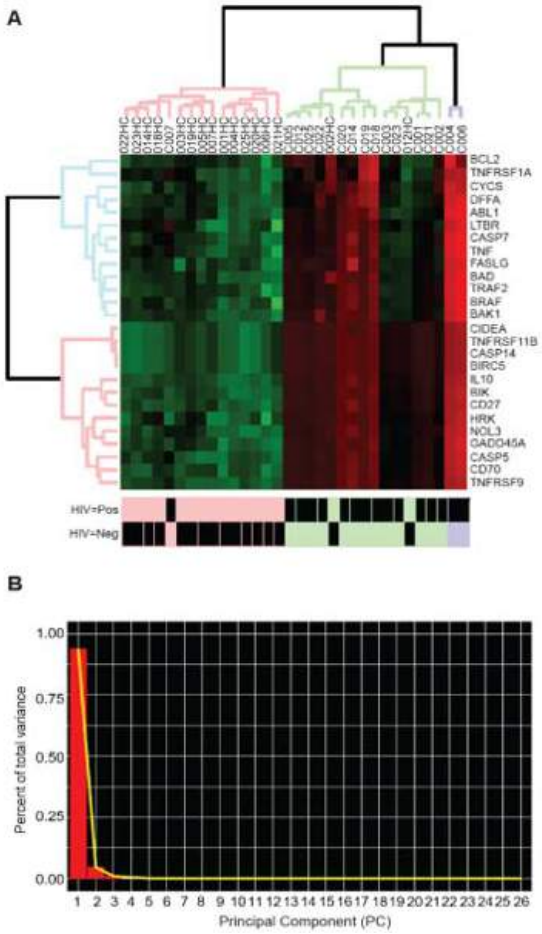
Background: GSK3532795/BMS-955176 has been evaluated through Phase 2b clinical trials. In Study 206220 evaluating the electrocardiographic effects (TQTS) of GSK3532795, two subjects receiving supratherapeutic doses of GSK3532795 developed neuropsychiatric serious adverse events (SAE). These isolated SAEs prompted an analysis of neuropsychiatric adverse events (AEs) across all clinical trials.
Methods: Thirteen trials involving healthy and HIV-1 infected adults receiving different GSK3532795 doses (5 mg QD to 240 mg BID) for varying duration (single dose to a maximum of 71 weeks), comparator drug, or placebo were included in this analysis which involved:
1) a clinical summary analysis of neuropsychiatric AEs and
2) an exploratory exposure-response (ER) analysis of most neuropsychiatric AEs in two trials: TQTS (Study 206220) and a Phase 2b study in HIV-1 infected adults (Study 205891).
Results: A total of 784 subjects received at least one dose of GSK3532795; 259 subjects received placebo/other treatments. For neurologic AEs, Grade 1 headache predominated in both groups. For psychiatric AEs, sleep abnormality AEs (abnormal dreams, insomnia, nightmare, sleep disorder, and difficulty sleeping) were the most common in both treatment groups but individually occurred at variable rates across studies. Other psychiatric AEs were infrequent and broadly similar across the two groups. Grade 3 AEs were rare and consisted of two cases at supra-therapeutic doses (240 mg QD and BID) in the TQTS; a single report of acute psychosis in one subject and another subject with homicidal ideation, suicidal ideation, and tachyphrenia. Finally, one HIV-1 infected subject had a Grade 3 nightmare (Study 205892). The ER analysis showed an increasing proportion of subjects having most neuropsychiatric AEs with increasing dose of GSK3532795. However, no significant ER relationship between GSK3532795 AUC(0-24) (Study 206220) or steady state AUC (Study 205891) and neuropsychiatric AEs was observed.
Conclusions: The overall incidence rates of neuropsychiatric AEs (mostly Grade 1) were similar between the GSK3532795 and placebo/comparator treatment arms. No significant ER relationship for neuropsychiatric AEs was observed with GSK3532795. Combined, the data from 13 clinical trials does not suggest a clinically significant signal for neuropsychiatric AEs in adults who receive the MI, GSK3532795.

WEPEB0541

Upregulation of apoptosis pathway genes in peripheral blood mononuclear cells of HIV treatment-experienced individuals with mitochondrial toxicity

E. Paintsil[1], Y. Foli[1], M. Li[1], M. Ghebremichael[2]
[1]*Yale University, New Haven, United States,* [2]*Harvard Medical School, Boston, United States*
Presenting author email: elijah.paintsil@yale.edu

Background: The therapeutic benefit of antiretroviral therapy (ART) is sometimes limited by long-term ART-induced mitochondrial toxicity. There is no universally accepted laboratory tests or clinical definitions that serve as gold standards for diagnosis of ART-induced toxicity. Apoptosis has been implicated as playing a role in ART toxicity. We sought to investigate the differential expression of genes of the apoptosis pathway in HIV-infected patients with ART-associated mitochondrial toxicity versus HIV-uninfected individuals.
Methods: This is a retrospective analysis of data and specimens collected during a prospective, case-control study of ART-induced mitochondrial toxicity. Cases were HIV-infected individuals with ART-associated mitochondrial toxicity (n=16), and controls were HIV-uninfected individuals (n=16). We used an 84-gene Human Apoptosis PCR Array to investigate the differential expression of genes of the apoptosis pathway in peripheral blood mononuclear cells (PBMCs) of study participants.
Results: We identified 26 out of 84 genes that were differentially expressed between cases and controls (Figure 1). Of the 26 genes, 18 were pro-apoptotic (TNFRSF1A, CYCS, DFFA, ABL1, LTBR, CASP7, FASLG, BAD, TRAF2, BAK1, CIDEA, TNFRSF11B, CASP14, BIK, GADD45A, CASP5, CD70, and TNFRSF9); 5 were anti-apoptotic (BCL2, BRAF, BIRC5, IL10, and NOL3); and 3 with overlapping functions (CD27, HRK, and TNF). Using penalized regression analysis, we identified two genes (DFFA and TNFRSF1A) which contributed to the differences in the gene profile between cases and controls. These two genes classified 75% of study participants correctly into either cases or controls.



[Differentially expressed apoptosis pathway genes]

Conclusions: Our findings suggest that apoptosis may be part of the causal pathway of ART-associated mitochondrial toxicity. Further studies are need to assess the utility of DFFA and TNFRSF1A as biomarkers for ART-induced mitochondrial toxicity. If validated, a quantitative PCR assay of these genes could be used to detect and monitor ART-induced mitochondrial toxicity.

WEPEB0542

Uptake of HLA-B*5701 screening and its impact on clinically suspected hypersensitivity reaction to abacavir in the OPERA® Observational Database

K. Mounzer[1], R. Hsu[2], C. Henegar[3], J. Fusco[4], V. Vannappagari[5], C. Stainsby[6], M. Shaefer[5], G. Fusco[3]
[1]*Philadelphia FIGHT, Philadelphia, United States,* [2]*AIDS Healthcare Foundation, New York, United States,* [3]*Epi, Durham, United States,* [4]*Epividian, Inc., Durham, United States,* [5]*ViiV Healthcare, Research Triangle Park, United States,* [6]*GlaxoSmithKline, London, United Kingdom*
Presenting author email: vani.x.vannappagari@viivhealthcare.com

Background: Early phase trials with abacavir sulfate identified a hypersensitivity reaction (HSR). HLA-B*5701 screening to identify patients at risk for HSR entered clinical practice in 2008. This analysis assesses the use and effectiveness of screening in real world practice.
Methods: HIV+ individuals initiating their first abacavir-containing regimen between 01/01/1999 and 01/01/2016 were identified in the OPERA cohort, a collaboration of 79 clinics in 15 US states. Each patient was observed from regimen start until discontinuation of abacavir, loss to follow-up, death, or data freeze (07/31/2016). Patient characteristics, HLA-B*5701 screening, and HSR events were assessed descriptively and compared by testing period (pre-screening; 01/01/1999-08/14/2008 versus post-screening: 08/15/2008-01/01/2016).
Results: Out of 71,627 HIV+ patients, 3,215 from the pre-screening period and 6,404 from the post-screening period qualified for analysis. The proportion of patients screened for HLA-B*5701 ever and prior to abacavir initiation has steadily increased over time. Of patients initiating abacavir-containing regimens in 2015 (the last full year of data), 84.3% were screened prior to abacavir prescription, compared to 40% in 2008 upon approval of the test. Using diagnoses of HSR or symptoms of HSR, 463 (4.8%) patients were identified for review by a physician panel for HSR events (7.2% pre-screening period versus 3.5% post-screening period (p<0.0001)). Following adjudication by the physician panel, whom considered clinical information including symptomatology, potential confounders (such as concurrent medications) and event progression, rates fell to 2.8% pre-screening and 1.6% post-screening (p<0.0001). When these events were limited to those determined to be definite or probable, rates were further reduced to 1.6% pre-screening and 0.5% post-screening (p=0.0005), and median time to event was 23 days (IQR: 13, 36 days) and did not differ between groups.

*[Figure. Proportion of patients HLA-B*5701 screened and definite/probable HSR events by year of abacavir initiation]*

Conclusions: HLA*B-5701 screening has increased steadily from its introduction in 2008 through 2015. Hypersensitivity reactions have decreased in the same time period.

WEPEB0543

Association of sub-optimal antiretroviral therapy (ART) adherence with inflammation in virologically-suppressed, HIV-infected individuals: a sub-analysis of the strategies for management of antiretroviral therapy (SMART) study

J.R. Castillo-Mancilla[1], A.N. Phillips[2], J.D. Neaton[3], J. Neuhaus[4], J.D. Lundgren[5], E.M. Gardner[6], INSIGHT SMART Study Group
[1]*University of Colorado-AMC, Medicine/Infectious Diseases, Aurora, United States,* [2]*University College London, Epidemiology and Biostatistics, London, United Kingdom,* [3]*University of Minnesota, School of Public Health, Minneapolis, United States,* [4]*University of Minnesota, Minneapolis, United States,* [5]*University of Copenhagen, Copenhagen, Denmark,* [6]*Denver Health Medical Center, Denver, United States*
Presenting author email: edward.m.gardner@dhha.org

Background: Observational cohort data suggest that variations in ART adherence are associated with enhanced inflammation, even in virologically suppressed individuals. We aimed to evaluate the association of ART adherence with inflammation and activation of coagulation in virologically-suppressed, HIV-infected individuals on ART in the SMART study.
Methods: We evaluated baseline 7-day self-reported adherence and plasma levels of interleukin (IL)-6, D-dimer and high-sensitivity C-reactive protein (hsCRP) in stored samples from virologically-suppressed (< 200 copies/mL), HIV-infected individuals on ART upon enrollment into the SMART study. Adherence was labeled as sub-optimal if a participant reported not taking "all of my pills" in the preceding 7-days for at least one antiretroviral medication. We utilized multivariable linear regression analysis to evaluate the association between adherence and levels of biomarkers at baseline. Data are presented as fold differences in biomarker concentrations in individuals who were sub-optimally vs. 100% adherent.
Results: A total of 3,056 participants (1519 White, 696 Black, 570 Hispanic, 200 Asian, 71 other race) were virologically-suppressed and had 7-day adherence data available at baseline. Of these, 404 (13%) reported being sub-optimally adherent. Median age was 44 (IQR 38-51) years. ART included a PI but not an NNRTI (38%), an NNRTI but not a PI (45%) or other (17%). The number of participants with available plasma levels of each biomarker is shown in the Table. Participants reporting sub-optimal adherence had higher plasma concentrations of IL-6 and D-dimer compared to participants who did not report any missed doses (Table).
Conclusions: Sub-optimal, self-reported 7-day ART adherence was associated with higher concentrations of IL-6 and D-dimer in virologically-suppressed, HIV-infected individuals on ART. Among the possible explanatory mechanisms behind this association could be that sub-optimal adherence triggers episodes of low-level HIV replication (i.e., below the limit of detection of clinical assays), or represents episodes of missed/unmeasured viremia prior to a visit. Maximization of ART adherence beyond viral suppression may result in improved residual inflammation.

Biomarker	Number of Participants	Fold higher level compared to 100% adherence[b]	95% CI	P-value
IL-6	2,776	1.09	(1.01-1.18)	0.02
D-dimer	2,763	1.11	(1.01-1.22)	0.03
hsCRP	2,793	1.04	(0.91-1.17)	0.58

[a]Adjusted for covariates including age, race, gender, body mass index, time on ART, risk group, baseline viral load, baseline and nadir CD4 cells, hepatitis B or C co-infection, smoking and regimen type. [b]100% adherence defined as no report of any missed doses in the preceding 7-day period.

[Table. Adjusted[a] fold difference in baseline inflammatory biomarker plasma concentrations in sub-optimally adherent, virologically-suppressed, HIV-infected individuals on ART enrolled in SMART.]

Presenting author email: c-psomas@chu-montpellier.fr

Background: The global immune activation (IA) observed in HIV-1-infected individuals is reduced under antiretroviral therapy, but persists, driven by various causes including the presence of HIV and coinfections, microbial translocation, metabolic disorders, Treg deficiency, immune senescence and eventually CD4+ T cell lymphopenia. IA fuels various morbidities in HIV patients with suppressed viremia. We hypothesized that, depending on the causes at work, virologic responders could present with different IA profiles (IAP), and develop thereby different IA-driven comorbidities.
Methods: To test this hypothesis, using 68 soluble and cell surface markers, we quantified activation in circulating CD4+ and CD8+ T cells, B cells, monocytes, NK cells, neutrophils, and endothelial cells, as well as inflammation in 120 HIV-1-infected adults over 45 years of age, aviremic for a mean duration of 102 ± 47 months and with a mean CD4 count of 688 ± 326 CD4+ T cell/microL. We performed a hierarchical clustering analysis to classify these patients according to their IAP. Lipopolysaccharide Binding Protein (LBP) levels were compared using Mann-Whithey test. Logistic regressions were carried out in order to study the relationship between IAP and consequences of IA.
Results: Five different IAP were identified. Regarding the causes of IA, an increase in plasma level of LBP, a marker of microbial translocation, was observed in patients with IAP4 as compared with the other patients (33.9 ± 9.3 and 29.8 ± 8.7 microg/mL, respectively, p = 0.01). Regarding the consequences of IA, IAP2 was linked to marks of metabolic syndrome and with hyperinsulinemia (OR 12.2 [95% CI 1.8-82.9], p = 0.01). Moreover, a past history of Kaposi Sarcoma was more frequent in patients with IAP3, compared with the other groups (OR 4.2 [95% CI 1.2-15.3], p = 0.03).
Conclusions: Various causes of IA might be responsible for the different IAP observed in treated HIV-1 infection, that could drive different comorbidities. Longitudinal studies could unveil biomarkers predictive of these comorbidities. Uncovering molecular mechanisms responsible for the causative link between IAP and comorbidities could unveil new therapeutic targets.

WEPEB0545

Associations between baseline inflammatory markers, lung function, and immediate vs. deferred ART in the START pulmonary substudy

A.D. Zanotto[1], G. Collins[1], J.V. Baker[2], M. Czarnecki[3], E. Loiza[4], V. Papastamopoulos[5], R. Wood[6], D.E. Nixon[7], K.M. Kunisaki[8], INSIGHT START Pulmonary Substudy Group
[1]*University of Minnesota, Minneapolis, United States,* [2]*Hennepin Country Medical Center, Minneapolis, United States,* [3]*INS, Wroclaw, Poland,* [4]*IDEAA Foundation, Buenos Aires, Argentina,* [5]*Evaggelismos General Hospital, Athens, Greece,* [6]*Desmond Tutu HIV Foundation, Cape Town, South Africa,* [7]*Vir, Richmond, United States,* [8]*Minneapolis VA Health Care System, Minneapolis, United States*
Presenting author email: zanot008@umn.edu

Background: HIV is an independent risk factor for chronic obstructive pulmonary disease (COPD). Mechanisms by which HIV leads to COPD are not clear, but systemic inflammation is one potential factor. In the START Pulmonary Substudy, immediate ART had no effect on the rate of lung function decline (slope of forced expiratory volume in 1-second [FEV1]) compared to deferred ART. We hypothesized that inflammation would be associated with worse FEV1 at baseline, faster FEV1 decline, and modify FEV1 slope responses to immediate versus deferred ART.
Methods: We enrolled ART-naive, HIV+ adults >25 years old, with baseline CD4+ T-cell counts >500 cells/mm3. Among the 1,026 participants in the study, inflammatory biomarkers (IL-6, hsCRP, and D-dimer) were measured from baseline specimens prior to randomization in 936 (91%). Spirometry was measured at baseline and annually. We tested for associations between biomarker concentrations and FEV1 %predicted at baseline and FEV1 slope during follow-up, adjusted for smoking status. We secondarily tested for a 3-way interaction between baseline inflammatory biomarker concentration, slope of FEV1, and treatment assignment (immediate vs. deferred ART).
Results: Cohort characteristics included (medians): age 36 years, 28% female, CD4+ T-cell count 646 cells/mm3, 29% current smokers, and FEV1 3.4L (97% of predicted normal). Higher baseline biomarker concentrations were associated with lower FEV1 %predicted at baseline but not subsequent FEV1 slope (Table). We found no significant interaction between the randomized treatment arm (immediate vs. deferred ART), baseline inflammatory biomarker concentrations and FEV1 slope for IL-6 (p=0.21), hsCRP (p=0.83), or D-dimer (p=0.73).

	Baseline FEV 1 %predicted	Baseline FEV 1 %predicted	Longitudinal FEV1 slope, mL/year	Longitudinal FEV1 slope, mL/year
biomarker (log 2)	β	p-value	β	p-value
IL-6 (pg/mL)	-1.03	0.04	-0.18	0.96
hsCRP (mcg/mL)	-0.98	<0.001	1.42	0.41
D-dimer (mcg/mL)	-1.62	0.003	-0.63	0.85

[Multivariable linear regression of lung function]

Conclusions: Higher concentrations of IL-6, hsCRP, and D-dimer were each associated with lower lung function at study entry, but not with subsequent rate of lung function decline nor with response to immediate vs. deferred ART. Reasons for the cross-sectional association, but lack of longitudinal association may include limited power, reverse causality, or residual confounding even after adjusting for smoking. We conclude that these particular biomarkers do not appear to have strong utility for predicting lung function decline or lung function responses to ART.

WEPEB0546

Progesterone and mitochondrial DNA (mtDNA) levels in placenta are inversely correlated among HIV+ and HIV- women in the CARMA-PREG cohort

M. Salvador Ordoño[1], I. Gadawski[1], B. Sattha[1], D.M. Money[1,2,3], H.C.F. Côté[1,2,4], I. Boucoiran[1,5,6], and the CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA)
[1]University of British Columbia, Vancouver, Canada, [2]Women's Health Research Institute, Vancouver, Canada, [3]BC Women's Hospital & Health Centre, Vancouver, Canada, [4]Centre for Blood Research, Vancouver, Canada, [5]CHU Sainte-Justine, Montreal, Canada, [6]CIHR Canadian HIV Trials Network, Montreal, Canada
Presenting author email: isabelle@boucoiran.fr

Background: Women living with HIV are at increased risk of preterm delivery, a contributor to infant morbidity and mortality. Synthesis of pregnenolone, the precursor of progesterone which is central to pregnancy maintenance, is dependent on placental mitochondrial function. Given that many antiretrovirals (ARVs) can affect mitochondrial function, we investigated the associations between placenta mtDNA content, an indicator of mitochondrial health, placenta progesterone levels, and preterm delivery, as these may be related.
Methods: Placental tissue, as well as clinical and sociodemographic data, were collected for pregnant women enrolled in the prospective Canadian cohort CARMA-PREG. Placental progesterone levels were measured by ELISA while mtDNA content was quantified by monochrome multiplex qPCR. Univariate associations between both progesterone and mtDNA measures and the following factors: preterm delivery (< 37w gestation, any etiology), ARV type (unboosted PI vs. ritonavir-boosted PI), and ARV backbone (AZT/3TC vs. ABC/3TC vs. other) during pregnancy were investigated using non-parametric tests.
Results: Placenta tissue was obtained from 136 HIV-infected and 60 HIV-uninfected participants aged 18-45y, of whom 24 (18%) and 9 (15%) had a preterm delivery, respectively. The majority of women living with HIV received a ritonavir-boosted PI (66% vs. 23% non-boosted PI vs. 11% other). HIV-exposed uninfected infants were born at an earlier gestational age (p=0.017), with a lower birth weight (p=0.011) than controls. Within this cohort sample, preterm delivery was high in both groups and showed no association with HIV status, placenta mtDNA or progesterone.
However, placenta mtDNA and progesterone levels were significantly negatively correlated to one another (n=196, rho=-0,242, p<0.0001). In addition, higher mtDNA showed some association with having received a non-boosted PI (vs. boosted PI, p=0.039). The ARV backbone showed no associations.
Conclusions: These preliminary unadjusted analyses suggest a relationship between lower levels of progesterone in the placenta and increased levels of mtDNA, possibly reflecting a compensatory mechanism for mitochondrial dysfunction. Possible associations with preterm delivery etiology and pregnancy complications will be examined once the sample size is larger.

WEPEB0547

MSM sexual orientation predicts stool microbiota composition in the Chicago LAMBCHOP trial

B. Williams[1,2], G. Chlipala[3], A. Hotton[4], A. Sigman[2], S. Keating[5], G. Huhn[6,7,8]
[1]Rush University, Infectious Disease, Chicago, United States, [2]Ruth M Rothstein CORE Center of Cook County, Chicago, United States, [3]University of Illinois Chicago, Medicinal Chemistry and Pharmacognosy, Center for Pharmaceutical Biotechnology, College of Pharmacy, Chicago, United States, [4]University of Illinois Chicago, Chicago, United States, [5]Blood Systems Research Institute, San Francisco, United States, [6]Rush University Medical Center, Infectious Disease, Chicago, United States, [7]Ruth M Rothstein CORE Center, Chicago, United States, [8]Stroger Hospital of Cook County, Internal Medicine, Chicago, United States
Presenting author email: brettwilliams0@gmail.com

Background: Microbial translocation (MT) from the gut and concomitant immune activation (IA) in controlled HIV infection are associated with mortality in HIV. Attempts to reduce MT/IA have focused on "normalizing" gut microbiota and improving gut barrier function. We present the microbiome analysis of the LAMBCHOP trial, which showed no improvement in MT/IA biomarkers with orally administered lubiprostone, a luminal agent that stimulates recovery of mucosal barrier function via restoration of tight junction protein complexes.
Methods: Stool was collected from 16 HIV infected individuals with suboptimal CD4 recovery and undetectable viral load for 48 weeks, before and after 4 weeks of lubiprostone. Sequence data were processed using a QIIME pipeline. Shannon and Bray-Curtis indices were calculated with default parameters in R using the vegan library. The rarefied genera data, taxonomic level 6, were used to calculated both indices. For Bray-Curtis indices, the rarefied data were filtered to remove any taxon with an abundance of less than 1% of the total abundance in the dataset.
Results: Median age was 49.5 years and median CD4 was 333. 13 were male, 6 were African American, 5 Hispanic and 5 caucasian. 8 were men who have sex with men (MSM). At baseline no taxa correlated, after correction for false discovery rate, with markers of MT/IA: iFABP, zonulin, IL6, sCD163, sCD14 or CRP. MSM status predicted microbiome composition but alcohol/drug use, smoking and pneumocystis prophylaxis did not. After four weeks of lubiprostone the MSM and non-MSM microbiota were more similar, though lubiprostone had no substantial effect on individual taxa. MSM as a risk factor did not predict baseline levels of MT/IA.
Conclusions: MSM status appears to have a substantial effect on gut microbiota. Lack of improvement in MT/IA with lubiprostone may be related to failure to change the gut microbiota, though no particular taxa appeared to drive MT/IA.

Carotid intima-media thickness in virologically suppressed HIV-infected Thai patients

S. Pleumkanitkul[1], O. Putcharoen[1], A. Chutinet[2], A. Avihingsanon[3], K. Ruxrungtham[4]
[1]Chulalongkorn University, Division of Infectious Disease, Bangkok, Thailand, [2]Division of Neurology, Bangkok, Thailand, [3]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]Division of Allergy and Immunology, Bangkok, Thailand
Presenting author email: psuwapan@gmail.com

Background: The combination antiretroviral therapy (cART) contributes to a significant decline not only in AIDS-related mortality but also the incidence of opportunity infections and AIDS related malignancy. HIV-infected patients with good response to cART have a closer gap of life expectancy to uninfected population. However, the incidences of non-communicable diseases (NCDs), e.g. cardiovascular diseases (CVDs), in HIV infected patients are increasing. Previous studies showed carotid intima-media thickness (cIMT), one of predictors for the risk of CVDs and mortality, was higher in HIV-infected patients than uninfected population. However, there has been no study for a comparison of cIMT of HIV-infected and uninfected adults in Asian population.
Methods: A cross-sectional study was conducted at The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT) and King Chulalongkorn Memorial Hospital, Bangkok, Thailand. The primary endpoint was the difference in cIMT between HIV-infected patients and uninfected controls. The risk factors for increment of cIMT were determined.
Results: Results: A total 90 adults were enrolled, 60 were HIV-infected. Ninety-six percent of HIV-infected had undetectable viral load with median CD4 of 602 (IQR: 487-811) cells/mL. Eighty-three percent of patients were receiving PI-based regimen. The overall median (IQR) age was 54.1 (52-60) years, and the male-to-female ratio was 1.1:1. The mean overall cIMT of common carotid arteries were not different between groups (0.665 mm vs. 0.649; p=0.277). Hypertriglyceridemia was more prevalent in HIV infected patients (48.3% vs. 26.7%; p=0.049). Serum

high-sensitivity C-reactive protein levels were comparable between groups (1.59 vs. 1.46 mg/dl; p=0.325) and not correlated with increase in cIMT. In univariate analysis, male sex, waist hip ratio, smoking and hypertension were found to be correlated with increased cIMT. In multivariate analysis, male sex and hypertension were correlated with increased cIMT.
Conclusions: Virologically controlled HIV infected patients had comparable cIMT to uninfected Thai adults. HIV-infected patients had significant more hypertriglyceridemia, due to long-term use of protease inhibitors. In this study, traditional risk factors for atherosclerosis correlated with increased cIMT but not HIV risk factor. Interventions to control these risk factors are required to reduce in risk of CVD in HIV-infected patients.

WEPEB0549

Site capacity to screen for and manage renal dysfunction among HIV-infected persons receiving care in low- and middle-income countries (LMICs)

C. Mugglin[1], L. Mulenga[2,3], A. Mweemba[2,3], C. Wyatt[4], Y. Abo[5], A. Avihingsanon[6,7], K. Wools-Kaloustian[8], C. Mc Gowan[9], D. Nash[10], M. Egger[1], C.W. Wester[9], on behalf of IeDEA
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [2]University of Zambia, School of Medicine, Lusaka, Zambia, [3]University Teaching Hospitals, Lusaka, Zambia, [4]Icahn School of Medicine at Mount Sinai, New York, United States, [5]CMSDS, Abidjan, Cote D'Ivoire, [6]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [7]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [8]Indiana University School of Medicine, Indianapolis, United States, [9]Vanderbilt University School of Medicine, Nashville, United States, [10]City University of New York, New York, United States
Presenting author email: catrina.mugglin@ispm.unibe.ch

Background: Acute kidney injury (AKI) and chronic kidney disease (CKD) are more common in HIV-infected, ART-treated adults than in the general population. Markers of renal dysfunction including microalbuminuria, proteinuria, and/or reduced glomerular filtration rate have been associated with increased mortality in HIV-infected patients. With approximately 16 million persons receiving ART in LMICs and limited resources to provide treatment for individuals with CKD and end-stage kidney disease, successful public health approaches require identifying individuals early in their disease risk continuum. Specific data in LMICs on HIV care and treatment site capacity to screen and manage persons at-risk of renal dysfunction is limited.
Methods: Ongoing survey of non-communicable disease (NCD) screening and management capacities and practices among a stratified random sample of HIV care and treatment sites in 36 LMICs within the International epidemiology Databases to Evaluate AIDS (IeDEA). The survey has currently been completed by 70 sites (49%); in 22 countries in Africa, Latin America and Asia. This preliminary analysis focuses on kidney disease screening and management capacity in 53 (75% urban) adult clinics. On site is defined as at this clinic or the same health-facility.
Results: Forty-nine (92%) of 53 sites report screening for kidney disease; with approximately half (58%) providing such services on-site. Serum creatinine and urine dipstick capacity is also available in the majority of sites; with at least 74% and 83% of sites providing these services (Table). A lower proportion of low- (44%) and lower-middle income (43%) sites (compared to 92% upper-middle income) have urine protein quantification services (urine albumin-to-creatinine ratio (uACR)) available. Renal biopsy capacity was extremely limited in low (0%) and lower-middle income (17%) settings.

	Low Income (N =18) n (%)	Lower-Middle Income (N= 23) n (%)	Upper-Middle Income (N= 12) n (%)	TOTAL (N= 53) n (%)
Screening	16 (89)	21 (91)	12 (100)	49 (92)
On-site management	11 (61)	9 (39)	11 (92)	31 (58)
On-site service availability				
Serum Creatinine Measurement	15 (83)	19 (83)	12 (100)	46 (87)
Urinalysis for proteinuria (dipstick)	15 (83)	17 (74)	12 (100)	44 (83)
Urine Protein quantification (i.e. uACR, uPCR)	8 (44)	10 (43)	11 (92)	29 (55)

[Availability by World Bank Income Classification]

Conclusions: The majority of LMIC HIV care sites provide screening for and managing kidney disease onsite. However, tests allowing for identification of earlier stage disease (e.g. uACR) and definitive histopathologic determination (biopsy) are largely unavailable. Such preliminary data provide baseline information to guide the design of future, prospective studies.

WEPEB0550

Prevalence of comorbidities and impact of HIV and comorbidities on health care resource utilization

H. Tossonian[1], R.-P. Lorgeoux[1], V. Baribeau[2], J. Lachaine[3]
[1]Gil, Mississauga, Canada, [2]PeriPharm Inc., Montreal, Canada, [3]Université de Montréal, Faculty of Pharmacy, Montreal, Canada
Presenting author email: harout.tossonian@gilead.com

Background: The aim of the study was to evaluate the prevalence of comorbidities in HIV patients as well as the impact of HIV and comorbidities on health care resource utilization using the Régie de l'assurance maladie du Québec (RAMQ) public drug plan database.
Methods: Patients who had received antiretroviral treatment (ART) for at least six months from 01/2006 to 06/2012 were selected. HIV-negative individuals from a random sample were matched for age, sex and time of follow-up and compared to HIV-positive patients. Renal, bone and cardio-metabolic comorbidities were defined using diagnosis codes for both cases and controls in the 2 years following cohort entry. Cohort entry was defined for the HIV-positive patients as the date of the first script of ART and for the matched control group of HIV-negative individuals as the date of the first any diagnosis or any prescription recorded in the database. Cases and controls were compared with independent t-test for continuous variables and chi-square test for categorical variables.
Results: A total of 3905 HIV-positive patients were included in the study with mean age of 45.3 and 77.3% being male. In the 2 years following cohort entry, 5.5% had renal, 26% had bone and 41.9% had cardio-metabolic comorbidities, with 17.1% having more than one type of comorbidity. HIV-positive patients had a higher Charlson comorbidity score compared to HIV-negative individuals (3.3 SD=3.3 vs. 0.3 SD=0.8, p< 0.01). HIV-positive patients had a higher mean total health care cost per patient per year in the 2 years following cohort entry than HIV-negative individuals which could be explained mostly by the higher mean number of hospitalization days (2.2 days SD=8.2 vs. 0.9 days SD=6.5, p< 0.01) and the higher number of prescriptions (105.3 SD=202.8 vs. 26.6 SD=71.0, p< 0.01). Similar results were obtained when analysis was restricted to HIV-positive vs. HIV-negative patients both with at least one comorbidity. Among the 1983 HIV-positive patients with at least one comorbidity, the comorbidities associated with the highest burden were renal-related followed by bone and cardio-metabolic comorbidities.
Conclusions: The impact of HIV and associated comorbidities on health care resource utilization was significant when we compared HIV-positive to HIV-negative individuals.

Background: According to the 2009 Malawi national STEPS survey, 36.9% male and 29.9% female participants from the general population had raised blood pressure (BP) or were on antihypertensive medication. As an integrated part of the ongoing prospective LighTen Cohort Study (ClinicalTrials.gov NCT02381275) we aimed at determining hypertension prevalence as well as easy to detect cardiovascular risk factors and organ damage in ambulatory HIV$^+$ patients prior to starting antiretroviral therapy in Lilongwe, Malawi.
Methods: BP values of patients (age ≥18 years) who consented to participate in the study were documented in a standardized fashion together with data concerning BMI, diabetes, smoking and known hypertension or antihypertensive medication. Definite arterial hypertension was defined as treated controlled or uncontrolled hypertension or BP ≥140/90 mmHg independent of hypertension history during ≥2 measurements on ≥2 occasions within 8 weeks after inclusion into the study. An estimated glomerular filtration rate (eGFR) of 30-59 ml/min/1.73m^2 (corresponding to CKD stage 3) or pulse pressure (PP) ≥60 mmHg in patients ≥60 years were considered as asymptomatic organ damage while eGFR < 30 ml/min/1.73m^2 or dipstick positive proteinuria were considered as established renal disease.
Results: Data from 1387/1415 HIV$^+$ patients (794 females, 593 males, mean age 36.0±9.3 years) could be analyzed. Definite hypertension was confirmed in 103 cases (61 females, mean age 43.8±9.6 years; 42 males, mean age 44.0±8.5 years) for a total prevalence of 7.4%. Among them, 34 had a BMI ≥30kg/m^2, 5 were smok-

ers and 5 presented with diabetes mellitus type 2. PP ≥60 mmHg was found in two patients and CKD stage 3 in 12 cases while 6 patients suffered from established renal disease. At least two additional cardiovascular risk factors were found in 15 men and three women, respectively.
Conclusions: Testing renal function and further diagnostics revealed additional cardiovascular risk factors in approximately 35% of HIV+ patients with an established diagnosis of hypertension. Systematic measurements of arterial blood pressure and kidney function together with integrated patient instruction, education and treatment programs at HIV centers may be helpful in reducing the burden of hypertension and its sequelae in settings like Malawi.

Looking beyond viral suppression: findings from The Well Project's 2016 user survey on factors influencing the health, well-being, and quality of life of women living with HIV

K. Heitzman Martel[1], J. Auerbach[2], J. Conley[1]
[1]The Well Project, Brooklyn, United States, [2]University of California, San Francisco, Medicine, San Francisco, United States
Presenting author email: kmartel@thewellproject.org

Background: The HIV care continuum has become the predominant framework for assessing progress in HIV treatment and prevention, with viral suppression as the ultimate outcome of interest. This is codified in the UNAIDS "90/90/90" campaign, adopted by numerous countries. But for women living with HIV, viral suppression may not be the only outcome of interest, as psycho-social factors—including those related to gender, HIV identity, and mental health—significantly affect their overall health, well-being, and quality of life.
Methods: In 2016, we conducted an online survey of The Well Project's (TWP) users to ascertain factors influencing experiences of women living with HIV (WLHIV) along and beyond the care continuum. TWP is a non-profit organization leveraging technology to facilitate information access, community support, and advocacy for WLHIV globally. Respondents were recruited through TWP's website, newsletters, virtual flyers, and social media, as well as outreach by TWP's CAB members and community partners.
The survey was administered through Survey Monkey and included closed- and open-ended questions. The total sample with complete survey data was 229 women and men. We report here on findings from the subsample of 136 self-identified WLHIV.
Results: WLHIV respondents came from North America (85.3%), Africa (11.7%), Asia (1.5%), and Europe (1.5%); average time since HIV diagnosis was 16.3 years. 97.8% reported seeing an HIV healthcare provider; 97.7% said they were currently taking ART. 77.3% self-reported having an undetectable viral load. Notwithstanding these high levels of engagement in care and viral suppression, WLHIV identified other important factors affecting their overall health, well-being, and quality of life that require further attention. These included stigma and discrimination inside (49.6%) and outside (62.7%) the healthcare system, experiences of trauma (76.5%), and additional mental, emotional, and behavioral health issues (39.8%) that hindered their access to or engagement in HIV care.
Conclusions: While viral suppression is a meaningful outcome for WLHIV, they do not perceive it as the only measure of their health and well-being. Other psychosocial factors, including trauma, stigma and discrimination, and behavioral health issues are important additional influences that must be addressed in order for them to achieve optimal quality of life.

WEPEB0553

The role of psychological flexibility and self-compassion in mental health and quality of life of HIV-infected adults

A. Martins, M.C. Canavarro, M. Pereira
University of Coimbra, Faculty of Psychology and Educational Sciences, Coimbra, Portugal
Presenting author email: marcopereira@fpce.uc.pt

Background: Living with HIV may be a stressful and emotionally demanding experience. People living with HIV (PLWH) face a range of issues impacting their mental health, namely anxiety and depression, and quality of life (QoL). Two newly constructs are particularly promising as buffers against the distress that individuals experience when confronting HIV. Indeed, psychological flexibility and self-compassion have been consistently associated with increased psychological well-being. In the HIV context, studies assessing the associations between these two constructs with mental health and QoL are scarce.
Therefore, the aim of this study was to examine the association between psychological flexibility and self-compassion and the mental health (anxiety and depression) and QoL in HIV-infected adults.
Methods: The sample of this cross-sectional study consisted of 89 adults infected with HIV (55.1% male), with a mean age of 41.69 years (SD=10.80; range: 19-65). Participants completed an online survey, between January 2016 and January 2017. Participants completed a self-reported questionnaire on sociodemographic and clinical information, the Acceptance and Action Questionnaire-II, the Self-Compassion Scale, the Hospital Anxiety and Depression Scale, and the EUROHIS-QOL 8-item index.
Results: On average, participants reported approximately 11 years (M=11.42; SD=8.15) since HIV diagnosis. Overall, 79.8% of the participants were HIV asymptomatic, and 77.5% reported a compliance of 100% to antiretroviral treatment in the last month. Both psychological flexibility and self-compassion were significantly and negatively correlated with anxiety and depression, and positively correlated with QoL. Regression analyses indicated that psychological flexibility and self-compassion were significantly associated with reduced levels of anxiety and depression, and higher QoL (the explained variances ranged between 40.7% and 50.4%). Self-compassion presented significant unique variance above and beyond psychological flexibility across study outcomes (the additional variance ranged between 4.8% and 9.9%).
Conclusions: The results of this study revealed that psychological flexibility and self-compassion were significantly associated with mental health outcomes and QoL. This study strengthens that third wave cognitive-behavioural approaches, as acceptance and commitment therapy and compassion-focused therapy, focused in increasing both psychological flexibility and self-compassion may hold promise in the search for effective interventions aimed at improving the mental health and QoL of PLWH.

Beyond viral suppression: the quality of life of people living with HIV in Sweden

G. Zeluf[1], L. Nilunger Mannheimer[2], C. Deogan[2], L. Nilsson Schönnesson[1], L.E. Eriksson[1], A.M. Ekström[3]
[1]Karolinska Institutet, Stockholm, Sweden, [2]Public Health Agency of Sweden and Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Dept of Public Health Sciences, Stockholm, Sweden
Presenting author email: anna.mia.ekstrom@ki.se

Background: Sweden is the first country to reach the UNAIDS ‚90-90-90' target: it is estimated that 90% of HIV cases are diagnosed, 99.8% of people living with HIV (PLHIV) are linked to care and 95% on antiretroviral treatment (ART) achieve viral suppression. It has been argued that viral suppression should not be the ultimate goal of treatment and that the wellbeing of PLHIV is equally important. Therefore, a ‚fourth 90' was a suggested addition to the 90-90-90 target, representing quality of life (QoL). The overall aim of the study was to investigate what factors are related to QoL among PLHIV in Sweden.
Methods: A nation-wide survey was conducted in 2014. It reached a representative sample of 17% of PLHIV in Sweden and consisted of an anonymous, self-reported questionnaire. Fifteen collaborating hospitals, clinics or needle-exchange centres, representing 75% of all known HIV patients, participated in the data collection. The questionnaire was developed in collaboration with Swedish HIV patient support organisations and was available in 10 different languages. When the study was conducted, the law forcing PLHIV to disclose their HIV status to sexual partners regardless of condom use or viral load, had just been modified to include important exemptions.
Results: In total, 1096 individuals responded to the questionnaire of whom 70% were men and 29% were women. About half of the respondents were born in Sweden and the most common routes of transmission were through sex between men (40%) and heterosexual sex (32%).The majority, 60%, reported QoL scores of 7-10 out of 10. Regression analysis showed that strong feelings of hopelessness, HIV-related stigma, taking medications against depression/anxiety, psychological side-effects of ART, drinking more alcohol than one wants to, injecting drug-use and self-medication with pharmacy drugs were associated with lower QoL. Negative change in one's sex life and low income were also significantly associated with lower QoL. Interestingly, gender, sexual orientation, country of birth and age were not significantly associated with QoL in this analysis.
Conclusions: Overall PLHIV in Sweden report high quality of life. Yet, HIV-related stigma and other HIV-related psychological stressors continue to compromise the QoL of PLHIV.

Presenting author email: marije@sun.ac.za

Background: Physiological changes during pregnancy may alter drug pharmacokinetics. Trimester differences in rifampin (RMP) and isoniazid (INH) exposure have not been described. We explored the effects of pregnancy gestation on RMP and INH pharmacokinetics in tuberculosis-infected women.
Methods: P1026s is an ongoing, non-blinded, phase IV, prospective study of antiretroviral and antituberculosis pharmacokinetics in HIV-infected and uninfected pregnant women. Intensive steady-state 24-hour pharmacokinetic profiles of RMP and INH were performed during the 2nd trimester (2T), 3rd trimester (3T) and 2-8 weeks postpartum (PP). Daily antituberculosis fixed-dose combination tablets were given according to WHO-recommended weight-banded dosing guidelines. RMP and INH plasma concentrations were measured using High Performance Liquid Chromatography (HPLC); detection limits being 0.117 µg/ml and 0.098 µg/ml, respectively. The pharmacokinetic parameters were characterized using non-compartmental analysis and compared to published non-pregnant South African adult data.
Results: Preliminary pharmacokinetic data are available for 10 South African participants; 7 African, 2 mixed descent and 1 Indian. All were sampled more than once. Eight women were HIV-infected (7 on efavirenz and 1 on lopinavir/ritonavir). The median age at 3T was 31 years (range 21-40) and median weight at 3T was 58.6 kg (range 49-99). Median gestational age at delivery was 38 weeks (range 36-41). RMP and INH pharmacokinetic data were available in 5, 8 and 3 women in 2T, 3T and PP. See Tables 1 and 2 respectively.

Parameter	2nd Trimester	3rd Trimester	Postpartum	Historical Control
No. evaluated / No. HIV-infected	5 / 5	8 / 6	3 / 2	87 / 9
AUC_{0-8} (µg·h/ml)	27.48 (25.74-33.68)	31.34 (21.15-39.74)	16.24 (13.21-33.12)	21.5 (15.3-31.7)
C_{max} (µg/ml)	7.23 (6.63-8.38)	6.11 (4.67-8.46)	4.88 (3.82-7.84)	5.9 (4.2-8.4)

[Table 1. Rifampin PK Parameters, Median(IQR)]

Parameter	2nd Trimester	3rd Trimester	Postpartum	Historical Control
No. evaluated / No. HIV-infected	5 / 5	8 / 6	3 / 2	141 / 14
AUC_{0-8} (µg·h/ml)	7.10 (4.85-13.03)	8.96 (7.06-12.29)	8.90 (5.32-20.51)	25.0 (18.9-32.8)
C_{max} (µg/ml)	3.27 (2.24-4.8)	3.44 (3.27-4.59)	3.73 (2.61-5.63)	6.5 (4.9-8.7)

[Table 2. Isoniazid PK Parameters, Median(IQR)]

Compared to a non-pregnant South African adult cohort (45% male, 10% HIV-infected not receiving antiretrovirals, McIlleron et al. 2006), RMP exposure was similar or higher in 2T and 3T. INH exposure was below the 25th percentile across all stages of pregnancy. Small sample size and unavailable comparator raw dataset prohibited formal statistical testing.
Conclusions: RMP concentrations in pregnancy compared well to non-pregnant concentrations. However, INH exposure was reduced throughout pregnancy. If confirmed with larger sample size, these data suggest that an increased dose of INH may be needed during pregnancy.

WEPEB0556

Pregnancy outcomes among HIV-infected women who conceived on antiretroviral therapy

Presenting author email: scu-uvin@lifespan.org

Background: As the availability of ART expands in resource-limited settings, it is critical to understand the impact these drugs may have on pregnancy and birth outcomes among women who conceive on ART.
Methods: We conducted a secondary analysis of women prospectively enrolled across three ART prevention or treatment trials (HPTN 052, ACTG A5208 and ACTG A5175). Included women who were on ART at conception, had reliable LMP dating and a recorded pregnancy outcome. Primary outcome was live birth versus other (spontaneous abortion; stillbirth; elective abortion; or ectopic pregnancy). Preterm birth (birth < 37 weeks) was a secondary outcome. Analyses used Cox proportional hazards regression models with time-varying covariates
Results: 359 women had pregnancies during the study period. 253 women (70%) met inclusion criteria and were included: 114 (45%) from HPTN 052, 89 (35%) from A5208, and 50 (20%) from A5175). 127 (50%) were taking NNRTI-based ART, 118 (47%) were taking PI-based ART, and 8 (3%) were taking 3-NRTIs at conception. Of women on NNRTI-based ART, 76% were taking an efavirenz-based regimen. Pregnancy outcomes are in Table 1. The median birth weight among 68 live born infants was 2900 g [IQR: 2500-3400 g]. In multivariable analysis adjusted for region, study, and pre-pregnancy ART class, older age was significantly associated with increased hazard of non-live birth [HR 1.05; 95% CI: 1.001-1.09; p=0.047]. In both univariable and multivariable analysis, no variables were significantly associated with preterm birth among women with a live birth.
Conclusions: Women who conceived on ART had very high rates of preterm birth and other poor obstetric outcomes. A limitation of our study is that the estimated due date (EDD) was not determined by ultrasound but by LMP. New studies that are specifically designed to investigate ARV drug exposure and birth outcomes are urgently needed and will have implications for maternal child health programs in settings with high HIV prevalence

WEPEB0557

Pre-treatment antiretroviral drug resistant mutations (DRM) and subsequent viral rebound on antiretroviral therapy (ART) among pregnant and postpartum women in Cape Town, South Africa: a nested case-control study

L. Myer[1,2], A. Redd[3,4], N.-Y. Hsiao[5], B. Lynch[3], T. Phillips[1,2], A. Eisenberg[3], A. Zerbe[6], J.A. McIntyre[1,7], L. Dunning[1], S.F. Porcella[3], E.J. Abrams[6,8], S.J. Reynolds[3,4], for the MCH-ART Study
[1]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [3]National Institute of Allergy and Infectious Diseases, NIH, Division of Intramural Research, Bethesda, United States, [4]Johns Hopkins University, School of Medicine, Baltimore, United States, [5]National Health Laboratory Services & University of Cape Town, Division of Medical Virology, Cape Town, South Africa, [6]Columbia University, ICAP, New York, United States, [7]Anova Health Institute, Johannesburg, South Africa, [8]Columbia University, College of Physicians & Surgeons, New York, United States
Presenting author email: landon.myer@uct.ac.za

Background: Viral rebound (VR) occurs frequently after initial viral suppression (VS) among women initiating ART during pregnancy in sub-Saharan Africa. However, the aetiology of VR and the role of pre-treatment drug resistance mutations (DRM) are not well understood in this patient population.
Methods: We examined associations between pre-ART DRM and VR>1000cps/mL in a routine primary care cohort. Intensified VL monitoring was conducted separately from routine care, with stored specimens every 2-3m for retrospective VL assessment. All women included here initiated TDF+FTC+EFV in pregnancy and achieved VS≤50cps/mL. After initial VS≤50cps/mL, cases experienced VR>1000cps/mL up to 12m postpartum while incidence-density matched controls maintained VS≤50cps/mL throughout follow-up. Using pre-ART specimens, the

RT region was amplified and sequenced with next-generation Miseq sequencing; consensus sequences containing at least 0.02% of the total reads for that sample were included, and DRM were based on >5% of consensus sequences. Analyses (i) compared DRM in cases/controls, (ii) estimated associations between DRM and time to VS and VR and (iii) calculated population attributable fraction (PAF) for VR associated with DRM.
Results: Cases experiencing VR>1000cps/mL after initial VS (n=103) were significantly younger versus controls who maintained VS (n=80); pre-ART VL was similar (median=4.0 log_{10}cps/mL). Cases were more likely to report previous ARV exposure either through short-course PMTCT (30%) or ART (10%) versus controls (14% and 1%, respectively; p<0.05). DRM were found in 10% of cases and 3% of controls (exact p=0.070) with only NNRTI mutations detected (K103N,K101E,V106M,G190E). DRM were strongly associated with previous ART use (p<0.001). Time to VS was not associated with pre-ART DRM (p=0.899), but women with pre-ART DRM had twice the rate of VR after initial VS versus women without (adjusted hazard ratio=2.15; 95%CI=1.08-4.30). Based on these data, DRM may be involved in the aetiology of 6% of all cases of VR>1000cps/mL after initial VS (PAF uncertainty interval=4-13%).
Conclusions: Pre-ART DRM appear uncommon among pregnant women in this setting, but when present are significantly associated with VR>1000cps/mL after initial VS≤50cps/mL. At a population level, pre-ART DRM account for a small minority of VR, suggesting that non-adherence may play a greater role in early VR during pregnancy and postpartum.

WEPEB0558

Maternal outcomes of pregnancies complicated by HIV: preliminary results of a retrospective matched cohort study from 2004 to 2014

R.K. Scott[1], E. Higgins[2], M. Davis[3], S. Fernandez[4], S. Pedra-Nobre[2], M. Burke[2], T. Doyle[2], C. McAllister[2], M. Macleary[2], H. Al-Kouatly[2]
[1]MedStar Health Research Institute and Washington Hospital Center, Womens' and Infants' Services (WIS), Baltimore, United States, [2]Washington Hospital Center, Womens' and Infants' Services (WIS), Washington, United States, [3]Georgetown University, Washington, United States, [4]MedStar Health Research Institute, Washington, United States
Presenting author email: rachelkscott@hotmail.com

Background: Although pregnancy in HIV-positive women is complicated by medical and psychosocial comorbidities, maternal pregnancy outcomes are understudied. To test the hypothesis that maternal morbidity is higher in HIV-positive pregnancies, we conducted a retrospective matched cohort of HIV-positive pregnancies at MedStar Washington Hospital Center (MWHC).
Methods: We included all HIV-positive pregnancies delivered at MWHC from 2004-2014, excluding multiple-gestations and abortions. For each HIV-positive pregnancy, we identified two HIV-negative pregnancies, propensity-score matched on age, race, parity, zip-code and insurance status within a year of delivery. Data collection is ongoing. We used chi-squared and Fisher's exact tests for categorical variables and t-tests for continuous variables.
Results: 420 HIV-positive pregnancies met inclusion criteria. We have collected data on 326 HIV-positive pregnancies and 530 HIV-negative controls. Mean maternal age was 27. The majority were African-American (88%) and multiparous. The majority of HIV-positive women acquired HIV through sexual transmission(36.5% vs. 7.4% perinatally-acquired vs. 55.8% unknown).
HIV-positive women were less likely to be married (19.8 vs. 12%, p<0.001) and more likely to be homeless (7.1 vs. 2.5%, p=0.002), unemployed (50 vs. 37%, p<0.001), enrolled in government-sponsored insurance (77 vs. 61%, p<0.001), have social services involvement (5.2 vs. 0.4%, p<0.001), and children in foster care (3.1 vs. 0.6%, p=0.009). They had greater past history of domestic-violence (15.6 vs. 4.5%, p<0.001), sexual abuse (10.4 vs. 4.3%, p=0.001), depression (19.9 vs. 4.9, p<0.001), anxiety (8 vs. 0.9%, p<0.001), and substance use (41.4 vs. 26.6%, p<0.001). Current pregnancies complicated by HIV, had increased depression (12 vs. 2.5%, p<0.001) and substance drug use (27.3 vs. 15.5%, p< 0.001).
Sexually transmitted infections were higher in HIV-positive pregnancies (29.1 vs. 12.5%, p<0.001), as were urinary tract infections (19.6 vs. 9.4%, p<0.001), and pneumonia(1.2 vs. 0%, p=0.041).There was no difference in overall preterm-delivery, however, spontaneous preterm-delivery was higher in HIV-positive pregnancies(8.9 vs. 4.3%, p=0.002). Cesarean deliveries were also higher (55.6 vs. 32.1%, p<0.001), with increased wound cellulitis(1.8 vs. 0.2%, p=0.027).
Conclusions: This is the largest single-site cohort of HIV-positive pregnancies in the United States. HIV-positive pregnancies were more likely to be of lower socioeconomic status with challenging social situations and striking psychosocial comorbidities. HIV-positive pregnancies were at increased risk of infectious morbidity and spontaneous preterm-delivery.

WEPEB0559

Is tenofovir use in pregnancy associated with preterm delivery? A Canadian perinatal HIV surveillance program analysis

J. Brophy[1], T. Lee[2], A. Bitnun[3], F. Kakkar[4], J. Singer[2], A. Alimenti[5], D. Money[6], W. Vaudry[7], L. Sauve[8], Canadian Pediatric and Perinatal HIV/AIDS Research Group
[1]Children's Hospital of Eastern Ontario, Department of Pediatrics, Division of Infectious Diseases, Ottawa, Canada, [2]Canadian HIV Trials Network, Vancouver, Canada, [3]The Hospital for Sick Children, Department of Pediatrics, Division of Infectious Diseases, Toronto, Canada, [4]CHU Sainte-Justine, Department of Pediatrics, Division of Infectious Diseases, Montreal, Canada, [5]BC Women's Hospital & Health Centre, Department of Pediatrics, Vancouver, Canada, [6]BC Women's Hospital & Health Centre, Obstetrics and Gynaecology, Vancouver, Canada, [7]Stollery Children's Hospital, Department of Pediatrics, Division of Infectious Diseases, Edmonton, Canada, [8]British Columbia Children's Hospital, Department of Pediatrics, Division of Infectious Diseases, Vancouver, Canada
Presenting author email: jbrophy@cheo.on.ca

Background: Tenofovir-based cART was associated with significantly higher rates of very preterm delivery and infant death in the recently published PROMISE trial (which compared outcomes from women treated with zidovudine/single-dose nevirapine, zidovudine/ lamivudine/lopinavir-ritonavir or tenofovir/lamivudine/ lopinavir-ritonavir). We assessed rates of preterm delivery according to cART components in the Canadian Perinatal HIV Surveillance Program (CPHSP).
Methods: Data collected annually from 22 pediatric and HIV centres participating in the CPHSP were reviewed for 1997-2015, including: rates of preterm (< 37weeks) delivery, antiretroviral choice, maternal demographics and clinical parameters.
Results: Among 2787 cART-treated mother-infant pairs from 1997-2015, 1703 (61.1%) received zidovudine, 574 received abacavir (20.6%) and 496 received tenofovir (17.8%). Tenofovir use in pregnancy began in 2004 (0.77% of pregnancies) and increased every year since up to 54.1% in 2015; conversely, zidovudine use decreased from 100% in 1997 to 14.7% in 2015. The overall preterm delivery rate was 16.0%, with a significantly higher rate in mothers treated with tenofovir-based versus non-tenofovir based cART (19.4% vs 15.2%, p=0.024). Preterm delivery was not associated with abacavir-based vs non-abacavir-based cART (16.0%) vs 15.9%) or with zidovudine-based vs non-zidovudine-based cART (15.5% vs 16.7%) There was no difference in proportion of preterm delivery among women exposed to tenofovir with versus without a protease inhibitor (19.3% vs. 19.5%), non-nucleoside reverse transcriptase inhibitor (18.0% vs 19.6%) or integrase inhibitor (17.8% vs 19.3%). Other significant predictors of preterm delivery included: race/ethnicity (Indigenous 26.9% vs White 17.2% vs Black 13.0%, p< 0.001), maternal risk factor (intravenous drug use 27.6% vs sexual 13.8% vs other 12.1%, p< 0.001), and viral load (VL) closest to delivery (detectable 24.7% vs undetectable 15.5%, p< 0.001), but not once-daily combinations or trimester of cART start. Multivariate analysis (restricted to 2006-2015 when VL data was more complete) revealed tenofovir (p=0.021) and zidovudine use (p=0.019), IVDU (p=0.009), and detectable VL (p=0.015) as predictive of preterm birth.
Conclusions: In Canada, there was a higher risk of preterm delivery amongst mothers treated with tenofovir-based versus non-tenofovir-based cART. Allowing for biases of observational cohort studies, this finding warrants further investigation to determine the safest antiretroviral treatment in pregnancy.

Presenting author email: clive.gray@uct.ac.za

Background: While antiretroviral treatment (ART) for HIV-infected pregnant women can significantly reduce mother-to-child HIV transmission and improve maternal survival, prolonged in-utero exposure to antiretrovirals may have adverse effects on birth outcomes and neonatal development. However, there is scant data on the impact of ART exposure on fetal development and birth outcomes, particularly from sub-Saharan Africa. Working within a larger birth cohort in Cape Town, South Africa, we report on a nested sub-study of the impact of ART use during pregnancy on placental pathology and birth outcomes.

Methods: Histopathology of placentas after delivery were examined from two groups: HIV-infected mothers receiving stable ART commenced before pregnancy (n=33) and women initiating ART at ±20w gestation (n=45). All placentas were fixed in 10% formalin and examined for stage/grade of chorioamnionitis (maternal inflammation), cord/plate vessel vasculitis (fetal inflammation), focal infarction and meconium exposure.
In analysis, we examined associations between chorioamnionitis and appropriate (AGA)- or small-for-gestational age (SGA <10th centile) and pre-term (PT≤34 weeks) deliveries.
Results: There were equal proportions of pre-term births in the stable ART and initiating ART groups (9%), but a higher proportion of SGA births in women on stable ART than in those initiating ART (18.2% vs 6.5%; p=0.0153). This was associated with a greater proportion of stage 1 chorioamnionitis in placentas from women on stable versus initiating ART (15% vs 4%; p=02) along with evidence for prolonged exposure to meconium (21% vs 9%; p=0.015). Placentas from women initiating ART showed relatively more plate vessel vasculitis (20% vs 9%; p=0.04), but less focal infarction (4.4% vs 12%; p=0.065) when compared to women on stable ART.
Conclusions: HIV-infected pregnant women commencing ART before pregnancy experienced relatively high levels of SGA deliveries. This may be due to maternally-derived inflammation of the placenta, fetal distress and possibly disrupted blood supply due to infarction. Interestingly, placentas from pregnant women initiating ART showed evidence of fetal inflammation, but this was not associated with SGA deliveries.

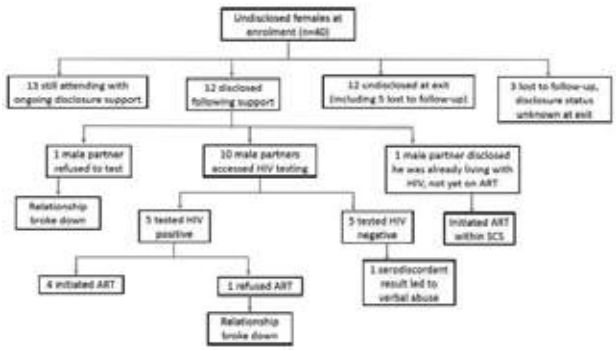
Factors associated with non-disclosure among females accessing a safer conception service in Johannesburg, South Africa and outcomes following disclosure support

N.E.C.G. Davies[1], D. Pillay[1], N. Naidoo[1], S. Mullick[1], N. Sikhosana[1], S. Schwartz[1,2]
[1]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States
Presenting author email: ndavies@wrhi.ac.za

Background: Safer conception services (SCS) enable HIV-affected couples to minimise horizontal and vertical HIV transmission risks during conception efforts. However, non-disclosure within couples planning pregnancy creates difficulties including ethical challenges for healthcare providers, lower partner engagement in care and sub-optimal risk reduction strategy use. Understanding drivers of non-disclosure is critical to strengthening programming. We describe factors associated with disclosure among female SCS clients in Johannesburg and outcomes observed following a disclosure support intervention.
Methods: All SCS clients completed a baseline assessment, including disclosure status. Undisclosed clients received ongoing disclosure support including counselling and opportunities for couples' HIV-testing. Baseline characteristics between disclosed and undisclosed women were compared using chi-squared statistics and t-tests. Undisclosed clients' clinical records were reviewed for disclosure-related events.
Results: From June 2015-January 2017, 362 women, median age 33yrs (IQR 30-37yrs), enrolled. Forty (11%) were undisclosed at enrolment, of which 8 (20%) had detectable viral loads (>200 copies/ml[3]). At baseline, undisclosed women reported shorter relationships than disclosed women (3.1 vs 6.6yrs, p<0.001), were less likely to have any child with their partner (2% vs 28% disclosed, p=0.001), and were less likely to report always using condoms in the month before enrolment (26% vs 44% disclosed, p=0.043). Age, nationality, income, employment, education, years since HIV diagnosis, ART uptake and duration and CD4 cell count nadir were not associated with baseline disclosure status. Following disclosure support, 12 women disclosed (Figure 1).



[Figure 1: Disclosure outcomes following support]

Conclusions: Non-disclosure of HIV-status remains common, even amongst couples actively planning pregnancy. Disclosure is significantly less likely if a woman has no children with her current partner, but increases with relationship duration. Disclosure support can assist with disclosure, leading to increased male testing, diagnosis and ART uptake. However, many women remain unable to disclose and pressured disclosure may introduce risks including relationship breakdown, gender-based violence and withdrawal from care.

WEPEB0562

Uptake of safer conception strategies among women living with HIV in Canada who report pregnancy with an HIV-serodiscordant partner

A. Kaida[1], D. Money[2,3], N. Pick[3,4], A. Carter[1,5], V.L. Kennedy[6], K. Webster[1], L. Wang[5], J. Zhu[5], R. Gormley[1,5], A. de Pokomandy[7,8], M. Loutfy[6,9], on behalf of the CHIWOS Research Team
[1]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [2]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [3]Oak Tree Clinic, BC Women's Health Centre, Vancouver, Canada, [4]University of British Columbia, Department of Medicine, Division of Infectious Diseases, Vancouver, Canada, [5]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [6]Women's College Hospital, Women's College Research Institute, Toronto, Canada, [7]McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, [8]McGill University, Department of Family Medicine, Montreal, Canada, [9]University of Toronto, Department of Medicine and Institute of Health Policy, Management and Evaluation, Toronto, Canada
Presenting author email: kangela@sfu.ca

Background: Safer conception strategies reduce sexual HIV transmission, while allowing for pregnancy. Canada is one of three countries with national safer conception guidelines, but little is known about uptake. We measured prevalence, types, and correlates of safer conception among women living with HIV (WLWH) who reported pregnancy with an HIV-serodiscordant partner.
Methods: We analysed retrospective questionnaire data from the Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS; 2013-2015). Cis-gender women who reported ≥1 pregnancy after HIV diagnosis were included. Among women reporting an HIV-serodiscordant
(i.e., HIV-negative or HIV status unknown) pregnancy partner, we assessed uptake of safer conception strategies during the most recent pregnancy. Multivariable logistic regression examined independent correlates of safer conception among women who reported planned pregnancies.
Results: Of 288 participants (20.2% of 1,425 enrolled), 67% (n=194) reported an HIV-serodiscordant pregnancy partner. Among these women, current median age was 38 years (IQR: 33,43), median years between most recent pregnancy and study enrolment was 4 [IQR: 2-11], and 64% of pregnancies were unplanned. Overall, 26% reported using a safer conception method, with higher uptake among women with planned (41%) versus unplanned pregnancies (17%) (p< 0.01). Among women with planned pregnancies (n=70), reported safer conception methods included: viral suppression with antiretroviral therapy (ART) (34%); manual insemination (31%); timed condomless sex to peak fertility (17%); partner PrEP (7%); sperm donation (7%); sperm washing (< 5%); and artificial insemination (e.g. IUI) (< 5%). In addition, 76% reported being on ART prior to pregnancy although viral suppression status was unknown. Having ever discussed reproductive goals with a healthcare provider after HIV diagnosis [AOR: 23.3 (95% CI: 2.19, 249)] was the only covariate independently associated with safer conception uptake.
Conclusions: One-quarter of WLWH who had an HIV-serodiscordant pregnancy partner reported using safer conception, including 41% with planned and 17% with unplanned pregnancies. However, nearly three-quarters of women reported ART use prior to pregnancy and thus likely benefitted from lowered sexual HIV transmission risk without awareness of this as a safer conception strategy. Discussions of reproductive goals and options are essential to routine HIV care for WLWH to support pregnancy planning and facilitate uptake of safer conception.

WEPEB0563

Beyond HIV-serodiscordance: four types of partnership discordance that affect engagement in safer conception care

L.T. Matthews[1,2], F. Bajunirwe[3], B.F. Burns[1], J. Kabakyenga[3], M. Bwana[3], C. Ng[4], J. Kastner[5], N. Sanyu[3], A. Kusasira[3], J.E. Haberer[1,6], D.R. Bangsberg[7], A. Kaida[8]
[1]Massachusetts General Hospital, Global Health, Boston, United States, [2]Massachusetts General Hospital, Infectious Disease, Boston, United States, [3]Mbarara University of Science and Technology, Mbarara, Uganda, [4]Harvard T H Chan School of Public Health, Boston, United States, [5]Research Institute McGill University Health Centre, Montreal, Canada, [6]Massachusetts General Hospital, Division of General Medicine, Boston, United States, [7]Oregon Health & Science University-Portland State University School of Public Health, Portland, United States, [8]Simon Fraser University, Vancouver, Canada
Presenting author email: ltmatthews@mgh.harvard.edu

Background: Many men and women living with HIV and their partners want to have children. For those in HIV-serodiscordant partnerships, condomless sex to conceive introduces HIV transmission risks. We conducted in-depth interviews with men and women living with HIV and their HIV-uninfected or unknown-serostatus partners to inform safer conception programming.
Methods: To explore acceptability and feasibility of safer conception methods among HIV-affected couples in Uganda, we recruited couples through HIV-positive men and women on antiretroviral therapy ("index") who reported
(1) an HIV-negative/unknown serostatus partner ("partner"),
(2) HIV-serostatus disclosure to partner, and
(3) personal or partner desire for a child within two years.
We conducted in-depth interviews with 40 individuals from 20 couples to assess awareness and acceptability of five safer conception strategies: antiretroviral therapy for the infected partner, pre-exposure prophylaxis for the uninfected partner, condomless sex timed to peak fertility, manual insemination, and male circumcision.
Results: The 20 index participants had a median age of 32.5 years and median of 2 living children; 11 were women and 80% had plasma HIV-RNA < 400 copies/mL. Awareness of HIV prevention strategies beyond condoms and abstinence was limited and precluded assessment of safer conception method acceptability. Thematic analysis revealed four types of partnership discordance as primary barriers to safer conception practices:
(1) HIV-serostatus disclosure: Although disclosure to partner was an inclusion criterion, disclosure was often incomplete and/or unilateral.
(2) Childbearing intention: Participants often had divergent childbearing plans from partners and made incorrect assumptions about the partner's wishes.
(3) HIV risk perception: participants had disparate ideas regarding risk of HIV transmission and the acceptable level of HIV-acquisition/transmission risk to meet reproductive goals.
(4) Nature of the relationship: discord in understanding the nature of the relationship (e.g. exclusive vs. non-exclusive) complicated decisions about safer conception plans.
Only 2 of 20 partnerships in our sample were concordant across all four domains.
Conclusions: Enthusiasm for safer conception programming is growing. Our findings highlight the importance of addressing communication around gendered discordant partnership goals, knowledge, and perceptions in addition to offering technical safer conception advice to maximize reach, uptake, adherence to, and retention in safer conception programming.

WEPEB0564

Menopausal status and symptoms in women living with HIV in the UK: results from the PRIME study

S. Tariq, A. Rolland, F. Burns, C. Sabin, R. Gilson
UCL, Research Department of Infection and Population Health, London, United Kingdom
Presenting author email: c.sabin@ucl.ac.uk

Background: There remains a paucity of data on HIV and the menopause. We present preliminary data on menopausal status and symptomatology among women living with HIV (WLHIV) in the UK.
Methods: An analysis of data on the first 400 participants recruited to the PRIME Study; a prospective cohort of WLHIV aged 45-60. Menopausal status was based on self-reported menstrual pattern and categorized according to modified STRAW+10 criteria. Postmenopausal status (PostMP) was defined as last menstrual period [LMP]>12 months; perimenopausal status (PeriMP) as LMP≤12 months with menstrual irregularity. Menopausal symptoms were captured using the Menopause Rating Scale.
Results: Median age of the study population was 49 years (interquartile range: 47-52).The majority were Black African (n=282, 72.5%), with low rates of smoking (n=35, 9.1%) and drug use (n=9, 2.4%). Almost all women (n=381, 97.4%) were on antiretroviral therapy; a minority had a CD4 count< 200 cells/mm^3 (n=37, 11.4%) or detectable HIV viral load (n=46, 12.6%). The majority were PeriMP (n=186, 46.5%) or PostMP (n=140, 35.0%); a fifth were premenopausal (PreMP, n=74). Women reported high levels of somatic (n=349, 88.6%), psychological (n=305, 77.8%) and urogenital (n=259, 67.6%) symptoms. The most frequently reported symptoms were physical and mental exhaustion (63.9%), muscle and joint problems (66.3%), sleep disturbance (63.1%) and hot flushes (63.0%). PeriMP and PostMP women reported symptoms more frequently than PreMP women (p<0.005). Less than half (n=101, 47.9%) of PeriMP and PostMP women with vasomotor symptoms had heard of hormone replacement therapy (HRT), with less than 10% using HRT (n=13). Less than 5% of those with urogenital symptoms reported using topical oestrogens (n=8, 3.9%). Over half of all participants (n=195, 52.0%), stated they had not received sufficient information about the menopause.
Conclusions: This is the largest study to date of menopause symptomatology in WLHIV in the UK. We report high levels of somatic, psychological and urogenital symptoms. PeriMP and PostMP women were most likely to report symptoms in all domains. Despite high levels of somatic and urogenital symptoms, very few women were using hormonal treatment, and there was evidence of significant informational need. We suggest development of services to support to WLHIV through the menopause.

WEPEB0565

Experience of hormone replacement therapy (HRT) in postmenopausal women living with HIV

M. Samuel, L. Hamzah, J. Welch, A. Yamoah, H. Hamoda, C. Taylor
King's College Hospital NHS Foundation Trust, Sexual Health and HIV Medicine, London, United Kingdom
Presenting author email: itty.samuel@nhs.net

Background: One-third of people living in the United Kingdom are female and increasing numbers of women with HIV are reaching menopause. Hormone replacement therapy (HRT) is beneficial to HIV positive women who are symptomatic and/or with early menopause and may improve bone health. At King's College Hospital 40% of HIV positive patients are female and 625(63%) are aged >45 years. Postmenopausal women referred to an HIV medical gynaecology clinic for review and HRT counselling.
Assess the uptake of HRT in HIV positive postmenopausal women, the effectiveness of HRT in treating menopausal symptoms and demographic and HIV characteristics of those with early, premature or natural menopause
Methods: Retrospective case note review of post-menopausal women with HIV attending the medical gynaecology clinic between 1st Jan 2011-31st Dec 2016. Menopause was classified by age at menopause as premature (< 40 years), early (40-45 years) or natural (>45) and baseline characteristics and management described.
Results: Of the 579 women referred to medical gynaecology, 73(12%) were postmenopausal (88% black ethnicity, 95% undetectable on treatment, median(IQR) current and nadir CD4 630(435,780) and 259(111,396) cells/μl respectively) The age range at menopause was between 36-53 years; 11(15%) had premature and 15(21%) early menopause. There was no evidence of a difference between demographic/HIV characteristics between menopause categories (P< 0.5 for all). There was a trend to higher parity among natural menopause compared to early or premature (median IQR) parity 2(1,2) vs. 1(0,2) and 1(0,1) respectively, p=0.02). 69 women attended; 49(71%) to discuss menopause management , of which 28(57%) accepted HRT. 23(82%) were prescribed systemic HRT; 19(83%) had continuous or sequential oestrogen patch or gel plus micronized progestogen. 11(58%) required oestrogen up-titration to improve symptoms. 4 experienced side effects (bleeding N=3, mood disturbance N=1). All women had symptomatic relief within 6 months of starting HRT; 4 discontinued due to side effects and anxiety about breast cancer. 24 underwent bone mineral density evaluation, 15(62.5%) were osteopenic and 2(8%) had osteoporosis.
Conclusions: HRT was acceptable to the majority of women with HIV who were counselled and offered treatment. All women had symptomatic improvement and adverse effects were rare. Dose adjustments were required in the majority patients.

WEPEB0566

Examining the relationships among antimullerian hormone and leukocyte telomere length in HIV-positive and negative women enrolled in the Children and Women: antiRetrovirals and Markers of Aging (CARMA) cohort

C. Van Ommen[1], A. Hsieh[1], A. Albert[2], I. Gadawska[1], E. Kimmel[1], E. Maan[3], J. Prior[1], D. Money[1,2,3], N. Pick[1,3], H. Cote[1,2], M. Murray[1,2,3], CIHR Team on Cellular Aging and HIV Comorbidities in Women and Children (CARMA)
[1]University of British Columbia, Vancouver, Canada, [2]Women's Health Research Institute, Vancouver, Canada, [3]Oak Tree Clinic, Vancouver, Canada
Presenting author email: hcote@pathology.ubc.ca

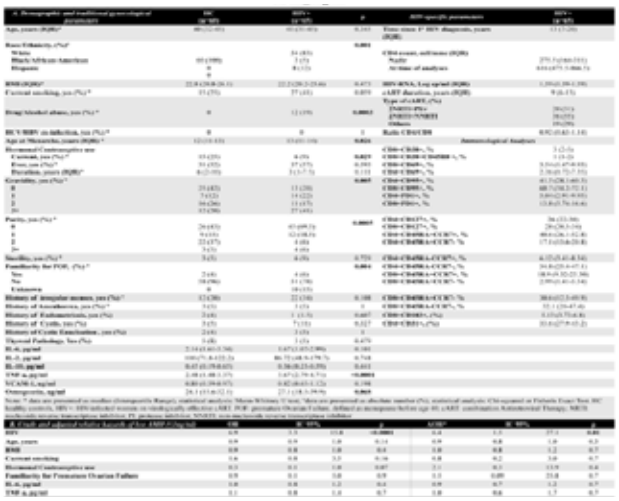
Background: HIV infection is associated with younger age at menopause and shorter leukocyte telomere length (LTL), a marker of cellular aging. Anti-Mullerian hormone (AMH) levels decline with age and can estimate ovarian reserve. We sought to examine the associations among LTL, AMH and HIV to better understand the relationship between cellular and ovarian aging in women living with HIV (WLWH).
Methods: The study included 233 WLWH and 154 HIV-negative non-pregnant women ≥12 years of age enrolled in the CARMA cohort with available blood samples. Relative LTL and AMH were measured by multiplex qPCR and ELISA, respectively. Generalized linear models with log links to account for the non-normal distribution of AMH were used. Possible predictors included age, HIV status, LTL, body mass index (BMI), smoking (current vs. past vs. never), current opioid use, CD4 nadir, peak HIV viral load (VL), current detectable VL and antiretroviral therapy (naïve vs. not). Likelihood ratio tests were used to assess variable importance.
Results: In our cohort, WLWH had shorter LTL (7.2 vs. 7.5 p=0.004) and lower AMH levels (1.9ng/mL vs. 3.1ng/mL p=0.01) compared to HIV-negative controls of similar age (35.0y vs. 34.6y p=0.52). As both AMH and LTL decline with aging, a significant relationship between them (p< 0.0001) did not remain after adjusting for age (p=0.12). WLWH were more likely to be Black (25.8% vs. 5.8% p< 0.001), currently smoking (45.1% vs. 30.5% p=0.01), currently using opioids (25.8% vs. 13% p=0.003) and of higher BMI (26.2 vs. 25.3 p=0.03), than HIV- controls. In analyses omitting ethnicity due to collinearity with HIV status, smoking and opioid use, HIV status (p< 0.0001) and age (p<0.0001) were significantly related to AMH levels, with HIV seropositivity decreasing AMH by 39% at any given age. Among WLWH, age (p< 0.0001) and current opioid use (p=0.01) independently predicted lower AMH levels which were 40% lower in opioid users.
Conclusions: Our data support previous work demonstrating lower AMH levels in WLWH compared to controls. Although LTL was not a significant predictor of AMH in this population, we show that, in addition to HIV infection, opioid use may be associated with decreased ovarian reserve in WLWH.

WEPEB0567

Residual activation/inflammation and HIV-associated co-morbidities do not predict premature ovarian ageing in cART-treated HIV-infected women

E. Merlini[1], V. Sacchi[2], E.S. Cannizzo[1], L. Gazzola[1], M. Basilissi[1], A. d'Arminio Monforte[1], M. Ravizza[2], G. Marchetti[1]
[1]University of Milan, Clinic of Inf Diseases, Health Sciences, Milan, Italy, [2]University of Milan, Clinic of Obstetrics and Gynecology, Milan, Italy
Presenting author email: esther.merlini@unimi.it

Background: Early menopause and lower circulating anti-Mullerian Hormone (AMH), ovarian ageing marker, have been described in HIV+ women. During suppressive cART, heightened immune-activation/inflammation persist and associate with premature ageing. Little is known on the effects of the hormonal milieu on immune activation/inflammation and on HIV-associated co-morbidities in ageing HIV-infected women. Thus, we aimed to investigate circulating AMH and the possible association(s) with markers of immune activation/inflammation and cardiovascular/bone damage in a cohort of HIV-infected women on effective cART.
Methods: Population: 65 HIV+ women on cART (HIV-RNA< 40 cp/ml) aged 25-50years; 60 age-matched healthy women (HC). Epidemiological, gynecological, HIV-related data were collected. We measured: (i) plasma AMH, IL-6 (ELISA), IL-2, IL-10, TNFa, VCAM-1, osteopontin (Luminex) (ii) CD4/CD8 activation (CD38/CD69), apoptosis (CD95), exhaustion (PD1), maturation (CD45RA/CD45R0/CD127/CCR7), recent thymic emigrants (CD31/CD103) (flow cytometry). Mann Whitney, Chi-squared were used. We defined low AMH ≤1ng/ml. Univariate and Multivariate Logistic Regression Analyses were used to assess factors associated with lowAMH (≤1ng/ml).
Results: Compared to HC, HIV+ women were more frequently non-Caucasian, drug/alcohol abusers, with history of late menarche, lower hormonal contraceptive use, higher gravidity and lower parity (Table.1a).
HIV+ showed significantly lower AMH (0.93 [0.81-1.59] vs 1.45 [1.11-1.78]; p=.004) and higher circulating TNFa (Table.1a).
HIV infection was the only factor independently associated with a 6- fold increased risk of low AMH in both uni- and multivariate logistic regression (Table.1b). In HIV-infected women, no other clinical, HIV-related and immunological parameters resulted associated with circulating AMH.



[Table 1. Demographic/gynecological/HIV-related features of the study population and risk factors for AMH ≤1ng/ml]

Conclusions: Despite effective cART, HIV+ women still display an increased risk of low circulating AMH versus age-matched peers, indicating premature ovarian ageing. The lack of associations with residual immune activation/inflammation, indicates that the higher probability of poor ovarian reserve in successfully treated HIV+ women is mediated by factors that are not captured by pro-inflammatory and cardiovascular/bone damage markers, and that might include tissue HIV reservoirs or co-infections.

WEPEB0568

Contraceptive utilization and fertility preferences among Cameroonian women with and without HIV infection

H. Budhwani[1], K.R. Hearld[1], J. Dionne-Odom[1], S. Manga[2], K. Nulah[2], M. Khan[3], T. Welty[2], E. Welty[2], A. Tita[1]
[1]University of Alabama at Birmingham, Birmingham, United States, [2]Cameroon Baptist Convention Health Services, Kumbo, Cameroon, [3]Kaiser Permanente, San Leandro, United States
Presenting author email: budhwani@uab.edu

Background: HIV prevalence is high in sub-Saharan Africa and the majority of residents living with HIV are of reproductive age. Family planning and the utilization of contraceptives play a significant role in preventing vertical and horizontal HIV transmission. However, decision-making around contraception is poorly understood in many African nations, including Cameroon. Considering this critical knowledge gap, we examined associates of modern contraceptive utilization among Cameroonian women with and without HIV infection.
Methods: De-identified medical records were identified from women screened for cervical cancer as part of the Cameroon Baptist Convention Health Services Women's Health Program in 2007-2013. Bivariate analysis compared personal characteristics and contraceptive practices between HIV-positive and HIV-negative women. Multivariate analysis used logistic regression to model the use of modern methods of contraception.

	N / % HIV + N=2,876	N / % HIV - N=16,662	χ^2
Use Modern Methods*	740 / 34.51%	4,141 / 31.15%	χ^2=9.64 p<0.01
Desire to Become Pregnant Soon* (Yes)	470 / 30.13%	2,830 / 31.66%	χ^2=1.49 p=0.47
Polygamous* (No, 0 Cowives)	757 / 73.78%	7,861 / 82.36%	χ^2=48.89 p<0.001
Polygamous* (Yes, 1+ Cowives)	184 / 17.93%	1,065 / 11.16%	
Parity (0)	210 / 7.30%	1,695 / 10.17%	χ^2=204.49 p<0.001
Parity (1-2)	854 / 29.69%	3,419 / 20.52%	
Parity (3-4)	698 / 24.27%	3,254 / 19.53%	
Parity (5+)	1,114 / 38.73%	8,294 / 49.78%	

[Table 1. Bivariate Results of HIV+ and HIV- Women]

Results: The study included 19,538 women with age 16-45 years. Modern contraceptive utilization was low at 31%. See Table 1 for bivariate results. Women living with HIV had 85% higher odds of modern contraception use (OR: 1.85, p<0.001).

As expected, women with higher parity and higher education levels had higher odds of using modern contraception (OR 1.17, p<0.001 for parity; OR: 3.37, p<0.001 for post-secondary school attendance). Polygamy was negatively associated with modern contraception use; women with three or more cowives had 63% lower odds of modern contraception use (OR: 0.37, p<0.001). All reported odds ratios are adjusted. *Percentages are affected by missing data.
Conclusions: Although it is encouraging that HIV-infected women in Cameroon utilized modern contraceptives at a higher rate than HIV-uninfected women, only one of three women in either group used modern contraceptives during the study period. Some used less reliable, traditional methods (e.g. natural family planning). There are opportunities to improve family planning efforts to reduce vertical and horizontal HIV transmission. Further research is needed to elucidate the decision-making process pertaining to modern contraceptive utilization in sub-Saharan Africa.

WEPEB0569

High prevalence of bacterial vaginosis among women seeking contraception in Kenya

E. Irungu[1], K. Thomas[2], K. Ngure[1], T. Hong[2], M. Krows[2], N. Mugo[3], J. Marrazzo[4]
[1]Jomo Kenyatta University of Agriculture and Technology, Department of Public Health, Nairobi, Kenya, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Kenya Medical Research Institute, Centre for Clinical Research, Nairobi, Kenya, [4]University of Alabama, Division of Infectious Diseases, Birmingham, United States
Presenting author email: mugoiri_99@yahoo.com

Background: The prevalence of bacterial vaginosis (BV), which has been associated with increased risk of HIV acquisition and transmission, is high among young women in sub-Saharan Africa, a region that bears the largest incidence of new HIV infections. Women seeking contraceptive services have an opportunity to be evaluated and managed for BV. We sought to determine the prevalence and correlates of BV among women desiring contraception.
Methods: Women screening for a study to evaluate the effects of a contraceptive vaginal ring on vaginal microbiota in Thika, Kenya were assessed. BV diagnosis was made using Amsel's clinical criteria. Factors associated with BV were analyzed using multivariate logistic regression techniques.
Results: Of the 363 women, 246 (69%) were aged < 30 years and 195 (54%) had more than eight years of education. More than three-quarters of the women (280 (78%)) reported having an income and 42 (12%) reported weekly consumption of alcohol. Of the 247 (69%) women who reported having a main sex partner, 132 (53%) were living with this partner. Median number of reported sex acts in the prior month was 3 [IQR 1-8], with 60 (20%) of the women reporting condom use every time they had sex. Daily vaginal washing and use of vaginal lubricants were reported by 215 (60%) and 32 (9%) women, respectively. Close to half (42%) of the women reported an abnormal vaginal discharge.
One hundred and sixteen women (34.6%) had BV. Living with a main sexual partner was associated a reduced likelihood of having BV (OR 0.43 (95% CI 0.20, 0.92). Additionally, having an abnormal vaginal discharge (p < 0.001), lesions in the genital area (p = 0.04) or having a yeast infection (p = 0.02) were also associated with having BV. Vaginal washing and condom use were not significantly associated with BV.
Conclusions: The prevalence of BV among young women seeking contraception was high. Reproductive health workers have an opportunity to evaluate, manage, and educate women who want to use contraception about BV and associated risks, and this may reduce their risk of acquiring HIV.

WEPEB0570

Desire to prove fertility and contraceptive misconceptions delay family planning and condom use until after pregnancy among Kenyan adolescents

Background: Adolescent girls have a high risk of unintended pregnancy and HIV acquisition in Kenya. We conducted a mixed methods study to characterize contraceptive knowledge and determinants of use among postpartum adolescents.
Methods: We recruited postpartum HIV-uninfected adolescents from 2 maternal-child health clinics in Western Kenya to participate in a survey and focus group discussion (FGD); 4 FGDs were conducted, stratified by site and age (14-18, 19-21). We also recruited health care providers offering family planning (FP) services to participate in a survey and 2 FGDs (1/site).
Results: Overall, 32 adolescents and 28 providers participated. Median provider age was 36 (interquartile range [IQR]: 31-47), and median number of years providing FP was 5 (IQR: 3-10). Misconceptions about FP and HIV risk were common among both providers and adolescents. Nearly half (40%) of providers believed intrauterine devices (IUDs) increased risk of HIV acquisition, and 63% believed they were unsafe to use among HIV-infected women. Adolescents were familiar with condoms for HIV and pregnancy prevention, but believed condoms were only appropriate when a partner was known to be HIV-infected, rather than when partners HIV status was unknown or concordant negative. Providers identified lack of training, experience, and counseling time as barriers to offering the full range of FP methods; they limited counseling to short-term methods when there were long queues or if they lacked knowledge or experience with other methods. Limited counseling options coupled with lack of training and experience with implants and IUDs contributed to lower use of these methods among young women at risk for HIV. Prior to marriage and/or childbearing adolescents lacked family and community support for FP, but adolescents also said they did not use FP because they felt it was important to prove their fertility prior to childbearing. However, after they became mothers adolescents received encouragement and familial/community support to use FP and had increased awareness of FP benefits.
Conclusions: Adolescents would benefit from novel strategies to receive better contraceptive support and education prior to childbearing (including dual method use with condoms) and improved provider training to prevent unintended pregnancies and HIV transmission.

WEPEB0571

Differences in genital tract HIV RNA shedding by injectable progestin contraceptive (IPC) exposure among antiretroviral therapy (ART)-naïve and ART-using HIV-infected women in Cape Town, South Africa

C. Todd[1], H. Jones[2], N. Langwenya[3], D. Hoover[4], A. Ronan[3], L. Myer[3]
[1]FHI 360, Behavioral, Epidemiological & Clinical Sciences, Durham, United States, [2]City University of New York School of Public Health, Epidemiology & Biostatistics, New York, United States, [3]University of Cape Town, Centre for Infectious Diseases Epidemiology and Research (CIDER), Cape Town, South Africa, [4]Rutgers University, Statistics & Biostatistics, Piscataway, United States
Presenting author email: ntokozolangwenya@gmail.com

Background: IPCs may increase female-to-male sexual HIV transmission risk. ART use reduces genital tract HIV shedding. Few data exist regarding IPC use and shedding in ART-naïve and ART-using women. We compared genital tract HIV viral load (gVL) and recent IPC exposure among women by ART use.
Methods: Within a larger trial of intrauterine device use among HIV-infected women, we enrolled:
(i) ART-using (>6 months) women with recent (<12 months) plasma VL (pVL) <1000 copies/dL and;
(ii) women not yet eligible for ART by local guidelines (pre-ART). All women underwent reproductive tract infection (RTI) testing and treatment within 1 month of enrollment, and at enrollment completed questionnaires on contraceptive history and provided specimens for pVL and gVL (via menstrual cup). IPC exposure was defined as depot medroxyprogesterone acetate (DMPA) or norethindrone enantate (Net-En) use within 120 days before enrollment; enrollment was timed to coincide with next IPC dose. Associations between IPC and detectable gVL were analyzed using exact tests and logistic regression, stratified by ART status.
Results: Of 199 women (132 ART-using, 67 pre-ART), 39% reported recent IPC use. ART-using women were less likely to have detectable gVL or pVL (Table 1; p=0.002); detectable pVL was strongly correlated with detectable gVL (AOR=5.28, 95% CI=1.93-14.5) only among ART users.

Variable	Pre-ART	ART	Recent IPC Exposure	No Recent IPC Exposure
Age (median, IQR)	30 (26, 34)	32 (28, 36)	32 (28, 36)	31 (27, 34)
IPC use in last 120 days (%, n)	39% (26)	42% (51)	---	---
Any RTI* at screening (%, n)	36% (24)	24% (32)	27% (21)	29% (35)
Baseline detectable gVL (%, n)	64% (40/63)	16% (21/130)	36% (26)	30% (36)
Baseline detectable pVL (%, n)	95% (63/66)	20% (26/130)	44% (33/75)	46% (56/121)
Baseline log10 plasma VL (median, IQR)	3.91 (3.17, 4.48)	2.73 (2.01, 3.44)	3.07 (2.44, 3.66)	3.21 (2.52, 4.01)

**Neisseria gonorrhea, Chlamydia trachomatis, Trichomonas vaginalis, & bacterial vaginosis.*

[Table 1. Key participant characteristics]

For ART users, recent IPC was associated with detectable gVL (Table 2) and remained independently associated when adjusted for age, RTI, and detectable pVL (AOR=3.27, 95%CI=1.16-9.21; p=0.025). Among ART users, the difference was strongest for women reporting recent Net-En use (Table 2).

Bivariate comparison of genital HIV shedding with recent exposure to and specific type of IPC, by ART status								
	Recent vs. No Recent IPC use	p-value	DMPA vs. Net-En	p-value	Net-En vs. No Recent IPC Use	p-value	DMPA vs. No Recent IPC Use	p-value
Pre-ART	58% (14/24) vs. 67% (26/39)	0.593	64% (9/14) vs. 50% (5/10)	0.678	50% vs. 67%	0.465	64% vs. 67%	1.00
ART-using	25% (12/49) vs. 11% (9/81)	0.052	21% (8/38) vs 36% (4/11)	0.427	36% vs. 11%	0.046	21% vs. 11%	0.167

[Table 2.]

Conclusions: These novel data suggest recent IPC use may be associated with increased gVL in ART-using women. Given widespread concern about potential for IPC to enhance HIV transmission, this association warrants further investigation, with attention to potential differential effects of Net-En vs. DMPA.

WEPEB0572

Tolerability and satisfaction of levonorgestrel versus etonogestrel contraceptive implants among women living with HIV

S. Nakalema[1], K. Scarsi[2], G. Anguzu[1], F. Mubiru[1], K. Darin[3], A. Kusiima[1], I. Kyohairwe[1], M. Lamorde[1], C. Chappell[4]
[1]Infectious Disease Institute, Kampala, Uganda, [2]University of Nebraska Medical Center, Omaha, United States, [3]Northwestern University, Chicago, United States, [4]University of Pittsburgh, Pittsburgh, United States
Presenting author email: snakalema@idi.co.ug

Background: In Uganda, uptake of contraceptive implants remains low, possibly due to fear of side effects. We present data on side effects and satisfaction related to the levonorgestrel (LNG) implant versus the etonogestrel (ENG) implant among Ugandan women living with HIV.
Methods: Two studies evaluated LNG or ENG implant pharmacokinetics and tolerability. Each study enrolled 60 women into three groups (n=20/group): efavirenz-based ART, nevirapine-based ART, or ART-naive. Tolerability and satisfaction data were combined across ART groups. At each visit, participants were asked about implant-associated side effects using a structured questionnaire; and contraceptive satisfaction was assessed using a Likert scale. Occurrence of side effects (graded by DAIDS severity tables) and the frequency of being "very satisfied" with the implant at weeks 4, 12 and 24 were compared between the studies by chi-square.
Results: In total, 120 consenting adult women were enrolled in the studies. Three women were excluded from the analysis by week 24 (ART initiation, study nonadherence, and consent withdrawal). Baseline characteristics were similar between studies. There were no statistically significant differences between studies at any visit, except for increased headache at week 12 and increased metrrohagia weeks 12 and 24 in the ENG group (Table, p=0.03, 0.01 and 0.02, respectively). All reported side effects were Grade 1, except two in the LNG study (both weight gain) and three in the ENG study (one metrorrhagia; two dysmenorrhea), which were Grade 2. Overall, lower satisfaction with menstrual symptoms at week 4 and overall satisfaction at week 12 were observed with LNG compared to the ENG implant (Table, p< 0.001 and p=0.04, respectively).

Side effect or satisfaction	LNG Week 4 (n=58)	LNG Week 12 (n=58)	LNG Week 24 (n=57)	ENG Week 4 (n=60)	ENG Week 12 (n=60)	ENG Week 24 (n=60)
Nausea	7 (12.1%)	4 (6.9%)	3 (5.3%)	10 (16.7%)	5 (8.3%)	8 (13.3%)
Headache	16 (27.6%)	12 (20.7%)*	13 (22.8%)	25 (41.7%)	24 (40.0%)*	15 (25.0%)
Weight gain	15 (25.9%)	23 (39.7%)	18 (31.6%)	14 (23.3%)	17 (28.3%)	29 (48.3%)
Breast tenderness	4 (6.9%)	3 (5.2%)	3 (5.3%)	4 (6.7%)	4 (6.7%)	3 (5.0%)
Menorrhagia	10 (17.2%)	18 (31.0%)	11 (19.3%)	16 (26.7%)	16 (26.7%)	11 (18.3%)
Metrorrhagia	3 (5.2%)	6 (10.3%)*	2 (3.5%)*	5 (8.3%)	19 (31.7%)*	11 (18.3%)*
Amenorrhoea	23 (39.7%)	23 (39.7%)	26 (45.6)	18 (30.0%)	14 (23.3%)	20 (33.3%)
Satisfaction with menstrual symptoms	29 (50.0%)*	35 (60.3%)	44 (77.2%)	52 (86.7%)*	46 (76.7%)	53 (88.3%)
Overall satisfaction	49 (84.5%)	44 (75.9%)*	51 (89.5%)	55 (91.7%)	54 (90.0%)*	54 (90.0%)

[Table]

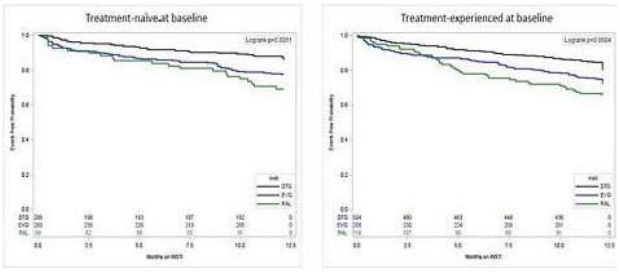
Conclusions: Ugandan women living with HIV had high levels of satisfaction and low rates of Grade 2 adverse events with both implants. Women on ART using contraceptive implants are unlikely to experience greater than mild adverse events in the first 24 weeks.

WEPEB0573

Initial regimen duration in female patients taking integrase strand transfer inhibitors (INSTI) in the OPERA® observational database

F. Carpio[1], C. Henegar[2], J. Fusco[2], E.B. Quinlivan[3], V. Vannappagari[4], M. Aboud[5], K. Smith[4], G. Fusco[2]
[1]AltaMed Health Care Service, Los Angeles, United States, [2]Epi, Durham, United States, [3]AIDS Healthcare Foundation, Atlanta, United States, [4]ViiV Healthcare, Research Triangle Park, United States, [5]ViiV Healthcare, Brentford, United Kingdom
Presenting author email: cassidy.henegar@epividian.com

Background: Women face unique complexities with antiretroviral therapy. This analysis compares durations of initial INSTI-based regimens in HIV+ females.
Methods: HIV+ women initiating their first INSTI-containing regimen between 08/12/2013 and 11/30/2015 were identified in the OPERA cohort, a collaboration of 79 clinics in 15 US states. Each patient was observed from regimen start until discontinuation, loss to follow-up, death, or data freeze (11/30/2016). Time to discontinuation was evaluated using Cox regression and Kaplan-Meier estimates.
Results: Out of 73,406 HIV+ patients, 537 treatment-naïve (dolutegravir (DTG):39%, elvitegravir (EVG):48%, raltegravir (RAL):13%) and 878 treatment-experienced (DTG:57%, EVG:29%, RAL:13%) women qualified for analysis.
In the first twelve months after initiation, women taking RAL or EVG were more likely to discontinue their initial INSTI than those taking DTG among both treatment-naïve (adjusted hazard ratio EVG vs. DTG: 1.61(95% CI: 1.09, 2.39); RAL vs. DTG: 2.27 (1.37,3.76)) and treatment-experienced women (EVG vs. DTG: 1.39 (1.03, 1.87); RAL vs. DTG: 2.11 (1.47, 3.02)).
Among women who switched to another regimen during all of follow-up (naïve DTG: 32%, RAL: 62%, EVG: 42%; experienced: DTG: 39%, RAL: 59%, EVG: 44%), a third of treatment-naïve women (DTG:33%, RAL:37%, EVG:36%) and over a quarter of treatment-experienced women (DTG:24%, RAL:27%, EVG:45%) switched to another INSTI.
Treatment interruptions of >45 days were also commonly observed immediately after discontinuation of the initial INSTI (naïve DTG: 30%, RAL: 19%, EVG: 31%; experienced DTG:26%, RAL: 13%, EVG: 19%).



[Figure. Kaplan-Meier estimates of time to discontinuation of first INSTI-based regimens in the first twelve months of treatment]

Conclusions: In a large cohort of HIV+ women in care, INSTI-based regimens were effective throughout the first year of follow-up for treatment-naïve and treatment-experienced women. Women receiving DTG were the least likely to discontinue during this period and over all of follow-up. Intra-class switching from initial INSTIs and drug interruptions suggest that women may be discontinuing for reasons other than virologic failure, and that access may be a major issue.

WEPEB0574

Uptake and correlates of cervical cancer screening among HIV-infected women attending HIV-care in Uganda

R.K. Wanyenze[1], J.B. Bwanika[1], J. Beyeza-Kashesya[2], S. Mugerwa[3], J. Arinaitwe[3], J.K. Matovu[1], V. Gwokyalya[1], D. Kasozi[1], J. Bukenya[1], F. Makumbi[1]
[1]Makerere University, School of Public Health, Kampala, Uganda, [2]Mulago National Referral Hospital, Kampala, Uganda, [3]Ministry of Health, Kampala, Uganda
Presenting author email: rwanyenze@hotmail.com

Background: Sub-Saharan Africa has the highest burden of cervical cancer globally and HIV infected women are at particularly high risk. Integration of cervical screening into HIV care is recommended but service uptake is rarely tracked. We assessed the uptake and correlates of cervical cancer screening among HIV infected women in care in Uganda.
Methods: A nationally representative sample of HIV infected women in care were interviewed in a cross-sectional survey conducted August-November 2016. Structured interviews were conducted with 5198 HIV infected women 15-49 years, from 245 HIV clinics. Knowledge of cervical cancer and uptake of cervical

screening were determined. Correlates of uptake of screening were assessed with modified Poisson regression model to obtain prevalence ratios (PR) using Stata version 12.0.
Results: Overall, 94.0% (4858) ever heard of cervical cancer and 66% (3732) knew a site for cervical screening. However, 47.4% (2302) didn't know the schedule for screening and 50% (2409) did not know the symptoms of cervical cancer. A third, (33.7%; 1719) rated their risk of acquiring cervical cancer as low while 16.8% (857) rated the risk as high. Uptake of screening was 30.3% (1561), ranging from 18.6% in the central region to 39.1% in Kampala. Women who never screened cited lack of information (29.6%; 1059), no time (25.5%; 913), lack of screening facilities (14.0%; 501), and information about procedure being painful 10.5% (376). Majority of the 245 health facilities (64%; 153) offered cervical cancer screening. Delivery at health facilities (adj.PR 1.69, CI 1.00-2.87), receipt of HIV care at HCII and private facilities (adj.PR1.55, CI 1.07-2.26 and adj.PR 1.96, CI 1.15-3.34, respectively), knowledge of cervical cancer (adj.PR 1.69, CI 1.29-2.21), where to screen from (adj.PR 8.31 CI 4.47-15.45) and low risk perception (adj.PR 1.50, CI 1.12-2.01) increased likelihood of screening. HPV vaccination was very low at 2%, but higher among adolescents 15-19 years, at 8%.
Conclusions: Cervical screening uptake was very low among HIV infected women in care in Uganda, especially in the central region. Improved awareness about cervical cancer, sources of services and addressing risk perception may increase uptake of cervical screening in this population.

Key populations

WEPEB0575

Perceived HIV stigma among men who have sex with men (MSM) patients with HIV in a single hospital in Northern Taiwan

A. Wu, Y.-T. Hsu
MacKay Memorial Hospital, Infectious Diseases, Taipei, Taiwan, Province of China
Presenting author email: watrlilies@gmail.com

Background: HIV-related stigma is a common obstacle facing the care in those people living with HIV especially among MSM. We attempt to measure HIV / AIDS-related stigma as experienced by patients from a hospital in Northern Taiwan.
Methods: The HIV stigma scale, as developed by Berger [1] and modified by Lindberg [2] in 2014 was used to measure HIV-related stigma on 68 MSM patients who visited MacKay Memorial Hospital in Taipei, Taiwan. The scale consisted of four subscales in Personalized Stigma, Disclosure Concerns, Negative Self-Image, and Concerns with Public Attitudes. These 39 items were answered with Likert scale responses. Patient's responses were analyzed using T-test for equality of means.
Results: Sixty-eight patients participated in the study. The mean age was 33. Majority of the patients had college level education (64.71%) and diagnosed more than 24 months (66.18%). 47.06% of the patients had a fixed partner. Most of the patients reported that at least one family member, partner or friend knew about their disease while greater than 50% of patients felt that other people were supportive or very supportive after finding out about their disease. Patients reported HIV-related stigma in all four dimensions of the HIV stigma scale, especially Diclosure Concerns.

Dimensions	Score	Standard Deviation
Personalized Stigma	2.46	0.86
Disclosure Concerns	3.18	0.75
Negative Self-Image	2.37	0.79
Concerns with Public Attitudes	2.97	0.79

[Table 1. HIV Stigma Scale Scores]

Statistical analyses revealed that patients who were received very supportively or supportively by others when others learnt of their disease were less likely to suffer from Personalized Stigma (p=0.002) and Negative Self Image (p=0.003).

Dimensions	Scores in Those with Supportive Contacts	Scores in Those with Unsupportive Contacts	P value
Personalized Stigma	35.38	43.59	0.002
Disclosure Concerns	27.87	29.24	0.224
Negative Self-Image	17.60	21.59	0.003
Concerns with Public Attitudes 19.91	19.91	21.94	0.051

[Table 2. Analysis]

Conclusions: In general, people living with HIV in Taiwan reported HIV-related stigma in all four dimensions of the HIV stigma scale, especially Disclosure Concerns. Patients who reported more support from family and peers experienced significantly less stigma in the areas of Personalized Stigma and Negative Self Image. Healthcare professionals should be address HIV-related stigma concerns when providing care for MSM patients with HIV.

WEPEB0576

Social capital and depression in HIV-infected young black men who have sex with men

S. Hussen[1], K. Easley[2], A. Camacho-Gonzalez[3], J. Smith[4], G. Harper[5], R. Stephenson[6], C. del Rio[1]
[1]Emory University, Hubert Department of Global Health, Atlanta, United States, [2]Emory University, Department of Biostatistics, Atlanta, United States, [3]Emory University, Department of Pediatrics, Atlanta, United States, [4]Emory University, Department of Health Behavior and Health Education, Atlanta, United States, [5]University of Michigan School of Public Health, Department of Health Behavior and Health Education, Ann Arbor, United States, [6]University of Michigan, Ann Arbor, United States
Presenting author email: sophia.ahmed.hussen@emory.edu

Background: Social capital, the sum of an individual's resource-containing, reciprocal, and trustworthy social network connections, has been proposed as an important facilitator of successful HIV care engagement. Depression, on the other hand, has been shown to negatively impact clinical outcomes among people living with HIV. We sought to explore relationships between social capital, depression and engagement in HIV care in a sample of young Black gay, bisexual and other men who have sex with men (YBMSM) in Atlanta, USA.
Methods: We recruited 81 HIV-infected YBMSM from the Grady Infectious Disease Program clinic. Each participant completed a survey including measures of social capital and depression. Social capital was measured with a modified Personal Social Capital Scale; which included items about the amount and types of support offered through social networks and community involvement. Depression was measured using the Centers for Epidemiologic Studies-Depression (CES-D) scale. Clinical outcomes (appointment attendance and HIV-1 viral load) were extracted from the medical record.
Results: Our sample ranged in age from 18-24 years (Mean=22, SD=1.5). Forty-nine percent (49%) had attended at least 75% of their scheduled appointments over the past year. Sixty-five percent (65%) were virally suppressed (HIV-1 VL ≤ 50 copies/ml). The median social capital score was 25, similar to prior research in other populations. Forty-seven percent (47%) had a positive depression screen. Depression affected viral suppression differently in YBMSM with lower (below median of 25) vs. higher social capital (p = 0.046, test for interaction). There was no association between depression and viral suppression among those with higher social capital (OR= 0.63; p=0.52). However, the odds of viral suppression among YBMSM with lower social capital was 93% lower in depressed vs. non-depressed participants (OR= 0.07, p= 0.002).
Conclusions: Depression was very common in our sample of HIV-infected YBMSM; nearly half of our participants had a positive screen. For these patients, social capital was an important protective factor, as the detrimental effect of depression on viral suppression was worsened among those with low social capital. Our results suggest a need for innovative network-level interventions to augment social capital among HIV-infected YBMSM, particularly those who are depressed.

WEPEB0577

Risky sexual behavior in French HIV-positive men who have sex with men (MSM): ANRS DRIVER study

M. Duracinsky[1], S. Fouéré[2], S. Dimi[3], C. Lalanne[4], O. Chassany[4], D. Zucman[3], DRIVER Study Group
[1]Hôpital Bicêtre/EA 7334 REMES, Recherche Clinique Ville-Hôpital, Méthodologies et Société, Université Paris 7, Paris, France, [2]Hôpital St Louis, Paris, France, [3]Hôpital Foch, Suresnes, France, [4]EA 7334 REMES, Recherche Clinique Ville-Hôpital, Méthodologies et Société, Paris, France
Presenting author email: duracinsky.m@gmail.com

Background: High risk sexual behavior is rising in MSM reflected by an increase in sexually transmitted infections (STI). The aim of the ANRS DRIVER study is to estimate the prevalence of asymptomatic STIs in HIV positive MSM and create a risk score of STI. We report the behavioral data.
Methods: Between April and December 2015, HIV positive MSM were enrolled in 13 Paris area hospitals. Sexual behavior was assessed using self-reported outcomes: risky sexual behavior was assessed using 2 scales - the Sexual Compulsivity Scale (SCS) and the Sexual Sensation Seeking Scale (SSSS) - as well as by ways of re-

sponses to a behavioral questionnaire inquiring about drug, alcohol, and condom use in several sexual situations. Chlamydia trachomatis and Neisseria gonorrhoeae were tested by PCR on urine, pharyngeal and anal swabs; syphilis by serum antibodies.
Results: 485 asymptomatic patients at their HIV semi-annual follow up visit were included (median age: 47 years, average time living with HIV: 13 years, undetectable viral load in 94%, average CD4+: 679/mm3. Nearly 63% had a history of STI (genital warts in 39%, syphilis in 45%), and 18% within the previous 12 months. An ongoing STI was found in 13.6% (syphilis 6%, CT or NG infection 8%). Risky behavior in sex, drugs and alcohol use are tabulated.

Risky sexual behaviors in the last six months: N=485	%
Use of Grindr networking application	46
Poppers use	40
Non protected anal intercourse	38
Non protected group sexual intercourse	31
Alcohol use during sexual intercourse	31
Cannabis use	23
Cocaine use	15
GBH use	8
Sex for money	7

[Table 1]

Fifteen percent of patients had an SCS score above 20 (vs 5-6% in the general population) reflecting high compulsivity. Respondents reported thinking about sex at work (16%), thinking about sex more frequently than they would like (14%), frequent uninhibited behavior (30%), seeking new sexual experiences (42%) and unprotected sex (42%). The median score of the SSSS was 22.8. The SSSS was positively correlated with the SCS (R = 0.58).
Conclusions: Risky sexual behavior and sexual compulsivity are common in the French HIV-positive MSM population.

WEPEB0578

Unusual and unique distribution of anal high-risk human papillomavirus among men who have sex with men living in the Central African Republic

R.S. Mbouma Bouassa[1], S. Camengo[2,3], C. Mossoro-Kpinde[3,4], M. Mbeko Simaleko[5], G. Grésenguet[3,5], L. Bélec[1]
[1]Laboratoire de Virologie, Hôpital Européen Georges Pompidou, and Université Paris Descartes, Paris Sorbonne Cité, Paris, France, [2]Hôpital de l'Amitié, Bangui, Central African Republic, [3]Faculté des Sciences de la Santé, Université de Bangui, Bangui, Central African Republic, [4]Laboratoire National de Biologie Clinique et de Santé Publique, Paris, Central African Republic, [5]Centre National de Référence des Infection Sexuellement Transmissibles et de la Thérapie Antirétrovirale, Bangui, Central African Republic
Presenting author email: ralphsydney87@yahoo.fr

Background: High-risk Human Papillomavirus (HR-HPV) infection is the causal agent of anal cancer in men who have sex with men (MSM). The prevalence of HR-HPV was evaluated by molecular biology in MSM living in Bangui, the capital of the Central African Republic (CAR).
Methods: Forty-two MSM attending the Centre National de Référence des Infections Sexuellement Transmissibles et de la Thérapie Antirétrovirale (CNRISTTAR) were prospectively enrolled and tested for HPV. Genomic DNA was extracted using the DNeasy Blood and Tissue kit (Qiagen, CA, USA). Human beta-globin DNA was detected by PCR. Anyplex II HPV28 (H28) HPV Genotyping Test (Seegene, Seoul, South Korea) was used for HPV genotype distribution in human beta-globin DNA positive samples.
Results: . Among the 42 anal specimens, 29 (69% [95% CI: 55.0-83.0%]) were positive for HPV DNA. Multiple genotypes infections were frequent in 86.2% (25/29; 95% CI: 73.6-98.7%) of positive anal samples and 88% of them were infected by an average of 2.5 HR-HPV (range, 1 to 8 genotypes per anal specimen). 13.8% of anal samples were infected with a single type of HPV and all of them were high-risk types. HPV-31 was found in 65% of single HPV infection. HR-HPV type 35 was the most prevalent genotype (27.5%), followed by HPV-42 and HPV-53 (24.1%), HPV-58 and -59 (20.7%) and HPV-31 and -61 (17.2%). Interestingly, HR-HPV -16 and -18 were poorly represented in 13.8% (4/29) and 10.3% (3/29), respectively. Only one sample was simultaneously infected by HPV-16 and HPV-18. Low-risk (LR) HPV-6 and HPV-11 were observed in 2 and 3 anal samples, respectively.
Conclusions: HR-HPV-35, LR-HPV-42 and LR-HPV-53 were the most prevalent genotypes in anal samples. These findings demonstrate unusual and unique distribution of HVP genotypes in the MSM population of Bangui, and indicate that the currently available 9-valent HPV vaccine would be poorly effective in this at-risk population.

Presenting author email: evy.yunihastuti@gmail.com

Background: Persistent anal infection with high-risk HPV (HR-HPV) is a major risk factor for anal cancers among MSMs. Knowledge about anal HR-HPV persistence in Asia is very limited. We studied anal HR-HPV persistence and its associated factors among MSM in Thailand, Indonesia and Malaysia.
Methods: MSM aged ≥18 years were enrolled from Bangkok, Jakarta, Bali and Kuala Lumpur and followed up 6 monthly intervals for 12 months. A Dacron swab was used to collect anal samples for HPV genotyping. Persistence anal HR-HPV was defined as the presence of HR-HPV type(s) at all three visits. Incidence anal HR-HPV was defined as new detection of HR-HPV type(s) at months 6 and 12 without HR-HPV type(s) at baseline. Baseline demographic data, risk behavior and HIV clinical data were included in the logistic regression models to identify factors associated with persistent anal HR-HPV infection.
Results: Of 392 (235 HIV-positive) MSM enrolled, HIV-positive MSM were older [mean age 35.8(SD 9.0) vs. 32.1(SD 9.2) years], more likely to have a history of sexually transmitted infections (27.7 vs. 18.5%), have had unprotected sex in the past 6 months (26.0 vs. 42.7%), and were less likely to be circumcised (35.3 vs. 45.9%). Of the HIV-positive MSM, 63.0% were taking antiretroviral treatment for a median (IQR) time of 3.0 (1.8-5.8) years.
High-risk HPV types were detected more frequently in HIV-positive MSM than HIV-negative MSM at baseline (66.5 vs. 50.8%, p=0.004). Overall persistence of any HR-HPV types was 33.3%, while the incidence was 8 per 100-person-months. HPV-16 was the most prevalent HR-HPV type (16.9%) at baseline, had the highest incidence (5.1 per 100 person-months), and the highest persistence (9.9 %).
Being HIV-positive (OR 3.66, 95%CI 1.84-7.26, p<0.001), living in Kuala Lumpur (OR 3.49, 95%CI 1.45-8.42, p=0.005), and employed (OR 2.01, 95%CI 1.22-3.33, p=0.007) increased the risk for the overall persistence of HR-HPV. Persistent HPV-16 was associated with being HIV-positive (OR 3.93, 95%CI 1.34-11.53, p=0.01) and living in Kuala Lumpur (OR 5.98, 95%CI 1.70-21.03, p=0.005).
Conclusions: More than half of MSM in South-East Asia had anal HR-HPV infection. HPV-16 was the most common incident and persistent HR-HPV type. HIV-positive status significantly increased the risk of persistent infection of HR-HPV types, including HPV-16.

Multidisciplinary management of MSM patients practicing chemsex and slam, in a LGBT-community sexual health clinic

T. L'yavanc, N. Pierre, A. Zugmeyer, D. Gosset, M. Ohayon
Centre de Santé Le 190, Paris, France
Presenting author email: michel.ohayon@tnn.aphp.fr

Background: Chemsex (use of drugs before or during sexual intercourse) and slam (chemsex with intravenous drugs injections) emerged since late 2000's in the gay community. The main complications are addictions, psychiatric disorders, and infectious diseases (HIV, HCV). Few data were published on this field, particularly treatment's guideline.
The objective of the study was to describe our focused healthcare program and evaluate quantitatively his efficiency.
Methods: This study is a retrospective analysis of participants who have recorded for addiction in a LGBT-community sexual health clinic in the center of Paris, the "190". For each participant, the frequencies of chemsex practice (daily, weekly, monthly, quarterly, on occasion, past, or none) at the first and the last consultation were recorded and compared. Participants who had a follow-up (defined as at least 3 consultations and at least 3 months of follow-up during the study interval) were included in the efficiency evaluation.
Results: From 2013 to 2016, 144 participants consulted because of chemsex, generating 1120 addictologic, psycho-sexological, or psychiatric consultations. All were men, average age 39 years, 59% were HIV-infected, 45% practiced slam, with a weekly or daily frequency for 2/3 of them. Among them, 79 MSM practicing chemsex initiated a follow-up for this reason: average age 39 years, 63% HIV-infected, 54% practicing slam, with a daily or weekly frequency for 3/4 of them. The follow-

up was mainly multidisciplinary (67%), mostly addictologic (89%) and psycho-sexo-logical (73%) but also psychiatric for 25%. The average of follow-up was 14 months and 12 consultations. Half of the patients involved in a follow-up reduced (39%) or stopped (9.9%) chemsex or slam practices.
Conclusions: The multidisciplinary management set up in the "190" satisfies a strong demand. Despite severe addictologic profiles, this follow-up has a positive quantitative impact since half of the participants reduced or stopped chemsex or slam consummation. It seems necessary to develop this kind of healthcare programs in structures receiving MSM.

Communication outlets of men who have sex with men in Nigeria and implications for program planning and interventions

A. Adepoju
KNCV Tuberculosis Foundation, HIV and TB Care, Igando, Nigeria
Presenting author email: schrodinga05@yahoo.com

Background: Men who have sex in Nigeria communicate in fearful and harsh environment where being gay has been criminalized. An understanding of common means of communication of Men who have Sex in Nigeria will provide insight on communication platform where HIV prevention interventions should focus for maximum impact. The objective of the study was to identify common means of communication outlets among men who have sex with men in Nigeria for intervention purpose.
Methods: A total of 6,114 key informant interviews were conducted. Population size estimates was incorporated into a mapping and characterization which took place between July and September 2015 across 20 Local Government Areas (LGAs) in Lagos, Nigeria. We utilized the capture-recapture method to identify MSM who were engaged in key informant interview. Data were also triangulated to ensure accurate estimate of three hidden and highly stigmatized populations in Lagos, Nigeria.
Results: In the capture phase, 329(25.4%) used emails, 1623(83%) used phone, 1543(78.6%) communicated through friend while the highest percentage of MSM 1816(86.2%) used the social media (Instagram, Facebook, twitter, SMS, WhatsApp, MSM parties and 2-go chat). In the recapture phase, 161(26.8%) used email as means of communication, 715(81.7%) used phone, 799(84.9%) communicated via a friend while 873(87.8%) used the social media.More than one quarter (27.3%) of MSM were interviwed in internet cafes during the study.
The commonest means of communication was the social media including 2-go, Instagram, MSM parties SMS, WhatsApp and Twitter 86.2% and 87.8% of MSM reported to have used these social media outlets in the capture and recapture phases respectively.
Conclusions: Overall, a high proportion of MSM in Nigeria utilized the social media as the commonest means of communication and meeting male sex partners online. The information in this study can be used to direct and target interventions or how best to model delivery of HIV prevention messaging to these MSM, who represent a young, highly educated and highly stigmatized group. These data suggest that further research assessing the feasibility and acceptability of social media interventions will be increasingly important to addressing the HIV epidemic among MSM across Nigeria.

WEPEB0582

Is access to direct-acting antivirals (DAA) universal? A comparison of socio-behavioral characteristics between pegylated-interferon treated and DAA-treated patients in the French ANRS CO13-HEPAVIH cohort of HIV-HCV co-infected patients

I. Yaya[1], P. Roux[1], F. Marcellin[1], L. Wittkop[2], L. Esterle[2], B. Spire[1], S. Dominguez[3], L. Piroth[4], P. Sogni[5], D. Salmon-Céron[6], P. Carrieri[1]
[1]INSERM U 912 - SESSTIM, Marseille, France, [2]Université Bordeaux, ISPED, Bordeaux, France, [3]AP-HP, INSERM U 955, Créteil, France, [4]CHU Dijon, Université de Bourgogne, Dijon, France, [5]AP-HP, Université Paris Descartes - INSERM U 1016, Paris, France, [6]AP-HP Hôpital Cochin, Université Paris Descartes, Paris, France
Presenting author email: issifou.yaya@inserm.fr

Background: Direct acting antivirals (DAA) have dramatically increased the efficacy and safety of hepatitis C virus (HCV) infection treatment in HIV-HCV co-infected patients. However, their high costs translate into reduced access to HCV treatment for specific groups of patients. This study aimed at comparing the socio-behavioral characteristics of patients initiating pegylated-interferon (Peg-IFN)-based HCV treatment with those initiating DAA-based treatment, in a French hospital-based cohort of HIV-HCV co-infected patients.
Methods: ANRS CO13-HEPAVIH is a national multicenter prospective cohort started in 2006, which enrolled 1,850 HIV-HCV co-infected patients followed-up in French hospital outpatient units. Both clinical/biological (medical records) and socio-behavioral (self-administered questionnaires) data were collected during follow-up. We selected patients with socio-behavioral data available before HCV treatment initiation. Univariable (Chi2 test) and multivariable (logistic regression) analyses were performed to compare pre-treatment characteristics of patients initiating Peg-IFN based with those initiating DAA-based treatment.
Results: A total of 596 patients were included in this analysis. Among them, 367 initiated peg-IFN-based treatment, and 229 DAA-based treatment. There were significant differences between both groups regarding patients' mean age (45 years ±6 for the Peg-IFN group vs. 52 years ±8 for the DAA group, p<0.001), unstable housing (21.1% vs. 11.3%, p=0.034), drug use (43.9% vs. 30.1%, p=0.0008), regular or daily use of cannabis (24.1% vs. 15.9%, p=0.0004) and history of drug injection (68.8% vs. 38.8%, p<0.0001).
In multivariable analysis, patients initiating DAA-based treatment were older than their Peg-IFN-based treatment counterparts (aOR=1.17; 95%CI [1.13; 1.21]). The former group were less likely to report unstable housing (aOR=0.50; 95%CI [0.26; 0.95]), cannabis use (regular or daily use: aOR=0.53 [0.3; 0.95]; non-regular use: aOR=0.44 [0.24; 0.81]), and a history of drug injection (aOR=0.60; 95%CI [0.39; 0.91]).
Conclusions: Although in this co-infection cohort, it is possible that a majority of patients with socio-economic problems and advanced disease were treated for HCV in the Peg-IFN era, it seems that prescription of DAA concerns fewer patients with more unstable lifestyles. As HCV treatment is prevention, improving access to DAA, in particular to individuals with high-risk behaviors, remains a major clinical and public health strategy.

Presenting author email: pabloryan@gmail.com

Background: High prevalence of sexualized drug use(SDU) has been described in several samples of HIV-positive (HIV+) patients. However, motivations to engage in SDU are still poorly studied. We aimed to describe the reasons for starting and participating in SDU in a sample of HIV+ patients in Madrid (Spain).
Methods: We used an anonymous survey to explore magnitude and factors related to SDU (mephedrone, ketamine, GHB, crystal meth, MDMA, cocaine and/or amphetamine) in a sample of HIV+ MSM attending in 22 HIV clinics in Madrid 2016. The survey was conducted using REDCap™. From May to December 2016 a total of 511 participants completed the survey. The present analysis includes the group of patients who referred SDU during the past year. We described sociodemographical characteristics, type of drugs and proportions of patients who referred each type of reason for starting or getting engaged in SDU.
Results: We analysed the responses of 190 patients who referred SDU in the last year. Most of them were middle aged (Mean(SD)=37.8 (7.5)), 72% Spanish born, 71% had salaries above 1000 euros, and 88% were on ART. The drugs more commonly used were: GHB (53.2%), Cocaine (51.6%), Mephedrone (50%), MDMA (21.1%) and crystal methanphetamine (18.4%).
Table 1 shows frequencies of patients by reasons of consumption the first time of engaging in practices associated to SDU (Table 1). Motivations that led to SDU subsequent times are shown in Table 2.

REASONS	N(%)
Get new pleasurable experiences	126 (66.3)
Try new drug uses	63 (33.2)
Facilitate painful sexual practices	39 (20.5)
Having sex with someone liked	37 (19.5)
Avoid negative feelings	23 (12.1)
Feeling accepted/included with others	15 (7.9)
Less concern about HIV-diagnosis	14 (7.4)
Do practices that others asked	3 (1.6)

[Table 1. Table 1. Reasons for SDU (first time)]

REASONS	N(%)
More arousal during sex	147 (77.4)
Sexual disinhibition, different practices	89 (46.8)
Longer sexual response/sessions	93 (48.9)
Avoid negative feelings	34 (17.9)
Overcoming shyness/insecurity	28 (14.7)
Make painful practices	26 (13.7)
Less concern about HIV-diagnosis	26 (13.7)
Feeling accepted/included with others	14 (7.4)

[Table 2. Reasons for SDU (any time)]

Conclusions: Most HIV+ MSM in our sample referred SDU to enhance and facilitate sexual practices. However, a relatively high proportion of patients had SDU to avoid unpleasant feelings or face problematic situations.

WEPEB0584

Unmet contraceptive need in HIV-positive Kenyan female sex workers

G. Muthee[1], K. Yuhas[2], K. Wilson[2], L. Masese[2], J. Kinuthia[3], W. Jaoko[4], K. Mandaliya[2], R.S. McClelland[2]
[1]Kenyatta National Hospital, Discordant Couple Center, Mombasa, Kenya, [2]University of Washington, Seattle, United States, [3]Center for Microbiology Research and Center for Clinical Research, Kenya Medical Research Institute, Nairobi, Kenya, [4]University of Nairobi, Nairobi, Kenya
Presenting author email: warugurug@gmail.com

Background: Public health interventions designed to reduce HIV and STI incidence in female sex workers (FSWs) often overlook their broader reproductive health needs. Unintended pregnancy is a major occupational risk factor for FSWs. The objective of this study was to examine the prevalence and correlates of unmet contraceptive need in this key population.
Methods: We examined data collected at enrollment of HIV-positive women entering the Mombasa Cohort, a prospective cohort study of FSWs in Kenya. Unmet contraceptive need was defined as intending to delay the birth of the next child, or not wanting any more children, yet not using modern contraception other than condoms alone. Poisson regression was used to calculate unadjusted and adjusted prevalence ratios (PRs) for factors associated with unmet contraceptive need.
Results: Of the 376 HIV-positive FSWs enrolled between October 2012 and December 2016, 216 (57.4%), 95% confidence interval [CI]: 52.3%-62.5%) had unmet contraceptive need. In multi-variable analysis, increasing age and experiencing physical abuse in the past 12 months were associated with a higher prevalence of unmet contraceptive need (Table 1). In the subset of 333 women who denied currently trying to become pregnant, desire for another child in the future was also associated with unmet contraceptive need after adjusting for age, workplace, and history of physical abuse (adjusted PR 1.32, 95%CI 1.13-1.54, p< 0.001).

Characteristic	N	Unmet need n (%)	PR (95% CI)	p-value	aPR (95% CI)	p-value
Age (years)				0.096		0.003
20-25	31	12 (38.7)	1		1	
26-35	131	71 (54.2)	1.40 (0.87, 2.24)		1.57 (0.96, 2.58)	
36-45	182	110 (60.4)	1.56 (0.99, 2.47)		1.95 (1.19, 3.20)	
>46	32	22 (68.8)	1.78 (1.08, 2.93)		2.33 (1.36, 3.98)	
Physical abuse in past year				0.095		0.039
No	241	190 (55.7)	1		1	
Yes	35	24 (68.6)	1.23 (0.96, 1.57)		1.28 (1.01, 1.62)	

[Table 1.]

Conclusions: This study demonstrated a high prevalence of unmet contraceptive need in HIV-positive FSWs. Interventions are needed to improve contraceptive access and uptake as a component of comprehensive HIV care for this population.

WEPEB0585

HIV risk and outcomes in transgender patients enrolled in a large integrated health care system

W. Towner[1], R. Contreras[2], Q. Yuan[2], R. Hechter[2]
[1]Kaiser Permanente Southern California, Department of Infectious Disease, Los Angeles, United States, [2]Kaiser Permanente Southern California, Department of Research and Evaluation, Pasadena, United States
Presenting author email: william.j.towner@kp.org

Background: Data on HIV risk and HIV related outcomes in transgender individuals is lacking. We sought to compare rates of HIV virologic suppression between transgender and cisgender HIV-infected patients in an integrated health care system in the United States. To estimate risk of HIV infection in the HIV-uninfected transgender population, we also examined history of sexually transmitted infections (STI).
Methods: We conducted an observational retrospective cohort study of HIV-infected adults and uninfected transgender patients who received care during 2010-2015 in Kaiser Permanente Southern California. History of STI diagnoses in HIV-uninfected transgender patients were ascertained using electronic medical records. HIV virologic suppression was defined as having at least one measurement of HIV RNA <200 copies/mL, and sustained suppression was defined as having 2 consecutive values of HIV RNA <200 copies/mL. Modified Poisson regression models adjusted for age and gender were used to assess the impact of transgender status on HIV RNA suppression and sustained suppression during the 12 months after entry into the cohort, as compared to HIV-infected cisgender patients.
Results:

Characteristics		Transgender HIV+ adults N=79	Non-transgender HIV+ adults N=11,427	P-value
Age, n (%)	18-39	34 (43.0)	3,633 (31.8)	0.0587
	40-59	42 (53.2)	6,626 (58.0)	
	60+/unknown	3 (3.8)	1,168 (10.2)	
Gender*, n (%)	Male	1 (1.3)	10,385 (90.9)	<0.0001
	Female	78 (98.7)	1,042 (9.1)	
Race/ethnicity, n (%)	Non-Hispanic White	13 (16.5)	4,629 (40.5)	<0.0001
	Hispanic	34 (43.0)	3,706 (32.4)	
	Non-Hispanic Black	21 (26.6)	1,909 (16.7)	
	Other/unknown	11 (13.9)	1,183 (10.4)	

*Among transgender patients, gender refers to transgender male and transgender female.

[Demographic Characteristics of Transgender and Non]

Among 3,286 HIV-uninfected transgender persons, the proportions of those ever had a diagnosis of syphilis, gonorrhea, or chlamydia were 1.52, 0.94 and 1.58 %, respectively. We identified 11,427 non-transgender and 79 transgender HIV-infected patients during the study period (Table). Compared to HIV-infected cisgender patients, HIV-infected transgender patients had a similar likelihood of achieving both virologic suppression (adjusted relative risk, aRR: 1.02, 95% CI: 0.92-1.12) and sustained suppression (aRR: 1.03, 95% CI: 0.90-1.17).
Conclusions: Amongst a diverse HIV-infected transgender cohort, no differences in HIV virologic outcomes were observed when compared to cisgender HIV-infected patients. Rate of STIs were high in the HIV-uninfected transgender group; therefore proactive HIV risk-reduction strategies in this population may be warranted.

WEPEB0586

High levels of treatment non-adherence due to concerns for interactions between antiretroviral therapy and feminizing hormones among transgender women in Los Angeles, CA

H.M. Braun[1,2], J. Candelario[3], C.L. Hanlon[4], E.R. Segura[2], J.L. Clark[2], J.S. Currier[2], J.E. Lake[2,5]
[1]Doris Duke International Clinical Research Fellowship, University of California, San Francisco School of Medicine, San Francisco, United States, [2]UCLA South American Program in HIV Prevention Research, David Geffen School of Medicine, Los Angeles, United States, [3]APAIT, Special Service for Groups, Los Angeles, United States, [4]Geisel School of Medicine, Dartmouth College, Hanover, United States, [5]McGovern Medical School at UTHealth, Department of Internal Medicine, Division of Infectious Diseases, Houston, United States
Presenting author email: jordan.e.lake@uth.tmc.edu

Background: Feminizing hormone therapies (HT) are critical to harmonizing gender identity and expression for transgender women (TW), and antiretroviral therapy (ART) is essential for HIV-infected (HIV+) individuals. However, both HT and ART have potential side effects, and drug-drug interactions (DDI) exist between some ART and HT. Despite this, limited data exists addressing knowledge of ART-HT side effects and DDIs among TW. We assessed knowledge of HT and ART side effects and DDIs, including effects on treatment adherence, among HIV+ and HIV- uninfected (HIV-) TW.
Methods: From March-July 2016, self-identified TW were recruited from APAIT, a community-based AIDS service organization in Los Angeles, California, for a cross-sectional study assessing HIV, HT and access to and engagement in health care. Participants reported sociodemographics, medical history and knowledge of ART-HT DDIs. All HIV+ TW were on ART.
Results: Participants (n=87; Table 1) had mean age 45 years; 62% were Hispanic, 54% HIV+ (mean CD4+ T lymphocyte count 555 cells/mm^3) and 69% were on HT. ART use included 40% integrase inhibitor-, 32% protease inhibitor- and 28% NNRTI-based ART. Most (77%) had a regular healthcare provider, although 25% (HIV- 13%, HIV+ 34%) reported unsupervised HT and only 68% (HIV- 78%, HIV+ 61%) discussed potential HT side effects with their provider. Although 57% of HIV+ TW reported concern for ART-HT interactions, only 49% discussed ART-HT DDI with their provider and 40% cited this concern as a reason for not taking ART (n=5), HT (n=5) or both (n=7) as directed.

	HIV- (n=40; 46%)	HIV+ (n=47; 54%)
Age (years)	43 (12)	48 (10)
Hispanic ethnicity	65%	60%
Black/African American race	13%	21%
No healthcare insurance	21%	33%
Current feminizing HT use	65%	72%
Planned future feminizing HT use	26%	16%
Substance Use (last 90 days)	25%	47%

*Mean and standard deviation or percent reported. HT=hormone therapy.

[Table 1: Participant Demographics]*

Conclusions: TW frequently have concerns about potential ART and HT side effects and DDIs that, coupled with sub-optimal provider engagement, contribute to both ART and HT non-adherence. Improved clinician and patient engagement and education are needed to address these concerns and optimize care for TW. Future research will address ART-HT interactions and side effect risk for TW, and investigate approaches to mitigate risk.

WEPEB0587

Factors associated with medical doctors' intention to discriminate against transgender patients in Kuala Lumpur, Malaysia

A. Vijay[1], J. Wickersham[1], Y.C. Tee[2], V. Pillai[2], J. White Hughto[1], K. Clark[3], A. Kamarulzaman[2], F. Altice[1]
[1]Yale School of Medicine, New Haven, United States, [2]University of Malaya, Kuala Lumpur, Malaysia, [3]University of California, Los Angeles, United States
Presenting author email: jeffrey.wickersham@yale.edu

Background: Transgender people (TGP) are frequent targets of discrimination as a result of their stigmatized social status. Discrimination in the context of healthcare is an important and understudied phenomenon that can lead to poor health outcomes. TGP who face stigma and discrimination are at an increased risk for depression, suicide, and HIV. In fact, transgender women have the highest HIV burden of any at-risk group, including men who have sex with men and injection drug users. The current study explores factors associated with medical doctors' intention to discriminate against TGP in Malaysia.
Methods: A total of 436 medical doctors at two major university medical centers in Kuala Lumpur, Malaysia, completed an online survey. Sociodemographic characteristics, stigma-related constructs and intentions to discriminate against TGP were measured. Bivariate Pearson correlations were performed to examine the associations between stigma-related constructs and discrimination intent. Bivariate and multivariate linear regression was used to evaluate independent covariates of discrimination intent.
Results: Medical doctors who felt more fearful of TGP and held more shameful attitudes about TGP expressed greater intention to discriminate against TGP, whereas doctors who endorsed the belief that TGP deserve good care were less likely to intend to discriminate. The final model accounted for 54% of the variance in discrimination intent, with 46% accounted for by stigma-related constructs and 8% accounted for by socio-demographic characteristics.
Conclusions: Constructs associated with transgender stigma play an important role in medical doctors' intention to discriminate against transgender patients. Future development of interventions to improve medical doctors' knowledge and attitudes of TGP may reduce discriminatory intent in the setting of medical care and improve quality of healthcare delivery for this important patient group.

Background: There is growing body of evidence that transgender women bear a heavy and disproportionate burden of HIV globally. Across Sub-Saharan Africa, there has been an increased awareness of the importance of addressing the needs of key populations, however, transgender women are often ignored or included as men who have sex with men (MSM). Preliminary data from three West-African nations found that HIV burden among transgender women was nearly three times that of cisgender MSM (19%vs7%, P< 0.01). Characterizing the specific HIV prevention and treatment needs among transgender women compared to cisgender MSM can guide the development and implementation of these programs.
Methods: Transgender women (n=937) and MSM (n=3,649) living with HIV were included who completed HIV testing and a structured survey instrument accrued with similar methods using respondent-driven sampling in Burkina Faso, Cote d'Ivoire, The Gambia, Lesotho, Malawi, Senegal, Swaziland, and Togo. Student t-tests were used to compare the proportions of each care continuum variable for transgender women and MSM.
Results: Transgender women (78%) were significantly more likely than MSM (74%) to have ever been tested for HIV (p=0.04) and to have been tested in the prior 12 months (50% versus 44%, p=0.004). A significantly greater proportion of transgender women (11%) compared with MSM (4%) had been told they had HIV by a doctor (p< 0.001). However, on HIV testing, 25% and 14%, respectively were HIV-positive (p< 0.001). Of those who were aware of their HIV status, 67% of transgender women and 42% of MSM were currently being treated (p=0.002).
Conclusions: These data confirm that transgender women across SSA demonstrate a heavy and disproportionate burden of HIV, even when compared with cisgender MSM. Moreover, the determinants of engagement in care differ between cisgender MSM and transgender women further reinforcing the need for specific implementations considerations for HIV prevention and treatment programs even in the more generalized HIV epidemics across Sub-Saharan Africa.

Presenting author email: sophie.abgrall@aphp.fr

Background: Achievement of the 90:90:90 UNAIDS target is conditioned by a sustained viral suppression on cART. Some studies in Western countries have suggested that virological rebound (VR) is more frequent in migrants.
Methods: We included 158 migrants from sub-Saharan Africa (SSA), 53 other migrants (OTH) and 288 French natives (FRA) enrolled from 2004 to 2008 in the French ANRS-COPANA cohort, who started a first cART (2 NRTIs with PI, NNRTI or II) and achieved viral suppression (VS) defined by viral load (VL) <50 cp/ml within one year. Probability of a subsequent VR, defined by one VL>1000 cp/ml or two consecutive VL between 50-1000 cp/ml, was compared between FRA, SSA and OTH by Kaplan-Meier survival analysis. Determinants of VR were assessed by using Cox models including geographical origin, demographic, clinical, biological and various socioeconomic data updated at the time of first VS, among which educational level, employment, income, self-reported financial difficulties, partnership, HIV status disclosure.
Results: cART was started a median time of 1.2 (0.3-2.9) years after HIV diagnosis and lead to VS within a median time of 4.2 (2.8-6.2) months. VR occurred in 116 persons (23%). The 4-year probability (95%CI) of VR was 15% (9-21) in FRA HSH, 16% (8-24) in FRA heterosexuals, 33% (25-41) in SSA and 30% (16-44) in OTH (p<0.001). Migrant status (HR, 2.44 (95%CI, 1.16-3.61) for SSA, 1.74 (0.96-3.18) for OTH, vs. FRA), female sex, type of cART, HIV non-disclosure, low educational level, financial difficulties, unemployment and not being owners/renters of their house were associated with VR, while calendar period, VL and CD4 count at cART initiation were not.
In multivariate analysis, HIV status non-disclosure (aHR 1.69, 1.05-2.70) and PI including-cART (aHR 1.76 (1.13-2.75) versus other cART) remained associated with VR. Migrants were no longer at a higher risk of VR after adjustment for sex, type of cART, educational level, financial difficulties and HIV disclosure. These last three factors had the biggest impact on changes between the crude and aHRs in migrants.
Conclusions: Social factors are strong determinants of the sustainability of the viral response on ART and must be addressed in a global HIV care strategy.

Should abacavir be a first-line option for adults with HIV in sub-Saharan Africa?

G.Q. Lee[1,2,3], S. McCluskey[3,4], Y. Boum[5], P.W. Hunt[6], J.N. Martin[6], D.R. Bangsberg[3,7], G. Xiaojiang[8], P.R. Harrigan[1], J.E. Haberer[7], M.J. Siedner[3,5,7]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [3]Harvard Medical School, Boston, United States, [4]Massachusetts General Hospital, Infectious Disease Division, Boston, United States, [5]Mbarara University of Science and Technology, Mbarara, Uganda, [6]University of California, San Francisco, United States, [7]Massachusetts General Hospital, Boston, United States, [8]National Cancer Institute, Center for Cancer Research, Frederick, United States
Presenting author email: klee54@mgh.harvard.edu

Background: Despite a poor toxicity profile, zidovudine supersedes abacavir as a first-line agent in many international treatment guidelines due to concerns about HLA-B*57:01-related abacavir-hypersensitivity. An important question is whether abacavir should become a first-line option in resource limited settings where HLA-B*57:01 is sufficiently rare.
In one of the largest HLA-typing efforts in sub-Saharan Africa, we assessed HLA alleles among 581 HIV-infected patients in Kampala (n=81) and Mbarara (n=500) to guide regional clinical decision-making.
Methods: Specimens were drawn from the UARTO cohort, including 81 pilot subjects enrolled from Kampala during 2002-2004 and 500 subjects enrolled from Mbarara during 2005-2010, just prior to antiretroviral therapy initiation. HLA-typing was performed using Roche/454/Fluidigm HLA Typing Kits following the Roche protocols. HLA alleles and genotypes were called using the Conexio ATF 454 HLA typing software.
Results: Samples from 52 (64%) individuals in Kampala, and 461 (92%) individuals in Mbarara yielded successful HLA-genotyping results. HLA-B*57:01 was not observed in the 52 Kampala subjects. In the main Mbarara cohort, one subject was heterozygous for HLA-B*57:01 among 461 subjects (0.2% prevalence). This subject did not receive abacavir during study observation from 2006 - 2011. Overall, during the entire follow up duration from 2005-2015 in Mbarara, only two other patients ever-used abacavir (0.4% usage rate); neither had HLA-B*57:01. The low prevalence of HLA-B*5701 is consistent with other smaller studies conducted in sub-Saharan Africa.
Conclusions: Given the low prevalence of HLA*B57:01 carriage in our cohort and others in sub-Saharan Africa (Table 1), the cautious use abacavir-based therapy may be more advisable than zidovudine-based therapy when tenofovir is not a viable option. The benefits of abacavir over zidovudine-based therapy should be considered in regional guidelines given abacavir has superior efficacy, once-daily dosing, and has been studied as a component of regimens containing integrase strand transfer inhibitors.

Presenting author email: helene.smith@cidrz.org

Background: High HIV prevalence is an ongoing challenge in Zambian correctional facilities. To provide inmates with the benefits of treatment as prevention (TasP), generate evidence to tailor universal test and treat (UTT) in correctional settings, and coordinate tuberculosis screening among HIV-infected inmates, we launched a UTT implementation research study at Lusaka Central (LC), one of Zambia's largest correctional facilities. We present interim findings here.
Methods: We offered immediate ART to inmates with newly diagnosed HIV or previously diagnosed HIV not yet on ART, regardless of CD4 or WHO stage. To enable UTT, we strengthened the LC health system by: training corrections officers and health workers; hiring a study nurse and clinician; and supporting routine HIV testing services (HTS) and viral load (VL) testing. To evaluate impact, we strengthened routine data systems, and prospectively collected data along the HIV cascade for a cohort of HIV-positive inmates consenting to immediate ART.
Results: From June—December 2016, 1,662 inmates were offered and 1,413 (85.0%) accepted HTS; 198 (14.0%) were found HIV-infected [177 men (89.4%), 21 women (10.6%)]. 172 (86.9%) were referred to the study for immediate ART with 149 (86.6%) meeting study eligibility criteria; 149 (100%) enrolled and 149 (100%) started ART [135 men (90.6%), 14 women (9.4%)] within 1 day (IQR:1-5 days). Mean age was 33.2 years (sd:7.8 years). Median baseline CD4 was 284 cells/mm^3 (IQR:191-401). Prior to ART, 144 (96.6%) inmates underwent TB screening, 7 were diagnosed with tuberculosis by Xpert and 3 clinically; all 10 (100%) started anti-tuberculosis treatment. After 5 months, 88 (59.1%) inmates receiving immediate ART remained in study follow-up and 61 (40.9%) had been released or transferred, with non-significantly more women (n/N=9/14, 64.3%) than men (n/N=79/135, 58.5%) retained in the cohort (p=0.68). Of 13 inmates with VL testing after ≥3 months on ART, 11 (84.6%) were suppressed (VL≤40 copies/ml).
Conclusions: Implementing UTT within a large correctional facility resulted in high uptake of HTS and immediate ART for inmates with advanced immunosuppression, and facilitated tuberculosis screening, diagnosis and treatment. Logistical complexities posed by the Zambian correctional setting, including frequent inmate transfer and release, threaten to interrupt the HIV care continuum for HIV-positive inmates.

A high mortality among male HIV-infected patients after prison release

F. Huber[1,2,3], A. Merceron[3], Y. Madec[4], G. Gadio[2,3], V. About[5], A. Pastre[5], I. Coupez[5], L. Adriouch[1], S. Vandentorren[6,7], M. Nacher[1,3,8]
[1]COREVIH, Centre Hospitalier de Cayenne, Cayenne, French Guiana, [2]Reseau Kikiwi, Cayenne, French Guiana, [3]Université de Guyane, Cayenne, French Guiana, [4]Emerging Diseases Epidemiology Unit, Pasteur Institute, Paris, French Guiana, [5]UCSA, Centre Hospitalier de Cayenne, Cayenne, French Guiana, [6]Sorbonne Universités, UPMC Univ Paris 06, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique (IPLESP UMRS 1136, Équipe de Recherche en Épidémiologie Sociale), Paris, France, [7]French National Public Health Agency, Saint Maurice, France, [8]Centre d'Investigation Clinique Epidemiologie Clinique Antilles Guyane, INSERM CIC 1424, Centre Hospitalier de Cayenne, Cayenne, French Guiana
Presenting author email: florence.huber@ch-cayenne.fr

Background: Outside North American settings, data on treatment outcome and vital status of HIV-positive former inmates are scarce. French Guiana is a South American French territory, where HIV prevalence consistently exceeds 1% in the adult population. In 2014, it fluctuated around 4%in the only correctional facility. After describing the population of HIV-positive inmates, we aimed to evaluate mortality after release, and to identify its predictive factors.
Methods: All HIV-infected adults released from an incarceration of 30 days or more, between 2007 and 2013, were enrolled in a retrospective cohort study. Mortality was described over time, using Kaplan-Meier estimates. Factors associated with mortality were identified through a non-parametric survival regression model.
Results: Of the 147 former inmates included, 82.3% were male. The median age was 37.3 years. The majority were migrants, 25.8% were homeless, 70.1% suffered from substance abuse. On admission, 78.1% had an early HIV-stage infection (CDC-stage A), with a median CD4 count of 397.5/mm3. Upon release, 74 (50.3%) were on ART, and 84.5% of them had a viral load≤200copies/mL. The main reasons for not being treated were: not fulfilling the criteria (74.6%), and refusing ART (15.1%). After release, 8.2% of the cohort had died, with a crude incidence of 33.8/1000 person-years. All recorded deaths were males, with an incidence of 42.2/1000 person-years. Comparing with the age-specific mortality rates for males in French Guiana, the standardized mortality ratio was 14.8.
In multivariate analysis, factors associated with death were age and a low CD4 count before release.
Conclusions: Despite access to ART while incarcerated, with good virological outcome, the post-release mortality was very high for males, almost 15 times what is observed in the male general population living in French Guiana, after age standardization. Access to ART in correctional facilities may be a necessary, but not sufficient condition to protect male inmates from death after release.

WEPEB0593

Real time monitoring adherence for HIV patients with recurrent virological failure: an opportunity to improve linkage to care in vulnerable population (ANRS 950113)

G. Gras[1], E. Aoustin[2], R. Verdon[3], V. Vitrat[4], K. Steffic[2], L. Grammatico-Guillon[2]
[1]CHU Bretonneau, Infectious Diseases, Tours, France, [2]CHU Bretonneau, Tours, France, [3]CHU Cote de Nacre, Caen, France, [4]CH Annecy Genevois, Annecy, France
Presenting author email: g.gras@chu-tours.fr

Background: Five to 10% of HIV patients taking antiretroviral therapy experienced recurrent virological failure (rVF). These patients have frequently serious social and psychological problems and caregivers are often helpless.
Now, adherence data can be transmitted wirelessly through cellular networks and paired with individually tailored interventions in real time. Feasibility about real time adherence monitoring in this specific HIV population is unknown.
Methods: A pilot multicenter (3), prospective study was conducted from 2015 to 2016. Patients living with HIV, > 18 years old with ≥ 2 separate events of virological failure were included. All study participants received a real-time adherence monitor (Wisepill Technologies) and were followed for 6 months. Patients received an SMS only if no signal was received from the monitor within 2 h of the expected dosing time. If no signal was received for more than 48 h, a mail notification was sent to caregivers (nurse and physician). Questionnaires about quality of live and real time monitoring were completed.
Results: Fourteen patients were included: mean age (years)=48.5, sex ratio H/F=6, median CD4 cells=382/mm^3, mean duration (years) of HIV infection=16.7. The mean number of line therapy was high (7) and half of them suffered from mental illness. Initially, viral load was > 50 cp/mL for nearly all patients (12/14=86%). One patient has stopped the study and 6 were lost to follow up (42%). After 3 months, viral load was < 50 cp/mL for 7 patients. After 6 months, among 7 remaining patients, only 2 were still undetectable. In first month, mean adherence was 74.3% before reminder and 84.8% in 2 hours following SMS-reminder. Mean adherence decrease along the study to 50% (59% with SMS-reminder) after 5 months (32% for patients with virological failure). After 6 months, 4PAS score (to assess therapeutic relationship between patient and caregivers) was high (40.8/44). Two patients reported real time monitoring as an intrusion into their private life.
Conclusions: Real time adherence monitoring appears to be acceptable and feasible in vulnerable HIV population with rVF. Further studies are needed to understand reasons to decrease adherence after 3 months and improve automatic and caregivers interventions.

E-cigarette use among persons living with HIV

R. Nance[1], R. Fredericksen[1], J. Delaney[1], K. Cropsey[2], G. Chander[3], M. Mugavero[2], K. Christopolous[4], E. Geng[4], W. Mathews[5], A. Hahn[1], K. Mayer[6], C. O'Cleirigh[6], J. Eron[7], M. Saag[2], M. Kitahata[1], H. Crane[1]
[1]University of Washington, Medicine, Seattle, United States, [2]UAB, Medicine, Birmingham, United States, [3]Johns Hopkins, Baltimore, United States, [4]UCSF, Medicine, San Francisco, United States, [5]UCSD, Medicine, San Diego, United States, [6]Fenway Health, Boston, United States, [7]UNC, Medicine, Chapel Hill, United States
Presenting author email: rmnance@uw.edu

Background: Cigarette smoking is common, but little is known about e-cigarette use among people living with HIV (PLWH). The goal of this study was to evaluate this.
Methods: This study was conducted in the Centers for AIDS Research Network of Integrated Clinical Systems (CNICS) cohort of PLWH in primary care. We included PLWH from six sites across the U.S. who reported having ever smoked cigarettes. E-cigarette use (daily, less than daily, none) as well as other cigarette and drug use and risk behaviors were collected via their most recent CNICS clinical assessment of self-report measures completed between 5/15-8/16 on touch-screen tablets at routine clinical care visits. Illicit drug use, at-risk alcohol use, depression, antiretroviral therapy (ART) use, ART adherence, and unsafe sex rates were compared between e-cigarette users and non-e-cigarette users with logistic regression models adjusted for age, sex, race, and cigarette smoking status.
Results: Of 2,956 PLWH in the sample, their mean age was 47; 87% were male, 53% white, 29% black, 14% Hispanic, and 51% current cigarette smokers. In the past year 4% reported daily, 22% less than daily, and 73% no e-cigarette use. Compared to non-users, e-cigarette users were younger (mean 44 vs. 49) and more likely to be white (61% vs. 50%), current cigarette smokers (69% vs. 44%), current opiate users (5% vs. 3%), current marijuana users (40% vs. 33%), not on ART (8% vs. 6%), and less adherent to ART (mean adherence 91% vs. 94%) (all p values < 0.05 in adjusted models). Those reporting less than daily e-cigarette use were more likely to currently smoke cigarettes (74%) than those who never smoked e-cigarettes (44%) and those with daily e-cigarette use (43%).
Conclusions: E-cigarette use is common among PLWH and associated with high rates of deleterious health behaviors. This highlights the importance of assessing e-cigarette use as part of care and recognizing users may include PLWH that need additional support to reduce risky behaviors such as illicit drug use. While cigarette smoking was less common among daily e-cigarette users, it was still high (43%), raising concerns about the effectiveness of PLWH using e-cigarettes for smoking cessation.

New Approaches and Tools for HIV Prevention

Bacterial vaginosis among sexually experienced young women in South Africa: prevalence, covariates and syndromic management

A. Kaida[1], J. Dietrich[2], F. Laher[2], M. Beksinska[3], M. Jaggernath[3], M. Bardsley[4], P. Smith[1], J. Smit[3], T. Ndung'u[5], G. Gray[2], M. Brockman[1]
[1]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [2]University of the Witwatersrand, Perinatal HIV Research Unit (PHRU), Soweto, South Africa, [3]University of the Witwatersrand, MatCH Research Unit (MRU), Durban, South Africa, [4]The London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]University of KwaZulu-Natal, HIV Pathogenesis Programme and KwaZulu-Natal Research Institute for TB and HIV, Durban, South Africa
Presenting author email: angelakaida@gmail.com

Background: Young South African women remain among the highest risk groups for HIV acquisition. Bacterial vaginosis (BV) increases HIV risk and may compromise efficacy of tenofovir gel pre-exposure prophylaxis (PrEP). In South Africa, treat-

ment of BV and other genital tract infections (GTIs) follows WHO-recommended syndromic management, which may underestimate cases, particularly among young women. We compared BV prevalence by symptom- and laboratory-based assessment among sexually experienced female youth, and investigated socio-behavioural and clinical correlates of prevalent infection.
Methods: We analyzed baseline data from female youth (aged 16-24) who reported HIV-negative or unknown status at enrolment in a youth-centred cohort in Durban and Soweto (n=425; Nov 2014-May 2016). Interviewer-administered surveys assessed demographics, behaviors, and presence of GTI symptoms. BV prevalence was assessed via reported symptoms and vaginal swab collection for Gram stain diagnosis (Nugent's score >6). We assessed sensitivity and specificity of syndromic screening compared with laboratory confirmation. Multivariable logistic regression identified independent covariates of BV.
Results: Among 195 sexually experienced females (median age 19), 46.9% had been previously pregnant, 35% had a sexual partner ≥5 years older, and 80% reported vaginal douching ≥1 time/week.
Thirty (15.4%) reported any BV symptom. In contrast, clinical tests identified BV in over half of young women (53.7%). Chlamydia prevalence was 18.1%, candidiasis 9.9%, Mycoplasma genitalium 8.8%, trichomoniasis 8.3%, gonorrhoea 6.7% and HIV 5.1%.
Overall, 21/30 participants reporting BV-associated symptoms had clinically-confirmed BV; however of 103 with confirmed BV, 82 were asymptomatic (sensitivity 20.3%, specificity 89.8%).
In adjusted analyses, women with BV had higher odds of co-infection with HIV [aOR: 7.83; 95% CI 0.90-68.0], M. genitalium [aOR: 38.2; 3.08-473.5], and lower gravidity. BV was non-significantly associated with having an intergenerational sex partner [aOR: 1.78; 95% CI 0.88-3.60].
Conclusions: BV prevalence among young women in South Africa is high, and often asymptomatic or unrecognized. Syndromic BV management has poor sensitivity and is thus suboptimal for this population. Associations of BV with HIV, sexually transmitted infections, and other markers of sexual experience highlight an urgent need for linked biomedical, clinical, and structural youth HIV prevention and sexual health approaches, which are resourced to incorporate laboratory-based services.

Presenting author email: jfernandezromero@bmcc.cuny.edu

Background: Griffithsin (GRFT) is a lectin with potent anti-HIV activity. The combination of GRFT with carrageenan (CG) results in synergy against herpes simplex (HSV) and also a potent activity against human papillomavirus (HPV).
Methods: Mice size FDI formulations containing 0.5% GRFT and 1.5% CG (n=6 per formulation/ PK time-point) were inserted vaginally in mice. Vaginal fluid (VF) was collected at baseline and different time-points post FDI insertion. ELISA was used to quantify GRFT in VF. The same formulations in addition to placebo controls (containing hydroxyethyl cellulose) were tested in the HPV16 PsV and HSV vaginal murine models. The formulations were applied vaginally 4 h before challenge with either virus. Fisher's exact test was used for comparison of mouse infection after challenge with HSV-2 and the Mann Whitney U test was used in the HPV16 PsV mouse model. RMs size FDI formulations containing 0.5% GRFT and 1.5% CG (n=6 per formulation/ PK time-point) were inserted vaginally in RMs. VF and plasma were collected at baseline and different time-points post FDI insertion. Vaginal biopsies were also collected at 4h post FDI insertion to measure ex vivo anti-SHIV activity. ELISA was used to quantify GRFT in VF. Curve-fitting analysis was used to calculate the EC_{50} of VF samples against HIV-1 using the TZM-bl assay. Correlations between levels of GRFT and anti-HIV activity in VF were calculated. Vaginal explants were challenged with SHIV SF162P3, washed, and cultured for 14d. Infection was monitored by HIV gag qRT-PCR. SOFT and CUM endpoint analyses were performed.
Results: GRFT concentrations above 2 µg/mL were found in mouse VF 4h after FDI insertion. There was a significant decrease in HSV-2 infection after GRFT/CG FDIs application (60%-73% uninfected, $p < 0.0052$ vs. placebo). GRFT/CG FDIs also significantly decreased HPV-16 PsV infection ($p< 0.0001$). GRFT was not detected in RMs plasma. No significant tissue-associated anti-SHIV activity was detected but GRFT concentrations and EC_{50} values against HIV in RMs VF were strongly correlated ($r=0.9691$; $p< 0.0001$).
Conclusions: GRFT/CG FDI showed a promising PK/PD profile for an on-demand vaginal microbicide and was effective at inhibiting HIV in vitro and HSV and HPV infection in vivo.

WEPEC0898

Partner and peer influence on young South African women's female condom use

J.E. Mantell[1], J.A. Smit[2], T.M. Exner[3], D. Bai[4], C.-S. Leu[5,6], M. Beksinska[2], S. Hoffman[7,8], Z. Mabude[9]

Presenting author email: jem57@cumc.columbia.edu

Background: Young women aged 15-24 are the new "face" of HIV, particularly in South Africa, amongst whom one in four new infections occur. HIV interventions have largely failed to curb infection in this group and non-adherence was a key barrier to their PrEP uptake in three trials. The female condom (FC) is a viable alternative to use of male condoms and PrEP, especially in South Africa which has the largest public-sector FC distribution program world-wide. This study investigated theory-driven predictors of FC use among young South African women who participated in a FC promotion intervention.
Methods: Data were drawn from a sample of young women participating in a FC intervention who were randomized to a grouped-based behavioral skills or one-session didactic condition. Eligibility criteria were: ≥18 years; full-time students; self-reported HIV-negative/unknown serostatus; not pregnant or wanting to become pregnant in the next 9 months; and reported condomless vaginal intercourse in the past 2 months. We examined associations between demographic characteristics, FC beliefs of self/partner, gender-role beliefs, history of sexual coercion, and FC use five months post-intervention among 199 women with complete FC use data using backward stepwise regression for the final model.
Results: Participants were Black; mean age was 20.4 years. In the final model, experience of sexual coercion (aOR)=4.11; p=.005), having a friend who had used the FC (aOR=1.95; p=.075), believing that one's partner has positive FC attitudes (aOR=1.55; p=.008), and greater use of FC for vaginal sex at prior assessment at 2.5 months post-intervention (aOR=1.12; p=.030) predicted FC use 5 months post-intervention. Women in the behavioral skills intervention were 2.5 times more likely to report FC use 5 months post-intervention (aOR=2.58; p=.030).
Conclusions: Perceived influence of partners and friends on young women's FC use suggests that their social networks could be an effective conduit for promoting positive FC norms and increasing initial and continued FC use. The higher odds of FC use among women with prior use and practice opportunities highlights the importance of skills-enhancement in FC use and partner negotiation.

WEPEC0899

Efficacy of a single session counseling program to promote safer sex among young Black MSM in the United States: a counseling option for patients taking PrEP

R. Crosby[1], L. Mena[2]
[1]University of Kentucky, Lexington, United States, [2]University of Mississippi Medical Center, Jackson, United States
Presenting author email: crosbyr3@gmail.com

Background: Among young Black men who have sex with men (YBMSM), to determine the 3-month efficacy of a single-session, clinic-based intervention that promoted the consistent use of condoms for anal and oral sex.
Methods: A pre-test, post-test randomized controlled trial was conducted, using a 3-month period of follow-up observation, in STI clinics. YBMSM (n = 347) completed both baseline and 3-month follow-up assessments between 2012 and 2015. The experimental condition comprised a single-session, one-to-one, evidence-based program (Focus on the Future) designed for tailored delivery in STI clinics. All study protocols were approved by internal review boards at participating institutions.
Results: Among HIV-uninfected YBMSM (n=265) receiving the intervention, 11.2% reported any condomless anal insertive sex at follow-up; compared to 20.6% among YBMSM in the control condition (rate ratio = .54, P = .04). Also among these same HIV-uninfected YBMSM, 12.0% reported any condomless anal receptive sex at follow-up; compared to 21.6% among YBMSM in the control condition (rate ratio = .55, P = .03). When combining insertive and receptive anal sex for

HIV-uninfected YBMSM, 18.3% receiving the intervention reported any condomless sex; compared to 31.1% among those in the control condition (rate ratio = .59, P = .01). Frequency of condomless oral sex among HIV-uninfected YBMSM was also significant. Among those receiving the intervention, 45.8% reported any condomless oral sex at follow-up; compared to 63.2% among YBMSM in the control condition (rate ratio = .72, P =0.03).
Significant findings, for these same four measures, among 92 YBMSM living were HIV were not observed.
Conclusions: This analysis of data from a Phase III RCT suggests that a single-session, clinic-based behavioral intervention may effectively promote the consistent use of condoms for anal and oral sex among HIV-uninfected YBMSM. The single-session program may be a valuable counseling tool for use in conjunction with quarterly clinic appointments for YBMSM using pre-exposure prophylaxis.

WEPEC0900

A cohort of new female condom acceptors: protected sex acts and mixing female and male condom use

M. Beksinska[1], Z. Mabude[1], J. Smit[1], R. Greener[1], P. Nkosi[1], J. Mantell[2]
[1]Match Research Unit (MRU) University of The Witwatersrand, Obstetrics and Gynaecology, Durban, South Africa, [2]HIV Center, Columbia University and New York State Psychiatric Institute, New York, United States
Presenting author email: mbeksinska@matchresearch.co.za

Background: The female condom (FC) is key to increasing HIV protection options for women and men, and is the only female-initiated HIV prevention barrier method. However, despite increased FC distribution globally it remains significantly low compared to male condoms. Although many acceptability studies have been conducted with FC users, data from long-term users are lacking.
Methods: A cohort study of new self-selected FC acceptors (n=598) and a subsample of their male partners (n=60), evaluated longitudinal assessment of key outcomes related to FC and MC use, HIV-related behaviours, and relationship characteristics. Semi-structured in-person interviews were conducted at baseline, and at 1, 6, and 12 months for women and at 1 and 12 months for men. Women aged 18-45 were enrolled from four public-sector health facilities in KwaZulu-Natal, South Africa. Follow-up was completed in 2016.
Results: The mean age for the cohort of new users was 28 years, 50% were unemployed, and 98% had a regular partner. 30% of the women reported that they were HIV-positive and 36% believed that they would "probably or definitely become HIV infected". Most women who tried an FC (78%) said they were confident to use FCs after between 1-3 uses. Cohort data indicated that condom use at last sex using either an FC or MC increased from 56% to almost 90% from baseline to one year. At one year 65.7% of FC users said they felt the FC was better or much better than the MC. "Partner refused to use FC" and "FC was difficult to use" were the main reasons given by women who reported not using the FC at follow-up visits.
Conclusions: Data indicates generally positive experiences of women who chose to accept FC as a method of STI/HIV and pregnancy prevention. Counseling on correct use and how to negotiate use with partners was key to continued use.

WEPEC0901

ShangRing circumcision in boys and men with topical vs. injectable anesthesia: results from a randomized controlled trial

M. Barone[1], Q. Awori[2], R. Lee[3], D. Ouma[2], N. Obura[2], M. Oundo[2], D. Mwamkita[2], M. Barasa[4], B. Chirchir[4], M. Kirui[4], P. Macharia[4], J. Oketch[5], P. Otiende[5], N. Nyangweso[5], M. Maina[6], N. Kiswi[6], M. Goldstein[3], J. Nyanchoka[2], P. Li[3]
[1]EngenderHealth, New York, United States, [2]EngenderHealth, Nairobi, Kenya, [3]Weill Cornell Medical College, New York, United States, [4]Bon Sante Consulting, Nairobi, Kenya, [5]Homa Bay County Hospital, Homa Bay, Kenya, [6]Vipingo Health Centre, Vipingo, Kenya
Presenting author email: mbarone@engenderhealth.org

Background: Circumcision devices can facilitate scale-up of voluntary medical male circumcision (VMMC) programs for HIV prevention in Sub-Saharan Africa. The ShangRing, a single-use circumcision device, is safe, simple to use, and well-accepted by men and boys. We conducted a randomized controlled trial to compare the safety, effectiveness, and acceptability of topical vs. injectable anesthesia for ShangRing circumcision.
Methods: We enrolled men and boys 10 years and older seeking VMMC at two sites in Kenya. Participants were randomized 2:1 to 2.5% lidocaine/2.5% prilocaine topical cream vs. the current practice of 1% injectable lidocaine. Circumcisions were performed using the no-flip ShangRing technique, with follow-up at 7 and 42 days' post-circumcision. The primary outcome was maximum pain experienced during the circumcision, as reported by participants immediately after the procedure, using a visual analogue scale (0=no pain, 10=worst possible pain).
Results: 344 men and boys underwent no-flip ShangRing circumcision between November 2015 and June 2016: 227 in the topical group and 117 in the injectable group. All circumcisions were successfully completed using the ShangRing. 9.3% of participants in the topical group required supplementation with injectable anesthesia before the procedure began. The highest degree of pain during the procedure reported by participants did not differ (p=0.14) between the groups; mean pain scores were 0.2±0.6 vs. 0.1±0.4 in the topical and injectable groups, respectively. There were no allergic reactions or anesthesia-related adverse events in either group and no differences between groups in procedure time, need for supplemental anesthesia during the procedure, or difficulty completing circumcisions. The majority of participants in both groups said there was nothing they disliked about the ShangRing circumcision, and they were very satisfied with the cosmetic results.
Conclusions: Topical anesthesia was effective, safe, and acceptable for use with ShangRing circumcision in males 10 years and older. There were no safety concerns or other adverse effects associated with switching to injected anesthesia in cases where topical was not effective. Use of topical anesthesia may further simplify the no-flip ShangRing technique, minimize needle phobia (potentially attracting more men and boys), decrease risk of needlestick injuries, and increase demand for VMMC in Africa.

WEPEC0902

Evaluating the profile of VMMC clients in order to increase yield in HIV testing for voluntary medical male circumcision (VMMC) programs

A. Hellar[1], J. Reed[2], K. Grabbe[2], A. Christensen[1], K. Curran[2], M. Drake[1], M. Machaku[1], G. Lija[3], E. Mlanga[4], Z. Mwandi[5], V. Kiggundu[6], E. Njeuhmeli[6]
[1]Jhpiego, VMMC, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Washington DC, HIV-ID Unit, Washington, United States, [3]Ministry of Health Community Development Gender Elderly and Children, National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of, [4]USAID, Dar es Salaam, Tanzania, United Republic of, [5]Jhpiego AIDSFree, Nairobi, Kenya, [6]USAID, Washington, United States
Presenting author email: augustino.hellar@jhpiego.org

Background: In Tanzania, fewer men than women test for HIV. The WHO VMMC minimum service package includes HIV testing, an opportunity to test this hard-to-reach population in a male-friendly setting. VMMC programs target HIV-negative males, but all men get services regardless of HIV status or age. Little is known about HIV prevalence among males in different age groups receiving VMMC. We examined the profile of clients likely to yield HIV positive results in the VMMC program in Tanzania.
Methods: We conducted a retrospective analysis of VMMC client-level data from September 2009-June 2016 at USAID/Jhpiego-supported VMMC sites in Tanzania. We assessed HIV testing trends and prevalence by age group to identify characteristics associated with high positivity.
Results: In total, 553,514 males were circumcised during this period. 429,270 (77%) were aged 10-19 years and 502,745 (90.8%) received HIV testing; 4,997 (0.99%) were HIV positive, 3,407 of these (68.2%) being newly-diagnosed. Compared to clients aged 10-14 those aged 20-24 (aOR=2.1), 25-29 (aOR=8.7), 30-34 (aOR=16.8), 35-49 (aOR=19.8) and 50+ (aOR=16.2) had a significantly higher HIV prevalence. Clients aged 15-19 (aOR=0.8) were least likely to test positive. Age group 25-29 was most likely to test HIV positive in the VMMC age bracket (15-29 years). Data on sexual activity was available for 144,756 (26%) clients, 23,397 (16%) reporting being sexually-active within 3 months prior to VMMC. 11.4% of the clients were married or cohabiting. HIV prevalence was higher among those sexually-active (aOR= 1.8), cohabiting (aOR=12.2) or married (aOR=1.3) even after adjusting for age.

Age group (years)	VMMC clients (#)	Tested for HIV (#, %)	HIV positive (#, %)	Newly diagnosed (#, %)
10-14	274,677	248,160 (90.35%)	1,133 (0.46%)	716 (63.20%)
15-19	155,986	143,473 (91.98%)	380 (0.26%)	265 (69.74%)
20-24	61,244	55,755 (91.04%)	465 (0.83%)	415 (89.25%)
25-29	25,443	22,853 (89.82%)	704 (3.08%)	591 (83.95%)
30-34	16,325	14,644 (89.70%)	810 (5.53%)	575 (70.99%)
35-49	16,654	14,988 (90%)	1,261 (8.41%)	727 (57.65%)
50+	3,185	2,872 (90.17%)	244 (8.50%)	118 (48.36%)
Total	553,514	502,745 (90.83%)	4,997 (0.99%)	3,407 (68.18%)

[Table 1: HIV Testing in VMMC by Age Groups]

Conclusions: Most clients were < 20 years, but HIV prevalence was higher in clients ≥25 years. VMMC programs target men aged 15-29 years, a lower prevalence group among VMMC clients in Tanzania. Targeting HIV testing services to those at high-risk (i.e. 25-29 year-olds, sexually-active, married or cohabiting) is an important strategy for improving HIV yield in VMMC settings.

WEPEC0903

Voluntary medical male circumcision (VMMC) as a platform to test more men for HIV and link them to care and treatment in Eastern and Southern Africa

A. Hellar[1], K. Grabbe[2], J. Reed[2], A. Marwiro[3], C. Ntsuape[4], M. Mahomed[5], J. Come[6], N. Soboil[7], D. Mumoye[8], M. Machaku[1], A. Christensen[1], G.J. Lija[9], J. Okuku[10], J. Zulu[11], K. Curran[2]

Presenting author email: augustino.hellar@jhpiego.org

Background: Voluntary medical male circumcision (VMMC) has been scaled-up in fourteen Eastern and Southern African countries since 2009. The VMMC service package includes HIV testing, which offers a unique opportunity to reach men and realize the UNAIDS 90-90-90 goals. According to WHO, 10.5 million men were circumcised in these countries through December, 2015. However, little is known on HIV testing and linkage to care for clients who test HIV-positive in these programs.
Methods: This was a multi-country, retrospective study of VMMC services implemented in Botswana, Mozambique, Namibia, Tanzania, and Zambia, under respective ministries of health, with support from PEPFAR and Jhpiego. We reviewed client-level databases for the period September 2009 through December 2016, though countries initiated VMMC services at different times during this period (Table 1). Data were analyzed to determine HIV positivity rate, new HIV diagnoses, and successful linkage to HIV care and treatment.
Results: Cumulatively, 1,225,083 men received VMMC in the five countries, of which 1,157,240 (94.5%) were tested for HIV. Among the five countries, 13,534 (1.2%) males tested HIV-positive, ranging from 1.0 - 7.2% with Namibia having the highest positivity rate. For four countries, Botswana, Namibia, Mozambique, and Tanzania, 12,952 HIV positive clients were identified with 11,196 (86.4%) being newly-diagnosed, and 8,772 (78.4%) of those newly diagnosed linked to HIV care and treatment.

Country	Time Period	# VMMC clients	# tested (%)	# Tested HIV-positive (%)	# New HIV-positive (%)	# Linked with HIV care/ treatment (%)
Botswana	Jan 2014- Dec 2016	14,538	14, 298 (98.4%)	242 (1.7%)	242 (100%)	76 (31.4%)
Mozambique	Oct 2009 - Nov 2016	589,415	580,231 (98.4%)	7,519 (1.3%)	7,519 (100%)	6,215 (82.7%)
Namibia	May - Nov 2016	2,917	2,576 (88.3%)	186 (7.2%)	27 (14.5%)	17 (63.0%)
Tanzania	Sept 2009- Sept 2016	557,570	504,545 (90.5%)	5,005 (1.0%)	3,408 (68.1%)	2,464 (72.3%)
Zambia	Apr 2015- Oct 2016	60,643	55,590 (91.7%)	582 (1.1%)	not reported	not reported
Total		1,225,083	1, 157, 240 (94.5%)	13, 534 (1.2%)	11,196	8, 772 (78.4%)

[Table 1: HIV Testing and Linkage in VMMC]

(NB: Total tested HIV positive is underreported for Mozambique and Botswana since they only reported newly diagnosed HIV positive clients).
Conclusions: VMMC provides a unique opportunity to offer HIV testing for men who are hard-to-reach through other HIV testing approaches. Although overall yield may be relatively low (1.2%), VMMC is successful at identifying new HIV infections among clients who did not previously know their status and linking them to HIV care and treatment. Stronger data on linkage from VMMC to HIV treatment is needed, and additional efforts should be made to ensure better linkages across the prevention, care and treatment continuum.

WEPEC0904

One arm, open label, prospective, cohort field study to assess safety and efficacy of a new PrePex male circumcision technique performed by nurses in resource-limited settings for HIV prevention

V. Mutabazi[1], J.P. Bitega[2], L.M. Ngeruka[3]
[1]Rwanda Biomedical Center, Respiratory Infections Unit, Kigali, Rwanda, [2]Ministry of Defence, Military Medical Insurance, Kigali, Rwanda, [3]Rwanda Military Hospital, Kigali, Rwanda
Presenting author email: mutabazivincent@gmail.com

Background: This study is conducted as part of WHO prequalification process for an update to the PrePex circumcision technique. The updated technique involves removing of the foreskin shortly after PrePex device placement. This technique maintains the PrePex advantages while resolving some of the procedure limitations, including anaerobic environment that may be prone for anaerobic bacteria growth, odor and foreskin hygiene. This study will assess the safety and efficacy of this updated technique in real life environment.
Methods: Rwanda National Ethics Committee approved the study. The study is conducted at Rwanda Military Hospital (RMH). Study includes a sample size of 500 men age 13 and above. Nurses with previous experience in PrePex technique are trained on the updated technique in a 30 minutes instruction course. The updated technique includes the following modifications: 30 minutes after device placement the foreskin is removed till the edges of device are visible, without use of injected anesthesia. All other PrePex steps are same as current technique. The removal of foreskin 30 minutes after placement is different from the current technique where removal of the foreskin is after 7 days.
Results: The study started in January 2017, to date only 12 subjects were enrolled and were followed until device removal on day 7. Numbness of the foreskin was achieved within 25 to 35 minutes from device placement. There was no need of anesthetic injection. Removal of the foreskin after device placement was reported to be easier than removal on day 7. During the 7 days of wearing the device, there was no adverse event reported and no complain on pain or odor. Removal of the device on day 7 was reported to be as simple as the removal of device with the current PrePex technique.
Conclusions: This study is in its early stage and we expect to gather data of 500 men by end of April 2017 and to report statistical conclusions. At this stage it is possible to state that the updated technique seems to be simple to perform and acceptable by clients.

WEPEC0905

Unusual discomfort as reported by clients receiving PrePex™ device circumcision in a pilot study in Mozambique: programmatic implications

M. Mahomed[1], E. Necochea[2], D. Bossemeyer[2], L. Nhambi[1], H. Muquingue[1], T. Ferreira[1]
[1]Jhpiego, Maputo, Mozambique, [2]Jhpiego, Baltimore, United States
Presenting author email: mehebub.mahomed@jhpiego.org

Background: WHO and UNAIDS recommend voluntary medical male circumcision (VMMC) as a priority intervention in high HIV prevalence settings, such as Mozambique, for considerable reduction of sexual transmission of HIV. In Mozambique, VMMC has been provided as surgery since 2009. This requires certified providers and rigorous biosafety measures, making challenging the achievement of the MOH goal of 2 million males circumcised by 2017. PrePex™does not require injectable anesthesia or suturing circumcision. Using such devices could reduce staff needs, procedure time and costs, and increase the acceptability of VMMC. In 2013, a pilot study of the PrePex™ device was started in Mozambique to assess the safety and acceptability of VMMC of this particular device among providers and clients.
Methods: At removal of the PrePex™ device, at day 7 post-placement, 111 clients were randomly asked for in-depth interviews about their experience, and whether they would recommend. The interview was repeated at the 28th day (control visit). Interview transcripts were entered, coded and scrutinized in ATLAS.Ti™, to identify issues with PrePex™ not included in the client information package, and thus classified as "unusual".
Results: In the interviews, 85.8% of the recipients of PrePex™ circumcision indicated they had a good experience with the device and 91.3% of the clients who used PrePex™ would recommend it to others. The interviews identified the occurrence of four presentations of discomfort not foreseen by the providers of device circumcision. The most frequent discomfort was the difficulty to keep the penis upright, followed by the tendency of the penis skin to adhere to underwear (complicating the act of urinating), quick soiling of the bandages before the scheduled visit, and need for frequent hygiene and cleansing due to odor when in bed. The complaints

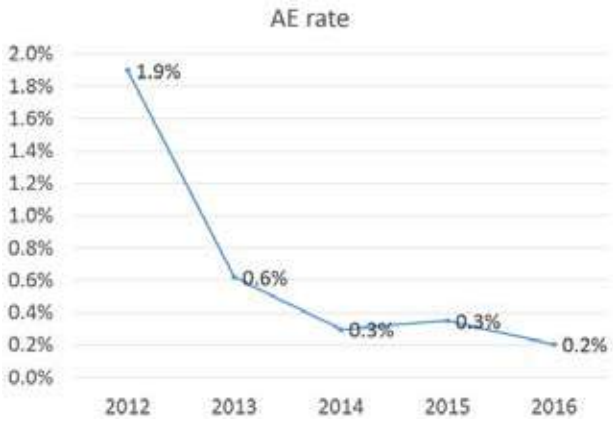
were associated with embarrassment in public (e.g., on a bus) and interference with social life.
Conclusions: Although satisfaction is high, unusual discomfort with PrePex™ may affect its acceptability. Therefore, appropriate measures should be considered when implementing large scale device circumcision, including information for clients on how to handle such situations need to be offered to device clients, and questionnaires to monitor the presence of forms of discomfort.

WEPEC0906

Safety first: remarkable improved quality of care despite rapid scale-up of five years VMMC Program in Lesotho

H. Mandali[1], V. Kikaya[1], M. Mokoena[1], M. Ntsupa[1], L. Motsoahae[1], P. Motsoari[1], A. Hellar[2], K. Curran[3], R. Manda[4], E. Njeuhmeli[5]
[1]Jhpiego Lesotho, TSEPO VMMC Program, Maseru, Lesotho, [2]Jhpiego Tanzania, AIDSFree, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego Washington DC, HIV/AIDS and Infectious Diseases, Washington, United States, [4]USAID Lesotho, Biomedical Prevention, Maseru, Lesotho, [5]USAID Washington, Biomedical Prevention, Washington, United States
Presenting author email: hamid.mandali@jhpiego.org

Background: Voluntary Medical Male Circumcision (VMMC) reduces the chances of HIV infection from females to males by approximately 60%. Lesotho adopted VMMC as a priority HIV prevention strategy in 2012. Focusing on outcome of care, programs are advised to implement mechanisms in which health care services will be systematically monitored and evaluated for access, quality and continuity of care. We reviewed the outcome of care through quality aspects of the program including by examining follow-up and adverse event rates and trends.
Methods: We conducted a retrospective review of the VMMC client database from September 2012 to September 2016. Reported follow-up and adverse events were categorized and reviewed by fiscal years and the overall trend summarized in a graph.
Results: A total of 129,982 clients were circumcised during the review period. Of these, 92,041 clients (75.8%) returned for at least one follow-up visit. The overall follow-up rate dropped at the second year of the program but improved gradually over time to 2016. In addition, the AE rates dropped gradually from 1.9% in FY12 to 0.2% in FY 16. In general, there was a remarkable improvement of the safety parameters over the review period.



[AE Rates VMMC Lesotho 5 Years]

Conclusions: Our review revealed significant improvement on follow-up rates and a drop in adverse event rates in over 5 years of program implementation. One of the explanations for these observations could be the regular refresher trainings to providers and counselors so that safety and quality of service become priorities. Mobilizers and community volunteers are also trained in all aspects of VMMC program including quality of care. Both clinical and demand creation teams need to take into account clients' satisfaction and care. Improved quality and perceived safety will increase demand for services from the community.

WEPEC0907

Using predictive analytics and cellular phones to book VMMC for HIV prevention among 18 - 35 years old South African males: the SWHP experience

P. Govender, C. Khumalo
Sactwu Worker Health Project / The Behaviour Change Agency, Cape Town, South Africa

Background: In 2010, the South African government introduced voluntary medical male circumcision (VMMC) as part of its national HIV prevention policy - to achieve a targeted 4.3 million circumcisions by the end of 2016. In their strategy to help government reach this target, the SACTWU Worker Health Programme (SWHP) offered VMMC as one of their free services. This is done at their clinics, mobile clinics, and government health care facilities. To improve VMMC uptake, innovative and effective approaches are needed. The objective of this pilot study was to examine the efficacy of using a free Unstructured Supplementary Service Data (USSD) number on their mobiles to book VMMC services.
Methods: Using behavioural economics, SWHP developed a demand creation campaign to boost the uptake of VMMC services among 18 - 35 years old males. Booking an appointment was made easier by dialing the number, *134*450# for free. Men would follow a few simple steps to make an appointment at a convenient date at a health care facility. This booking is followed by a confirmation SMS and a reminder SMS a day before the appointment. This data was used to predict and meet demand in areas where it was most needed. This study was piloted in three of the nine South African provinces: KwaZulu-Natal, Free State and Western Cape. The efficacy of this system was assessed at two months.
Results: From October to December 2016, 48 525 persons accessed the USSD number. A total of 11 533 (24%) were circumcised. The average age of the participants was 18. Most males (74%) were circumcised at clinics, followed by circumcision camps (26%). The most circumcisions took place in KwaZulu-Natal (80%), followed by the Free State (10%) and Western Cape (9%).
Conclusions: Our findings suggest that the integration of a nudge in the form of a carefully designed free USSD booking system into SWHP VMMC demand creation interventions was a success. Our results are also consistent with behavioural economics studies showing that small nudges can modify health behaviours. The effect of this novel intervention should now be tested on a broader scale and in different contexts.

WEPEC0908

The effect of the two Tetanus Toxiod (2TT) dose policy on voluntary medical male circumcision (VMMC) service delivery in Masaka region, Uganda

N. Kighoma[1], G. Nakigozi[2], F. Nalugoda[3], T. Murungi[4], J. Mwenike[1], M. Anyokorit[1], S. Watya[1,5], G. Kigozi[1]
[1]Rakai Health Sciences Program, Uganda Virus Research Institute, Studies, Kalisizo, Uganda, [2]Rakai Health Sciences Program, Uganda Virus Research Institute, Clinical Services, Kalisizo, Uganda, [3]Rakai Health Sciences Program, Uganda Virus Research Institute, Management, Kalisizo, Uganda, [4]Rakai Health Sciences Program, Uganda Virus Research Institute, Data, Kalisizo, Uganda, [5]URO CARE, Kampala, Uganda, Urology, Kampala, Uganda
Presenting author email: mnkighoma@yahoo.com

Background: VMMC is a proven HIV prevention intervention for men. Nine cases of tetanus infection that resulted into 6 deaths were reported and MoH recommended 2TT doses 28 days apart before circumcision.
We have observed a decline in VMMC uptake which could affect cost per circumcision and the number of infections that would be averted.
Modeling done in Rakai showed that the number of surgeries required preventing one infection over 10 years ranged between 19-58.
We assessed the effect of the 2TT dose policy on VMMC uptake, cost per circumcision, and number of new HIV infections averted over 10 years.
Methods: VMMC service data collected between April and November 2016 from Masaka region was used for this analysis. Between April and June (Period 1) all men received one TT dose and were circumcised on the same day. The 2TT dose policy was fully implemented between August and November 2016 (Period 2) and all men received 2TT doses before circumcision.
We used chi-square test to compare VMMC uptake and cost per circumcision before and after the introduction of the TT policy and estimated the number of new HIV infections that could occur over 10 years.
Results: Of all men who got TT1 in period 1, 99.3% (15,211/15,317) were circumcised compared to 56.2% (9,565/17,017) in period 2 ($p < 0.0001$).
During period 1 (TT1 only), the total number of surgeries done was 15,211, an average of 5,070 circumcisions per month. In period 2 (2TT doses), 9,565 circumcisions were done, an average of 2,391 per month. The difference in monthly circumcisions

between the 2 periods was 2,679 (52.8%) which translates into 10,716 missed circumcisions in 4 months and 32,148 in a year, despite availability of funds.
The operation cost per circumcision in period 2 increased by 55% compared to period 1.
The number of HIV infections that we would fail to avert over ten year's range from 554 to 1,692.
Conclusions: In Masaka region, the Ugandan TT policy led to a more than 50% reduction in the number of men receiving circumcision, increased the cost per circumcision, and can reduce the number of HIV infections averted.

WEPEC0909

Monitoring adverse events in a new mature male circumcision client cohort in Namibia

N. Soboil[1], C. Laube[2], A. Mwinyi[1], S. Rooinasie[1], M. Valombula[3]
[1]Jhpiego, Swakopmund, Namibia, [2]Jhpiego, Washington, United States, [3]Ministry of Health and Social Services, Swakopmund, Namibia
Presenting author email: nikki.soboil@jhpiego.org

Background: Jhpiego and the Namibian Ministry of Health and Social Services launched voluntary medical male circumcision (VMMC) services in Erongo Region Namibia in May 2016. Ninety percent of clients have been aged 20 years and above, in contrast to other regions in Namibia and other countries in East and Southern Africa, where the majority have been aged 10-19 years. A 2012 meta-analysis of 10 studies assessing safety of VMMC across 6 African countries found post-operative adverse event (AE) rates ranging between 0.7% and 37.4%, with an overall pooled proportion of 2.3%.
Methods: As part of routine service delivery, after receiving the full VMMC service package clients were advised to return for follow up at Days 2, 7, and as indicated thereafter. Clinical follow up data were extracted from client records of males circumcised between 13 May - 31 July 2016.
Results: Of 1,155 males who returned for at least one follow up visit, 67 (5.8%) experienced at least one mild (19, 1.6%), moderate (45, 3.9%), or severe (3, 0.3%) AE. Fifty four percent of post-operative AEs were wound dehiscence, and of those 20.6% presented on days 5-7 post-op, 57.1% on days 8-14, and 22.3% on day 15 or later.

Age (years)	VMMC clients returning for at least one follow-up visit n	Wound Dehiscence AEs n (%)	Other AEs n (%)	Cumulative AEs (all types) n (%)
15-19	67	2 (3.0)	3 (4.5)	5 (7.5)
20-24	309	9 (2.9)	6 (1.9)	15 (4.9)
25-29	327	13 (4.0)	10 (3.1)	23 (7.0)
30-34	211	8 (3.8)	2 (1.0)	10 (4.7)
35-39	116	1 (1.0)	4 (3.4)	5 (4.3)
40-44	75	2 (2.7)	4 (5.3)	6 (8.0)
45+	50	1 (2.0)	2 (4.0)	3 (6.0)
TOTAL	1155	36 (3.1)	31 (2.6)	67 (5.8)

[Table: AE rates recorded at VMMC services, Erongo Namibia, 13 May - 31 July 2016]

Conclusions: Observed AE rates exceed the pooled rate in the 2012 meta-analysis. Although further investigation is needed to isolate the cause(s) of high rates of AEs in general and wound dehiscence in particular, the highest concentrations of AEs align with ages of prime sexual activity. A hypothesis for investigation is many AEs resulted from early resumption of sexual activity (intercourse and masturbation) as the majority had onset later than the routine follow-up schedule. VMMC programs may be underestimating AE rates and should consider an extended follow-up schedule to avoid missing late-onset AEs.

WEPEC0910

Impact of a combination behavioural change communication programme on HIV risk reduction via service up-take in a fishing community in Rakai, Uganda

S. Mugamba[1], D. Nabukalu[1], T. Murungi[1], M.J. Wawer[2], D. Serwadda[3], R.H. Gray[2], F. Nalugoda[1], J.L. Ssembatya[1], E. Kato[1], R. Ssekubugu[1], A. Zikusooka[4], I. Kisitu[1], G. Kigozi[1]
[1]Rakai Health Sciences Program, Kalisizo, Uganda, [2]Johns Hopkins University, Bloomberg School of Public Health, Department of Population, Family and Reproductive Health, Baltimore, United States, [3]Makerere University School of Public Health, Kampala, Uganda, [4]Communication for Healthy Communities Project, 'Obulamu Campaign', FHI-360, Kampala, Uganda
Presenting author email: smugamba@rhsp.org

Background: Multi-channel behavioural change communication interventions are believed to be effective in scaling up the up-take of HIV prevention services, thus a reduction in the HIV risk. There is limited evidence of the effects these interventions on population-level interventions.
Combination behavioural change communication was assessed if it increases services uptake such as Voluntary Medical Male Circumcision (VMMC), HIV Counselling and Testing (HCT), and HIV Care and Treatment targeting HIV risk reduction in a fishing Community with high HIV prevalence (~ 41%) in Rakai District, Uganda.
Methods: Combination behavioural change communication (CBCC) strategies including sensitisation meetings/seminars, village "town hall" meetings, drama/theatre shows, film/video shows, health education in bars, and meetings for most at risk populations were provided to residents of Kasensero fishing community along lake Victoria, between November 2011 and May 2015. All strategies were packaged with HIV risk reduction messages.
Evaluation of the impact of CBCC on HIV incidence, risk behaviours and HIV prevention services utilisation among residents aged 15-49 was done through the Rakai Community Cohort Study (RCCS), a population-based longitudinal study.
A total of 2,744 participants (1,343 females and 1,401 males), and 3,061 (1,547 females and 1,514 males) were interviewed at baseline and follow up visits respectively. Data was collected using structured interview and analysis done using stata version 13. Chi-square test for trends was used to determine change in uptake of HIV prevention services.
Results: ART coverage among HIV-positive individuals increased from 54.6% (124/227) in 2011 to 75.1% (410/546, p=0.001) among women in 2015 and from 49.3% (71/144) to 62.4% (262/420, p=0.006) in men for the same period. VMMC coverage among non-Muslim men increased from 27% (322/1206) in 2011 to 53.1% (753/1418, p=0.001) in 2015. The proportion who had never tested for HIV decreased from 18.5% (284/1343) to 4.8% (74/1547, p=0.001) among females and from 32.8% (460/1401) to 5.7% (86/1514, p=0.001) among males.
Conclusions: Combination behavioural change communication interventions in HIV high risk communities increase uptake of HIV risk reduction services. Multi-channel messaging helps to support and reinforce each other in delivering the right message and should be recommended to other programming implementing services uptake for HIV risk reduction.

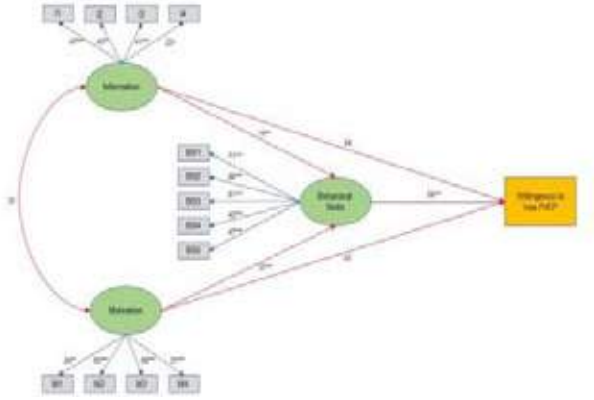
WEPEC0911

Willingness to use pre-exposure prophylaxis (PrEP): an empirical test of the information-motivation-behavioral skills (IMB) model among high-risk drug users in treatment

R. Shrestha[1,2], F. Altice[2,3], T. Huedo-Medina[2,4], P. Karki[2,4], M. Copenhaver[2,4]
[1]University of Connecticut Health Center, Community Medicine & Health Care, Farmington, United States, [2]University of Connecticut, Institute for Collaboration on Health, Intervention, and Policy, Storrs, United States, [3]Yale University, Department of Internal Medicine, New Haven, United States, [4]University of Connecticut, Department of Allied Health Sciences, Storrs, United States
Presenting author email: pramila.karki@uconn.edu

Background: With a rapid increase in the amount of research on the efficacy of PrEP for HIV prevention, complementary research on the willingness to use PrEP has grown, especially among MSM, with limited research focused among people who use drugs (PWUD). As part of the formative process, we utilized the Information-Motivation-Behavioral Skills (IMB) model of health behavior change to characterize and guide intervention development for promoting PrEP uptake among high-risk PWUD.
Methods: We recruited 400 HIV-negative, opioid-dependent individuals enrolled in a methadone maintenance program and reporting drug- and/or sex-related HIV risk. Participants reported on IMB model-based measures related to PrEP using an audio-computer-assisted self-interview. We evaluated the full IMB model of willingness to use PrEP using structural equation modelling in Mplus.

Results: As hypothesized, PrEP-related information and motivation were not significantly related to one another. Paths from information to behavioral skills (β=0.15, p=0.016) and from motivation to behavioral skills (β=0.37, p<0.001) were significant and in the predicted direction. Also as predicted by the IMB model, the path from behavioral skills to willingness to use PrEP was significant (β=0.58, p<0.001) and in the anticipated direction. The overall fit of the model was good according to standard model fit indices: $\chi 2$ (72, N=400)=113.08, p=0.024, CFI=0.95, TLI=0.93, RMSEA=0.09 (90% CI:0.05-0.14), SRMR=0.045), with the model accounting for approximately 36.6% of the variability in willingness to use PrEP (Figure 1).



[Figure 1: IMB model of willingness to use PrEP]

Conclusions: The results provide evidence as to the utility of the IMB model to increase willingness to use PrEP among high-risk PWUD. It therefore makes an important contribution to our understanding of the applicability of theoretically-grounded models of willingness to use PrEP among high-risk PWUD, who are one of the key risk populations who could benefit from the use of PrEP.

WEPEC0912

Using conjoint analysis to measure the acceptability of pre-exposure prophylaxis (PrEP) use for HIV prevention among high-risk drug users in treatment

R. Shrestha[1,2], P. Karki[2,3], F. Altice[2,4], M. Copenhaver[2,3]
[1]University of Connecticut Health Center, Community Medicine & Health Care, Farmington, United States, [2]University of Connecticut, Institute for Collaboration on Health, Intervention, and Policy, Storrs, United States, [3]University of Connecticut, Department of Allied Health Sciences, Storrs, United States, [4]Yale University, Department of Internal Medicine, New Haven, United States
Presenting author email: roman.shrestha@uconn.edu

Background: Pre-exposure prophylaxis (PrEP), the use of antiretroviral medication prior to exposure, could greatly reduce HIV infections. Despite unequivocal evidence of PrEP efficacy, its uptake remains strikingly low and inadequately scaled to need among most-at-risk populations, particularly people who use drugs (PWUD). This study illustrates the use of conjoint analysis (CA) method, an innovative method for systematically estimating consumer preferences across discrete attributes, to assess PrEP acceptability and the impact of PrEP program characteristics on acceptability.
Methods: 400 HIV-negative individuals, enrolled in a methadone maintenance program, and reporting drug- and/or sex-related HIV risk behaviors participated in a conjoint preferences for PrEP with different attributes. Eight hypothetical PrEP scenarios varying across six dichotomous attributes were constructed using a fractional factorial experimental design (Table 1). Participants rated acceptability of PrEP scenarios from 1 ("most likely to use") to 8 ("least likely to use"). We used conjoint procedure in SPSS, which utilizes a set of linear regressions, to generate acceptability of PrEP scenarios and relative importance (RI) of PrEP attribute levels.
Results: PrEP acceptability ranged from 30.6 to 86.3 on the scale of 0 - 100 across the eight hypothetical PrEP program scenarios (Table 1). The PrEP program scenario with the highest acceptability (scenario 1) had the following attribute levels: insurance covered, daily use, 95% effective, no side effects, treatment at HIV clinic and HIV testing needed every 6 months. The cost associated with PrEP was the most important attribute (RI=38.8), followed by efficacy (RI=20.5) and side effects (RI=11.9); other attributes had no significant effect.

		PrEP Attributes					
Scenarios	PrEP acceptability	Cost	Dose	Efficacy	Side Effects	Treatment Location	HIV Testing Needed
1	86.3	Insurance covered	Daily use	95%	None	HIV clinic	Every 6 months
2	82.1	Insurance covered	Before sex	95%	Nausea/ Dizziness	Drug treatment clinic	Every 3 months
3	70.7	Insurance covered	Daily use	75%	None	Drug treatment clinic	Every 3 months
4	57.2	Insurance covered	Before sex	75%	Nausea/ Dizziness	HIV clinic	Every 6 months
5	51.4	Out of Pocket	Before sex	95%	None	Drug treatment clinic	Every 6 months
6	39.8	Out of Pocket	Daily use	95%	Nausea/ Dizziness	HIV clinic	Every 3 months
7	31.5	Out of Pocket	Before sex	75%	None	HIV clinic	Every 3 months
8	30.6	Out of Pocket	Daily use	75%	Nausea/ Dizziness	Drug treatment clinic	Every 6 months

[Table 1: Acceptability of PrEP scenarios]

Conclusions: Our findings reported a high acceptability of PrEP in response to different PrEP program scenarios with different attribute profiles. As the result of having this information, researchers and policy-makers will be better equipped for evidence-informed targeting and dissemination efforts to optimize PrEP uptake among this underserved populations.

WEPEC0913

Survey of early barriers to PrEP uptake among clients and community members in the SEARCH study in rural Kenya and Uganda

C. Koss[1], J. Ayieko[2], A. Owaraganise[3], F. Mwangwa[3], J. Wallenta[1], D. Kwarisiima[3], T. Ruel[4], D. Black[1], C. Cohen[5], E. Bukusi[2], T. Clark[1], E. Charlebois[1], M. Petersen[6], M. Kamya[3,7], C. Camlin[5], D. Havlir[1]
[1]University of California, San Francisco, Department of Medicine, San Francisco, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]University of California, San Francisco, Department of Pediatrics, San Francisco, United States, [5]University of California, San Francisco, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [6]University of California, Berkeley, School of Public Health, Berkeley, United States, [7]Makerere University College of Health Sciences, Kampala, Uganda
Presenting author email: jimayieko@gmail.com

Background: Barriers to the uptake of open-label pre-exposure prophylaxis (PrEP) offered in a population-based context in high HIV prevalence settings have yet to be studied and could include additional barriers to those identified in prior studies in targeted populations.
Methods: SEARCH (NCT01864603) is a combination prevention study in 32 communities of ~10,000 persons each in rural Kenya and Uganda. The study is offering targeted PrEP to individuals age ≥15 years at risk for HIV based on an empirically-derived risk score for HIV seroconversion or self-identified risk for HIV, including serodiscordant partnership. We studied barriers to PrEP uptake via 1) surveys of clients who expressed interest in PrEP but did not start,
2) surveys of community members, and
3) discussions with PrEP counselors and providers in SEARCH.
Surveys consisted of open-ended questions about reasons for declining PrEP and perceptions about PrEP.
Results: In 6 communities, we surveyed 63 community members (40% men, 35% women, 25% youth) and 42 clients who did not start PrEP (38% women, median age 28 years [range 16-53], 45% at risk for HIV by empiric score, 43% self-identified at risk). Barriers to PrEP uptake were identified at multiple levels (Figure 1), including individual (pill attributes, side effects, specimen collection, low perceived risk of HIV acquisition, misconceptions about PrEP use), partner/household (need to consult with and receive approval from a spouse or parent prior to starting PrEP), structural (work or school attendance, distance to clinic, transport costs, mobility), and community (stigma, community beliefs). Many individuals expressed a preference for non-daily medication taken pericoitally or during holidays.

Level of Influence	Category	Barrier
Individual	Pill attributes Daily medication	Pill size is too large Difficulty swallowing pills Pills look like HIV medications Prefer to take medication periodically or during holidays Prefer periodic injections like family planning
	Fear of side effects or specimen collection	Food insecurity – cannot take drugs on empty stomach Fear of body weakness, nausea, and dizziness Blood draws required Shipment of specimens outside community for testing Hair is collected because PrEP causes brain damage
	Perception of low HIV risk Not ready to take PrEP	Not currently at risk Need time to think about decision to take PrEP
	Misconceptions about PrEP Mistrust	Protects against other sexually transmitted infections Taking for 1 month confers long-term HIV protection Can share PrEP with partner during encounters Treats or causes erectile dysfunction Reduces sexual desire, causes infertility May cause harm during pregnancy or breastfeeding If PrEP is effective, why is HIV testing needed? Concern that PrEP is offered to those who are HIV-infected
	Other HIV prevention strategies	Will decrease use of condoms, other safer sex practices Prefer to use condoms
Partner/ Household	Partner Parent/family	Need to consult partner prior to taking PrEP, fear reaction Intimate partner violence; women lack control of encounters Partner will think PrEP is contraceptive Youth fear asking parent for approval PrEP suggests promiscuity
Structural/ organizational	Health center	Distance to travel to health center Cost of transportation Wait times at clinic
	Work School Mobility	Loss of wages; unable to take time off to go to clinic Difficult to access or take PrEP while away at school Unable to access PrEP if working away from community
Community	Stigma Community beliefs	Fear of being seen getting PrEP at health centers PrEP suggests "misbehaving," will encourage premarital sex PrEP will be perceived as HIV treatment Limited knowledge of PrEP creates misconceptions Fear that religious institutions will not support PrEP use

[Figure 1: Multi-level barriers to PrEP Uptake]

Conclusions: In communities offered targeted PrEP in this population-based study, multi-level barriers to PrEP uptake, including structural/organizational, were identified. Strategies are needed to address these barriers, such as community sensitization, expanded provision of information on PrEP, and community-based delivery mechanisms to facilitate access to PrEP.

WEPEC0914

Perspectives on PrEP among men who have sex with men (MSM) and transgender women (TGW) prior to PrEP rollout in Singapore: a qualitative study

C.H. Choong[1], Y.Y. Chan[2], C.S. Wong[1], M.A. Ibrahim[2], O. Lim[1], M. Chio[3], C. Wong[2,4]
[1]Tan Tock Seng Hospital, Department of Infectious Diseases, Singapore, Singapore, [2]Tan Tock Seng Hospital, Department of Clinical Epidemiology, Singapore, Singapore, [3]National Skin Centre, The DSC Clinic, Singapore, Singapore, [4]FHI 360, Behavioral and Epidemiological Sciences, Durham, United States
Presenting author email: chen_seong_wong@ttsh.com.sg

Background: A PrEP acceptability study was conducted prior to PrEP rollout in Singapore to understand the potential motivators, concerns and barriers to the use of PrEP as a novel HIV prevention method among HIV-negative high-risk MSM and TGW in Singapore.
Methods: Seven focus group discussions (FGDs) (n=48) were conducted between August and September 2016. A semi-structured interview guide was used to explore and identify community perceptions of and concerns regarding the use of PrEP. All FGDs were audio-recorded and transcribed verbatim. Data was analysed using qualitative thematic analysis.
Results: Majority of the participants were unaware of PrEP. Few had heard about PrEP from friends and social media or mistook it as post-exposure prophylaxis (PEP). All participants reported concerns about the efficacy and effectiveness of PrEP, and risks of side effects such as kidney function issues. Additionally, TGW participants highlighted that PrEP might complicate their hormonal treatment.
The cost of PrEP was cited as a huge barrier; most were only willing to spend approximately USD200 for a three-monthly prescription and follow-up visits to the healthcare provider. For TGW participants, paying for rent and hormonal treatment were their priorities. Other barriers include the stigma associated with taking PrEP and HIV-testing, fear of disclosure and being labelled as HIV-positive.
With regard to PrEP dosing schedules, MSM participants preferred on-demand PrEP and to visit private clinics while TGW participants preferred obtaining daily PrEP from transgender-friendly community-based organisations, so as to avoid facing stigma and discrimination from healthcare providers.
In general, PrEP was perceived as an additional protection against HIV infection as condoms were still considered more cost-effective in preventing HIV and sexually-transmitted infections. To raise awareness on PrEP, participants felt that social media would be a useful channel and preferred for PrEP to be introduced to the general population, to avoid further stigma towards the MSM and TGW community.
Conclusions: Findings from this study showed that there is a critical need to develop clinical and educational guidelines on the use of PrEP, for both providers and users, respectively. Similarities and differences in perspectives of MSM and TGW will require different implementation and marketing approaches of the PrEP service.

WEPEC0915

Limited implementation of HIV pre-exposure prophylaxis among public health departments in North Carolina, United States

H. Zhang[1], S. Rhea[2], A. Fleischauer[2], C. Hurt[3], V. Mobley[2], H. Swygard[3], A. Sena[3,4], M. McKellar[5]
[1]Duke University Medical Center, Department of Medicine, Durham, United States, [2]North Carolina Department of Health and Human Services, Raleigh, United States, [3]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [4]Durham County Department of Public Health, Durham, United States, [5]Duke University Medical Center, Division of Infectious Diseases, Durham, United States
Presenting author email: helen.l.zhang@duke.edu

Background: Expansion of HIV pre-exposure prophylaxis (PrEP) access could help alleviate the disproportionately high burden of HIV infection in the Southern United States. This study characterizes activities, barriers, and necessary resources for PrEP implementation in North Carolina (NC) public health departments, which frequently serve clients at risk for HIV infection.
Methods: In May 2016, health directors of all county health departments in NC were invited to complete a web-based survey assessing PrEP-related activities, perceived barriers to PrEP implementation, and desired PrEP-related resources.
Results: Of 85 county health departments in NC, health directors of 56 (66%) responded to the survey. Of these departments, 2 (4%) reported PrEP prescribing, 7 (13%) externally referred for PrEP services, and 11 (20%) were considering or preparing to initiate PrEP-related activities at the time of the survey. Among the 54 departments not prescribing PrEP, the most frequently cited reasons were concerns about the cost of PrEP (n=25, 46%), lack of formal prescribing protocols (n=21, 39%), and belief that PrEP would be better managed at a primary care or specialty clinic (n=19, 35%). The two departments that reported prescribing PrEP did not identify any barriers to maintaining their activities. Among the 47 departments not prescribing or referring clients for PrEP, the most frequently cited reasons for lack of referral were absence of PrEP providers to whom referrals could be made (n=29, 62%), lack of PrEP awareness or knowledge among health department staff (n=13, 28%), and perceived lack of PrEP candidates (n=12, 26%). Among all respondents, the most frequently requested PrEP-related resources were training to help identify clients who might benefit from PrEP (n=39, 70%), training on PrEP prescribing and management (n=38, 68%), and PrEP education and outreach materials for clients (n=37, 66%).
Conclusions: PrEP prescribing and referral among public health departments in NC remains extremely limited. However, widespread interest in guidance for PrEP implementation among health directors suggests potential for future expansion. Increased PrEP-related training and support for public health department-based providers could enhance PrEP access for NC residents at risk for HIV infection, especially in rural and underserved areas.

WEPEC0916

Baseline characteristics of women and men enrolled in the US Sustainable Healthcenter Implementatation PrEP Pilot (SHIPP) study, 2014-2017

D.K. Smith[1], M. Coleman[2], M. Houlberg[3], H. Kwakwa[4], D. Lazar[5], S. McCallister[6], J. Brock[7], L. Mena[7], M.K. Rawlings[6]
[1]CDC, Epidemiology Branch, DHAP, NCHHSTP, Atlanta, United States, [2]Whitman-Walker Health, Washington, United States, [3]Howard Brown Health, Chicago, United States, [4]Philadelpha Department of Public Health, Philadelphia, United States, [5]Access Community Health Network, Chicago, United States, [6]Gilead Sciences, Foster City, United States, [7]University of Mississippi, Jackson, United States
Presenting author email: dsmith1@cdc.gov

Background: Daily oral preexposure prophylaxis (PrEP) with FTC/TDF (Truvada) is recommended for all adults at substantial risk of HIV acquisition in the US but use has been highest initially in urban, white, middle-aged gay and bisexual men who have sex with men (MSM). New models of sustainable PrEP delivery are urgently needed to reach additional populations that will benefit from PrEP use.
Methods: The SHIPP study provided FTC/TDF for PrEP to men and women who met CDC guidelines criteria at community healthcenters in neighborhoods with high HIV infection rates including: 2 in Chicago, IL; Philadelphia, PA; Washington,

DC; and Jackson, MS. All PrEP participants (observational cohort) were followed with medical record abstraction to monitor clinical outcomes. A subset who consented to participate in a medication adherence substudy (MAS) completed quarterly computer-assisted interviews about behaviors and attitudes, and had blood collection to assess tenofovir drug levels.
Results: From October 2014 to- December 2016, 1207 persons enrolled in the MAS, including 103 cis-gender women (8.5%), 37 TGW (3%), and 1012 MSM (84%). Mean age was 33 years, with 22% <25 years. The population was diverse: non-Hispanic white 464 (43%), non-Hispanic black 372 (35%), Hispanic 158(13%), and 213 (18%) of other race/ethnicity. Seventeen percent had a high school diploma or less education, 73% were employed full or part-time, 34% had health insurance, and 58% reported condomless anal or vaginal sex in the month before enrollment, with a mean of 9 reported sexual partners in the 6 months before enrollment. Fourteen percent had a regular partner with HIV; 79% reported concern about high rates of HIV infection among people like themselves. The most common reasons for deciding to start PrEP were: not using condoms as often as they should (30%); not trusting that using condoms alone would protect them (25%); and worry that they would get HIV infection without PrEP (22%).
Conclusions: The SHIPP Study successfully enrolled a racially, geographically, and gender diverse cohort receiving PrEP as clinical care in a large, observational community cohort with data from objective measures of medication adherence. These data will inform healthcare delivery models for underserved PrEP populations in the US.

WEPEC0917

Impact of targeted pre-exposure prophylaxis strategies for men who have sex with men (MSM) in the United States

R. Elion[1], F. Altice[2], K. Mayer[3], D.A. Wohl[4], J. Cohen[5], B. Vandewalle[6]
[1]George Washington University, Clinical Medicine, Washington, United States, [2]Yale University School of Medicine, Yale, United States, [3]Harvard University, School of Medicine, Boston, United States, [4]University of North Carolina, Division of Infectious Diseases, Chapel Hill, United States, [5]Tufts University, Tufts Center for the Study of Drug Development, Boston, United States, [6]Exigo Consultores, Lisbon, Portugal
Presenting author email: frederick.altice@gmail.com

Background: Pre-Exposure Prophylaxis (PrEP) with emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) has been demonstrated in various studies as effective HIV prevention, including among MSM. We aimed to estimate the impact of different prevention strategies using FTC/TDF for PrEP (FTC/TDF_PrEP).
Methods: CDC data were used as primary sources for epidemiological and behavioural assumptions, with an estimate of 3.9% of US adult males being MSM. The model was calibrated to 2010-2013 estimates of HIV prevalence, by age and race. PrEP efficacy-adherence relationship was derived from the iPrEx-OLE study and real world PrEP uptake, adherence and discontinuations from the PrEP DEMO project. Outcomes evaluated at 5 years included: (1) Number needed to treat (NNT) to prevent one transmission; (2) Percent reduction in HIV Prevalence (PRP) from 2015; (3) Public health benefits (PHB) measured as percentage of all avoided HIV infections that are among non-PrEP users.
Each of the following FTC/TDF_PrEP prevention strategies was considered: PrEP for MSM with CDC HIV Risk Index (HIRI-MSM) ≥10 (MSM-10+), PrEP for black MSM with HIRI-MSM ≥10 (BMSM-10+), PrEP for young (age < 25) black MSM with HIRI-MSM ≥10 (YBMSM-10+), and PrEP for MSM with HIRI-MSM ≥20 (MSM-20+).
Results: The proportion of FTC/TDF_PrEP eligible HIV-negative MSM in the US under each preventive strategy would be: 50.5%/21.6%/5.1%/2.3% with all MSM-10+/all MSM-20+/BMSM-10+/YBMSM-10+, respectively.
PrEP uptake and adherence among eligible MSM are predicted to be lowest in YBMSM-10+ (uptake: 66.2%; adherence: 63.1%). The NNT to prevent one new HIV infection is 70 if FTC/TDF_PrEP is targeted to all MSM-10+. This is reduced to 33, 10, and 48 if targeted to BMSM-10+, YBMSM-10+, and MSM20+, respectively. PrEP availability to MSM-10+ would reduce HIV incidence by 50.0% and prevalence by 17.8% over 5 years, while the PRP with the other preventive strategies would be 4.0% for BMSM-10+, 2.9% for YBMSM-10+, and 9.4% with MSM-20+. PHB are estimated to be highest among YBMSM-10+ (37.8%).
Conclusions: Offering FTC/TDF_PrEP to MSM based on sexual risk, age and/or race, optimizes the NNT and increases PHB. Strategies that assist with uptake and utilization in populations most at risk will be most impactful.

WEPEC0918

Compliance to and safety of tenofovirDF/emtricitabine/rilpivirine in post-exposure prophylaxis

C. Allavena[1], B. Bonnet[1], D. Merrien[2], F. Vivrel[1], H. Hitoto[3], S. Bouchez[1], N. Hall[1], V. Reliquet[1], C. Brunet-Cartier[1], N. Varache[3], S. Sécher[4], E. Billaud[1,4], COREVIH Pays de la Loire Study group

Presenting author email: clotilde.allavena@chu-nantes.fr

Background: Post-exposure prophylaxis (PEP) is used to decrease the risk of HIV acquisition after risk exposure and all guidelines recommend a regimen duration of 28 days. The choice of antiretroviral regimen should maximize acceptability and completion rates. Since October 2016, French guidelines recommend TenofovirDF/emtricitabine/rilpivirine (TDF/FTC/RPV) as first choice of PEP, although data with this regimen in the setting of PEP are limited.
Methods: Prospective, observational, open-label, multicenter study conducted in 4 centres of Pays de la Loire area (western France) to evaluate safety, tolerability, adherence and efficacy of a 28-day course of TDF/FTC/RPV (1 pill/day with food) within 48 hours of potential exposure to HIV. At Week (W) 4, all participants were contacted to collect adherence, side effects and completion of the regimen. Blood samples for biological and/or serological data were prescribed at W2, W4, W8 and W16.
Results: From 1st March to 31 December 2016, 129 subjects (130 PEP) were enrolled. Exposure was sexual in 117 subjects (heterosexual intercourse n=51, MSM n=66) and non sexual in 12 subjects (occupational n=7: percutaneous injury n= 6, non-intact skin exposure n= 1; non occupational n=5). Subjects' characteristics are detailed in Table1.

	Total	Non sexual risk	Sexual risk		
				Heterosex.	MSM
N=	129	12	117	51	66
Male, %	75.2	33.3	79.5	52.9	100
Age, years, median(IQR)	29 (25-38)	32.5 (26-43)	29 (25-37)	29 (24-34)	29 (26-40)
Born in France, %	82.9	83.3	82.9	74.5	89.4
High level education, %	71	70	71.1	67.5	74
In employment, %	64.3	58.3	65.6	58.5	71.4
Known HIV+ Source,%	16.9	41.7	14.5	5.9	21.2
Condomless exposure, %	-	-	50.8	46	54.5

[Table 1]

At 31 Dec 2017, 124 subjects reached W4: 104 subjects completed the 28-day course of TDF/FTC/RPV, 12 were lost to follow-up, and 8 subjects prematurely stopped treatment (source patient HIV negative in 4 cases, patient's decision in 1 case at D1, discontinuation for adverse event in 3 cases: asthenia in 1 case at D25 and gastro-intestinal disturbances in 2 cases at D3 and D15). No participant acquired HIV through W16 of follow-up.
Conclusions: Tolerability of TDF/FTC/RPV as once daily PEP was good with low rate of discontinuation for adverse event. These results validate the positioning of TDF/FTC/RPV as preferred regimen for PEP in France.

WEPEC0919

Changes in truvada (TVD) for HIV pre-exposure prophylaxis (PrEP) utilization in the United States: (2012-2016)

R. Mera Giler[1], D. Magnuson[1], H. Trevor[2], S. Bush[2], K. Rawlings[2], S. McCallister[3]
[1]Gilead Sciences, Epidemiology, Foster City, United States, [2]Gilead Sciences, Medical Affairs, Foster City, United States, [3]Gilead Sciences, Clinical Research, Foster City, United States
Presenting author email: robertino.mera@gilead.cm

Background: Truvada (TVD) for pre-exposure prophylaxis (PrEP) was approved by the FDA in July 2012 to reduce the risk of sexually acquired HIV-1 in adults at high risk.
In this study we describe the changes over time in TVD for PrEP utilization in the United States and characteristics of the individuals who started TVD from January 2012 through September 2016.
Methods: We used a nationally representative sample of blinded data from a US prescription claims database to assess individuals who received a TVD prescription, representing >80% of retail pharmacies in the US. The data warehouse also contains medical claims, including diagnosis, procedures and patient and provider demographics. We utilized a validated algorithm to identify the use of TVD for the PrEP indication by excluding use for HIV treatment, post-exposure prophylaxis and

off-label chronic Hepatitis B treatment. Logistic regression with linear splines was used to identify changes over time and compare HIV and PrEP characteristics.
Results: Between January 2012 and September 2016, a total of 98,731 unique individuals were identified as starting TVD for PrEP: 5,853 in 2012; 6,547 in 2013; 16,117 in 2014; 33,484 in 2015 and 36,732 in the first three quarters of 2016. Three distinct periods have been observed, the first from 1Q2012 to 1Q2014 of slow growth (9% per quarter); the second of rapid growth from 2Q2014 to 4Q2015 (17% per quarter) and a stabilization period from 1Q2016 to 3Q2016 (growth < 1% per quarter). The first and second periods had statistically significant (p< 0.001) increases (positive slopes), but not the third. In the first period, there were a greater proportion of women (41.6%), which declined to 11.5% and 9.8% in the second and the third periods respectively. When compared to HIV positive patients, uninfected individuals receiving TVD for PrEP were 2.59 times less likely to be female (95% CI 2.5-2.6), and 1.17 times more likely to be younger than 25 years old (95% CI 1.16-1.17).
Conclusions: There has been a steady and substantive uptake in starts of TVD for PrEP across the US with more than 11,000 subjects initiating therapy in every quarter of 2016.

WEPEC0920

Differences in attitudes toward pre-exposure prophylaxis (PrEP) among three key populations: awareness, willingness and anticipated condom use among serodiscordant couples in Taiwan

N.Y. Ko[1], H.J. Wu[1], C.W. Li[2], C. Strong[3], S.T. Hsu[4]
[1]National Cheng Kung University and Hospital, Nursing, Tainan, Taiwan, Province of China, [2]National Cheng Kung University Hospital, Internal Medicine, Tainan, Taiwan, Province of China, [3]National Cheng Kung University, Public Health, Tainan, Taiwan, Province of China, [4]Kaohsiung Municipal Kai-Syuan Psychiatric Hospital, Department of Community Psychiatry, Kaohsiung, Taiwan, Province of China
Presenting author email: nyko@mail.ncku.edu.tw

Background: In August 2016, Taiwan approved emtricitabine/ tenofovir disoproxil fumarate (Truvada) for use as pre-exposure prophylaxis (PrEP) against HIV. HIV-negative partners within serodiscordant couples are the key targets for PrEP but little is known about differences in attitude toward PrEP among key populations. We compared awareness, willingness to use PrEP and anticipated condom use between couples and differences in three key populations: heterosexuals, men who have sex with men (MSM), and people who inject drugs (PWID).
Methods: A cross-sectional study was conducted in an AIDS designated hospital in Taiwan. Demographics, awareness and attitudes toward PrEP, and sexual behaviors in the previous 3 months were collected. A total of 105 pairs of HIV serodiscordant couples were enrolled: 31 heterosexual pairs, 64 MSM pairs, and 10 PWID pairs.
Results: Overall, 39.5% are aware of post-exposure prophylaxis, 46.7% are aware of PrEP, and only 13.3% of HIV-negative partners of serodiscordant couples were willing to take PrEP. Most of participants (34.8%) favor "on demand" oral PrEP rather than daily PrEP (19.0%). Among the three key populations, MSM couples had the highest awareness (MSM: 60.9% vs. heterosexual: 19.4 % vs. PWID: 40%) and willingness of PrEP (MSM: 33.6% vs. heterosexual: 16.1 % vs. PWID: 5.0%). Agreement of willingness to use PrEP between HIV serodiscordant couples is moderate (Cohen´s Kappa coefficient: 0.37). 81.0% would like to self-pay for PrEP if monthly cost less than 30 US$. Majority of participants (83.8%) were less likely to use condoms if taking PrEP and heterosexual couples had the lowest rate of anticipated condom use. Willingness to use PrEP was associated with MSM (aOR: 2.62, 95% CI: 1.02-6.71), people aged below 30 (aOR: 2.66, 95% CI: 1.18-5.99), full-time job (aOR: 5.07, 95% CI: 1.40-18.37), with history of sexual transmitted diseases (aOR: 7.44, 95% CI: 2.93-18.88), heard PrEP experience from others (aOR: 2.68, 95% CI: 1.04-6.93) and less likely to have risk compensation (aOR: 4.20, 95%CI: 1.92-9.18).
Conclusions: MSM serodiscordant couples had the highest awareness and willingness to use PrEP than heterosexual and PWID. Policy makers need to consider the differences among key populations in order to scale-up PrEP implementation.

WEPEC0921

Self-perceived HIV risk and attitudes towards PrEP affected the decision to take PrEP among Thai MSM and transgender women

S. Pengnonyang[1], J. Jantarapakde[1], D. Linjongrat[2], N. Mahachokchai[2], S. Janyam[3], S. Samalu[3], P. Brutrat[4], T. Nakpor[5], P. Potasin[5], D. Trachunthong[1], T. Sungsing[1], P. Rodbamrung[1], P. Seekaew[1], K. Pussadee[6], N. Teeratakulpisarn[1], T. Jadwattanakul[7], N. Mitipat[8], S. Charoenying[9], S. Mills[9], M. Cassell[10], R. Vannakit[10], P. Phanuphak[1], N. Phanuphak[1], C. Lertpiriyasuwat[11]
[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]The Service Workers In Group Foundation, Bangkok, Thailand, [4]The Service Workers In Group Foundation, Chonburi, Thailand, [5]Sisters Foundation, Chonburi, Thailand, [6]HIV-NAT, Bangkok, Thailand, [7]Queen Savang Vadhana Memorial Hospital, Chonburi, Thailand, [8]Chonburi Provincial Health Office, Chonburi, Thailand, [9]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [10]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand, [11]Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand
Presenting author email: speng@trcarc.org

Background: With an HIV incidence of >3% annually, Thai men who have sex with men (MSM) and transgender women (TG) represent populations who should be offered Pre-Exposure Prophylaxis (PrEP) according to WHO guidelines. Characteristics of MSM and TG who should be targeted by PrEP programs in Thailand are unknown. We explored factors associated with the decision to take PrEP when offered among Thai MSM and TG.
Methods: Thai MSM and TG, aged ≥18 years, with unprotected anal sex with a man at least once within the past 6 months were offered PrEP at four community-based clinics in Bangkok and Pattaya. Self-administered questionnaires were provided at baseline and logistic regression was performed to identify factors associated with decisions to take PrEP.
Results: Of 409 participants who were offered PrEP, 40.1% decided to take PrEP. Mean (±SD) age was 27.1 (6.8) years. In the past six months, 5.6% used amphetamine-type stimulants and 11.0% had group sex. PrEP users were more likely than other participants to have: previous HIV testing (54.9% vs. 42.5%, p=0.02), moderate/high risk perceptions for HIV infection (56.7% vs. 41.3%, p=0.001), and multiple sexual partners (91.5% vs. 82.0%, p=0.04). PrEP users felt less embarrassed (0.6% vs. 7.0%, p=0.002) and less anxious (19.1% vs. 35.7%, p<0.001) to take PrEP, and had less dislike of taking any pills (6.1% vs. 22.5%, p<0.001).
Based on logistic regression, self perceptions of moderate (OR 3.39, 95%CI 1.21-9.50) or high (OR 5.75, 95%CI 1.74-18.96, p=0.03) HIV risk and not feeling anxious to take PrEP (OR 2.68, 95%CI 1.37-5.25, p=0.004) were associated with increased PrEP uptake, while the dislike of taking pills (OR 0.20, 95%CI 0.08-0.52, p=0.001) was associated with decreasing PrEP uptake.
Conclusions: PrEP campaigns in Thailand need to target MSM and TG who perceive themselves to have moderate/high risk of acquiring HIV, while also addressing stigma around PrEP use in the community. Studying alternative administration routes of PrEP, such as the use of long-acting injectables, is crucial as substantial proportions of MSM and TG dislike taking oral pills.

WEPEC0922

Behavioral and socio-demographic correlates of PrEP side effects in a national sample of U.S. men who have sex with men (MSM)

K.H. Mayer[1,2,3], K. Biello[1,4], D.S. Novak[5], D. Krakower[1,2,3], M.J. Mimiaga[1,4]
[1]Fenway Health, The Fenway Institute, Boston, United States, [2]Harvard Medical School, Medicine, Boston, United States, [3]Beth Israel Deaconess Medical Center, Medicine, Boston, United States, [4]Brown University, Epidemiology, Providence, United States, [5]On-, Cambridge, United States
Presenting author email: kmayer@fenwayhealth.org

Background: Consistent oral PrEP adherence is necessary for maximal efficacy, but medication side effects (SE) may attenuate adherence. Identifying those most likely to experience an SE can inform intervention efforts.
Methods: An on-line survey was mounted on 2 popular sexual networking sites during March 2016 to assess sociodemographics, sexual behavior, PrEP knowledge, attitudes and use. Factors independently associated with experiencing a SE after PrEP initiation were evaluated using multivariable logistic regression with backward selection.
Results: Of 4,698 respondents, 21% were 18 to 24 y.o. and 38% were 40 or older. Almost half (47%) identified as White, 25% as Black, 11% as Latino/Hispanic. About 2/3 reported condomless anal intercourse (C.A.I.) at least once in the prior 3 months. Despite this, only 15% reported prior PrEP use. Almost all (91%) PrEP users rated taking PrEP as somewhat or very easy. Among PrEP users, 44% re-

ported a SE, with the most common being increased flatulence (17%), nausea (12%), and anorexia (7%). Although the SE disappeared within two weeks for 54% of the respondents, 26% indicated that the SE persisted and were present when they took the survey. Of those who reported SE, 10% discontinued PrEP because of them; 14% discontinued PrEP for other reasons, and 76% remained on PrEP. Black MSM had an increased odds of reporting SE: aOR 1.7 (95% C.I. 1.1, 2.9), p=0.027, compared to White MSM. Older MSM and those reporting chlamydia in the prior year had a decreased odds of reporting SE: aOR 0.4 (95% C.I. 0.2,0.9), p=0.027, compared to 18-24 y.o., and aOR 0.5 (95% C.I. 0.3,0.8), p=0.007 compared to those without an STI in the prior year, respectively.
Conclusions: In this online MSM sample, gastrointestinal SE were common among PrEP users, but few MSM discontinued PrEP as a result of SE. The increased odds of SE among Black MSM suggests that SE education, proactive clinical support, and evaluation of other PrEP modalities are indicated in order to potentially increase uptake and adherence in this population.

WEPEC0923

Opportunities and challenges of using pre-exposure prophylaxis to prevent HIV infection among men who have sex with men in Hong Kong: awareness, acceptability and potential issues

J.T.F. Lau, Z. Wang, M. Ip, P.K.H. Mo, R. She
Chinese University of Hong Kong, Centre for Health Behaviors Research, Hong Kong, China
Presenting author email: jlau@cuhk.edu.hk

Background: Pre-exposure prophylaxis (PrEP) is an effective evidence-based biomedical HIV intervention strongly recommended to MSM by the World Health Organization (WHO). The HIV epidemic has been worsening among MSM in Hong Kong. Effective means of interventions are greatly warranted. This study aimed to provide proactive understanding on awareness, acceptability and potential issues related to PrEP among local MSM.
Methods: A cross-sectional survey was conducted. Participants were Hong Kong Chinese MSM aged 18-60 years old. Those self-reported as being HIV positive were excluded. A total of 403 participants were recruited and completed the anonymous self-administered questionnaire.
Results: Of all participants, 26.6% had heard of PrEP, while only 1% had ever used PrEP. After being briefed about the facts of PrEP (i.e., efficacy, WHO recommendation, potential side effects and dosing requirements), 45.2% showed behavioural intention to use daily PrEP in the next six months if it was provided for free by governmental hospitals or clinics. Whereas, 28.0%, 13.9% and 3% would reduce condom use with male regular sex partners, male non-regular partners and female sex partners after using PrEP, respectively. Moreover, 57.6% would not take up regular HIV testing (every three months) after using PrEP, while 25.1% would stop using PrEP without consulting doctors.
After adjusting for these significant background variables, significant factors associated with behavioural intention to use free daily PrEP included: 1) prior awareness of PrEP (Adjusted odds ratio, AOR: 1.92; 95%CI: 1.19, 3.08), 2) perceived risk of HIV infection (AOR: 1.47, 95%CI: 1.13, 1.91), 3) perceived benefit of PrEP (AOR: 1.18, 95%CI: 1.06, 1.31), 4) perceived barriers of using PrEP (AOR: 0.67, 95%CI: 0.58, 0.76), 5) perceived self-efficacy of using free daily PrEP (AOR: 1.55, 95%CI: 1.38, 1.74), and 6) receiving support from peers for using PrEP (AOR: 2.88, 95%CI: 1.01, 8.59).
Conclusions: PrEP is still new for local MSM as their awareness and utilization are low. Future health promotion modifying perceptions and using peer influence may be useful to promote PrEP. Some critical issues need to be addressed before implementation, such as non-adherence, regular testing and risk compensation. More research is needed to prepare for future demonstration study.

WEPEC0924

Knowledge and willingness to use Pre-Exposure Prophylaxis (PrEP) among African Americans in the United States: results from the National Survey on HIV in the Black Community (NSHBC)

B. Ojikutu[1], L. Bogart[2], M. Higgins-Biddle[3], W. Allen[4], T. Dominque[5], K. Mayer[6]
[1]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States, [2]RAND Corporation, Santa Monica, United States, [3]John Snow, Inc., Boston, United States, [4]Harvard University, Boston, United States, [5]University of Pennsylvania, Philadelphia, United States, [6]The Fenway Institute, Boston, United States
Presenting author email: bojikutu@partners.org

Background: In the United States, 44% of estimated new HIV diagnoses were among African Americans, who comprise only 12% of the population. Yet, few data exist regarding willingness among African Americans to use pre-exposure prophylaxis (PrEP) to prevent HIV infection. This study explores knowledge of and willingness to use PrEP among a nationally representative sample of African Americans.
Methods: From February to April 2016, an online survey assessing sociodemographic characteristics, HIV risk behaviors, HIV beliefs, knowledge of and willingness to use PrEP was administered to a nationally representative sample of African Americans aged 18 to 50.
Results: 868 individuals completed the survey [mean age = 33.6 (±9.2); 43.7% male]. Among all respondents, 14.8% were aware of PrEP, and 26.2% would be willing to take PrEP. In bivariate analysis including all respondents, those who had not seen a health care provider within the last year and those who reported experiencing racial discrimination were less willing to use PrEP. In multivariate analysis controlling for age, education, gender, HIV risk status, and depression, not seeing a health care provider remained significant [AOR 0.5, 95%CI (0.4, 0.8), p< 0.002]. Among high-risk participants (reporting anal sex, condomless sex with more than one partner, transactional sex, and/or MSM, N=331), 15% knew that there was a pill to prevent HIV, and 26.5% would be willing to use PrEP. The most common reasons for lack of willingness among high-risk respondents were: "I'm not at risk of HIV infection" (73%) and "I don't believe it would work" (29%). Among high-risk women, 15% were aware of PrEP, and 33% would be willing to take PrEP. Among high-risk males, 28% were aware of PrEP, and 41% would be willing to take PrEP. No difference in willingness to take PrEP was noted by gender, and there was no significant difference in willingness to take PrEP between MSM and high-risk heterosexual males.
Conclusions: Among a nationally representative sample of African Americans, few high-risk individuals were aware of and would be willing to use PrEP. Interventions to increase HIV risk awareness and improve access to health care are needed to increase PrEP use among African Americans.

WEPEC0925

Feasibility, acceptability and adherence with short term PrEP in female sexual partners of migrant miners in Mozambique

M. Lahuerta[1], A. Zerbe[1], R. Baggaley[2], J. Falcao[1], L. Ahoua[1], P. DiMattei[1], F. Morales[1], I. Ramiro[3], P. Mulondo[4], W.M. El-Sadr[1]
[1]ICAP Columbia University, Mailman School of Public Health, New York, United States, [2]World Health Organization, HIV Department, Geneva, Switzerland, [3]Ministry of Health, Maputo, Mozambique, [4]TEBA Development, Gaza Province, Mozambique
Presenting author email: ml2842@columbia.edu

Background: Oral pre-exposure prophylaxis (PrEP) offers great promise for HIV prevention. The use of PrEP for short-term protection has not been assessed. We evaluated the feasibility, acceptability and adherence with short-term PrEP among female sexual partners of migrant miners in Gaza, Mozambique.
Methods: HIV-negative women who reported being a sexual partner of a male migrant miner were offered daily TDF/FTC for 6 weeks concurrent with when miners return to Gaza. Study visits occurred at baseline, Week 4, 6 and 8 (2-weeks post PrEP cessation). Dry blood spots (DBS) were collected at Week 4 and 6.
Results: Seventy-four women (median age: 42 years) participated, the majority (95%) reported one sexual partner and 80% reported never or rarely using condoms. At baseline, 41% had never tested for HIV and 65% reported being unaware of partners' HIV status. Over half (53%) anticipated no difficulties in taking PrEP and 80% cited protection from HIV as reason to participate. Of all women, 72 (97%) initiated PrEP. At Week 4, most common side effects were dizziness and headache. Seven participants (10%) discontinued PrEP before Week 6, but only one due to side effects. Missed doses in the last 7 days were reported by 8% at Week 4 and 3% at Week 6. Of the 65 (90%) women with DBS at Week 4, 79% had detectable tenofovir-diphosphate (TFV-DP) and 44% had levels consistent with ≥4 pills/week (TFV-DP levels≥700 fmol/punch). Of the 63 (88%) women with DBS at Week 6, 76% had detectable TFV-DP and 42% had levels consistent with ≥4 pills/

week. At Week 6, 86% reported not disclosing PrEP use to partner mostly due to fear "that he would not let me take part in study/take pills." By the end of the study, 98% were willing to continue taking PrEP to protect themselves from HIV.
Conclusions: This is the first study to assess use of short-term PrEP among female partners of migrant workers. Short-term PrEP was found to be feasible and acceptable. A high proportion of women had detectable TDF-DP levels during follow-up. Short-term PrEP offers promise for populations who are at high-risk for HIV during specific periods.

WEPEC0926

Low awareness and uptake of HIV pre-exposure prophylaxis among male sex workers in the Northeastern United States

K.B. Biello[1,2], P.A. Chan[3], A. Edeza[4], S.A. Safren[5], K.H. Mayer[2,6], M.J. Mimiaga[1,2]
[1]Brown University, Behavioral & Social Sciences and Epidemiology, Providence, United States, [2]Fenway Health, The Fenway Institute, Boston, United States, [3]Brown University School of Medicine, Providence, United States, [4]Brown University, Behavioral & Social Sciences, Providence, United States, [5]University of Miami, Department of Psychology, Coral Gables, United States, [6]Harvard Medical School, Boston, United States
Presenting author email: katie_biello@brown.edu

Background: Male sex workers (MSW), who exchange sex for money with other men, have nearly 25 times the risk of HIV compared to other men, and could benefit from using pre-exposure prophylaxis (PrEP) for HIV prevention. In order for broad implementation, awareness of and interest in PrEP among those at highest risk must be fostered. We examined awareness of and interest in using pre-exposure prophylaxis (PrEP) among MSWs.
Methods: MSW with 3+ clients in the prior month were recruited through community-based organizations and outreach efforts in Massachusetts (MA) and Rhode Island (RI) in 2014-2016. Men underwent a comprehensive quantitative assessment which included sociodemographics, sexual risk behaviors, substance use, and PrEP awareness and interest. Variables associated with PrEP awareness and with interest in using PrEP were evaluated using separate multivariable logistic regression models.
Results: A total of 100 men (MA:49, RI:51) underwent the assessment (mean age:33.6 years). Forty percent identified as White, 32% as Black, and 19% as Latino/Hispanic. Thirty-six percent identified as gay. Sixty-five percent were unemployed and 43% had unstable housing. Most (90%) reported being "high" on drugs and 26% reported injecting drugs in the past six months. Sixty percent screened positive for clinical depression and 43% for alcohol dependence. In the past month, participants reported an average 2.2 CAS acts with male clients and 6.9 CAS acts with non-paying partners. Over half (56%) had previously heard of PrEP; 13% reported ever taking PrEP. After reading a brief description of PrEP, 80% indicated that they would be interested in taking PrEP to prevent sexual transmission of HIV. In multivariable models, low PrEP awareness was significantly ($p< 0.05$) associated with: not identifying as gay (aOR=2.99;95%CI=1.03,8.64), being unemployed (aOR=4.05;95%CI=1.35,12.19) and fewer CAS with clients (aOR=0.68;95%CI=0.49,0.95. Low PrEP interest was associated with: soliciting clients on the street (vs. online only) (aOR=5.32;95%CI=1.08,26.26) and having stable housing (aOR=4.88;95%CI=1.17,20.23).
Conclusions: MSW are at high risk for HIV infection, and could benefit from PrEP. MSW who do not identify as gay and those who are unemployed may benefit from PrEP education programs and tailored messaging. PrEP implementation efforts and interventions are needed to improve PrEP uptake among MSWs.

WEPEC0927

Shifting HIV prevention methods among men who have sex with men in Montreal: pre-exposure prophylaxis treatment among former post-exposure prophylaxis users

Z. Greenwald, M. Beauchemin, A. Goyette, J. Szabo, S. Lavoie, R. Thomas
Clinique Medicale l'Actuel, Montréal, Canada

Background: Post-Exposure Prophylaxis (PEP) treatment has been offered at Clinique médicale l'Actuel (Montréal) since 2000. In 2013, Pre-Exposure Prophylaxis (PrEP) was integrated into the counselling service for PEP patients at l'Actuel.
We aim to describe the proportion of patients beginning PrEP following PEP and compare their risk profiles to PrEP patients without prior PEP use.
Methods: We use retrospective PrEP and PEP databases to describe the proportion of MSM patients beginning PrEP following PEP treatment from January 2013 to November 2016. Patients who reported PEP use prior to 2013 were excluded. Demographic and behavioural traits of individuals on PrEP with and without prior PEP use were compared using chi-square and two-sided t-tests with 95% confidence intervals (CI). Co-variates include age, income, education, number of sexual partners, drug use and STI history.
Results: 1758 MSM received PEP treatment(s) since 2013 and 392 patients (22.3%) subsequently began PrEP. These patients were compared with 814 PrEP patients who never received PEP. Former PEP users tended to be younger (35.3 vs. 37.2), report higher rates of antecedent Chlamydia (58.7% vs. 50.0%) and more frequent HIV testing (64% report HIV testing every six months vs. 49% in PrEP patients who never received PEP).

		Prior PEP use, N=392 (N, %)	Never used PEP, N=814 (N, %)	P-value
Age (mean, 95% CI)		35.3 (34.3-36.3)	37.2 (36.4-37.9)	**<0.01**
Education	Secondary	11.8%	17.2%	0.06
	College	21.1%	22.3%	
	University	67.1%	60.5%	
Annual revenue	<20 000	21%	17%	0.36
	20 001-35 000	11.3%	14.1%	
	35 001-55 000	21.6%	23.5%	
	55 001-75 000	21.6%	18.2%	
	>75 000	24.5%	27.2%	

[Table 1: Cohort sociodemographic characteristics]

		Prior PEP use, N=392 (%)	Never used PEP, N=814 (%)	P-value
Number of sexual partners during the 12 months prior to PrEP start (Mean, 95% CI)		25.5 (18.1-32.8)	25.2 (19.3-31.1)	0.95
Sex under the influence of druges/alcohol during the 12 months prior to initiating PrEP		80.3%	77.4%	0.14
History of STIs prior to initiating PrEP (overall)		81.4%	77.4%	0.14
Antecedent Chlamydia		58.7%	50%	**0.02**
Frequency of HIV testing prior to PrEP	Every six months	63.7%	48.5%	**<0.01**
	Once a year	30.3%	36.3%	
	Once every two years	5%	5.9%	
	Once every 5 years	0.7%	5.3%	
	Only once or twice ever	0.3%	4%	

[Table 2: Cohort risk factors]

Conclusions: Individuals who have sought PEP are receptive to recommendations for PrEP. PrEP users with and without former PEP use report similar traits, indicating that PrEP services are successfully reaching patients with risk factors for HIV infection. PrEP should be offered systematically to MSM through the primary care system to reduce emergency PEPs and HIV transmission.

WEPEC0928

A latent class analysis of preferences for pre-exposure prophylaxis among men who have sex with men in Ukraine

A. Ogunbajo[1], O. Dubov[2,3], L. Fraenkel[4], R. Yorik[5], R. Altice[4]
[1]Brown University, Department of Behavioral & Social Sciences, Providence, United States, [2]Yale Univetsity, New Haven, United States, [3]Loma Linda University, Loma Linda, United States, [4]Yale School of Medicine, New Haven, United States, [5]PACT Ukraine, Kiev, Ukraine
Presenting author email: adedotun_ogunbajo@brown.edu

Background: Ukrainian men who have sex with men (MSM) remain a highly stigmatized group with HIV prevalence as high as 23%. Despite documented effectiveness of pre-exposure prophylaxis (PrEP), PrEP remains unavailable in Ukraine. The aim of this study was to elicit MSM preferences for PrEP to inform the future development of a PrEP program with the highest likelihood of uptake and retention among Ukrainian MSM.
Methods: In March 2016, 1184 MSM were recruited through social networking applications to complete a stated preference [choice-based conjoint (CBC)] survey. Respondents completed 14 choice tasks presenting experimentally-varied combinations of five attributes related to PrEP administration (dosing frequency, dispensing venue, prescription practices, adherence support, and costs). Latent class analysis (LCA) was used to both estimate the relative importance of attributes and preferences across nine possible PrEP delivery programs and classify MSM into distinct clusters based on response to CBC survey.

Results: Participants were in their late 20s (mean=28 years), college-educated (75%), employed full time (49%), did not live independently (69%) and struggled to meet the most important needs with their income (26%). Over half (52%) of participants screened positive for depression and religion was at least moderately important for 39% of participants. Participant preferences clustered into five distinct groups. PrEP affordability was the most influential attribute across groups, followed by dosing strategy. Only one group preferred injectable PrEP (n=216), while other four groups disliked daily PrEP and strongly preferred the ‚on demand' option. One group (n=258) almost exclusively considered cost in their decision making. One group (n=151) had very low level of interest in PrEP initiation correlated with low self-perceived risk for HIV (p<0.05). The two most at-risk groups (n=415) were also more sensitive to changes in program delivery.
Conclusions: PrEP uptake among MSM is most likely to be successful when PrEP is affordable, its' implementation is targeted, and provided as "on-demand" with associated education, and when more thorough medical care and related testing is provided to at-risk populations. The introduction of PrEP as a HIV prevention tool will need affirmation by the Ukrainian government, and framed around guidelines that reflect safety, efficacy, and patient preferences.

WEPEC0929

Optimizing access to Pre-exposure Prophylaxis based on preferences of Men Who Have Sex with Men in the United States: a latent class analysis

O. Dubov[1,2], A. Ogunbajo[3], L. Fraenkel[4], R. Yorik[5], R. Altice[4]
[1]Loma Linda University, Loma Linda, United States, [2]Yale University, New Haven, United States, [3]Brown School of Public Health, Providence, United States, [4]Yale School of Medicine, New Haven, United States, [5]PACT Ukraine, Kiev, Ukraine
Presenting author email: adedotun_ogunbajo@brown.edu

Background: Despite documented effectiveness of pre-exposure prophylaxis (PrEP), PrEP uptake remains low among men who have sex with men (MSM), the population bearing the highest HIV burden in the United States. Little is known about factors that influence MSM likelihood of engagement in PrEP. Consequently, we elicited MSM preferences on components of a hypothetical PrEP program to inform development of future initiatives aimed at increasing uptake of PrEP among MSM.
Methods: Between May and August 2015, 554 MSM in the U.S. were recruited through social networking applications to complete a stated preference [choice-based conjoint (CBC)] survey. Respondents completed 14 choice tasks presenting experimentally-varied combinations of five attributes related to PrEP administration (dosing frequency, dispensing venue, prescription practices, adherence support, and costs). Latent class analysis was used to estimate the relative importance of each attribute and preferences across seven possible PrEP delivery programs.
Results: Overall, the median age was 40 years (range = 21-53 years). Subjects were primarily white (87%), college-educated or higher (64%) and employed full-time (72%). The majority of respondents lived in an urban area (67%) and the geographical distribution of the sample lived in the Midwest (18%), Northeast (21%), Southeast (16%), Southwest (16%), and West (28%). Preferences clustered into five groups. PrEP affordability was the most influential attribute across groups, followed by dosing strategy. Only one group liked daily and on-demand PrEP equally (n=74) while the other four groups disliked the on-demand intermittent option. Monthly injectable PrEP is preferred by two (n=210) out of the five groups, including young MSM. Two groups (n=267) were willing to take PrEP across all the hypothetical programs. One group (n=183) almost exclusively considered costs in their decision making. Participants in the most racially diverse among groups (n= 88) had very low level of interest in PrEP initiation.
Conclusions: : Our data suggest that PrEP uptake will be maximized by making daily PrEP affordable to MSM and streamlining PrEP consultation visits for young MSM. A successful PrEP program should allocate resources towards alleviating structural barriers to PrEP access educating MSM of color on PrEP benefits, and should emphasize protection of privacy to maximize uptake among rural/suburban MSM.

WEPEC0930

Awareness, utilization and willingness to use PrEP among Japanese MSM using geosocial-networking application

M. Yamaguchi[1], T. Miwa[2], T. Ohtsuki[2], Y. Ikushima[2], M. Tarui[2,3],
LASH (Love Life and Sexual Health) Study Team for Supporting PLHIV and PWUD in Regional Communities, Granted by MHLW Japan
[1]Bunan Hospital, Internal Medicine, Kawaguchi, Japan, [2]PLACE Tokyo, Tokyo, Japan, [3]Keio University, Tokyo, Japan
Presenting author email: masapan69@gmail.com

Background: The efficacy and effectiveness of pre-exposure prophylaxis (PrEP) for HIV prevention have been established in many studies, and WHO guidelines recommend daily oral PrEP for those at substantial risk, including men who have sex with men (MSM). However, PrEP has neither been implemented nor approved yet in many Asian countries, including Japan.
Methods: In this study, we investigated the awareness, utilization of, and willingness to use PrEP among Japanese MSM using geosocial-networking-app..
A nationwide, self-administered internet survey about relationship, sexual life, and mental health for Japanese MSM who use gay specific geosocial-networking-app was conducted between September 22th and October 22th 2016.
Results: Among 10,544 respondents, 7,587 completed all questionnaires (completion rate 72%, median age; 34 [IQR=15]). Analyzed samples included men who have sex with a man and did not report being HIV-positive (N=7,054). Of these, only 10.4% were aware of PrEP and 0.1% had used PrEP before, though more than two-thirds (68%) of participants reported they would like to use PrEP for HIV prevention if available.
Main reported concerns for PrEP were; cost (93.3%), toxicity (90.7%), effectiveness (81.2%), accessibility (68.1%), durability and sustainability (57.7%), and drug resistance (46.6%). Less than a third (29.9%) reported that they would be likely to decrease condom use while on PrEP.
Conclusions: These findings suggest that many Japanese MSM would be willing to take PrEP, though the levels of awareness and utilization are still low. There is thus a need to disseminate information appropriately about PrEP to the Japanese MSM community.
Furthermore, implementation studies will be needed to assess the feasibility and acceptability among this community.

WEPEC0931

PrEP uptake, safety and efficacy in a hospital-based clinic in Paris

S. Balavoine[1], M. Noret[1], B. Loze[1], C. Pintado[1], A. Leplatois[1], P. Charbonneau[1], K. Moudachirou[2], A. Djessima-Taba[2], L. Niedbalski[1], M. Siguier[1], A. Aslan[1], D. Ponscarme[1], P. Penot[1], C. Gatey[1], F. Clavel[3], A.-C. Crémieux[1], F. Lorho[1], E. Dalle[1], S. Parlier[1], J. Delgado[1], R. Veron[1], J. Fonsart[4], C. Delaugerre[5], W. Rozenbaum[1], J.M. Molina[1]
[1]Saint Louis Hospital, Infectious Diseases, Paris, France, [2]Association AIDES, Paris, France, [3]Saint Louis Hospital, INSERM UMR 941, Paris, France, [4]Saint Louis Hospital, Laboratory of Biochemistry, Paris, France, [5]Saint Louis Hospital, Laboratory of Virology, Paris, France

Background: TDF/FTC was approved for PrEP in November 2015 in France in individuals at high risk of sexual acquisition of HIV. Both daily and on-demand PrEP are allowed for MSM. We wished to assess PrEP uptake, safety and efficacy in our hospital-based clinic .
Methods: We conducted a prospective cohort study from November 10, 2015 to November 30, 2016 of all people coming to our clinic to get TDF/FTC for PrEP. Individuals were seen every 3 months with HIV tests and creatinine plasma levels. Counseling by a peer-community member was offered at each visit. Screen tests for sexually transmitted infections (STIs) were performed at the physician's discretion. We assessed PrEP uptake, safety, and the incidence of HIV and other STIs.
Results: Overall 801 individuals were seen, with a mean of 61 new individuals per month. Six (0.75%) had HIV-infection at the first visit and 785 started PrEP accumulating 215 person-years of follow-up. All but 6 were MSM with a median age of 37 years. Most individuals (78.6%) started PrEP on demand. During the study period, 24 (3%) were lost to follow-up, 16 (2%) moved to another PrEP clinic, 13 (1.7%) discontinued PrEP, and 3 acquired HIV-infection (incidence: 1.4 per 100 py). All 3 breakthrough HIV-infections were diagnosed at the second visit in individuals who either did not start or discontinued PrEP, one of whom had a virus harboring the M184V mutation. At the 6-month visit 113/136 individuals (83%) had tenofovir detected in plasma.
During follow-up, 97 adverse events were reported, mainly gastro-intestinal AES (72%) with no drug discontinuation. A single participant (0.1%) had a decrease in plasma creatinine clearance <60 ml/mn. The proportion of participants reporting condomless sex at their last intercourse increased from 52.8% at baseline to 77.4% at the end of follow-up.

During follow-up 233 new STIs were diagnosed (30 syphilis, 101 chlamydia, 100 gonorrhea, and 2 HCV infections) in 175 patients with an incidence of 81.3 per 100 py.
Conclusions: PrEP uptake is high among MSM with a high retention rate. Rare breakthrough HIV-infections occurred in non adherent patients despite a high rate of STIs.

WEPEC0932

High interest in pre-exposure prophylaxis with truvada among female sex workers: baseline data from the Senegal PrEP Demonstration Project

A. Mboup[1,2], M. Sarr[3], G. Gottlieb[4], D. Gueye[5], C. Suarez[3], S. Hawes[6], M. Alary[7], J. Presley[8], M. Aikenhead[8], C. Toure Kane[5], S. Mboup[5]
[1]Université Laval, Département de Médecine Sociale et Préventive, Faculté de Médecine, Québec, Canada, [2]Centre de Recherche du CHU de Québec, Québec, Canada, [3]Westat, Rockville, United States, [4]University of Washington, Seattle, United States, [5]Reseau Africain pour la Recherche sur le SIDA, Dakar, Senegal, [6]Uni, Seattle, United States, [7]Université Laval, Québec, Canada, [8]Bill and Melinda Gates Foundation, Seattle, United States
Presenting author email: aminata.mboup.1@laval.ca

Background: Recent breakthroughs in antiretroviral (ARV)-based prevention provide new opportunities to rethink HIV prevention strategies, especially for key populations such as female sex workers (FSWs). As more and more pre-exposure prophylaxis (PrEP) demonstration projects are being initiated, more information is needed about levels of interest and characteristics of individuals who elect to take PrEP in real-world clinical settings for future scale-up plans.
Methods: The Senegal PrEP Demonstration Project is a prospective, open-label cohort study assessing the delivery of oral Truvada (emtricitabine/tenofovir DF) PrEP to FSWs in 4 Ministry of Health (MoH)-run clinics in Dakar, Senegal. This is within a context of regulated sex work, where FSWs can register with the system for monthly HIV/STIs visits in MoH-run clinics. Adherence was assessed through self-report, pharmacy records, drug levels at specified visits, and using Medical Event Monitoring System (MEMS). Participants were assessed for eligibility and offered up to 12-months of emtricitabine/tenofovir DF for PrEP. Predictors of enrollment were assessed, and characteristics of enrolled participants described.
Results: Between July and November 2015, 350 individuals were approached, 325 (92.9%) were preliminarily eligible, and 271 (83.4%) were enrolled. Eight (2.3%) had undiagnosed HIV infection at screening. The average age of those enrolled was 37.7 years (standard deviation=8.9). Most FSWs were Senegalese (96.7%), and never attended school (61.3%). Uptake was very high, with 83% of eligible participants choosing to enroll and take PrEP. Unregistered sex workers were significantly more likely to enroll than registered sex workers (RR = 1.16; 95% CI: 1.06 - 1.26; p = 0.004). Overall, 91.82% (101 out of 110) of eligible unregistered FSWs chose to enroll in the PrEP versus 79.44% (170 out of 214) of eligible registered FSWs. We did not find significant differences of uptake by site, age, education, or marital status.
Conclusions: Interest in PrEP was very high among FSWs when offered in Ministry of Health (MoH)-run clinics in Dakar, Senegal. This highlights the role that these clinics can play in expanding PrEP access nationwide.

WEPEC0933

Acceptability of a dapivirine vaginal ring among US adolescent females in Phase 2a safety trial (MTN 023)

P.M. Gorbach[1], J. Moore[2], H. Brosnan[2], K. Squires[3], K. Bunge[4], G. Zimet[5], B. Mensch[6], L. Soto-Torres[7], L. Levy[8], MTN 023 Protocol Team
[1]University of California, Epidemiology & Infectious Diseases, Los Angeles, United States, [2]UCLA, Epidemiology, Los Angeles, United States, [3]Thomas Jefferson University, Philadelphia, United States, [4]Magee-Womens Hospital of UPMC, Pittsburgh, United States, [5]Indiana University, Bloomington, United States, [6]Population Council, New York, United States, [7]NIAID, Washington, United States, [8]FHI 360, Washington, United States
Presenting author email: pgorbach@ucla.edu

Background: Modest protection against HIV infection for women over age 25 in sub-Saharan Africa has been reported in recent Phase III trials of a vaginal ring (VR) continuously releasing the antiretroviral drug dapivirine. No protection was found for women under 21 years likely due to poorer adherence. Better understanding of VR acceptability and adherence is needed for younger women.
Methods: Ninety-six 15-17 year old adolescents from four U.S. cities were enrolled in a Phase 2a placebo-controlled safety trial of the dapivirine VR. Of these, 21 were randomly selected for in-depth semi-structured interviews (IDI) at their final clinic visit. Participants used the VR for either 12 or 24 weeks. Trained interviewers conducted visual web-interviews. Open-ended questions covered participant overall experiences and feelings using the VR, and her reports of partner attitudes and experiences with the ring, including during sexual intercourse. Interviews were digitally recorded, transcribed verbatim, entered into Atlas TI, and analyzed using thematic content analysis.
Results: The 21 IDIs were conducted with 5 and 16 adolescents on study for 12 and 24 weeks, respectively. Most participants reported initial concern with the size of the ring but few reported discomfort or concerns after insertion. Few removed the ring or experienced expulsion, but when removal occurred, reasons were hygiene (to clean it) or curiosity (to check or show partner). Many reported the partner could feel the ring during sexual activity. Concerns raised about using the ring included hygiene, discharge ascribed to the VR, and discomfort about sex because partner could feel it. Nevertheless, most reported not feeling the ring much while in situ nor paying attention to it.
Conclusions: Our findings indicate there may be high acceptability of VR as a HIV prevention method for US adolescent females. Principal concerns for young women are partners' feeling the ring during sex and hygiene issues - issues that may be managed proactively by clinic staff to help increase acceptability and adherence.

WEPEC0934

Safety and efficacy of tenofovir disoproxil fumurate-based HIV pre-exposure prophylaxis in a patient with a solitary kidney

T.T. Tobias, B.K. Sugimoto
The Permanente Medical Group, Infectious Diseases, Oakland, United States
Presenting author email: tadd.t.tobias@kp.org

Background: The safety and efficacy of emtricitabine-tenofovir disoproxil fumarate (FTC-TDF) is unknown for HIV preexposure prophylaxis (PrEP) in persons with preexisting renal disease. PubMed literature review found no citations of PrEP using FTC-TDF in patients with a solitary kidney and only two reports of treatment in HIV-infected patients with a solitary kidney.
Methods: Case report of 32 year old male with a solitary kidney presenting for evaluation and initiation of PrEP using FTC-TDF.
Results: Our patient, a 32 year old caucasian male kidney donor (2011), sought evaluation for PrEP when he was diagnosed with rectal chlamydia. He identified HIV acquisition risk as male-to-male condomless anal intercourse, reported one serving of alcohol/week, denied current or past substance use, denied concurrent medications, and denied body building supplementation. Physical examination was remarkable for a left hydrocele. At baseline, June 2016, the patient was normotensive, weighed 174#, height of 5´8", and body mass index of 26.4 kg/m2. Serum creatinine (SCr) was 1.21 mg/dL, estimated creatinine clearance (eCrCl) based on the Cockroft-Gault equation was 97.28 mL/min. Hepatitis B serologies confirmed immunity as a result of vaccination. Daily FTC-TDF was initiated after a shared decision-making process. Renal function monitored every two weeks for the first month, then monthly for three months, then quarterly if serum creatinine remained < 1.6 mg/dL. The patient was counseled to avoid NSAIDs and maintain adequate hydration. Two weeks after initiation, SCr was 1.18 mg/dL and eCrCl was 98.83 mL/min. At four weeks, SCr was 1.36 mg/dL and eCrCl was 86.74 mL/min. At nine weeks, SCr was 1.2 mg/dL and eCrCl was 98.3 mL/min. At sixteen weeks, SCr was 1.2 mg/dL and eCrCl was 98.3 mL/min. At twenty-four weeks, SCr was 1.32 mg/dL and eCrCl was 86.86 mL/min.
Conclusions: FTC-TDF was well tolerated at 24 weeks in an otherwise healthy HIV-negative male with a solitary kidney. The variation of estimated creatinine clearance was assessed as clinically insignificant. Follow up HIV Ag/Ab screenings were nonreactive. This case report suggests oral daily FTC-TDF PrEP may be safe and effective for persons with decreased renal function but more research is required.

WEPEC0935

Dysbiotic vaginal bacteria induce altered tenofovir pharmacokinetics

R. Cheu[1,2], E. Coronado[1,2], A. Zevin[1,2], C. Miller[1,2], A. Burgener[3,4,5], N. Klatt[1,2]
[1]University of Washington, Pharmaceutics, Seattle, United States, [2]Washington National Primate Research Center, Seattle, United States, [3]National HIV and Retroviral Labs, Winnipeg, Canada, [4]JC Wilt Center for Infectious Diseases, Winnipeg, Canada, [5]Public Health Agency of Canada, Winnipeg, Canada
Presenting author email: rycheu@uw.edu

Background: Antiretroviral pre-exposure prophylaxis (PrEP) trials to prevent HIV infection have produced widely varying results in women. Adherence has been postulated for the diverse trial outcomes, however little is known about what biological factors contribute to this variability. Vaginal dysbiosis is characterized by a change in microbial communities from predominantly healthy Lactobacillus spp. to diverse anaerobic bacteria, including Gardnerella vaginalis. We have recently demonstrated that vaginal bacteria can metabolize tenofovir (TFV), and here we investigate the

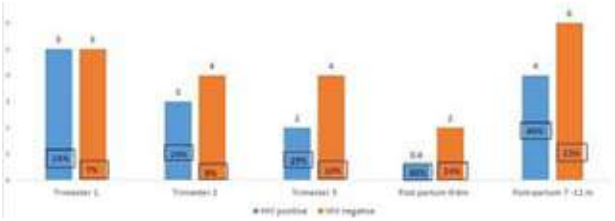
mechanism(s) underlying this. We hypothesize that dysbiotic bacteria alter drug uptake pharmacokinetics (PK) and damage target cells.
Methods: To elucidate the mechanisms for negative consequences of dysbiotic bacteria on PrEP, we cultured Jurkat cells with G. vaginalis, Lactobacillus spp., as well as supernatants from cultures, in the presence of TFV. Controls included cells alone, TFV alone, TFV + cells. To determine uptake, loss of TFV was measured extracellularly, while adenine (the major metabolite of bacteria-driven TFV metabolism) and TFV-diphosphate (target cell uptake) were measured intracellularly. Mass spectrometry was used to determine TFV and its metabolites.
Results: We demonstrated how vaginal bacteria alter drug PK. We observed a rapid decline in TFV (p=0.0004), significantly less formation of TFV-DP (p=0.0042), and more formation of adenine (p< 0.0001) after being cultured with G. vaginalis when compared with Lactobacillus and Jurkat cells. We also demonstrated inhibition of drug uptake into target cells with just G. vaginalis supernatant alone (p=0.0004). Of interest, Lactobacillus, did not inhibit drug uptake, prevent formation of the active metabolite TFV-DP, or biodegrade TFV into adenine, but maintained levels similar to negative controls.
Conclusions: Here we demonstrate that dysbiotic bacteria alter drug PK by inhibiting target cell uptake and metabolizing TFV preventing therapeutic levels from being reached. In contrast, healthy vaginal mucosal bacterial communities (Lactobacillus) do not interfere with TFV PK. Low levels of TFV-DP formation with G. vaginalis incubations highlight how vaginal bacteria play a role in PrEP efficacy. The inhibition of uptake with G. vaginalis supernatants potentially demonstrate how bacterial products may directly impact epithelial cells and alter PrEP efficacy. These in-vitro experiments provide mechanistic insights into how vaginal dysbiosis may lead to decreased PrEP efficacy.

WEPEC0936

Dynamic sexual risk behaviours during pregnancy and post-partum periods in Cape Town, South Africa: implications for PrEP delivery in pregnant and breastfeeding mothers

D. Joseph Davey[1,2,3], E. Farley[2], Y. Gomba[2], L.-G. Bekker[4], P. Gorbach[1], J.D. Klausner[3], T. Coates[3], L. Myer[2]
[1]University of California, Fielding School of Public Health, Department of Epidemiology, Los Angeles, United States, [2]University of Cape Town, School of Public Health and Family Medicine, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [3]University of California, David Geffen School of Medicine, Los Angeles, United States, [4]Desmond Tutu HIV Foundation, Cape Town, South Africa
Presenting author email: pgorbach@ucla.edu

Background: HIV acquisition during pregnancy and breastfeeding contributes significantly toward pediatric HIV infection. PrEP in pregnancy/breastfeeding women is gaining interest, but little is known about sexual behaviors during pregnancy/postpartum to help target PrEP interventions.
Methods: Sex-PP is a cross-sectional study in pregnant/postpartum women attending primary care services. Interviewer-administered questionnaires investigated demographic and sexual behaviors associations of these during and after pregnancy were assessed bivariately and with multivariable logistic regression stratified by serostatus.



[Figure 1. Mean frequency of sex acts per month by pregnancy and postpartum status and HIV status (bars) and % sex acts with condom used (boxes) (n=377 pregnant and postpartum women)]

Results: We enrolled 377 women (mean age, 28 years; 56% pregnant; 60% HIV-). Overall 44% were in a steady relationship with the father of the index pregnancy/child (FOC). Most HIV- women reported the same serostatus as the FOC (64%) or didn't know (35%); 19% of HIV+ women reported being serodiscordant, 44% didn't know (p<0.05). Alcohol use during pregnancy was reported by 32% of HIV+ and 27% of HIV- women of whom 35% and 43% reported drinking ≥6 drinks on ≥1 occasion, respectively. During pregnancy, 98% women reported sex, compared to 35% and 88% during the periods 0-6 and 7-12 months postpartum, respectively; 18% of pregnant and 13% of postpartum women reported ≥1 partner in past 12-months. More frequent mean sex acts were reported in the first trimester of pregnancy and >6 months postpartum than other periods. Condom use varied by trimester, postpartum period and serostatus (p<0.05) (Figure 1). In multivariable models, HIV- pregnant women had increased odds of condomless sex during pregnancy (aOR=3.24; 95% CI=2.03-5.17) and decreased odds of knowing their partner's serostatus (aOR=0.27; 95% CI=0.09-0.34) than HIV+ women adjusting for age and alcohol use.
Conclusions: Significant HIV transmission and acquisition risk during pregnancy/postpartum periods were identified including alcohol use, multiple partners and lack of knowledge of partner's serostatus. Sexual risk behaviors change significantly across pregnancy and postpartum periods, presenting previously unrecognized challenges to prevention efforts, including PrEP delivery.

WEPEC0937

Structural barriers, mental health, and PrEP initiation/non-initiation and adherence among Black MSM in 3 U.S. cities - HPTN 073 study

[1]Binghamton University, Human Development, Binghamton, United States, [2]University of Rochester, School of Nursing, Rochester, United States, [3]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division (VIDD), Seattle, United States, [4]George Washington University Milken Institute School of Public Health, Epidemiology and Biostatistics, Washington, United States, [5]UCLA David Geffen School of Medicine, Family Medicine, Los Angeles, United States, [6]University of North Carolina at Chapel Hill, Infectious Diseases Clinic, Chapel Hill, United States, [7]FHI 360, Global Health Division, Durham, United States, [8]Johns Hopkins School of Medicine, Pathology, Baltimore, United States, [9]Johns Hopkins University School of Medicine, Clinical Pharmacology, Baltimore, United States, [10]Johns Hopkins University School of Medicine, Pathology, Baltimore, United States, [11]John Wesley Community Health Institute, Division of HIV Services, Los Angeles, United States, [12]Fenway Health, The Fenway Institute, Boston, United States, [13]Harvard Medical School, Boston, United States, [14]New York Institute of Technology, School of Health Professions, Old Westbury, United States, [15]University at Albany - SUNY, School of Social Welfare, Albany, United States
Presenting author email: lwilton@binghamton.edu

Background: Black men who have sex with men (BMSM) have substantial disproportionate HIV infection burden in the United States. Research has indicated that structural barriers relate to increased vulnerability to HIV for BMSM; however, few studies have investigated the relationships between structural barriers, mental health, and PrEP initiation/non-initiation and self-reported adherence among BMSM.
Methods: HPTN 073 was an open label PrEP demonstration study where at risk HIV-uninfected BMSM from 3 US cities (Los Angeles, CA, Washington DC, and Chapel Hill, NC) were offered once daily oral FTC/TDF at no personal cost, client-centered care coordination, and were followed for 12 months between August 2013 and September 2014. Logistic regression was used to test for unadjusted and adjusted associations between baseline structural factors (education, employment status, income, housing status, not having enough money, and access to health care insurance) and mental health characteristics (depression symptoms, social support) predicting PrEP initiation/non-initiation and self-reported adherence (≥ 60%) at week 26 with site as a covariate. Factors with p value ≤ 0.3 were included in the adjusted model.
Results: Of the 226 BMSM enrolled, 178 (79%) participants accepted PrEP. Those who were employed or reported having enough money (rent, food or utilities) were more likely to initiate PrEP (Table 1). Having enough money was significantly associated with PrEP initiation in the adjusted model. Self-reported PrEP adherence was 78% (108/139) among those who initiated PrEP. Self-reported high adherence was significantly associated with full-time employment and two-year or higher educational degree.

	PrEP Acceptance OR (95% CI)	PrEP Acceptance AOR (95% CI)	PrEP Adherence OR (95% CI)	PrEP Adherence AOR (95% CI)

Footnote: * Indicates <0.05 significance.

[Table 1]

Conclusions: Our findings suggest that integrating strategies that address structural barriers and mental health needs are critical in strengthening PrEP program development and implementation efforts for BMSM. These efforts may facilitate access to a broader reach of BMSM to meet their unique needs related to PrEP uptake and adherence.

WEPEC0938

Barriers and facilitators to potential future long-acting biomedical HIV prevention strategies for transgender women

C. Rael[1], W. Bockting[1], C. MacCrate[1], M. Martinez[1], W. Mellman[1], P. Valente[1], R. Giguere[2], G. Greene[3], R. D'Aquila[3], S. Sherman[4], K. Footer[4], A. Carballo-Diéguez[1]
[1]*Columbia University, New York, United States,* [2]*New York State Psychiatric Institute, New York, United States,* [3]*Northwestern University, Chicago, United States,* [4]*Johns Hopkins University, Baltimore, United States*
Presenting author email: cr2857@cumc.columbia.edu

Background: HIV prevalence is high among Latina (49.6%), African-American (48.1%), and White (3.5%) transgender women (TGW) in New York City (NYC). Additionally, NYC TGW have the highest proportion of newly identified HIV-positive test results (20.0%) of any U.S. risk group. Long-acting delivery methods of pre-exposure prophylaxis (PrEP) show some promise in clinical trials. Effective implementation of long-acting HIV prevention strategies requires understanding the challenges and facilitators associated with use, especially for unique populations, such as TGW. This study aimed to identify TGW's barriers/facilitators and likes/dislikes about the following potential future long-acting HIV prevention strategies: biodegradable PrEP implant, non-biodegradable PrEP implant, long-acting PrEP injection.
Methods: Four focus groups were completed with HIV-negative (ascertained by OraQuick Advance rapid HIV test) TGW to understand the acceptability and feasibility of PrEP implants and injections. Strategies were presented through a series of short videos and companion text summaries that featured photos of each method. Themes discussed in focus groups about products included participants' likes/dislikes, barriers/facilitators, strategies to overcome uptake/adherence challenges, ideal implant/injection sites, preferred dosing schedules, number and size of implants/injections, side-effect tolerability, perceived compatibility with hormone regimens, and strategies to promote these tools among TGW. Data were independently analyzed by two coders.
Results: Participants found non-daily dosing of PrEP favorable. TGW emphasized that ensuring the absence of interactions between PrEP and feminizing hormones is essential for uptake. Specifically, for many TGW, hormones are a priority; compromising their short or long-term effects is unacceptable. Several participants expressed concern about the 30-day oral pill lead-in and preferred the removable implant, which would not require this. Others were apprehensive about the inability to remove the injection and biodegradable implant, but acknowledged that the oral lead-in would identify issues with drug tolerability/allergy. Several TGW favored the injection, since its administration is similar to hormone replacement therapy. Some participants felt that developing strategies to administer injections without provider visits could improve acceptability and/or adherence, since additional office visits impose additional cost and inconvenience.
Conclusions: It is necessary to diversify the types of available HIV prevention methods, since different products appeal to different TGW. Long-acting methods appear to be promising, despite challenges.

WEPEC0939

One-year experience with pre-exposure prophylaxis (PrEP) implementation in France with TDF/FTC

J.M. Molina[1], G. Pialoux[2], M. Ohayon[3], L. Cotte[4], N. Valin[5], J. Ghosn[6], E. Cua[7], C. Pintado[1], J. Chas[2], P. Petour[8], G. Barriere[8], F. Durand[8]
[1]*Saint Louis Hospital, Infectious Diseases, Paris, France,* [2]*Tenon Hospital, Paris, France,* [3]*Le 190, Sexual Health Center, Paris, France,* [4]*Croix Rousse Hospital, Lyon, France,* [5]*Saint Antoine Hospital, Paris, France,* [6]*Hotel Dieu Hospital, Paris, France,* [7]*L'Archet Hospital, Nice, France,* [8]*Gilead Sciences, Boulogne-Billancourt, France*
Presenting author email: cua.e@chu-nice.fr

Background: FDA approved TDF/FTC for PrEP in adults at high risk of sexually-transmitted HIV on July 2012. In 2015, the French Medicine Agency (ANSM) initiated a Temporary Recommendation for Use (RTU) to allow the use of TDF/FTC for PrEP in France in January 2016.
Methods: The RTU is a specific French procedure that secures and regulates an off-label indication of a medicine for unmet medical needs. PrEP RTU protocol allowed TDF/FTC use in adults at high risk of sexual HIV acquisition, using a daily or an on-demand regimen (as prescribed in the ANRS IPERGAY trial). Subject registration is mandatory within the RTU framework. Data are collected by physicians using a dedicated and secured web subject monitoring interface. The RTU protocol provides 3 forms to monitor the use of TDF/FTC for PrEP: initiation form with baseline characteristics, HIV seroconversion form, adverse events and pregnancies form. Data are analyzed and reported to ANSM every 3 months.
Results: From January 2016 to December 2016, 2805 subjects were registered by 199 prescribers in more than 130 clinics in France. Median age was 36 (30-44, IQR), 98.6% were males and 97.4% of them were MSM. The on-demand regimen was prescribed to 59% of subjects. In the 12 months prior to PrEP initiation, 30.6% had ≥ 2 STIs, 10.9% used post-exposure prophylaxis and 19.9% used psychoactive drugs. Four HIV seroconversions occurred for a total follow-up time of 1100 patient-years; rate: 0.36/100 patient-years, CI95% [0.07-7.20]. Two acute HIV seroconversions occurred before inclusion in the RTU with no resistance-associated mutation (RAM). One presented HIV seroconversion at month 1 visit with a 500 cp/ml HIV RNA and a M184I RAM. One presented HIV seroconversion 2 months after PrEP was interrupted by the patient with no RAM detected.
Conclusions: The RTU framework provided the first data in real life setting in France for TDF/FTC for PrEP. All subjects were at high risk of sexual HIV acquisition, most of them were MSM and used an on-demand regimen. Low rate of seroconversion after initiation of TDF/FTC for PrEP was reported underlining the need for close monitoring of these high risk individuals.

WEPEC0940

End-user research on Multipurpose Prevention Technologies (MPT) for HIV and pregnancy prevention: young women's ratings of three delivery forms in a randomized, cross-over study in Kenya and South Africa

A. Minnis[1,2], S. Roberts[1], K. Agot[3], R. Weinrib[1], K. Ahmed[4], K. Manenzhe[4], F. Owino[3], A. van der Straten[1,5], Trio Study Group
[1]*RTI International, Women's Global Health Imperative, San Francisco, United States,* [2]*University of California, School of Public Health, Berkeley, United States,* [3]*Impact Research and Development Organization, Kisumu, Kenya,* [4]*Setshaba Research Centre, Soshanguve, South Africa,* [5]*University of California, Department of Medicine, San Francisco, United States*
Presenting author email: aminnis@rti.org

Background: End-user input is needed to inform development of MPT products, combining PrEP and contraception, to maximize uptake and use. We compared ratings of three placebo MPT delivery forms after use among young women in Kenya and South Africa and examined factors associated with product ratings.
Methods: The TRIO Study enrolled 277 HIV-negative, sexually active, non-pregnant women aged 18-30 in a randomized cross-over study to use each placebo MPT (daily oral tablets, monthly vaginal rings and monthly injections) for one month. At the end of each use period, we asked participants to rate how much they liked the product on a 5-point Likert scale (1=low) and assessed participant opinions of product attributes. We compared mean ratings for each product using paired t-tests and used multivariable linear regression to examine attribute- and behavior-related characteristics associated with ratings for each product, adjusting for age, site and randomization group.
Results: Mean age was 23.2 years. Mean product ratings increased for all products after the one-month period of use, with the greatest increase (1 point, $p< 0.001$) for rings, the least familiar product. After use, mean rating were significantly higher for injections (4.3 [SD=1.0]) compared with tablets (3.0 [SD=1.3]) and rings (3.3 [SD=1.4]) ($p< 0.001$); mean ratings for rings were significantly higher than for tablets ($p=0.015$). Ratings did not vary by age, but Kenyan women (vs. South African) reported a higher rating for tablets (3.2 vs. 2.7, $p=0.005$) and a lower rating for rings (3.1 vs. 3.5, $p=0.042$). In multivariable analysis, acceptability of key product characteristics (look, ease of use and interference with normal activities) were each associated with a significant increase of ≥1 point in the mean rating across all three products ($p\leq0.001$). Product use without partner knowledge was associated with a higher mean rating for rings ($b=0.50$; $p=0.006$) but not for tablets or injections.
Conclusions: After a one-month period of use, young women rated injections most highly among three placebo MPT delivery forms, and rated rings more favorably than tablets. The acceptability of product attributes contributed significantly to the rating of all products, highlighting the value of choice in HIV prevention to accommodate diverse users.

WEPEC0941

PK and effect on HIV ex-vivo infectivity of elvitegravir in postexposure prophylaxis

A. Inciarte[1,2,3], L. Leal[1,2], A. Crepo[2], L.M. Bedoya[4], A.D. Kashuba[5], J. Llach[1], P. Alcami[4], J.M. Gatell[1,2], M. Plana[2], F. Garcia[1,2,3], STRIB-PEP Study Group
[1]Hospital Clínic of Barcelona, Infectious Diseases Unit, Barcelona, Spain, [2]Institut d'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Barcelona, Spain, [3]Uni, Barcelona, Spain, [4]Instituto de Salud Carlos III, Madrid, Spain, [5]Univ of North Carolina at Chapel Hill, North Carolina, United States
Presenting author email: ajinciar@clinic.ub.es

Background: The most common way of HIV transmission is through mucosal tissues. Characterizing pharmacokinetics (PK) , ex vivo efficacy on HIV infectivity and effect on immune system of Elvitegravir (EVG) could be informative for optimizing postexposure prophylaxis (PEP).
Methods: This is a substudy of a clinical trial (n=160) comparing tolerability of 2 PEP strategies: tenofovir/emtricitabine plus ritonavir-boosted lopinavir or cobicistat-boosted elvitegravir received during 28 days. PK (in blood, rectal fluid and rectal tissue), ex-vivo HIV-1 infectivity (estimated using antigen p24 quantification in HIV-1 strain BaL-1 infected explants) and effect on rectal mucosa immune system of EVG were assessed at day 28 and day 90 (considered as baseline).
Results: Overall EVG was well tolerated and there were no serious adverse effects during the study. EVG concentrations in plasma, rectal fluid and rectal tissue were 1200ng/mL, 770ng/sb, 1124ng/g, respectively. A strong correlation on EVG levels were found between different compartments (r=0.4, p= 0,028).
No significant differences were observed in infectivity between day 28 (last dose of PEP) and 90 (60 days after PEP was discontinued) (p= 0.4).
Infectivity was inversely correlated with activation of CD8-T cells in rectal mucosal tissue [CD38+DR+ (r= -0.87, p<0.005), HLA-DR+ (r= -0.85 p<0.007), and CCR5+ (r= -0.9 p<0.002)].
Conclusions: We found that EVG PK levels on different compartments were correlated. However, EVG did not prevent ex vivo infection on human rectal explants after 28 day of PEP. On the other hand, activation of CD8-T cells in mucosa seems to hinder infectivity in our model. Further studies are needed to validate these results.

WEPEC0942

Cost-effectiveness of pre-exposure prophylaxis for HIV prevention during conception

A. Leech[1], J. Burgess[2], M. Sullivan[3], W. Kuohung[3], M. Horný[2], M.-L. Drainoni[2], C. Christiansen[2], B. Linas[3]
[1]Tufts Medical Center, Center for the Evaluation of Value and Risk in Health, Boston, United States, [2]Boston University School of Public Health, Boston, United States, [3]Boston Medical Center, Boston, United States
Presenting author email: aleech@tuftsmedicalcenter.org

Background: Pre-exposure prophylaxis (PrEP) for HIV serodiscordant couples seeking conception provides modest prevention benefits when the HIV-infected partner is on anti-retroviral therapy (ART). Further, the relative benefits and costs of PrEP compared to assisted reproductive technologies are not known.
Methods: We developed a Markov cohort simulation to compare six HIV prevention strategies for serodiscordant couples seeking conception: ART alone and with PrEP, both with and without intercourse limited to ovulatory period; intrauterine insemination (IUI); and in vitro fertilization (IVF). We considered a scenario in which the male partner was suppressed on ART, and another in which he was not reliably suppressed. Outcomes included HIV transmissions to mother and baby, discounted quality-adjusted life years (QALY), discounted lifetime medical costs, and incremental cost-effectiveness ratios (ICERs). Data from PARTNER, HPTN 052, and Partners PrEP informed transmission parameters. We assumed a lifetime horizon, and healthcare sector cost perspective (2015 $US).
Results: Limiting unprotected intercourse to the ovulatory period provided better outcomes than non-targeted intercourse and was cost saving. Adding PrEP to ART with targeted intercourse prevented 3 HIV transmissions per 10,000 women and added 0.0016 QALYs.
However, IUI provided still better outcomes than PrEP with targeted intercourse, at a lower cost per QALY gained. The ICER of IUI compared to ART with targeted intercourse was > $3 million/QALY. Similarly, the ICER of IVF compared to IUI was >$5 million/QALY. With non-reliably suppressed male partners, reproductive technologies provided greater benefit than PrEP at lower cost/QALY gained. Sperm wash with IUI was cost-effective at $99,432/QALY.
Only when the male partner was not reliably suppressed and IUI not available did PrEP with targeted intercourse become economically attractive (ICER = $161,645/QALY).

Risk reductive strategy	HIV+ women/ 10,000	HIV+ babies/ 10,000	Life expectancy (Undisc.)	QALY (Discounted)	Lifetime costs (Discounted)	ICER ($/ QALY)
cART (b) intercourse limited to ovulation	10.4	0.16	42.682	19.9558	$139,475	--
cART (a) non-targeted ovulation	14	0.21	42.680	19.9542	$139,579	dominated
cART + PrEP (b) intercourse limited to ovulation	7.7	0.12	42.683	19.9575	$147,748	dominated
cART + PrEP (a) non-targeted ovulation	8.9	0.13	42.683	19.9567	$147,783	dominated
cART + IUI	1.6	0.02	42.686	19.9608	$157,876	$3,658,462
cART + IVF	1.6	0.01	42.686	19.9608	$173,816	dominated

[Effectiveness, cost, & cost-effectiveness]

Conclusions: From a U.S. healthcare sector perspective, PrEP for serodiscordant couples seeking conception is best employed in scenarios in which the male partner is not reliably suppressed on ART and assisted reproductive technologies are not available.

WEPEC0943

Retention in care outcomes associated with pre-exposure prophylaxis implementation science programs in three United States cities

P. Chan[1], R. Patel[2], L. Mena[3], J. Rose[4], B. Buck[3], T. Arnold[3], C. Crowley[1], A. Tributino[1], M. Montgomery[1], C. Oldenburg[5], A. Nunn[1]
[1]Brown University, Providence, United States, [2]Washington Unversity in St. Louis, St. Louis, United States, [3]University of Mississippi, Jackson, United States, [4]Wesleyan University, Middletown, United States, [5]University of California, San Francisco, United States
Presenting author email: philip_chan@brown.edu

Background: Few studies have evaluated long-term PrEP use and retention in care outcomes in real-world clinical programs outside of research settings.
Methods: We analyzed data from a longitudinal cohort of men who have sex with men (MSM) prescribed PrEP at clinical programs in three United States cities: Providence, Rhode Island (RI); Jackson, Mississippi (MS); and St. Louis, Missouri (MO). Demographic, behavioral, laboratory and insurance characteristics were reviewed. We assessed retention in PrEP care at three, six and 12 months. Multivariate analyses were used to predict variables associated with retention in PrEP care. We also assessed HIV seroconversions in patients prescribed PrEP.
Results: A total of 505 (RI: 197 MS: 156; MO: 152) MSM were prescribed PrEP; 90.7% filled prescriptions (RI: 85.3%; MS: 92.3%; MO: 96.1%; p=0.001). Patients in MS and MO were more commonly African American than in RI (66.7% and 26.3% vs. 6.1%, respectively), but less frequently Hispanic/Latino (1.3% and 6.6% vs. 22.2%, respectively). Among 336 patients prescribed PrEP for at least 12 months, 78.6% were retained in care at three months (RI: 77.9%; MS: 74.0%; MO: 84.4%; p=0.20), 66.4% were retained in PrEP care at six months (RI: 63.6%; MS: 66.0%; MO: 70.8%; p=0.51), and 48.5% were retained in PrEP care at 12 months (RI: 45.0%: MS: 42.0%; MO: 60.4%; p=0.02). Multivariate analyses revealed no differences in age, race, ethnicity, income, education, and insurance on 3- and 6-month retention, but uninsured MSM were less likely to be retained at 12 months (aOR=0.38, 95% CI=0.18, 0.79). A total of 1.2% (6/505) of patients became HIV infected while in PrEP care including one in RI who had suspected acute HIV infection at baseline, three in MO who were sub-optimally adherent, and two in MS who had stopped taking PrEP.
Conclusions: Retention in care trends varied by setting but generally declined over time; having health insurance was an important predictor of 12 month retention in care outcomes. Further research is needed to identify the individual, social and structural factors that may impede or enhance retention in PrEP care.

WEPEC0944

Mental health vulnerabilities mediate effects of socio-cultural factors on PrEP initiation/non-initiation and adherence among Black MSM in 3 U. S. cities - HPTN 073

L. Wilton[1], L.E. Nelson[2], G. Beauchamp[3], M. Magnus[4], S. Shoptaw[5], L. Hightow-Weidman[6], Y. Chen[3], J. Lucas[7], E. Piwowar-Manning[8], C. Hendrix[9], M. Marzinke[8], C. Hucks-Ortiz[10], K.H. Mayer[11,12], S.D. Fields[13], D.P. Wheeler[14]
[1]Binghamton University, Human Development, Binghamton, United States, [2]University of Rochester, School of Nursing, Rochester, United States, [3]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [4]George Washington University Milken Institute School of Public Health, Epidemiology and Biostatistics, Washington, United States, [5]University of California, Los Angeles (UCLA), Family Medicine, Los Angeles, United States, [6]University of North Carolina at Chapel Hill, Infectious Diseases Clinic, Chapel Hill, United States, [7]FHI 360, Global Health Division, Durham, United States, [8]Johns Hopkins University School of Medicine, Pathology, Baltimore, United States, [9]Johns Hopkins University School of Medicine, Clinical Pharmacology, Baltimore, United States, [10]John Wesley Community Health Institute, Division of HIV Services, Los Angeles, United States, [11]Fenway Health, The Fenway Institute, Boston, United States, [12]Harvard Medical School, Boston, United States, [13]New York Institute of Technology, School of Health Professions, Old Westbury, United States, [14]University at Albany - SUNY, School of Social Welfare, Albany, United States
Presenting author email: lwilton@binghamton.edu

Background: Black men who have sex with men (BMSM) constitute the largest proportion of new HIV infection rates in the U.S. Socio-cultural factors (e.g., the negotiation of racial and sexual identities combined with internalized homophobia) serve as culturally specific psychosocial issues for BMSM. This study tested the hypothesis that mental health factors (depressive symptoms, social support) mediate the relationship between socio-cultural factors (ethnic identity, racial/sexual identity congruence, internalized homophobia) and PrEP initiation/non-initiation and self-reported PrEP adherence/non-adherence among Black MSM. We hypothesized that men who demonstrated higher mental health vulnerabilities would intersect with socio-cultural factors in relation to PrEP outcomes.
Methods: HPTN 073 was an open label PrEP demonstration study where HIV-uninfected BMSM from 3 U.S. cities (Los Angeles, CA, Washington DC, and Chapel Hill, NC) were offered once daily oral FTC/TDF, client-centered care coordination, and were followed for 12 months between August 2013 and September 2014. Logistic regression was used to examine associations between baseline socio-cultural factors and mental health factors predicting PrEP initiation/non-initiation and self-reported adherence (≥ 60%) at week 26 with site as a covariate. Significance of the indirect effect was tested using Proess.sas macro.
Results: Of the 226 BMSM enrolled, 178 (79%) participants accepted PrEP. Those who scored higher for ethnic identity and internalized homophobia were less likely to initiate PrEP in both unadjusted and adjusted models (Table 1). At week 26, self-reported PrEP adherence among the 139 who initiated was 78% (108/139). None of the social-cultural factors were significantly associated with PrEP adherence. Baseline depression symptoms and social support seem to mediate the relationship between internalized homophobia and PrEP acceptance.
Conclusions: To our knowledge, this represents the first study to examine socio-cultural influences of PrEP initiation and adherence among BMSM in the U.S. which contributes to new empirical and conceptual frameworks to enhance future PrEP prevention programs. Our findings suggest that socio-cultural factors involving ethnic and sexual identity affirmation need to be considered for in the development and implementation of PrEP biomedical prevention strategies for BMSM.

	PrEP Acceptance OR (95% CI)	PrEP Acceptance AOR (95% CI)	Total Indirect Effect (95% CI) on PrEP Acceptance	PrEP Adherence OR (95% CI)	Total Indirect Effect (95% CI) on PrEP Adherence

WEPEC0945

The impact of messaging on the PrEP cascade among female sex workers (FSWs): a case study of SWOP-Kenya

J. Ouko, P. Sore, J. Kioko, S. Gatangi, C. Wachihi, G. Gakii, J. Kimani, L. Gelmon
Kenya AIDS Control Project, Nairobi, Kenya
Presenting author email: jouko@phdaf.org

Background: PrEP is a new prevention technology that has been proven to significantly reduce HIV infections among populations at high risk, though its effective delivery to FSWs had not been well documented. We conducted a pilot project whose aim was to provide evidence to inform the deliverability of PrEP as part of HIV combination prevention package among the FSWs in Nairobi, Kenya. More specifically, it set out to develop strategies and messages for reaching out to the FSWs to promote uptake and sustained adherence to PrEP.
Methods: The overall project used a prospective cohort design. A hot spot based peer led model was used for awareness creation and linkage for PrEP uptake. A complementary qualitative aspect through in-depth interviews and focus groups with PrEP users and peer educators were then conducted at different points in time to inform and address implementation challenges that were encountered.
Despite the demand creation activities, enrollments were slow at project onset and additional strategies had to be adapted to facilitate faster patient accrual. These changes were made based on data generated through IDIs and FGDs.
Results: PrEP Cascade - A total of 2044 FSWs were reached with information on PrEP. However, only 36.2% (739) visited the facility to inquire about PrEP, with 78.5% (580) being screened for eligibility. 99.3% (576) were found eligible but only 346 were initiated on PrEP. 148 FSWs are still active on PrEP while 155 have been exited and 43 discontinued.
The qualitative studies revealed that our messaging was poor due to inadequate IEC materials, disjointed demand creation activities, conflicting information being delivered by different Peer Educators, usage of technical terms in the materials and the selected persons used for delivering the messages.
Conclusions: Use of a peer led model for awareness creation and subsequent linkage to PrEP uptake proved successful but poor messaging was a challenge. We therefore recommended an effective information and demand creation strategy with standardized materials for both health care workers and Peer Educators for PrEP scale up.

WEPEC0946

"Be-PrEP-ared ": a PrEP demonstration project among men who have sex with men in Belgium - preliminary results

B. Vuylsteke[1], T. Reyniers[1], I. De Baetselier[1], K. Wouters[1], C. Nöstlinger[1,2], M. Laga[1]
[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]University of Vienna, Vienna, Austria
Presenting author email: kwouters@itg.be

Background: In Belgium, HIV incidence is still high among MSM and new prevention approaches are needed. The Be-PrEP-ared study aims to assess uptake and feasibility of different PrEP regimens to reduce HIV acquisition among MSM at high risk for HIV.
Methods: An open-label prospective cohort study enrolling 200 MSM at high risk for HIV with a mixed method social science component. Study participants receive daily or event-driven Truvada for 18 months based on their choice, and they are allowed to switch, discontinue or restart regimens at the three-monthly visits. At each visit, participants receive preventive counselling. Biomedical data (i.e. blood, urine, anal and pharyngeal samples for kidney-, liver function, HIV- and STI testing) and self-reported behavioural data are collected (i.e. sexual behaviour, adherence). Participants report their daily sexual behaviour and pill use on a web-based diary.
Results: From 09/ 2015 - 12/2016, 219 persons were screened and 200 enrolled (197 MSM; 3 transgender women). Mean age at screening was 39 years (range 22 - 70 yrs) and 79% were Belgians. Gonorrhoea, chlamydial infection and syphilis were detected in 11%, 11%, and 8% respectively. At enrolment, 23% reported anal sex with more than 15 anonymous partners, 61% reported the use of recreational drugs before sex and 63% reported participation in group sex in the last 3 months. Twenty-one percent had used Post Exposure Prophylaxis in the last 12 months.
Initially, 76% chose daily and 24% event-driven PrEP. After a total of 96 follow-up years, no new HIV infection was observed. The incidence of N. gonorrhoeae and C. trachomatis was respectively 37 and 39 per 100PY. Thirty-one participants (15%) switched regimens or discontinued PrEP during follow-up at least once. Main reasons for switching includes changes of life/partner situations, frequency of sexual contacts, simplicity, travel and side effects of Truvada. Updated results of longitudinal data will be presented at the conference.
Conclusions: Among this population at high risk for HIV, daily PrEP use is most popular as first choice. However a large proportion of participants switch regimens, tailored to their individual needs. Despite high rates of STI during follow up, no new HIV infections were observed.

WEPEC0947

One case of HIV-1 infection with M184I mutation despite pre-exposure prophylaxis (PrEP)

G. Pialoux[1,2], M.-G. Lebrette[1], N. Day[3], M.-A. Danet[1], J. Chas[1], P. Thibault[1], C. Monfort[1], G. Peytavin[4], C. Amiel[2,5]
[1]Hôpital Tenon-APHP, Infectious Diseases, Paris, France, [2]UPMC-Sorbonne, Infectious Diseases, Paris, France, [3]Laboratoires Cerballiance, Paris, France, [4]Hôpital Bichat-APHP, Pharmacy and Toxicology, Paris, France, [5]Hôpital Tenon-APHP, Virology, Paris, France
Presenting author email: gilles.pialoux@aphp.fr

Background: The results of randomized controlled trials on Preexposure Prophylaxis (PrEP) demonstrate nearly 100% prevention efficacy in men who have sex with men (MSM) when adherence to PrEP is high. In January 2016, the French Medicine Agency (ANSM) set up a Temporary Recommendation to Use (RTU) TDF/FTC as a PrEP (daily or an on-demand regimen) in adults at high risk of sexual HIV infection.
Methods: When PrEP is prescribed, data are collected on a web subject monitoring interface including an HIV seroconversion form. We report here the first case of a MSM who seroconverted with a FTC/3TC resistant HIV-1 strain after 1 month of PrEP, despite clinical and pharmacokinetic data that suggested adherence to TDF/FTC.
Results: Between January and December 2016, 2805 subjects were included in the french RTU protocol. Only 1 subject presented an HIV-1 seroconversion at month 1 visit. This 31-year-old MSM had an HIV negative serology on March 9. He initiated PrEP (2 pills on Day 1 then 1/day) on March 19. On April 9 his serology was discordant (Biomerieux neg/Diasorin pos). On April 13 he seroconverted with a plasmatic viral load (pVL) at 766 copies/ml (2.88 log) and a western-blot showing reactivities to p24 and slightly to p18/p52. A viral load was retrospectively performed on serum on March 3 and was under threshold's detection. Genotype resistance testing revealed a CRF60_BC recombinant virus with a M184I mutation and polymorphism mutations on the protease (10I, 15V, 69K, 89I). This man has been probably infected at a ChemSex week-end on March 25-28 with multiple partner relationships, mostly passive behavior and psychoactive substance intake. He was considered as treatment adherent with the elements of questioning and plasma dosage performed on April 9 and 13. According to the sequence of events and to the french epidemiological data on HIV strains in acute infection most probably the selection of M184I mutation appeared under TDF/FTC pressure.
Conclusions: In the real-life context of PrEP in France, 1 early HIV seroconversion was reported, emphasizing the need for a very close monitoring when taking in charge patients at high risk of sexual infection.

WEPEC0948

Effect of menses and tampon use on the pharmacokinetics of Dapivirine Vaginal Ring

A. Nel, M. Smit, J. Nuttall, N. Van Niekerk
International Partnership for Microbicides, Silver Spring, United States
Presenting author email: anel@ipmglobal.org.za

Background: Dapivirine Vaginal Ring (DVR), containing 25mg dapivirine, has been shown to be safe and efficacious in two Phase III clinical trials. This trial investigated the effect of menses and tampon use on local and systemic pharmacokinetics of dapivirine delivered by DVR.
Methods: An open-label, randomised, cross-over trial was conducted among 22 healthy, HIV-negative women, aged 18-40 years. Participants received 3 treatments, separated by washout periods of 28 days, according to a randomly assigned treatment sequence: DVR with menses, without tampon use; DVR with menses, with tampon use; DVR with no menses. Oral contraceptives were used to regulate onset or absence of menses between Days 14 and 19 post-ring insertion. Dapivirine concentrations were determined in plasma and vaginal fluid (VF), and residual dapivirine was assessed in used rings.
Results: Both plasma and VF concentrations decreased after onset of menses. For plasma, $AUC_{11\text{-}21days}$ was 6% lower during menses with or without tampon use, relative to no menses (ratio: 0.94; 90% CI: 0.88-1.00). At the end of menses, concentrations increased to levels associated with no menses by Day 28. Menses and tampon use had a greater impact on VF concentrations: $AUC_{11\text{-}21days}$ was reduced by 35% during menses without tampon use (ratio "menses/no menses": 0.65; 90% CI: 0.53-0.80), and by 48% during menses with tampon use (ratio "menses/no menses": 0.52; 90% CI: 0.42-0.65). The lowest mean VF concentrations occurred on Day 15: 4797 and 7701ng/g for menses with and without tampon use, compared to 38350ng/g (no menses), but were well above the in vitro IC_{99} in cervical tissue (3.3ng/mL). VF concentrations subsequently increased to levels associated with no menses by Day 21. Ring residual levels seemed unaffected by menses and tampon use, with mean values of 20.3, 20.7 and 20.2mg following menses without tampon use, menses with tampon use, and no menses, respectively.
Conclusions: Plasma dapivirine concentrations were marginally lower during menses. VF concentrations were markedly reduced during the first 2 days of menses; at the end of menses, levels rapidly increased to pre-menses concentrations. A greater reduction in VF concentration was observed with tampon use; however, the lowest mean value was >1400 times above IC_{99}.

WEPEC0949

Network meta-analysis of post-exposure prophylaxis (PEP) randomized clinical trials: a rankogram for PEP

L. Leal[1], E. De Lazzari[1], A. Inciarte[1], V. Díaz-Brito[1], A. Milinkovic[2], C. Lucero[1], E. González[1], A. León[1], J.M. Gatell[1], F. García[1]
[1]Hospital Clínic Barcelona - IDIBAPS, Barcelona, Spain, [2]University College London, London, United Kingdom
Presenting author email: laleal@clinic.ub.es

Background: Compliance of 28 day course of PEP is often limited by frequent drop-outs and the toxicity of antiretroviral drugs which could limit its efficacy. Several studies have been conducted searching for better tolerated regimens as a priority. In order to evaluate which PEP regimen has the best completion rate we performed a meta-analysis of 5 randomized clinical trials (RCT) comparing different PEP regimens reporting outcomes on 1,105 PEP initiations.
Methods: Three out of the 5 selected RCT compared previous standard of care (SOC) ritonavir-boosted lopinavir (LPV/r) versus a different antiretroviral (ARV) in each trial: atazanavir (ATV), cobicistat-boosted elvitegravir (ELV/c) and raltegravir (RAL), and versus maraviroc (MVC) in 2 RCT. We conducted a network meta-analysis to estimate the pooled odds ratio (OR) for LPV/r versus MVC and the probability of each treatment for showing a better 28 day PEP completion rate. We also plotted a rankogram based on the probability of each treatment being at a particular order (the best, second, third, fourth and the worst).
Results: Non-occupational exposure to HIV was the main reason for PEP, being this an inclusion criterion in 4 studies. In the remaining study, 30 occupational exposures were described. A 3-drug regimen was prescribed in all studies, where tenofovir-disoproxil/emtricitabine was the most frequently used backbone. All studies followed European recommendations on prescription and follow-up. 454 (41%) PEP non-completion were reported for any reason. The OR for each ARV compared to LPV/r was: ATV: OR 0.95 95% CI 0.58-1.56; EVG/c: OR 0.65 95% CI 0.30-1.37; RAL: OR 0.68 95% CI 0.41-1.13, and since only for MVC comparison there were more than one RCT, the only pooled OR was for MVC: OR 0.69 95% CI 0.47-1.01. We estimated the probability of each treatment of being the best. Since the outcome is PEP completion, the best treatment is that with the highest (most positive) treatment effect (table 1). This rankogram showed that EVG/c has 45.6% probability of being the best treatment, followed by MVC, RAL, ATV and LPV/r.
Conclusions: Newly antiretroviral drugs, particularly as a single tablet regimen, showed a better PEP completion rate than previous SOC.

Institutional barriers to post-exposure prophylaxis access and related services among survivors of sexual violence in Gaza Province in Mozambique: a qualitative study

M.A. Sitoe[1], M. Posse[2], A.C. Monteiro[2], C.L. Fonseca[3], A. Angel[4]
[1]Elizabeth Glaser Pediatric Foundation, Maputo, Mozambique, [2]Elizabeth Glaser Pediatric AIDS Foundation, Maputo, Mozambique, [3]Elizabeth Glaser Pediatric AIDS Foundation, Technical, Maputo, Mozambique, [4]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Los Angels, CA, United States
Presenting author email: msitoe@pedaids.org

Background: The timely provision of health care services for survivors of sexual violence is crucial to prevent HIV transmission. The government of Mozambique approved implementation of the national integrated care plan, which includes a recommendation to provide post-exposure prophylaxis (PEP) for sexual assault survivors. There are indications that there may be gaps in the implementation of that plan, because it is a multi-sectoral issue (health facility, police sector and community), meaning it should be everybody's or nobody´s responsibility. Un study done in Mozambique showed that only about 31% of survivors arrived at health facility was administered PEP within 72 hours of the sexual violence incident. The objective of this study was to identify institutional barriers that affect access to PEP in six districts of Gaza province, Mozambique.
Methods: Twenty eight in-depth interviews were conducted with personnel involved in sexual assault survivors care that we called "key actors" (15 health workers, four police, and nine community leaders) recruited in six heath facilities supported by EGPAF, through convenience sampling in August 2015. The interviews were conducted in Portuguese and in Changana (local language). The interviews were

audio-recorded and transcribed in Portuguese. The transcripts were codified and a thematic analysis was done using the MAXqda12 program.
Results: Reported institutional barriers that affect access to PEP, in order of most mentioned,
include: lack of coordination between the cadres of key actors; lack of integrated (police and health assistance) sexual assault services at the health facility; lack of transport to bring survivors from communities to police stations or health facilities; unavailability of all sexual assault assistance services available 24 hours a day at the health facility; and lack of key actors trained in care of survivors.
Conclusions: Although the implementation plan for the national integrated care program is already
in place and PEP is available free of charge in all health facilities, there are still challenges that need to be overcome in order for PEP access to be effective. Strategies that ensure that key actors are adequately informed, working cohesively, and equipped to respond to the needs of survivors should be a national priority.

WEPEC0951

Understanding PrEP demand among adolescents/young adults and HIV discordant couples in SEARCH: qualitative findings

C.S. Camlin[1,2], M. Getahun[1], J. Ayieko[3], A. Owaraganise[4], F. Mwangwa[4], C.A. Koss[5], D. Kwarisiima[6], C.R. Cohen[1], E.A. Bukusi[3], T.D. Clark[5], M.L. Petersen[7], M.R. Kamya[4,8], D.V. Havlir[5], E.D. Charlebois[2]

Presenting author email: carol.camlin@ucsf.edu

Background: Pre-exposure prophylaxis (PrEP) is a vital new prevention tool, yet, while much is known about PrEP adherence in clinical trial populations, there are critical knowledge gaps to inform open-label implementation in sub-Saharan African populations.
Methods: This qualitative study sought to inform introduction of PrEP to communities participating in a test-and-treat trial in Kenya and Uganda (SEARCH, NCT01864603). Focus group discussions (FGDs), conducted September-October 2016 in two communities, explored risk perceptions, attitudes, norms, and preferences, in six groups: males and females aged 16-24 and HIV-infected and -uninfected female and male members of HIV-discordant couples. Recordings were transcribed and translated for theory-informed analyses.
Results: Adolescents were excited, curious, yet held misconceptions and fears about PrEP. Many mistrusted medical authorities and wanted ‚proof' of PrEP efficacy (via others' testimonies). Young men discussed PrEP as a vehicle for reducing risks while pursuing opportunities for sex, reflecting a normative masculinity valorizing sexual conquest. Young women were more conflicted: they debated engaging in unprotected transactional sex, and discussed PrEP as a means to reduce risks with older male ‚sponsors'. Adolescents reported talking openly with peers about HIV, but not parents, whose disapproval they feared. They requested designated areas or days for PrEP, separate from ART clinics.
Members of sero-discordant couples using PrEP encouraged others to overcome fears. HIV+ members desired to protect partners and ensure their children have a future caregiver. Those with supportive spouses credited couples-VCT and care-provider support for their harmony. Others described marital conflict; HIV+ women feared husbands' affairs would lead to infection and they would be blamed. HIV- members were anxious about HIV risk, with some women angry about husbands' affairs; condom use was rare and disliked by most men and some women. Participants openly discussed extramarital affairs; transactional sex was normal for women when husbands couldn't provide for children. Women feared other women's gossip, while men reported speaking freely with one another.
Conclusions: Population-specific messaging could build demand for PrEP to address motivations and needs of at-risk populations. Couples-based prevention and treatment services are critically important, while education and improving parent-child communication/support may be needed to overcome barriers to PrEP uptake among adolescents.

WEPEC0952

No HIV infections despite high-risk behaviour and STI incidence among gay/bisexual men taking daily pre-exposure prophylaxis (PrEP): the PRELUDE demonstration project

I. Zablotska[1], S. Vaccher[2], M. Bloch[3], A. Carr[4], R. Foster[5], A. Grulich[2], R. Guy[2], J. McAllister[4], C. Ooi[6], M. Poynten[2], D. Templton[2]

Presenting author email: izablm@yahoo.com

Background: In randomized clinical trials, PrEP efficacy among GBM was high, but few studies reported about PrEP implementation. Here we report the primary outcomes - HIV incidence, STI incidence, PrEP adherence, and sexual behaviour - in the PrEP demonstration study PrELUDE in Sydney, Australia.
Methods: PrELUDE was a demonstration single-arm, open-label study which evaluated the daily regimen of oral tenofovir/emtricitabine as HIV pre-exposure prophylaxis (PrEP) among high-risk gay/bisexual men (GBM). Participants were enrolled from November 2014 to August 2015 and were followed till December 2016. HIV/STI testing was conducted 3-monthly plus as clinically indicated. Online surveys collected detailed information about sexual practices and medication adherence 3-monthly.
Results: PrELUDE enrolled 317 males; 309 (97.5%) identified as GBM. The median age was 37 (range 22-70) years. Expected HIV incidence was 4 per 100py. No HIV infections were identified during 381.3 person-years (py) of follow-up (HIV incidence 0%, 95% CI:0-0.96 per 100py). While 45 (14.1%) wanted PrEP only for specific events and 64 (20.1%) for short periods around exposure, self-reported daily PrEP adherence was 94.4%, 92.9% and 90.3% at Months 1, 6 and 12, respectively. At enrolment, 42 GBM had HIV-positive regular partners; 40 (95.2%) reported condomless anal intercourse (CLAI) in preceding 3 months (no change over time). With HIV-positive/unknown-status casual partners, CLAI in the last 3 months increased from 80.0% at baseline to 91.1% at 12 months on PrEP (p-trend< 0.01). At enrolment, 16.8% were diagnosed with ≥1 STI (3.3% with anogenital gonorrhea (aGN), 9.5%, anogenital chlamydia (aCT) and 0.7% infectious syphilis (SYP)). The overall incidence of these STIs during the study follow-up was 92.0 (82.2-102.6) per 100py (aGN: 32.4 (26.7-38.9), aCT: 50.2 (42.0-60.2), and SYP: 9.5 (6.5-13.3) per 100py). 13.5% of all STIs were diagnosed between regular assessments, upon symptomatic presentations.
Conclusions: No HIV infections occurred during the study period, despite increases in high-risk CLAI and high incidence of STI. Thus PRELUDE demonstrated that high-risk GBM used daily PrEP appropriately, though they remained at substantial risk of STIs. Longer follow-up is necessary to better understand the real-life adherence, sexual practices and STI rates among PrEP users over longer duration of PrEP use.

WEPEC0953

HIV prevention is not all about HIV efficacy: how the uptake and effectiveness of HIV prevention products may rely on pregnancy and sexually transmitted infection prevention

P. Vickerman[1], M. Quaife[2], M. Kilbourne-Brook[3], M. Mvundura[3], M. Cabrera[4], R. Eakle[4], S. Delany-Moretlwe[4], F. Terris-Prestholt[2]
[1]University of Bristol, Bristol, United Kingdom, [2]LSHTM, London, United Kingdom, [3]PATH, Seattle, United States, [4]Wits RHI, Johannesburg, South Africa
Presenting author email: peter.vickerman@bristol.ac.uk

Background: In sub-Saharan Africa, considerable HIV-burden exists amongst women. It is hoped that new anti-retroviral (ARV) based prevention technologies could decrease this burden, but this will depend on user behaviour. Uptake of new products could be improved if they protect against pregnancy or sexually transmitted infections (STI).
Methods: We use a discrete choice experiment to project the likely uptake (% of women that use a product) of oral pre-exposure prophylaxis (PrEP), vaginal rings, injectable long-lasting ARV agents (4-12 weekly injection), and gel-based ARV products (with/without diaphragm) amongst adolescent and adult women, and how uptake could depend on whether the product protects against pregnancy or STI acquisition. For different product scenarios, and assuming baseline condom use of 50%, a simple model was used to determine how the uptake of different products could decrease an individual's average HIV transmission risk.
Results: In adolescent women, analyses suggest there will be limited uptake (< 7% use) and impact (< 8% decrease in HIV transmission risk) of any new product unless they also provide pregnancy protection, which could triple the level of use and impact achieved by a product. Conversely, adult women have lower preference for these additional benefits, with moderate use (≤16% for each product) and impact (12-16% decrease) being projected if the products only protect against HIV-

acquisition. In terms of product preference, both adult and adolescent women have highest preference for injectable ARVs, with oral PrEP having high preference if injectable ARVs are not available. The ring will also be used by adult women, with lower predicted use by adolescents. Gel-based products were popular with adolescent women if they provided pregnancy protection when no other products did. However, even in the most favourable scenario, where all five prevention products are available and provide pregnancy and STI protection, projections still suggest that >20% of women will remain unprotected and one-third of the baseline transmission risk will remain.
Conclusions: Incorporating multiple prevention components into new ARV-based prevention products could dramatically increase their uptake and impact in certain sub-groups. The development of multipurpose technologies could be important for tackling the heightened burden of HIV amongst women.

WEPEC0954

First year of PreP in a Parisian hospital STIs clinic: prevention must go on

J. Chas[1], M.-A. Danet[1], M. Hamidi[1], M.-G. Lebrette[1], F. Haneche[1], B. Lafon-Desmurs[1], R. Missonnier[1], A. Canestri[1], L. Lassel[1], S. Lasry[1,2], M. Ohayon[1,2], S. Allaf[3], B. Boissavy[1], C. Amiel[4,5], G. Pialoux[1,5]
[1]Hôpital Tenon-APHP, Infectious Diseases, Paris, France, [2]Centre Le 190, Paris, France, [3]Hôpital Tenon-APHP, Pharmacy, Paris, France, [4]Hôpital Tenon-APHP, Virology, Paris, France, [5]UPMC-Sorbonne, Paris, France
Presenting author email: gilles.pialoux@aphp.fr

Background: Effectiveness of PrEP using TDF/FTC for prevention of sexually acquired HIV infection has been demonstrated in trials and open-label studies; however, few data on sexual behaviors, STIs or chemsex practices have been reported among PrEP users outside clinical studies.
Methods: We describe characteristics of individuals evaluated for PreP initiations, reasons for not starting PreP, rate of retention in care, incidence of HIV, other STIs and practice of chemsex in a PreP Unit (Tenon hospital- Paris) from January 2016 (beginning of the Temporary Recommendation for Use which allow TDF/FTC for PreP in France) through January 2017. We used a multidisciplinary approach to provide clinical monitoring, treatment, adherence support by infectious disease physicians, counselors, nurses, and administrative staff.
Results: About 337 referrals for Prep, there were 313 PrEP initiatons (92,9%); mainly reasons for not starting PrEP included low risk for HIV (3,3%), HIV infection diagnosed at baseline (1,5%), postexposure prophylaxis initiation (0,9%), estimated creatinine clearance ≤60 mL/minute (0,3%). Mean age was 38 years [20-66] and 319 (94,7%) were MSM. In the last 3 months, median of sexual partners was 15 [0-250], median of unprotected sexual intercourses was 4 [0-400], 202 (59,9%) reported chemsex whose 12 (3.6%) of slam at least once during follow-up, with mainly amphetamine (42,8%) and synthetic cathinones (35,31%). The last intercourse was receptive anal sex in 52,2%, unprotected in 54%, under chemsex in 24,63%. During the follow-up, the rate of declarative good PreP observance was 95.5%, 134 individuals (39,8%) were diagnosed with at least 1 STI for a total of 251 STI diagnosed with 94,1% asymptomatic. There was only 1 HIV diagnosed during the follow-up at 1 month in an individual with a resistance of FTC (M184I). There were only 3% lost of follow-up.
Conclusions: In one year, there was only one new HIV infection despite high rates of non symptomatic STIs and use of chemsex. With the implementation of PrEP in the MSMs community, a better understanding of "risk compensation" is needed to understand how changes in sexual behavior may impact risk for HIV and other STIs among PrEP users.

WEPEC0955

HIV prevention method preferences within sexual partnerships reported by HIV-negative MSM in Tijuana, Mexico

H.A. Pines[1], D.M. Smith[1], A. Harvey-Vera[1], G. Rangel[2], S.J. Semple[3], T.L. Patterson[3]
[1]University of California, San Diego, Medicine, La Jolla, United States, [2]United States-Mexico Border Health Commission, Tijuana, Mexico, [3]University of California, San Diego, Psychiatry, La Jolla, United States
Presenting author email: hpines@ucsd.edu

Background: To assess potential uptake of pre-exposure prophylaxis (PrEP) and risk compensation (i.e., decreased condom use) among men who have sex with men (MSM), we examined HIV prevention method preferences within sexual partnerships reported by MSM in Tijuana, Mexico.
Methods: To date (3/2016-12/2016), 309 HIV-negative MSM recruited via respondent-driven sampling and venue-based sampling have completed surveys designed to collect socio-demographic, behavioral, and psychosocial data, as well as information on up to 20 sexual partners in the past 4 months, including their preferred HIV prevention method during sex with each partner if PrEP and condoms were available for free (i.e., PrEP only, condoms only, or PrEP with condoms). Multinomial logistic generalized linear mixed models were used to identify individual and partnership characteristics associated with HIV prevention method preferences within partnerships with male or transgender partners.
Results: Participants had a median age of 39 years (interquartile range [IQR]=29, 46; 28% under 30 years) and mostly identified as male (97%), Latino (94%), and bisexual (54%) or gay (33%). Participants reported on 927 partnerships with male or transgender partners in the past 4 months (median=2; IQR=1, 4), of which 50% had engaged in condomless anal intercourse (CAI). Using PrEP with condoms (56%) was preferred to using condoms only (27%) and using PrEP only (17%) for HIV prevention during sex within partnerships. After adjusting for individual and partnership characteristics, compared to using condoms only, using PrEP with condoms was preferred within partnerships reported by gay-identifying participants (adjusted odds ratio [AOR]=2.0, 95% confidence interval [CI]:1.1, 3.6), while using PrEP only was preferred within partnerships reported by participants who perceived themselves to be at risk for HIV (AOR=2.5, 95% CI: 1.1, 5.7) and partnerships that practiced CAI in the past 4 months (AOR=5.7, 95% CI: 2.7, 11.8).
Conclusions: Using PrEP with condoms was the preferred HIV prevention method during sex within partnerships reported by MSM in Tijuana suggesting that future PrEP uptake could be high within this population. Encouragingly future PrEP uptake may not lead to risk compensation given that preferring PrEP only was most common in the context of high-risk partnerships that already engage in CAI.

WEPEC0956

Acceptability of TMC278 LA: long-acting injectable pre-exposure prophylaxis (PrEP) in HPTN 076

E.E. Tolley[1], S. Li[2], M. Atujuna[3], P. Musara[4], J. Justman[5], S. Pathak[2], L.-G. Bekker[3], J. Farrior[6], N. Sista[6]
[1]FHI 360, Behavioral and Social Science Research, Durham, United States, [2]Fred Hutchinson Cancer Center, Seattle, United States, [3]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [4]University of Zimbabwe, Harare, Zimbabwe, [5]Columbia University, New York, United States, [6]FHI 360, Science Facilitation, Durham, United States
Presenting author email: btolley@fhi360.org

Background: Continuing high HIV incidence and low adherence to daily oral and topical HIV prevention agents in clinical trials among African women underscore the need for HIV prevention products that are more acceptable and easier to use. Strong global demand for injectable contraception suggests that new, long-acting, injectable HIV Pre-Exposure Prophylaxis (PrEP) formulations could meet this need. HPTN 076, a randomized, controlled trial comparing the safety of TMC278 LA to placebo, administered every eight weeks over a forty-week period, provided an opportunity to examine and compare acceptability of a long-acting injectable PrEP product among HIV-uninfected women in Zimbabwe, South Africa and two United States (US) sites.
Methods: We compared the acceptability of injectable study product attributes, prevention preferences and future interest in injectable PrEP by site (African versus US) and arm via quantitative surveys administered at the first, fourth and sixth injection visits. Focus Group Discussions (FGDs) were also conducted after completion of the sixth injection visit.
Results: The study enrolled 136 (100 African, 36 US) participants with a median age of 31 years [IQR 25-38]. Most participants (≥75%) rated injectable attributes (number, quantity, location, frequency) as very acceptable. While few reported rash or other side effects, 61-67% reported pain with injection, with non-significant differences over time and between arms; and during FGDs, participants described initial fear of the injectable and variable experiences with pain. Although half of participants desired no changes in the mode of injection, others reported a preference for one injection, rather than two, and/or for injection in the arm rather than buttock. Nonetheless, most preferred injectable PrEP to daily oral pills (56-96% versus 4-25%). This preference was significantly higher among participants from the African than US sites, and increased over time in all sites. FGD discussions provide further context for both product acceptability and trial-related experiences.
Conclusions: This study provides evidence that a long-acting injectable PrEP product is highly acceptable among young women in both African and US settings. It also provides insights into women's motivations for product use and trial participation, as well as product preferences and concerns that could inform future product development, trial implementation and introductory efforts.

WEPEC0957

Structural barriers and reasons why we are still failing to stop HIV in an era of effective pre-exposure prophylaxis (PrEP): *a mixed-method study*

M. Magnus[1], M. Levy[2], M. Balachandran[1], L. Wilton[3], M. Siegel[1], S. Calabrese[1], S. Fields[4], R. Brewer[5], A. Dright[1], J. Peterson[1], I. Kuo[1]
[1]George Washington University, Washington, United States, [2]George Washington University, Epidemiology and Biostatistics, Washington, United States, [3]Binghamton University, New York, United States, [4]New York Institute of Technology, New York, United States, [5]Louisiana Public Health Institute, New Orleans, United States
Presenting author email: mattelevy@gwu.edu

Background: Despite a growing armamentarium of HIV prevention strategies, HIV continues to spread among subpopulations at risk such as Black men who have sex with men (BMSM). Structural barriers to services (cost, location of services, stigma, and lack of culturally competent providers) are associated with poor diffusion of interventions, resulting in severe healthcare access disparities. Emblematic of this is that BMSM, who have the highest HIV rates in the US, are among those least likely to be prescribed PrEP. Examining correlates of structural barriers to PrEP is critical to inform ways to disseminate potentially life-saving medications.
Methods: This was a mixed method study of HIV-negative BMSM ≥18 years old with at least one study-defined structural barrier to uptake of HIV prevention services. Participants (N=75) completed both qualitative in-depth interviews and quantitative surveys regarding uptake of HIV prevention interventions. An additional N=93 BMSM participated in an online survey to test concepts identified and N=25 BMSM participated in a longer qualitative interview alone. Interviews were thematically coded based on grounded theory. Quantitative data were analyzed using descriptive statistics and logistic regression. Concepts derived from the interviews were mapped along the PrEP continuum.
Results: As shown, data from the N=193 participants reached saturation on key structural barriers to uptake of PrEP. Qualitative and quantitative findings echoed one another to provide a comprehensive examination of barriers to PrEP uptake among BMSM including reduced disclosure of risk to providers and knowledge about PrEP, barriers to accessing sites where drug is offered, and adherence.

Awareness of and Willingness to Be Prescribed PrEP [Qualitative example] "My Doctor never asked me "Are you having sex with men?" I just asked for it. And he said, ‚Oh okay' and then circled something on a piece of paper." "I think they wasn't aware. Or they probably thought that it wasn't a concern for them to ask that question, first of all."
Access to Healthcare [Qualitative example] "Interviewer: So, what about your check ups? Do you go... what do you do for your checkups? Respondent: Check ups as in? Interviewer: Like your physical checkups or your annual checkups. Respondent: I don't actually do any of that" "I know particularly a lot of my friends that are black and gay don't go to the Doctor that regularly. I think it's kind of a stigma.
Likely to Be Tested for HIV [Quantitative example] "They don't do that there. I always thought that they just do it automatically. I just never been offered it. I just assumed that they just check everything. They take blood. Oh I am guessing they're checking for HIV and different illnesses."
Likely to Receive PrEP Prescription [Quantitative example] Only general health / preventive services were significantly associated with having health care insurance, not HIV prevention services (p<0.05) Health insurance did not eliminate substantial barriers to prevention in this population (p<0.05) Community clinics better than other care settings for HIV prevention options (p<0.05)
Likely to Be Adherent to PrEP [Qualitative example] "Yeah, you're in the moment of that movie, so you don't want to push pause because you know, you'll lose it. So that's what it is..." "Of course they made the condom up and they done did this and they done did this, a pill, da-da-da-da, but a person, say for instance I'm negative and this person have HIV I'm not going to have sex with that person if I know they have HIV so they're not going to tell me that they have HIV." "People may be starting to get ideas about you having HIV because you're in the study or because they see you taking the study drugs. And to be honest, and I just kind of leave them on my dresser or inside my medicine cabinet, and people will ask me "Oh why do you have all these pill bottles?"
*Selected samples only due to word count constraints. Additional data analyzed and available; presentation will include additional text extracts and adjusted Odds Ratios (95% CI) associated with each step along the continuum.

[Barriers along the PrEP Continuum]

Conclusions: These data suggest myriad systematic changes must be made to leverage PrEP. These include outreach to those at risk beyond the clinic walls, teaching providers to engage in sexual health conversations, support engagement, and provide adherence support.

WEPEC0958

Preliminary focus group findings on PrEP product acceptability and key attributes: people who inject drugs and female sex workers

K. Footer[1], S. Sherman[2], G. Greene[3], A. Carballo-Diéguez[4], P. Valente[5], C. Rael[5], R. Giguere[4], R. D'Aquilla[3]
[1]Johns Hopkins School of Public Health, Epidemiology and Health Behavior and Society, Paris, France, [2]Johns Hopkins School of Public Health, Health Behavior and Society / Epidemiology, Baltimore, United States, [3]Northwestern University, Chicago, United States, [4]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, United States, [5]Columbia University, New York, United States
Presenting author email: kfooter1@gmail.com

Background: Pre-Exposure Prophylaxis (PrEP) has the potential to prevent HIV infection among high-risk groups, including female sex workers and people who inject drugs. A range of new products are in development that may address key barriers to acceptability and adherence among these vulnerable populations. The objective of this research was to qualitatively explore acceptability around three different PrEP product types: new subcutaneous implants, new injectable forms as well as existing pill based methods.
Methods: We conducted focus groups (n=9) over a 3-month period in Baltimore City, USA among street based female sex workers and people who inject drugs (male and female). Non-probability sampling was used to recruit participants. Questionnaires were used to collect demographic information and risk behaviors on all participants. Group facilitators led participants (between four and nine participants per group) through a 45-minute focus group guide, supported by product description videos and handouts. The guide explored each PrEP method and sought feedback on comparisons and preferences. Analysis was conducted using a framework method.
Results: Sexual risk taking was high across all groups, particularly females who inject drugs where 49% reported recent sex without a condom. PrEP knowledge was low amongst all groups. Pill method of delivery was associated with feelings of agency and control. However, of the injectable and implant methods, long lasting forms were preferred. Participants were interested in methods that did not require too many repeat administrations over a short-time period and methods that were minimally invasive and perceptible. Socio-structural barriers, including regular health care access and structural vulnerabilities such as homelessness, emerged as relevant to the acceptability of all three delivery methods.
Conclusions: The findings from this study provide the first data on the attributes and acceptability of new forms of PrEP delivery amongst two high-risk populations that are both currently in need of effective HIV prevention technologies. Results of this research will inform the future development and testing of injectable and implant forms of PrEP.

WEPEC0959

Effective contraceptive use and PrEP adherence among East African women in HIV serodiscordant couples partnerships

K. Ngure[1,2], J. Velloza[2], C. Celum[2,3,4], R. Patel[2], J. Baeten[2,3,4], N. Mugo[2,5], E. Bukusi[2,6,7], J. Haberer[8], J. Odoyo[6], R. Heffron[2,3]
[1]Jomo Kenyatta University of Agriculture and Technology, Public Health, Nairobi, Kenya, [2]University of Washington, Global Health, Seattle, United States, [3]University of Washington, Epidemiology, Seattle, United States, [4]University of Washington, Medicine, Seattle, United States, [5]Kenya Medical Research Institute, Center for Clinical Research, Nairobi, Kenya, [6]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [7]University of Washington, Obstetrics and Gynecology, Seattle, United States, [8]Massachusetts General Hospital, Medicine, Cambridge, United States
Presenting author email: k_ngure@hotmail.com

Background: In sub-Saharan Africa, women at high risk of HIV may also want to delay pregnancy and be at risk for unintended pregnancy. For these women, concurrent use of daily oral pre-exposure prophylaxis (PrEP) and an effective contraception are recommended. However, little is known about how the use of effective contraception influences PrEP adherence.
Methods: We analyzed data from 334 Kenyan and Ugandan HIV-uninfected women from the Partners Demonstration Project, an open-label study of the integrated delivery of PrEP and antiretroviral therapy (ART) for HIV serodiscordant couples. In this delivery model, HIV-uninfected women were offered PrEP at quarterly visits and encouraged to discontinue PrEP once the HIV-infected partner used ART for ≥6 months. Effective contraceptive use (including implants, IUDs, injectable, oral, or surgical methods) was self-reported at all visits. In multivariable generalized estimating equations, we modeled the association between effective contraceptive use and high PrEP adherence (≥80% of expected MEMS caps openings) and discontinuation since the prior visit.

Results: Among the 311 women who did not have immediate fertility desires at baseline, 115 (37.5%) women were using effective contraception: 15.1% injectables, 11.9% implants, 5.1% pills, and 2.3% IUD. All of these 311 participants initiated PrEP during the study and high PrEP adherence was reported at 73.1% of visits following PrEP dispensation. 56 (18.0%) of women remained on effective contraceptive throughout study follow-up and 162 (52.1%) were never on a contraceptive method during the study. After adjusting for fertility desires, ART use by the HIV-infected partner, and condom use, high PrEP adherence was as likely during visits following report of effective contraceptive use (37.8%) as visits without (32.4%), adjusted RR [aRR]=1.06; 95% CI=0.91-1.25; p-value=0.44.
Conclusions: Among African women at high risk of HIV infection, effective contraceptive use did not appear to impact adherence to PrEP.

WEPEC0960

Acceptability of emerging technologies for sustained, long-acting HIV pre-exposure prophylaxis (PrEP) among young men who have sex with men (MSM) in the U.S.

G.J. Greene[1], M. Matson[2], A. Carballo-Diéguez[3], T.J. Hope[2], P.F. Kiser[2], R.T. D'Aquila[2]
[1]Northwestern University, Medical Social Sciences, Chicago, United States, [2]Northwestern University, Chicago, United States, [3]Columbia University, New York, United States
Presenting author email: george-greene@northwestern.edu

Background: Approximately 67% of all diagnosed HIV infections occurred in MSM in the U.S. in 2014, with adolescent and adult MSM experiencing an increase in number of HIV infections. The CDC recommends oral PrEP for populations at high risk of HIV infection, such as young MSM. Given adherence challenges in daily pill-taking, alternative strategies are under investigation.
The aims of this study were to: a) understand attitudes toward the use of sustained, long-acting injections and implants to deliver PrEP; and b) identify key attributes for future product development.
Methods: From June to August 2016, 6 focus groups were conducted in a Chicago, IL. A convenience sample of young MSM (18-29 years old; mean = 23.4 years) were recruited through Facebook, community-based organizations, and research participant databases. The majority (56%) were non-White (24% African American; 16% Asian) and 20% reported a Hispanic ethnic background. The sample included current PrEP users and non-users. The study team used thematic analysis to identify themes and patterns across the data.
Results: Similar themes emerged across the focus groups in their attitudes toward the use of injections and implants to deliver PrEP. With regard to injections, participants favorably discussed privacy and familiarity with injection procedures. Some were concerned about the danger of not being able to remove the medicine in the event of HIV infection. Key attributes were:
a) duration of 2-6 months; and
b) 1-3 injections per dose.
With regard to implants (biodegradable and non-biodegradable), participants favorably discussed privacy and duration. For the non-biodegradable implant, participants were apprehensive about multiple surgical procedures (insertion and removal). For the biodegradable implant, participants were concerned about whether or not it could be removed in the event of HIV infection. Key attributes were:
a) duration of 6-12 months; and
b) 1-2 implants per insertion.
Conclusions: Future research should continue to develop technologies to improve PrEP adherence and effectiveness, particularly among young MSM. Proposed injections and implants are acceptable to the extent that they are private, long lasting, and convenient. With less frequent adherence requirements, uptake of sustained, long-acting PrEP technologies could be enhanced by aligning development with user preferences.

WEPEC0961

Differences between regimen choices and types of exposure in HIV post-exposure prophylaxis before and after the guidelines implementation in Brazil

J.P. Toledo, A.R. Pati Pascom, M. Meireles, C.J. Braga Batista, M. de Queiroz, A. Schwartz Benzaken
Ministry of Health, Department of STI, HIV/AIDS and Viral Hepatitis, Brasília, Brazil
Presenting author email: ana.roberta@aids.gov.br

Background: Post-exposure prophylaxis (PEP) is one of the main tools to prevent HIV infection. Although it was first made available in Brazil in 2010, the guidelines for prescription were published in 2015 as part of the combination prevention strategy. The guidelines simplified PEP prescription and defined TDF+3TC+ATV/r as the preferential regimen choice. The objective of this study is to characterize PEP use according to regimen and type of exposure and assess the differences before and after the guidelines implementation.
Methods: We included in the analysis programmatic data from PEP dispensation in Brazil, between 2014 and 2016. Data were described using proportions. Chi-square tests were used to investigate the association between PEP regimen and the year of dispensation and type of exposure.
Results: Between 2014 and 2016, 120,347 PEP treatments were delivered for people aged 15+ and 55,175 (46%) of them were made in 2016. Non-occupational exposure dispensations increased approximately 136% between 2014 and 2016, before and after the PEP guidelines implementation. Sexual exposure was the reason 28,244 people (51%) sought for PEP in 2016 (compared to 30% in 2014 - 7,786 dispensations). In 2016, 85% of the regimens dispensed due to sexual exposure consisted of TDF+3TC+ATV/r (compared to 0.5% in 2014) and 4% of AZT+3TC+TDF (compared to 55% in 2014). Other regimens delivered due sexual exposure, in 2016 were TDF+3TC+LPV/r (4%) and AZT+3TC+LPV/r (2%). There was an increase in the dispensation of TDF+3TC+ATV/r among those who had an occupational exposure as well, from 24% to 79%.
Conclusions: Up to a few years ago, local services focused the PEP delivery mainly on occupational and sexual violence exposures. With the implementation of the guidelines, the Ministry of Health focused on the expansion of PEP delivery for occasional sexual exposure. Furthermore, the implementation was paired with the promotion of the right to access PEP regardless of type of exposure. We observed that the changes proposed by the current guidelines were absorbed and implemented by health providers, especially regarding the preferential regimen. Besides, the roll out of PEP delivery for everybody without moral judgments regarding the type of exposure referred by the patient was also accomplished.

InterPrEP (II): internet-based pre-exposure prophylaxis (PrEP) with generic tenofovir DF/emtricitabine (TDF/FTC) in London - analysis of safety and outcomes

N. Nwokolo[1], I. Aloysius[1], J. Zdravkov[1], G. Whitlock[1], J. Alldis[1], A. Aylward[2], A. Arvind[2], X.Z. Wang[3], I. Day-Weber[3], R. Smith[4], V. Houghton-Price[4], A. Hill[5], M. McClure[3], M. Boffito[1,3,5]
[1]Chelsea and Westminster Hospital, London, United Kingdom, [2]Imperial College School of Medicine, London, United Kingdom, [3]Imperial College, London, United Kingdom, [4]MetaVirology Ltd, London, United Kingdom, [5]St Stephen's AIDS Trust, London, United Kingdom
Presenting author email: nneka.nwokolo@nhs.net

Background: The PROUD and IPERGAY trials demonstrated an 86% reduction in new HIV diagnoses from PrEP. However, PrEP is not available on the National Health Service (NHS) in England. Consequently, people are buying generic versions of TDF/FTC via websites such as www.iwantprepnow, which is legal under UK import laws. In February 2016, we enabled people buying PrEP online to test regularly for HIV, hepatitis B/C and sexually transmitted infections (STIs) and to monitor renal function and antiretroviral drug concentrations. We have recorded a 40% reduction in new HIV diagnoses at the 56 Dean Street Clinic in London, from 2015-2016, in parallel with the introduction of generic PrEP. However, concerns remain about STIs and the quality of PrEP purchased online.
Methods: Notes review of HIV-negative individuals on generic PrEP attending 56 Dean Street from February 2016 - January 2017. Patients were given risk reduction advice and evaluated for HIV, hepatitis B/C, renal function and STIs (gonorrhoea, chlamydia and syphilis) and offered 3-monthly follow-up. Plasma Therapeutic Drug Monitoring for TFV and FTC was also offered. Drug concentrations were measured by ultra-performance liquid chromatography.
Results: Of the 398 individuals on PrEP, 99.7% were Male, 81% White; 87.5% took PrEP daily and 12.5% event-driven; 85% of individuals were on generic TDF/FTC from Cipla Ltd (Tenvir-EM). Adequate drug levels were seen in 96% (335/346). Baseline eGFR (>60ml/min) and/or urinalysis was normal in 99% (318/320) with no deterioration in 100% (150/150) of individuals attending follow-up. 42% of patients reported using "chems" in the 12 months before starting PrEP and 25% reported this whilst taking PrEP. During follow-up, 36% of patients were diagnosed with an STI. There were no new cases of HIV diagnosed on PrEP (0%, 95% C.I.: 0.0 - 4.0%). There were no new cases of hepatitis B and one new case of hepatitis C.
Conclusions: Despite 36% of patients being diagnosed with a new STI while taking generic PrEP, there were no new cases of HIV over the duration of this observational study. Concentrations of TFV and FTC were similar to those in individuals on branded Truvada from Gilead. Strategies to reduce incident STIs remain crucial.

WEPEC0963

PrEP awareness, interest and engagement among Baltimore female sex workers

J.N. Park[1], J. Raifman[1], K. Footer[2], M. Decker[3], N. Galai[1], S. Sherman[2]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Health Behavior & Society, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, Population, Family & Reproductive Health, Baltimore, United States
Presenting author email: ju.park@jhu.edu

Background: In the U.S., women account for nearly one fifth of new HIV cases but only 11% PrEP prescriptions in 2015. Female sex workers (FSW) experience high burden of HIV globally, and a recent meta-analysis of 14 U.S. studies of FSW reported a pooled HIV prevalence of 17.3%. We examined PrEP awareness, interest and correlates of interest among cis-FSW.
Methods: In 2016-2017, a prospective cohort of street-based FSW were recruited through time-location sampling in Baltimore. Participants completed a structured survey and rapid HIV testing (OraQuick©).
Results: Among HIV-negative FSW (N=235), mean age was 36 years, 66% were non-Hispanic white, 52% did not graduate high school, 66% engaged in daily sex work, 39% had condomless vaginal/anal sex with clients, 64% were recently homeless, 81% had health insurance and 33% had disclosed engaging in sex work to a clinician. Lifetime experiences of physical or sexual client violence were prevalent (39% and 32%). Most (78%) had not previously heard of PrEP, only 3% had talked to doctor/nurse about PrEP and none had ever taken PrEP. However, 72% reported that they were interested in "taking a pill every day to prevent HIV." A large majority reported ease in taking the pill (83%) and visiting their doctor for a blood test every 3 months (77%). The majority (83%) would still take PrEP if they had to use condoms "to fully protect from HIV." Bivariate associations with interest in daily oral PrEP included daily sex work (OR=2.1,95%CI=1.2-3.8,p=0.01) and lifetime physical client violence (OR=1.8,95%CI=1.0-3.3,p=0.06). Daily sex work was independently associated with interest in daily oral PrEP after adjusting for age (aOR=2.3,95%CI=1.2-4.3,p=0.009).
Conclusions: Street-based FSW are a high HIV risk population in the U.S. The majority are interested in taking PrEP even in the context of regular doctor visits and condom use with higher interest among FSW who work daily or have experienced client violence. Interventions to engage FSW and their healthcare providers are warranted.

WEPEC0964

The invisible product: preferences for long-acting injectable and implantable PrEP among South African youth

E. Montgomery[1], M. Atujuna[2], S. Ndwayana[2], E. Krogstad[2], M. Hartmann[3], R. Weinrib[3], L.-G. Bekker[2], A. Minnis[3]
[1]RTI International, Women's Global Health Imperative, Los Angeles, United States, [2]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [3]RTI International, Women's Global Health Imperative, San Francisco, United States
Presenting author email: emontgomery@rti.org

Background: Uptake and sustained adherence to HIV prevention methods is a widely recognized challenge that long-acting injectable and implantable approaches aim to overcome. Youth are a key end-user target population for these methods. Examination of product attributes and preferences that might impact youth's adherence provides an opportunity to inform product development and optimize the potential impact of long-acting HIV prevention methods.
Methods: In Cape Town, 50 in-depth interviews with male (n=18) and female (n=32) youth aged 18-25 were conducted in English or Xhosa by trained social scientists. Interview guides used a socio-ecological framework to explore external factors at the individual, interpersonal, and structural levels influencing uptake of and adherence to prevention technologies as well as preferences for specific product attributes. We purposively selected youth with a variety of HIV prevention product experience including oral PrEP (n=28; 10 female); injectable PrEP (12 female), or the vaginal ring (10 female), to ensure participants could provide opinions rooted in actual experience.
Results: Participants averaged 22 years of age, 97% have sex only with men (14 male, 31 female). Irrespective of previous method-use experience, gender, or sexual orientation, participants expressed preference for injectables and implants, compared to other methods, because of their longer duration, increased discretion and reduced stigma. Systemic absorption ("it stays in the body") resonated with youth. Attributes suggesting dimensions of "invisibility" were favored: e.g. effortless flow through the body for extended periods; pain-free with no side effects; products that would not be noticed or felt by friends, family, partners or community-members nor necessitate disclosure.
Although still favored, implants were perceived as less "invisible" due to concerns that rods would move inside the body or cause visible scarring that would reveal usage. Several youth expressed concerns about gang members attacking an implant-user to cut out, steal and smoke the drug in the implant.
Conclusions: Several attributes of long-acting HIV prevention methods were perceived as important to young South African end-users, and will be used to quantitatively assess relative preferences and attribute trade-offs in a follow-on discrete choice survey. End-user preferences of attributes can be used to inform product development and testing to optimize adherence among youth.

WEPEC0965

A structural driver of HIV risk behaviors among street-based, cis-female sex workers in Baltimore, Maryland, USA: police encounters

S. Sherman[1], J. Park[2], K. Footer[3], B. Silberzahn[3], S. Huettner[4], M. Decker[5], N. Galai[2]
[1]Johns Hopkins Bloomberg School of Public Health, Health Behavior and Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, Department of Health Behavior and Society, Baltimore, United States, [4]Johns Hopkins School of Medicine, Department of Pediatrics, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Department of Population Family and Reproductive Health, Baltimore, United States
Presenting author email: ssherman@jhsph.edu

Background: Three decades into the HIV epidemic, high HIV rates persist among female sex workers (FSWs) worldwide. Structural factors, including law enforcement responses to sex work and engagement with FSWs are increasingly recognized as driving FSWs' HIV vulnerability. We examined correlates of unsafe sex with clients among street-based cis-FSWs (N=250) in Baltimore, Maryland, USA.
Methods: A prospective cohort of cis-FSWs were recruited through targeted time-location sampling throughout Baltimore city from April 2016-January 2017. Participants completed a baseline structured survey administered via CAPI and rapid HIV testing (OraQuick©). We examined frequencies of demographic, drug use and police encounter variables as well as HIV status. We also examined a multivariate model of recent (past 3 months) unprotected vaginal or anal sex with clients. All analyses were conducted using Stata/SE 14.2.
Results: The mean age was 34 years, 67% were non-Hispanic white, 53% did not graduate high school, 66% engaged in daily sex work, 63% were homeless, and 70% were ever incarcerated. 76% reported having injected drugs and 86% reported smoking crack in the past year. 39% reported any unprotected sex with clients (past 3 months) and 6% tested HIV-positive. Women had frequent and varied police encounters in the past year, having experienced: bullying/intimidation (37%); sexual or inappropriate comments on appearance (34%); threatened with a weapon or had one used against them (11%); and physically forced to have vaginal/anal sex with police (2%). Police rarely (40%) explained their reasons for stopping participants. Controlling for relevant demographic variables, recent unprotected vaginal and anal sex with clients was associated with: police officers not explaining their reasons for stopping participants (aOR=2.0,95%CI=1.1-3.7,p=0.027) and recent homelessness (aOR=1.9,95%CI=1.0-3.5,p=0.036).
Conclusions: The study indicates high levels of human rights abuse against FSWs at the hands of police. These abuses were associated with unsafe sexual practices with clients, elevating women's HIV risk. Structural interventions are needed to target police and hold them accountable for their actions.

WEPEC0966

"Test and Treat" among people who inject drugs: results from a demonstration project in Vietnam

M. Kato[1], H.H. Nguyen[2], T.T.T. Dinh[3], L.Q. Pham[3], V.T.T. Nguyen[1], T.H. Tran[4], T.H. Pham[4], N.T. Do[2], N.H. Long[2], Y.-R. Lo[5], G.M. Le[3], D.D. Bui[2], V-HEART Study Group
[1]World Health Organization, Vietnam Country Office, Ha Noi, Vietnam, [2]Vietnam Authority of HIV/AIDS Control, Ministry of Health, Hanoi, Vietnam, [3]Hanoi Medical University, Hanoi, Vietnam, [4]National Institute of Hygiene and Epidemiology, Hanoi, Vietnam, [5]World Health Organization, Regional Office for the Western Pacific, Manila, Philippines
Presenting author email: katom@who.int

Background: In Vietnam, injecting drug use is the leading cause of HIV transmission. Mathematical models suggest periodic HIV testing and counselling (HTC) and initiating antiretroviral therapy (ART) irrespective of CD4 count in people who inject drugs (PWID) can markedly reduce new HIV infection and AIDS deaths. Programme experience with this approach in resource-limited countries had been limited. A demonstration project was conducted in two high-burden provinces to assess feasibility and inform policy development.

Methods: HTC was recommended to PWID every six months and immediate ART, i.e. initiation irrespective of CD4 count, was offered to HIV positive PWID upon consent. PWID were followed for 12 months, and retention, HIV viral load (VL), and risk behaviors were monitored. Retention in care was compared before and after immediate ART was introduced.
Results: From April 2014 to July 2015, 287 HIV positive PWID started immediate ART. The majority (98%) were men, 32% had baseline CD4 count greater than 350 cells/mm^3 and median baseline VL was 4.8 (interquartile range 4.2-5.2) $\log_{10}$ copies/ml. 238 participants (83%) were retained on ART after 12 months (28 died and 21 lost-to-follow-up). Retention was 80.4% and 88.2% among PWID with baseline CD4 counts below and above 350 cells/mm^3, respectively. Current employment, marriage, CD4 counts > 100 cells/mm^3, no history of imprisonment and receiving methadone maintenance were associated with higher retention. Retention in care after 12 months following introduction of immediate ART intervention (83%) was significantly higher than the rate in the preceding period (ART initiated at CD4 count ≤ 350 cells/mm^3) (78%), primarily due to much lower attrition during pre-ART care. Among 222 PWID who had VL tested at 12 months, 205 (92%) achieved viral suppression (< 1000 copies/ml). Viral suppression was 94% and 90% among PWID with baseline CD4 counts below and above 350 cells/mm^3, respectively. There was improvement in consistent condom use and no decline in clean needle use within the 12 month follow-up.
Conclusions: Early ART initiation resulted in improved retention and comparable viral suppression among PWID without increasing self-reported risk behaviors. The results informed the national guidelines development to recommend immediate ART among key populations.

WEPEC0967

HIV transmission from condomless anal intercourse differs by initial ART regimen in HIV-infected MSM

J. Berenguer[1], J. Parrondo[2], R.J. Landovitz[3]
[1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]JParrondo Health, Madrid, Spain, [3]UCLA Center for Clinical AIDS Research & Education, Los Angeles, United States
Presenting author email: jbb4@me.com

Background: INSTI-based cART is associated with rapid viral decay. Sexual transmission of HIV is correlated with viral load. This study explores the impact of INSTI, NNRTI, or PI-based regimens in treatment naïve MSM on the probability of HIV transmission (P-HIV-Tr) using mathematical modeling.
Methods: We used discrete event simulation modeling to estimate P-HIV-Tr during W0-8 and W8-24 after initiation of cART. We modeled 10^6 theoretical patients from each of three naïve treatment studies. P-HIV-Tr was modeled using inputs from recent meta-analyses and from MSM in the START trial. VL decay was modeled from the databases of SINGLE (DTG vs. EFV), SPRING-2 (DTG vs. RAL) and FLAMINGO (DTG vs. r/DRV). We assumed no change in behavior after cART initiation; partner PrEP use and STIs are not considered.
Results: VL data included men from SINGLE (277 EFV, 298 DTG), SPRING-2 (317 RAL; 317 DTG), FLAMINGO (179 r/DRV; 200 DTG). Compared to no treatment, EFV led to 34% and 71% fewer HIV-Tr events during W0-8 and W8-24; DTG led to 42% and 73%. In SPRING-2, DTG led to 55% and 74% fewer events, and RAL led to 55% and 73%. In FLAMINGO, r/DRV led to 53% and 70% fewer events, and DTG led to 62% and 73%. All pair-wise comparisons of HIV-Tr between agents compared in each study, and with no treatment were highly statistically significant in our model (p< .001), with the exception of RAL vs DTG (**See Table**).
Conclusions: VL decay kinetics have important implications for HIV-Tr from ncAI. During W0-8, DTG-based cART reduced HIV-Tr events compared to EFV and r/DRV-based cART. The differential effect was maintained between W8-24. All regimens reduced HIV-Tr substantially compared to no treatment. Regimen selection, and initial use of INSTI's in particular, has the potential to impact HIV horizontal transmission early treatment.

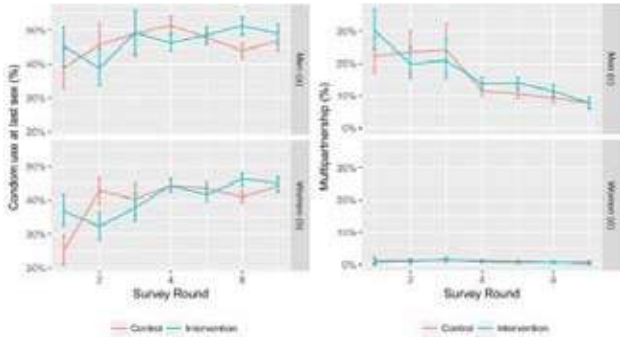
Bordeaux, Inserm, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [2]INSERM, ISPED, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [3]UMR 196 (Paris Descartes IRD), SageSud ERL Inserm 1244, Paris, France, [4]Africa Health Research Institute, Somkhele, South Africa, [5]University College London, Division of Infection and Immunity, London, United Kingdom, [6]University of Southampton, Faculty of Medicine and Faculty of Human, Social and Mathematical Sciences, Southampton, United Kingdom
Presenting author email: n.mcgrath@soton.ac.uk

Background: There are concerns that the implementation of Universal Test and Treat (UTT) could increase population-level sexual risk behaviours. We analysed the effect of universal ART vs CD4-guided ART (start at CD4≥350 then ≥500) on sexual behaviours over time, in the context of the cluster-randomised TasP trial.
Methods: As part of the 6-monthly home-based survey rounds conducted in 11x2 clusters, a sexual behaviour questionnaire was administered to all residents ≥16 years. We used GEE modelling stratified by gender, to compare reported condom use at last sex (CLS), and multi-partnership (≥2 sexual partners) among those sexually-active in the previous six months across trial arms. We tested whether the sexual behaviours changed over time differently in each arm by inclusion of an interaction term between survey round and arm, using the Quasi-likelihood Independence Criterion (QIC) statistic to compare models.
Results: The analysis included 43,106 reports of partnerships (22,974 control, 20,132 intervention) across 7 survey rounds (SR), between 03/2012 and 06/2016. There were no consistent or substantive changes in CLS over time neither by gender nor by arm (fig 1a, 1b); inclusion of an interaction term improved the model fit, reflecting small differences between arms in CLS over time. Less than 1.5% of women reported multiple partnerships at any SR, too few for modelling (fig 1d). The proportion of men reporting multiple partnerships decreased significantly during the study (aOR 0.79, 95% CI 0.75, 0.83), p< 0.001), similarly for each arm (interaction not significant), with overall a small, but significant higher proportion reported in the universal ART arm (13.7%) vs CD4-guided ART (12.1%) (OR=1.15, 95% CI (1.03, 1.27), p=0.02 (fig 1c).



[Figure 1]

Conclusions: There is no evidence of increased unprotected sex with universal ART in this South African population. Continued monitoring of population-level sexual behaviour indicators, in particular multiple partnerships, is needed as the UTT strategy is rolled out.

WEPEC0969

The evolution of HIV prevalence in North-Eastern France and future estimates with increased levels of antiretroviral therapy

Presenting author email: e.jeanmaire@chru-nancy.fr

Background: "Treatment as Prevention" (TasP) aims to reduce new HIV infections through higher enrolment on suppressive antiretroviral therapy (ART). We describe the current epidemic and possible impact of TasP in North-Eastern France.
Methods: Socio-demographic, clinical and laboratory variables were collected in an electronic medical database (Nadis®) during follow-up of HIV-infected patients in North-Eastern France. The numbers of individuals living with HIV in each year were estimated from diagnoses up to that year minus recorded deaths for each gender, transmission mode, country of birth and treatment status.
Results: From 1985 to the present, 6995 individuals were diagnosed with HIV in North-Eastern France, of whom 72% were men; men were significantly older (mean 37.6 versus 34.7 years, p<0.0001); CD4 count at diagnosis did not differ by gender (median 401 for men vs 379 for women). Unprotected sexual intercourse was the main mode of transmission, 87% for women and 89% for men with 61% of transmissions to men through MSM. Women were more likely to be immigrants (45% versus 13%), whereas men were more likely to have been born in France (52% versus 27%). Individuals born in foreign countries ('Other') tended to show CD4 <300 cells/mm^3 at diagnosis (46% versus 31% for those born in France).
Diagnoses were more likely to be correlated with untreated rather than treated prevalence in each group. Although country of birth did not impact dependence of MSM diagnoses on estimated prevalence (ρ=0.23 diagnoses/year per untreated MSM living with HIV, p<0.0001), heterosexual diagnoses were better correlated with prevalence within country groups; male (untreated) prevalence to female diagnoses: ρ=0.29 (born in France), ρ=0.73 (Other); female prevalence to male diagnoses: ρ=0.36 (France), ρ=0.19 (Other). Using these transmission rates, mathematical modelling estimated that enrolling ≥35% of untreated individuals per year onto ART was required to reduce future HIV diagnoses. Enrolling 75% of untreated individuals per year would decrease diagnoses ten-fold by 2021; prevalence in 2021 would be 10% lower than with 35% ART enrollment.
Conclusions: Increased enrolment of individuals on ART can substantially impact numbers of new HIV infections in this region of France.

WEPEC0970

HIV exposure and infant feeding mode impacts on T cell vaccine responses and memory maturation in early life

T. Nundalall
University of Cape Town, Pathology, Division of Immunology, Cape Town, South Africa
Presenting author email: shana.nundalall@uct.ac.za

Background: Advances in prevention of mother-to-child transmission (PMTCT) of HIV-1 have prevented HIV infections in almost 97% of infants born to HIV-infected mothers. Of concern is the effect of increasing numbers of HIV-exposed, uninfected infants (HEU) on higher rates of infection-related morbidity and altered responses to standard childhood vaccines. This study addresses the effect of HIV exposure and feeding modality on T-cell responsiveness to acellular Pertussis (aP) vaccination, memory maturation and cell activation.
Methods: Infants were recruited immediately after birth. Blood was collected at birth, day 4, weeks 7, 15 and 36 and 250ul was stimulated with and without Pertussis (aP) antigen in a 12-hour whole blood assay. Cells were then fixed and cryopreserved for banked analyis by multiparameter flow cytometry. An 11 colour panel was used to stain for memory maturation, activation and polyfunction: CD3+CD4+CD8+CD45RA+CD27+HLA-DR+Ki67+ cell antigens and expression of IFNγ, IL-2 and TNFα cytokines. Data analysis was completed using Flow.Jo V9, GraphPad prism V6, Pestle 1.7 and Spice V5.33.
Results: There was a greater frequency of early (CD45RA-CD27+) and late (CD45RA-CD27-) differentiated CD4+/CD8+ memory cells in HEU infants in the first week of life relative to HU infant controls. Additionally, HEU infants had lower frequencies of aP-specific CD8+, any cytokine expressing T-cells at week 7, but higher frequencies of single expressing aP-specific CD8+ IL-2 and IFNγ cells at week 15 compared to HU infants. There was also an added impact of formula feeding (FF), where HEU FF infants had higher levels of CD8+ activation and memory differentiation but lower levels of CD4 memory differentiation at week 7 compared to breast fed HEU infants. These infants also possessed higher aP-specific CD8+ cells expressing overall cytokines and single TNFα expressing CD8+ T-cell at week 7 and week 36.
Conclusions: Collectively, our data suggest that exposure to maternal HIV impacts T-cell ontogeny early in life and that cytokine responsiveness to antigen can be altered by feeding practise. Changes due to HIV exposure appear transient, as by week 36, there are no differences between HEU and HU infants. However, FF causes long-term cell activation and higher aP vaccine responses.

WEPEC0971

Immunogenicity and safety of 4 prime-boost combinations of HIV vaccine candidates (MVA HIV-B; LIPO-5; GTU-MultiHIV B) in healthy volunteers: ANRS/INSERM VRI01 phase I/II randomized trial

J.-D. Lelièvre[1,2,3], C. Lacabaratz[1,2,3], A. Wiedemann[1,2,3], C. Bauduin[1,4,5], L. Hardel[1,4,5], V. Rieux[1,2,6], O. Launay[7,8], F. Lucht[9,10], I. Poizot-Martin[11], M. Surenaud[1,2], A. Diallo[6], K. Reijonen[12], R. Thiebaut[1,4,5], Y. Levy[1,2,13], L. Richert[1,4,5]
[1]VRI, Creteil, France, [2]INSERM, U 955, Creteil, France, [3]UPEC, Creteil, France, [4]INSERM, U 1219, Bordeaux, France, [5]ISPED, Bordeaux, France, [6]ANRS, Paris, France, [7]APHP, Hopital Cochin, Paris, France, [8]INSERM F-CRIN, I-REVAC, Paris, France, [9]CHU Saint Etienne, Hôpital Nord, Saint Etienne, France, [10]INSERM F-CRIN, Paris, France, [11]CHU Marseille, Marseille, France, [12]FIT Biotech, Tampere, Finland, [13]APHP, CHU Henri Mondor, Creteil, France
Presenting author email: jean-daniel.lelievre@aphp.fr

Background: Heterologous prime-boost strategies are considered among the most promising HIV vaccine strategies. We hypothesized that the priming component is important for induction of strong immune responses and that an innovative trial design allows for rapid selection of promising strategies.
Methods: ANRS/INSERM VRI01 is an open-label randomized multicenter trial of 3 candidate vaccines administered as prime or boost: MVA HIV-B (coding for Gag, Pol, Nef); LIPO-5 (lipopeptides from Gag, Pol, Nef); and GTU$^{\Diamond}$-MultiHIV B (DNA coding for Rev, Nef, Tat, Gag, gp160 clade B). Healthy volunteers were randomized 1:1:1:1 to four parallel groups: G1 (M2L2): MVA HIV-B (Wks 0, 8) then LIPO-5 (Wks 20, 28); G2 (L2M2): LIPO-5 (Wks 0, 8) then MVA HIV-B (Wks 20, 28); G3 (D3L2): GTU$^{\Diamond}$-MultiHIV B (Wks 0, 4, 12) then LIPO-5 (Wks 20, 28); G4 (D3M2): GTU$^{\Diamond}$-MultiHIV B (Wks 0, 4, 12) then MVA HIV-B (Wks 20, 28). Vaccine responders were defined by a positive IFN-γ-ELISPOT to ≥1 HIV peptide pool measured 2 Wks after each injection. Co-primary endpoints were safety and the proportion of IFN-γ-ELISPOT responders at Wk30, aiming to discard strategies with ≤ 50% responders.
Results: Nighty-two volunteers were randomized (mean age 30 years, 54% male) and received ≥1 injection. Four, 0, 6 and 1 SAEs possibly related to vaccination were reported in G1, G2, G3, G4, respectively, including one myelitis possibly related to LIPO-5.
Frequency of IFN-γ-ELISPOT responders and median SFC/10^6 PBMC among responders post-prime were: 59% and 328 SFC (G1 post-prime MVA); 5% and 323 SFC (G2 post-prime LIPO-5), 0% (pooled G3+4 post-prime GTU$^{\Diamond}$-MultiHIV B). Following boosting, at Wk30 (primary endpoint, ITT analysis) these responses were 33% and 250 SFC (M2L2); 43% and 528 SFC (L2M2), 0% (D3L2); and 67% (P=0. 06 for superiority to 50% threshold) and 324 SFC (D3M2). In Wk30 per protocol analyses D3M2 was significantly above the predefined minimum immunogenicity level: 74% responders (P=0.02 for superiority to 50% threshold).
Conclusions: This optimized trial design helped to identify MVAHIV-B as a safe and immunogenic T-cell vaccine given as either prime or boost in various combinations. GTU$^{\Diamond}$-MultiHIVB/MVA HIV-B met the pre-defined minimum immunogenicity criterion to pursue clinical development.

Presenting author email: christine.durier@inserm.fr

Background: The ANRS COV1-COHVAC cohort aims to describe the long-term safety of preventive HIV-vaccines administered in 17 phase I and II clinical trials to healthy volunteers. COHVAC stopped prematurely at the end of September 2016 due to the absence of safety signal.
Methods: 488/496 volunteers were included in the cohort and 355 agreed to participate in prospective follow-up. Data were collected retrospectively from first vaccine administration and prospectively (one visit/year). At each visit, health events evoking neurological, ophthalmological and immunological disorders (any grade) and other grade 3/4 events were collected; questionnaire about behaviors was self-administered and HIV ELISA was done. Age and sex-adjusted mortality and incidence rates (SMR, SIR) were studied in relation to the French population.
Results: Mean total follow-up after first vaccination was 10.1 years (0.1 to 24.3). As of November 2016, targeted events occurred in 56% of participants. Among events of interest, 27% of volunteers had neurological impairment (mostly sciatica, migraine), 14% had an ophthalmologic event (cataract, glaucoma) and 1.6% an autoimmune disease. Among cancers, breast cancer was the most frequent (n=6), however its incidence in COHVAC was not different from that of women in the French population (SIR=1.47, IC95%=[0.54, 3.20]; p=0.45). The mortality of women in COHVAC was not different (SMR=0.73; p=0.41) while that of men was significantly lower (SMR=0.22; p=0.0003) from the French population. At last follow-up visit, 19 volunteers still presented vaccine induced seropositivity. All of them had received rgp160 in median 23 years (17 to 24) previously. Participants were mostly in couple, aged 58 in median at last follow-up and had mostly high social level and involvement. The main motivations of participation in the trials were altruism, proximity to an HIV-infected person and the future generation. Analysis of self-administered questionnaires (Year 0 to Y3) revealed a stable and low percentage (men: 7%, women: 1%) declaring risky sexual practices.
Conclusions: No long-term safety alert was identified during follow-up. Vaccine induced seropositivity may persist for more than 23 years after vaccination. Participation in vaccine trials did not imply increased risk-taking with regard to HIV infection.

WEPEC0973

ADCC and neutralizing antibody responses in HIV-1-infected children

S. Dispinseri[1], M. Tolazzi[1], M. Cavarelli[2], A.M. Plebani[3], G. Scarlatti[1]
[1]San Raffaele Scientific Institute, Division of Immunology, Tranplantation and Infecyious Diseases, Milan, Italy, [2]CEA, Division of Immuno-Virology, Paris, France, [3]Foundation IRCCS cà Granda Ospedale Maggiore Policlinico Milan, Pediatric Emergency Unit, Milan, Italy
Presenting author email: dispinseri.stefania@hsr.it

Background: RV144 vaccine trial showed a modest protection against HIV-1 infection and an inverse correlation with antibody dependent cellular cytotoxicity (ADCC) activity. To inform vaccine development we studied in HIV-infected children ADCC, the development of neutralizing antibodies (NAbs) against autologous and heterologous viruses as well as of antibody reactivity to Env epitopes and childhood vaccination antigens.
Methods: Fifteen vertically infected Italian children were included in the study. Seven developed a severe immune suppression (CDC3) before two years of age and six thereafter. The remaining two children were not classified as CDC3 for at least five years. Plasma were tested for the presence of autologous NAbs in a PBMC-based assay to several primary isolates obtained during disease follow up. Heterologous Nabs were revealed by TZMbl assay to 4 Tier 2 PSVs with plasma at years three to five if autologous Nabs were observed. ADCC was detected by Grantoxilux assay using gp120BAL-coated target cells. Seroreactivity to HIV-1 gp41, autologous gp120 V3-loop peptides and tetanus and diphtheria toxoid by ELISA.
Results: Newborns displayed antibodies, of maternal origins, to an HIV-1 gp41 epitope but did not neutralize the transmitted virus. NAbs developed usually within 1 year of age to the early virus concomitantly with anti-V3-loop antibodies. Ten of 15 children developed Nabs against one or more autologous isolate during the follow-up, which persisted throughout disease but showed emergence of escape variants. All children except one developed heterologous NAbs to at least one Tier 2 virus of 4 tested. All children except one developed ADCC during follow-up within 2 years of age, which persisted thereafter. In general, the antibody titers to tetanus and diphtheria antigens were higher during the first 18 months of age and eventually dropped thereafter. These data suggest that HIV-1 infected children can mount immunodominant antibody responses.
Conclusions: Autologous NAbs develop usually within 1 year of age to the transmitted virus, persist throughout disease but induced viral escape. Heterologous neutralization against at least one Tier 2 virus as well as ADCC activity were common in children within 2 years.

WEPEC0974

HIV population-level adaptation can rapidly diminish the impact of a partially effective vaccine

K. Peebles[1,2], P.T. Edlefsen[3], M. Rolland[4,5], J.T. Murphy[6], G.S. Gottlieb[1,7], N. Abernethy[8,9], J.I. Mullins[6,7,10], J.E. Mittler[6], S.M. Goodreau[11,12], J.T. Herbeck[1]

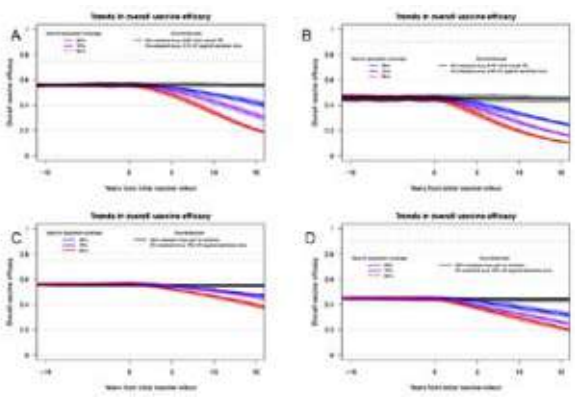
Presenting author email: kpeebles@uw.edu

Background: Development of an HIV vaccine is considered essential to ending the HIV/AIDS pandemic. However, vaccines can result in the emergence and spread of vaccine-resistant strains, a consequence that is largely ignored in previous mathematical modeling of the potential impact of an HIV vaccine. Analyses of breakthrough infections in the marginally successful HIV vaccine trial, RV144, identified HIV genotypes with differential rates of transmission in vaccine and placebo recipients. We therefore hypothesized that, for HIV vaccination programs based on partially effective vaccines similar to RV144, HIV adaptation will diminish vaccine impact.
Methods: We developed two individual-based stochastic models of HIV dynamics, one calibrated to the South African epidemic and one calibrated to US men who have sex with men (MSM). We simulated large-scale vaccination programs and, critically, included HIV strain diversity with respect to vaccine response. We varied population vaccine coverage (50%, 70%, or 90%), vaccine efficacy (75% or 90%), and the proportion of vaccine-resistant viruses (25% or 50%).



[Figure 1. Trends in overall vaccine efficacy (VE) from heterosexual (panels A and B) and MSM (panels C and D) models. Panels depict results from scenarios with an initial resistant strain proportion of 25% (panels A and C) and 50% (panels B and D) and sensitive virus VE of 75% (panels A and C) and 90% (panels B and D)]

Results: Population-level viral adaptation was observed in all model scenarios, leading to decreased overall vaccine efficacy (Figure 1) and substantially fewer infections averted by vaccination. Compared to scenarios without viral evolution, 7%-25% fewer cumulative infections are averted within ten years of vaccine roll-out among MSM, and 10%-39% fewer cumulative infections are averted in South Africa. Translating this to the epidemic in South Africa, this represents up to 600,000 new infections within 10 years of vaccine rollout that are due solely to HIV adaptation.
Conclusions: These findings suggest that approaches to HIV vaccine development, program implementation, and epidemic modeling may require attention to potential viral evolutionary responses to vaccination.

WEPEC0975

Engaging underserved key populatios in Kyrgyzstan: what works?

D. Madybaeva
NGO 'AIDS Foundation East West in the Kyrgyzstan', Research, Bishkek, Kyrgyzstan
Presenting author email: dinara.madybaeva@afew.kg

Background: From 2010 to 2014, HIV incidence almost doubled in Kyrgyzstan (Republican AIDS Center, 2015). Experts recognize that one of the possible reasons for the growth of HIV is limited coverage of vulnerable groups. The aim of this study is to investigate the factors influencing the motivation of members of key populations to participate in HIV prevention programs.
Methods: Main method was - semi-structure in depth interview (N=105).
Additional method -interview "face to face" (N=345). Total- 450 representatives of 3 key populations have been studied (IDU, SW, LGBTIQ), aged 18 and >, having experience of participation in HIV prevention programs, 10 outreach workers and 4 managers of non-governmental partners organization.
Data collection has been carried with the help of trained interviewers, representatives of the communities.
Results: Available services satisfy the respondents partly because they do not completely cover all the needs and requirements of respondents, the exception of educational materials. Providing medicines and medical equipment (syringes, condoms), complex medical examination, legal support , employment, recovery of documents of permanent residence are very popular services, but in most cases are not being on desired and sufficient level.
Outreach workers are the main source of information about prevention programs, HIV and TB infection and about medical organizations (87%-IDU, 61%-SW and 51%-LGBT) and the medical equipment syringes, condoms and lubricants (81%-IDU, 68%-LGBT, 84%- SW). They enjoy sufficient authority and trust among community members (more than 80% per groups). SW and LGBT noted that outreach workers need to more often contact (78%-LGBT, 54%-SW, 29%-IDU). It is crucial that they are representatives of the community, because they exactly know all the details.
Conclusions: Outreach work must be valued as key tool to reach and encourage members of key populations to participate in HIV prevention programs. Motivating outreach workers will increase the quality of their work, resulting in higher coverage of vulnerable groups, and leading to more effective HIV prevention programs. Factors as fear of being identified, harassment by law enforcement officials, the mismatch between demand and supply of inaccessible services were identified as the main barriers to receiving preventive services.

Background: Antiretroviral pre-exposure prophylaxis (PrEP) effectively prevents HIV when taken daily. However, there are limited ways to objectively monitor adherence in the clinic. Urine is highly correlated with plasma tenofovir (TFV) levels. Urine TFV levels >1000ng/mL demonstrate recent (last 1-2 days) adherence, levels 10-1000 demonstrate inconsistent dosing in the previous week, and levels < 10 indicate no TFV in the previous week. In this study, we determined the sensitivity of urine TFV levels with dried blood spot (DBS) values.
Methods: Fifty-three paired urine-DBS specimens were obtained from 53 patients enrolled in a PrEP adherence study at Washington University in St. Louis (USA) between May and August 2016. Sensitivity, specificity, and positive and negative predictive values (PPV, NPV) were calculated for urine TFV >1000ng/mL, using DBS as a gold standard with DBS TFV-disphosphate (DP) ≥700 (4 or more doses/week) and ≥1250 (7 or more doses/week) fmol/punch and DBS emtricitabine-triphosphate (FTC-TP) levels (dosing within 48 hours).
Results: Patient median age was 29 years, 92% were male, 53% white, 91% MSM, and median time on PrEP was 11 months. 92% of patients had urine TFV >1000ng/mL, 2% had 10-1000ng/mL, and 6% had < 10ng/mL. Majority (94%) had ≥700 fmol/punch DBS TFV-DP. Urine TFV levels >1000ng/mL demonstrated sensitivity of 94% (95% CI: 83-99) and PPV was 96% (95% CI: 86-100) for ≥700 fmol/punch and 100% (95% CI: 90-100) and 71% (95% CI: 57-83) for ≥1250 fmol/punch. Urine TFV´s specificity and NPV were not reported for DBS given high levels of adherence among the patient sample. Urine TFV >1000ng/mL had a sensitivity of 98% (95% CI: 89-100) and PPV was 96% (95% CI: 86-100) for detectable DBS FTC-TP. Urine TFV specificity and NPV were 60% (95% CI: 15-95) and 75% (95% CI: 19-99) for DBS FTC-TP.
Conclusions: Clinic settings would benefit from rapid and objective PrEP monitoring. Urine TFV levels had high sensitivity and PPV compared to DBS TDF-DP and FTC-TP in a sample of very adherent PrEP patients. Both measures contribute to a growing toolbox of adherence biomarkers to improve PrEP care by identifying patients in need of intensified counseling.

Venue-based HIV-testing: an effective screening strategy for high-risk populations in Lima, Peru

L.-T. Allan-Blitz[1], C. Herrera[2], G.M. Calvo[3], C.F. Caceres[3], J.D. Klausner[4,5], K.A. Konda[4,5,6]
[1]University of California, David Geffen School of Medicine, Los Angeles, United States, [2]University of California, Department of Medicine, Los Angeles, United States, [3]Universidad Peruana Cayetano Heredia, Unit of Health, Sexuality and Human Development, and Laboratory of Sexual Health, Lima, Peru, [4]University of California, Division of Infectious Diseases, Department of Medicine, Los Angeles, United States, [5]University of California, Department of Epidemiology, Fielding School of Public Health, Los Angeles, United States, [6]Universidad Peruana Cayetano Heredia, Unit of Health, Sexuality and Human Development and Laboratory of Sexual Health, Lima, Peru
Presenting author email: carlos.caceres@upch.pe

Background: Improving access to and uptake of HIV testing is an important strategy for HIV prevention. Currently, only a small proportion of high-risk men who have sex with men (MSM) and transgender women are screened for HIV in accordance with WHO recommendations in Lima, Peru. Venue-based sampling methods may improve identification of new HIV infections.
Methods: We offered onsite HIV testing at several locations popular among MSM and transgender women communities in Lima. A survey of risk-behavior, HIV testing history, and testing preferences was also administered. Participants who refused testing completed a survey inquiring reasons for refusal and received coupons for free HIV testing at HIV testing centers. All fieldwork was completed in 2016. We used a multivariable Poisson regression to create a model calculating Prevalence Ratios (PRs) for factors associated with HIV infection.
Results: We tested 303 participants for HIV, 29% were transgender women. Only 26% reported testing every six months in accordance with WHO recommendations, and 19% had never been tested for HIV previously. Of those tested, 90% reported they would test for HIV more frequently if testing were offered in alternative venues; with the majority (56%) expressing a preference for public places (e.g. parks, plazas). We identified 69 new cases of HIV infection 23% (95% CI 18-28%). Prevalent HIV infection was independently associated with reporting recent receipt of money in exchange for sex (PR=1.12; 95% CI 1.02-1.23), sex with a partner of unknown serostatus (PR=1.19; 95% CI 1.10-1.29), and a versatile sex role for anal sex (PR=1.15; 95% CI 1.04-1.26) when compared to insertive alone; the model was also adjusted for number of male sex partners. Of the 282 participants who refused onsite testing, the most common reasons for refusal were insufficient time (35%), and preference for a more discrete location (27%). Participation was 59% overall ranging from 33% at disco and a sauna to 89% at a street-based venue and a small video-club.
Conclusions: A high proportion of MSM and transgender women remain inadequately screened for HIV. Venue-based testing can improve screening uptake among under-screened high-risk populations in Lima Peru, and is effective for case finding.

WEPEC0978

Choice, use and persistence with three delivery forms (tablets, ring, injections) among young African women

A. van der Straten[1,2], C. Helen[1], K. Agot[3], K. Ahmed[4], R. Weinrib[1], K. Manenzhe[4], F. Owino[3], J. Schwartz[5], A. Minnis[1,6]
[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]University of California, Medicine, San Francisco, United States, [3]Impact Research and Development Organization, Kisumu, Kenya, [4]Setshaba Research Center, Shoshanguve, South Africa, [5]CONRAD/Eastern Virginia Medical School, Arlington, United States, [6]University of Berkeley, School of Public Health, Berkekey, United States
Presenting author email: ariane@rti.org

Background: Preventing HIV and unintended pregnancies are key health priorities in young women. To understand attributes of future Multipurpose Prevention Technologies associated with adherence, we evaluated three placebo delivery forms in a cohort of Kenyan and South African women.
Methods: HIV-negative, sexually active, non-pregnant women aged 18-30 were enrolled and randomized to use each placebo product (daily oral tablets, monthly injections and monthly vaginal rings) for one month (N=277). At their Month-3 visit (M3), participants chose one product to use for two additional months. We assessed the following components of adherence during the usage period: Initiation/compliance with two injections of 1ml saline in the gluteus. For tablets/rings we assessed regimen initiation and completion (last dose/ring in situ at return visit) by direct observation at the clinic, and execution (correct use) by questionnaire. Non-persistence was measured by the proportion of women who switched product at their Month-4 visit (M4). We examined demographic and behavioral correlates of non-persistence by multivariable logistic regression.
Results: Ninety percent (N=249) reached M3, and 89% (N=247) completed the study (M5). Mean age was 23.2 years, 49% were Kenyan and 51% South African. At M3 all chose a product (64% injections, 21% tablets, 15% ring) and >99% initiated use. At M4, >80% completed their tablet/ring regimen. For each product, initiation, execution and completion levels were similar at M4 and M5. Fifty women (20%) were non-persistent. The top reasons for switching were: wanting to gain experience with another product, preference for another mode of administration, and perceived side effects. Only one mild ring-related adverse event (vaginal pruritis) was documented during the usage period. Choosing injections at M3 (versus ring) was associated with a substantial reduction in the odds of non-persistence in South Africa only (AOR=0.2, p=0.012).
Conclusions: All participants agreed to choose and use a placebo product, a majority appeared adherent and all products were safe. Injections were chosen most often, used with perfect compliance, and in South Africa, were associated with higher persistence. Larger multisite studies with active products are needed to further inform the tolerability of and persistence with these delivery forms across settings.

Young African American MSMs speak out: recommendations for enhancing retention in PrEP care for US implementation science programs in the Deep South

T. Arnold[1], L. Mena[1], B. Buck[1], P. Chan[2], M. Monger[1], C. Gomillia[1], J. Agee[1], I. Jones[1], G. Thomas[2], A. Nunn[2]
[1]University of Mississippi Medical Center, Jackson, United States, [2]Brown University, Providence, United States
Presenting author email: tarnold@umc.edu

Background: Young African American men who have sex with men (YAAMSM) in the Deep South are retained in PrEP care at disproportionately lower rates than their White counterparts. Little is understood about how to effectively retain young African American MSM in PrEP care in real-world settings.
Methods: We conducted a two-phase qualitative study that included key informant interviews and two focus groups. We used grounded theory and purposeful sampling strategy to guide this study. Participants included YAAMSM enrolled in a real-world PrEP implementation science program in Jackson, MS. Interviews and focus groups with 43 YAAMSM explored factors that enable or pose barriers for retaining YAAMSM in PrEP care, including social, structural, clinical and behavioral factors. We solicited normative recommendations for developing interventions focused on enhancing retention in PrEP care for YAAMSM. We concluded recruitment when saturation was met and common themes emerged.
Results: Structural factors such as cost and access to financial assistance for medications and clinical services undermined retention in PrEP care. Social factors such as stigma associated with being perceived as gay or HIV positive posed barriers to retention in care. Behavioral factors including changing sexual risk behaviors and low perceived HIV risk prompted some participants to discontinue PrEP. Clinical factors including both perceived and actual side effects prompted some participants to discontinue PrEP. Participants commonly solicited "PreP wrap-around services," suggesting that PrEP navigators could offer important support services for enhancing retention in care for YAAMSM. Participants also recommended extending clinic hours, offering transportation support services and behavioral counseling, providing text message reminders about clinical appointments, providing culturally competent care and reducing copayments for medications and related clinical services.
Conclusions: Social, structural, behavioral and clinical factors contribute to retention in PrEP care for young YAAMSM. PrEP navigators who help patients overcome these challenges may enhance retention in care for YAAMSM enrolled in PrEP programs in the Deep South of the US.

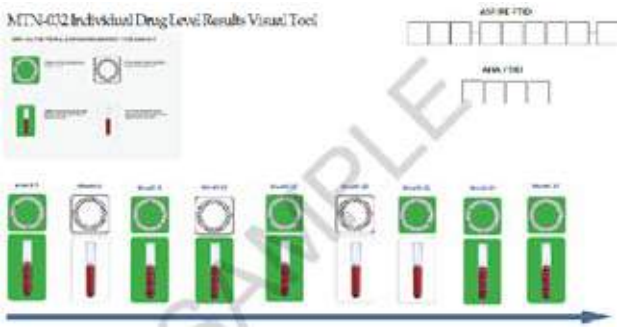
Reasons for non-adherence to the dapivirine vaginal ring during MTN-020/ASPIRE: results of the MTN-032/AHA study

E. Montgomery[1], J. Stadler[2], S. Naidoo[3], A. Katz[4], M. Chitukuta[5], L. Mansoor[6], J. Etima[7], K. Reddy[2], C. Zimba[8], M. Garcia[9], L. Soto-Torres[10]
[1]RTI International, Women's Global Health Imperative, Los Angeles, United States, [2]Wits Reproductive Health and HIV Research Institute, Johannesburg, South Africa, [3]Medical Research Council of South Africa, Durban, South Africa, [4]RTI International, Women's Global Health Imperative, San Francisco, United States, [5]UZ-UCSF Collaborative Research Programme, Harare, Zimbabwe, [6]CAPRISA, Durban, South Africa, [7]MU-JHU, Kampala, Uganda, [8]UNC Project, Lilongwe CRS, Lilongwe, Malawi, [9]FHI 360, Durham, United States, [10]DAIDS, Bethesda, United States
Presenting author email: emontgomery@rti.org

Background: MTN-020/ASPIRE and IPM-027/Ring Study recently proved the dapivirine vaginal ring was safe and effective with consistent use. To optimize the impact of this promising female-initiated prevention method, adherence barriers must be understood and addressed. MTN-032 explored women's ring use challenges through open-ended discussion of their objective adherence data.
Methods: Former ASPIRE participants were stratified by age group (18-21; 22-45) and randomly selected at 7 sites in Malawi, South Africa, Uganda and Zimbabwe, 12-17 months after trial exit. Young women were intentionally over-sampled because they were less adherent and not protected by the ring in ASPIRE. Using in-depth interviews or focus groups, ring use challenges were explored using structured guides and visual tools including individual-level depictions of dapivirine levels detected in plasma and returned rings.



[abstractpic2]

Results: 187 participants aged 19-48 were enrolled; 37% were 18-21 at ASPIRE enrollment. Although many (24%) had concordant plasma and residual ring results suggesting consistent use at every visit measured, most women (73%) had results suggesting inconsistent use throughout ASPIRE. Visual tools elicited participant descriptions of many instances of non-adherence, including removals ranging from short-term (for sex or bathing), to multiday (menses) to multi-week (often with reinsertion 1-3 days before the next visit). Reasons for non-use included influence from peers and communities mistrusting researchers (particularly foreign); worries about ring causing cancer or infertility; non-disclosure to partners and partner objections; and experience of discomfort or side effects. Young women's non-adherence was most commonly attributed (by themselves and older women) to being less "serious" about the future, HIV prevention and the study (and motivated predominantly by benefits); more fearful of childbearing/fertility-related consequences; and to having less control over their relationships.
Conclusions: When presented with objective adherence data, participants provided explanations for ring non-adherence during ASPIRE. These data can be used to pre-emptively mitigate adherence challenges in future ring studies/activities, e.g. MTN-025/HOPE.

Very high adherence to HIV PrEP over one year confirmed by four measures in an open-label demonstration project (PRELUDE) in NSW, Australia

S.J. Vaccher[1], M. Marzinke[2], A.E. Grulich[3], C. Ooi[4], A. Carr[5], B.G. Haire[3], C. Selvey[6], D.J. Templeton[3,7], M. Holt[8], L. Crooks[8,9], I. Zablotska[3], PrELUDE Study Team
[1]Kirby Institute, University of New South Wales, Kensington, Australia, [2]Johns Hopkins University, Baltimore, United States, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]Western Sydney Sexual Health Centre, Parramatta, Australia, [5]St Vincent's Hospital, Sydney, Australia, [6]NSW Ministry of Health, North Sydney, Australia, [7]RPA Sexual Health and Central Clinical School, The University of Sydney, Sydney, Australia, [8]Centre for Social Research in Health, University of New South Wales, Sydney, Australia, [9]Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Sydney, Australia
Presenting author email: svaccher@kirby.unsw.edu.au

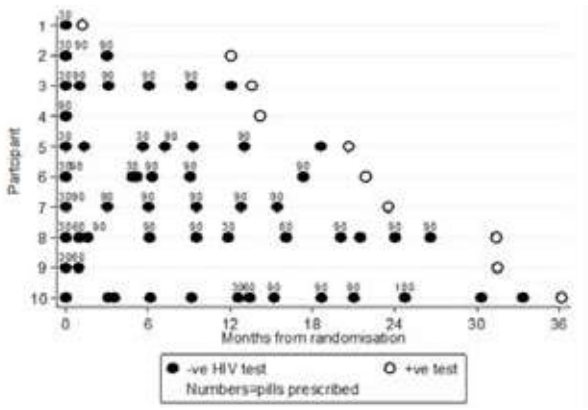
Background: The efficacy of HIV pre-exposure prophylaxis (PrEP) depends upon adherence.
Daily PrEP adherence was assessed over 12 months using two biological measures and two measures of self-report (SR). Drug concentrations in plasma and peripheral blood mononuclear cells (PBMC), and patient SR to clinicians and via online surveys were evaluated. Concordance between SR and biological measures was assessed.
Methods: PRELUDE is an open-label PrEP demonstration project of 327 high-HIV risk, predominantly (96%) gay/bisexual men in New South Wales (NSW), Australia. Participants self-reported the number of tablets taken in the previous week to clinicians, and the last three months via online surveys. SR adherence required daily dosing, as prescribed. Blood was collected from 108 consecutively presenting participants 1, 6 and 12 months post-PrEP initiation. Liquid chromatography-mass spectrometry was used for drug quantification. Biological adherence was defined as plasma tenofovir (TFV) ≥40.0 ng/mL and PBMC tenofovir-diphosphate (TFV-DP) ≥16.8 fmol/10^6 cells, indicative of daily dosing in the three days and one week prior to blood collection, respectively. Results were analysed using descriptive statistics and ANOVAs with Bonferroni's post-hoc correction. Kappa tests were used to determine measurement agreement.
Results: Amongst participants with blood samples from all three time points (n=87), mean adherence was 92% (95% confidence interval 88 - 95%) across all measures (Table 1). Median (interquartile range) PBMC TFV-DP concentrations significantly decreased between months 1 (100 (64 - 176) fmol/10^6 cells) and 6 (61 (40 - 94) fmol/10^6 cells; p<0.001), and months 6 and 12 (51 (29 - 74) fmol/10^6 cells); p=0.01), but not in plasma or SR data (p>0.05). Concordance between PBMC TFV-DP and plasma TFV, survey SR, and clinician SR was 87%, 92%, and 87% respectively.
Conclusions: Very high levels of daily adherence to PrEP amongst early adopters were confirmed using four different measures, although there was a decrease in PBMC TFV-DP over time. Strong concordance between blood drug concentrations and SR data suggests that SR may be a suitable measure of adherence in clinical practice. To ensure effective ongoing PrEP use, longer-term observation is required.

WEPEC0982

Adherence intentions, long-term adherence and HIV acquisition among PrEP users in the PROUD open-label randomised control trial of PrEP in England

M. Gafos[1], E. White[1], D. White[2], A. Clarke[3], V. Apea[4], E. Brodnicki[1], N. Mackie[5], A. Sullivan[6], G. Schembri[7], C. Lacey[8], R. Horne[9], D. Dunn[1], S. McCormack[1]
[1]MRC Clinical Trials Unit at UCL, Institute of Clinical Trials & Methodology, London, United Kingdom, [2]Hea, Birmingam, United Kingdom, [3]Roy, Claude Nichol Centre, Brighton, United Kingdom, [4]Barts Health NHS Trust, Ambrose King Centre, London, United Kingdom, [5]Imperial College NHS Foundation Trust, St Mary's Hospital, London, United Kingdom, [6]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [7]Central Manchester University Hospitals NHS Foundation Trust, Manchester Centre for Sexual Health, Manchester, United Kingdom, [8]York Hospitals NHS Foundation Trust, York, United Kingdom, [9]UCL, School of Pharmacy, London, United Kingdom
Presenting author email: m.gafos@ucl.ac.uk

Background: PROUD demonstrated an 86% reduction in HIV-acquisition among participants offered PrEP in the first year of follow-up, with high levels of adherence. Relatively little is known about long-term PrEP adherence. We report adherence intentions, long-term adherence and HIV-acquisition among PrEP users in PROUD.
Methods: We tabulated data from the 'end-of-study-questionnaire' (EoS), which asked about adherence intentions. We calculated the medication possession ratio (MPR) as the number of pills prescribed, divided by number of days elapsed since PrEP initiation. We describe sero-conversions among participants who initiated PrEP.
Results: PROUD ran from Nov12 to Nov16, enrolled 544 participants and accumulated 1,253.3 person years of follow-up. Of 310 participants who completed the EoS, 86% aimed to use PrEP daily during the study, reducing to 61% wanting to use it daily after the trial. 98% thought their adherence was ‚good enough' during periods of risk. 36% reported intentionally interrupting/stopping PrEP. Of 481 participants who initiated PrEP, 327(68%) received a prescription within the last 6-months of the study. The MPR from PrEP initiation to end of first-year of use was high at 92%, reducing cumulatively to 82% and 76% from initiation to end of years 2 and 3. We observed 10 HIV infections among participants who initiated PrEP. One participant acquired HIV before baseline, four stopped attending clinic without providing a reason, two stopped attending clinic after reporting changing to on-demand dosing or stopping PrEP, and three attended clinic but did not collect PrEP (Figure 1).



[Figure 1. HIV tests and PrEP prescriptions for the 10 participants who acquired HIV after starting PrEP]

Conclusions: In this study, which recommended daily-dosing, the majority of participants intended to use PrEP daily, over a third reported intentionally interrupting PrEP and a third stopped using PrEP within 4-years of initiation. When attending clinic, adherence was high but declined over time. The seroconversion data highlights the urgent need for interventions to help people know when to cycle on and off PrEP.

WEPEC0983

Making health a priority: the influence of family structure and household composition on youth's PrEP use in Cape Town, South Africa

M. Atujuna[1], A. Minnis[2], M. Hartmann[2], E. Krogstad[3], S.B. Ndwayana[3], S. Orourke[2], L.-G. Bekker[3], E.T. Montgomery[2]
[1]Desmond Tutu HIV Centre, University of Cape Town, Medicine, Cape Town, South Africa, [2]Research Triangle Institute International, San Francisco, United States, [3]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa
Presenting author email: millicent.atujuna@hiv-research.org.za

Background: PrEP constitutes a key HIV prevention tool, yet PrEP initiation and adherence is shaped by numerous factors, including an individual's ability to prioritize health behaviors. Existing literature describes the effects of HIV prevention and treatment behaviors on family structure and household composition; however, the inverse is not well elucidated. For youth, in particular, family/household factors could have important effects on PrEP use. We examine these relationships using qualitative data from iPrevent, an end-user study designed to explore factors that optimize PrEP adherence among youth in South Africa.
Methods: Fifty former PrEP trial participants (32 females: 10 vaginal ring, 12 injectable, 10 tablet; and 18 males: all oral PrEP), from informal communities in Cape Town completed in-depth interviews if they were HIV negative, sexually active, and aged 18-24 years. We explored how household environment and family support affected sexual and reproductive health (SRH) decision-making, partner disclosure regarding PrEP use and sustained PrEP use through trial participation. We analyzed transcripts following a framework analysis approach.
Results: Two broad types of families emerged: a loosely-knit family, where intimate discussions around sex, SRH and PrEP use were absent; and a close-knit family where these topics were openly discussed. These two family types defined and shaped how youth navigated health issues, generally, including PrEP use. Family

support positively affected youth's abilities to view health as a priority and hence adopt protection against HIV. Youth from loosely-knit families where support was absent found it difficult to use PreP, and were more likely to seek partner support, including disclosure of PrEP use, to partners as a substitute. While this enabled them to engage in HIV prevention, their partners made key decisions around sex. Youth from close-knit families typically disclosed PrEP use to their families, and not partners, and were accorded familial support. They described greater autonomy in sexual decision-making.
Conclusions: Youth are a unique key population and the manner in which they navigate PrEP use is critical to prevention. We found support to be fundamental to PrEP use; however, family support empowered youth more than partner support, highlighting its important role in adoption of HIV prevention behaviors.

WEPEC0984

Changes in ART adherence among Rwandan youth following a trauma-informed cognitive behavioral intervention

G. Donenberg[1], M. Cohen[2], C. Ingabire[3], M. Fabri[4], A. Kendall[5], E. Remera[6], E. Emerson[5], J. Tuyishime[7], S. Nsanzimana[8], The KIP Study Group
[1]University of Illinois at Chicago, Public Health and Medicine, Chicago, United States, [2]Women's Equity in Access to Care & Treatment, Boston, United States, [3]Kigali Imbereheza Project, Kigali, United States, [4]Women's Equity in Access to Care & Treatment, Chinle, United States, [5]University of Illinois at Chicago, Community Outreach Intervention Projects, Chicago, United States, [6]Rwanda Biomedical Centre, HIV, Kigali, Rwanda, [7]Women's Equity in Access to Care and Treatment, Kigali, Rwanda, [8]Rwanda Bio-Medical Center/Ministry of Health, Kigali, Rwanda
Presenting author email: gerid@uic.edu

Background: Like most of sub-Saharan Africa, Rwandan youth are at the epicenter of the AIDS epidemic accounting for 40% of infections. ART adherence is a global health priority, as poor adherence may lead to virus resistant strains, limited future treatment options, and continued new transmissions. High levels of adherence have been reported among adults, but studies of adolescents suggest youth are less adherent, achieve less viral suppression, and have larger viral rebound than adults. Evidenced-based interventions for youth are sorely needed to increase ART adherence. Recognizing the role of the genocide in Rwanda's HIV epidemic, this study evaluated the efficacy of an adherence-enhanced, trauma-informed cognitive behavioral intervention (TI-CBTe) to improve adherence.
Methods: Participants were 360 14-21 year old HIV-infected Rwandan males (49%) and females in care at one of the two HIV clinics in Kigali. Youth were recruited by research staff and guardian consent and youth assent were obtained. Youth completed baseline assessments and were randomly assigned to TI-CBTe or the clinic's standard of care (SOC). Six sessions, each two hours, were delivered once a week by young adult peers. Youth completed 6-month follow-up assessments and reported on their adherence to ART in the past 30 days on a scale from 1 to 6 and their symptoms of trauma.
Results: Analyses compared youth who received TI-CBTe versus SOC on self-reported ART adherence and trauma at 6-month follow up. Groups did not significantly differ at 6-months in adherence for the full sample, but boys who received TI-CBTe reported significantly greater improvement in adherence than boys in the SOC, F (1, 109) = 4.194, p = .043. Similarly, trauma symptoms were not associated with change in adherence overall, but for youth who reported higher trauma at baseline, those who received TI-CBTe reported greater improvement than youth in the SOC, F (1, 36) = 4.925, p = .033.
Conclusions: Findings suggest that a culturally-adapted adherence-enhanced cognitive behavioral intervention can improve ART adherence for Rwandan males and youth with elevated trauma symptoms. Future research should examine whether these positive changes are sustained beyond 6-months and how to enhance treatment efficacy for females.

Seeking casual sex partners via the internet, Bangkok MSM cohort study, 2006-2016

W. Wimonsate[1], S. Pattanasin[1], K. Panchroen[1], A. Sriporn[1], S. Yafant[1], C. Ungsedhapand[1], A. Chitwarakorn[2], M.C. Thigpen[1,3], A. Hickey[1,3], T.H. Holtz[1,3]
[1]Thailand MOPH - U.S. CDC Collaboration, HIV/STD Research Program, Nonthaburi, Thailand, [2]Thailand Ministry of Public Health, Department of Disease Control and Prevention, Nonthaburi, Thailand, [3]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States
Presenting author email: tkh3@cdc.gov

Background: The internet has changed how men who have sex with men (MSM) seek sex partners. We investigated factors associated with meeting casual sex partners via the internet among participants of the Bangkok MSM Cohort Study (BMCS).
Methods: We enrolled Bangkok MSM aged ≥18 years into BMCS between April 2006-November 2010. Participants were followed every four months for up to five years. We collected demographic information at enrollment and behavioral data at every visit using audio computer-assisted self-interview. Participants were asked about casual sex partners and how they met these partners during the past four months. We used Generalized Estimating Equations (GEE), accounting for repeated measures correlations within participants, to model factors associated with meeting casual sex partners via the internet.
Results: From April 2006-February 2016, we enrolled 1,744 MSM in BMCS; 1,590 (91%) had at least one follow-up visit. At enrollment, 37% (638/1,744) reported having casual sex partners and having met partners via the internet. Among 1,375 MSM who reported having casual sex partners in at least two visits, seeking partners via the internet was significantly higher among MSM who—at the time of enrollment—were full-time or part-time students (adjusted Odds Ratio [aOR] 1.3, 95% Confidence Interval [CI] 1.1-1.6) and self-identified as non-heterosexual (aOR 6.2, 95% CI 2.8-13.5). At each individual follow-up visit, seeking partners via the internet was more common among participants who reported age 18-29 years at initial enrollment (aOR 1.8, 95% CI 1.5-2.2), recreational drugs use (aOR 1.3, 95% CI 1.04-1.5), erectile dysfunction drug use (aOR 1.6, 95% CI 1.3-1.9), having group sex (aOR 1.9, 95% CI 1.6-2.2), and inconsistent condom use with male casual partners (aOR 1.2, 95% CI 1.02-1.3), when compared with the rest of the cohort. Using the GEE also found that at each four months the proportion of men meeting sex partners via the internet increased by 1.1% (aOR 1.011, 95% CI 1.008-1.014).
Conclusions: About one third of participants in BMCS had casual sex partners and met these partners via the internet. This behavior increased significantly over time. Meeting casual partners via the internet was associated with high-risk behaviors for HIV acquisition

WEPEC0986

Is it necessary to validate key population hotspots on a regular basis? An experience from Burundi

D. Gashobotse[1], V. Ranebennur[2], M. Hamdallah[2], D. Mpinganzima[3], A. Bizoza[3], L. Tiffany[4], H. Mahler[2], T. Lillie[4]
[1]FHI 360, LINKAGES Project, Bujumbura, Burundi, [2]FHI 360, LINKAGES Project, Washington, United States, [3]CADSAO, Bujumbura, Burundi, [4]FHI 360, Global Health and Nutrition, Washington DC, United States
Presenting author email: tlillie@fhi360.org

Background: LINKAGES is a USAID- and PEPFAR-funded project that is improving access and links to HIV prevention, care, and treatment services for key populations (KPs). Accurate information on hotspots where KPs congregate is critical to focusing outreach and prevention efforts. A hotspot list for Burundi was available from a 2013 PLACE study, a methodology that identifies priority prevention areas but that cannot be conducted frequently due to cost and time requirements. LINKAGES Burundi conducted a rapid programmatic mapping exercise to systematically update and validate the hotspots identified by PLACE 2013 and to identify new ones to facilitate rapid program start-up.
Methods: The project employed 20 female sex workers (FSWs) and 10 men who have sex with men (MSM) to visit all hotspots and conduct interviews among primary (KPs) and secondary (pimps, taxi drivers, vendors, shop owners) key informants in five districts in Burundi from October to November 2016. A structured tool was used to collect information on the size of the population in each hotspot, peak time and days of operation, KPs' use of social media and mobile phones, services available, mobility of the population, and new sites where KPs congregate.
Results: Of 830 (724 FSW and 96128 MSM) sites identified by PLACE in 2013, only 413 (50%) (363 FSW and 50 MSM) were still active. While conducting this validation, we also identified 436 (388 FSW and 48 MSM) new sites that emerged since 2013, for a total of 849 active sites, 59% of which were in the capital province of Bujumbura. The most prevalent type of hotspot was bar/night club (73%) followed by lodge/hotel (10%).
Conclusions: Fifty percent of KP hotspot sites from 2013 were no longer active in 2016—an indication that repeated programmatic mapping is essential for program planning with highly mobile KPs. The results of our validation exercise enable effective distribution of resources, microplanning by local NGOs working with peer outreach workers, and rapid scale-up of programs.

WEPEC0987

Intention toward HIV testing among men who have sex with men in Taiwan: a survey-based on health belief model

S.T. Huang, J.R. Huang, J.S. Chu, H.Y. Lo
Taiwan Centers for Disease Control, Taipei, Taiwan, Province of China
Presenting author email: sthuang@cdc.gov.tw

Background: The 90-90-90 targets might eliminate the HIV epidemic in Taiwan. However, 25% of people living with HIV don't know their HIV status currently. Men who have sex with men (MSM) are the most affected population and account for the majority of newly diagnosed HIV infections. We conducted the survey which was based on Health Belief Model (HBM), a health behavior change theory, to understand the health beliefs to HIV testing among MSM in Taiwan.
Methods: An anonymous survey was conducted between April and May, 2016. We recruited participants from eight MSM community health centers located in different regions. Intention toward HIV testing, demographic characteristics, sex-related behaviors, and HBM constructs, of MSM were collected via questionnaires. We performed multi-variate logistic regression to identify the factors associated with testing intention among MSM.
Results: A total of 1,393 responses were included for final analysis. The high testing intention group consisted of 911 (65.4%) MSM. Logistic regression showed that MSM who were 25-34 years-old (AOR=1.52), had anal intercourse experience (AOR=2.09), had more than two casual sexual partners per year (AOR=1.65), experienced chem-sex (AOR=3.88), used geosocial apps (AOR=1.55), received HIV testing before (AOR=3.81), were more likely to have high testing intention in the next year. In contrast, MSM who used condoms during last anal sex (AOR=0.68) had lower testing intention.
MSM perceiving high (AOR=2.16) and moderate (AOR=1.95) risk of HIV had higher intention toward HIV testing than MSM with low perceived risk. High (AOR=1.68) and moderate (AOR=1.59) perceived benefits, high (AOR=2.15) and moderate (AOR=4.26) self-efficacy were associated with higher testing intention. MSM with high perceived severity had higher HIV testing intention (AOR=1.66) than those with low perceived severity, but moderate perceived severity were not significantly associated with testing intention.
Conclusions: Several demographic characteristics related to testing intention of MSM were identified from this study. We could design targeted HIV testing campaign to those MSM more effectively. Besides, we also find out various facilitators to testing intention. This findings could help us to implement HIV testing programs and increase the uptake of HIV testing among MSM in Taiwan. Therefore, the 90-90-90 targets could be achieved.

WEPEC0988

Barriers to HIV-testing and linkage to care among Latino youth in Atlanta

A.F. Camacho-Gonzalez[1,2], A. Murray[3], K. Drumhiller[3], L. Rusiecki[4], J. Hood[1], S.A. Hussen[2,5,6], V.D. Cantos[6], S. Gillespie[7], M. Sutton[3], R. Chakraborty[1,2]
[1]Emory University School of Medicine, Department of Pediatrics, Division of Pediatric Infectious Diseases, Atlanta, United States, [2]Grady Health Systems, Ponce Family and Youth Clinic, Atlanta, United States, [3]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [4]Emory University Rollins School of Public Health, Atlanta, United States, [5]Emory University Rollins School of Public Health, Hubert Department of Global Health, Atlanta, United States, [6]Emory University School of Medicine, Department of Medicine, Division of Infectious Diseases, Atlanta, United States, [7]Emory University School of Medicine, Department of Pediatrics, Atlanta, United States
Presenting author email: sophia.ahmed.hussen@emory.edu

Background: Latinos account for 24% of new HIV diagnosis in the US with a significant increase in incidence between 2010-2014 among young gay and bisexual men. Georgia's Latino population grew by 96% from 2000 to 2010, with the biggest increase seen in youth. Despite an overall increase in testing and HIV prevention efforts, HIV-infected Latinos progress to AIDS faster than any other US racial or ethnic group. Understanding barriers for testing and linkage to care among Latino youth (LY) is therefore increasingly important.
Methods: We conducted quantitative surveys and five exploratory qualitative focus groups with LY, ages 18-24 years, from the Atlanta Metropolitan Statistical Area. Audio Computer-Assisted Self-Interviewing surveys gauged HIV testing preferences, and risk factors for avoiding testing and/or medical care. Using computer-assisted thematic analyses, we examined focus group responses addressing barriers to HIV testing, treatment, and counseling.
Results: Of 29 study participants, 52% were male, 58% were from Mexico, 59% had ≤ high school education; 79% lived with their guardian; mean age was 19.6 years (SD: 1.74 years). Eighty-nine percent disliked the idea of venue testing, 69% preferred the oral swab as a method of HIV testing, and 69% perceived that HIV-positive LY defer entering medical care despite knowing their status. Reasons cited included fear of medical treatment (59%), depression, denial and fear of discrimination (55% each), and being unaware of available services and treatment venues (35%). Three themes were identified as barriers for testing:
1) fear of rejection,
2) the need to normalize testing, and;
3) stigma.
Treatment affordability and existential attitude were identified as potential barriers for treatment among HIV-positive youth. Upon providing the results of an HIV positive test, the participants emphasized the need to receive information about their disease and the next steps to follow.
Conclusions: Venue testing may not be the best strategy for increasing HIV screening of at-risk LY. Normalizing testing and structuring an empathetic disclosure process that addresses potential misconceptions and fears, and offers a clear pathway to successful treatment is essential to improving linkage to care among LY.

WEPEC0989

Quantifying the ability to capture transgender identities in existing data systems

K. Watkins[1], T. Pham[1], L. Roberts[1], R. Grimes[2], M. Mcneese[1], B. Yang[1], C. Hallmark[1]
[1]City of Houston, Houston Health Department, Houston, United States, [2]University of Texas Health Science Center at Houston, Division of General Internal Medicine, Houston, United States
Presenting author email: richard.m.grimes@uth.tmc.edu

Background: Although transgender individuals are recognized as a population disproportionately impacted by HIV, quantifying the number of transgender people living with HIV is difficult due to underreporting of gender identity. In 2016, the U.S. Health Resources and Services Administration mandated reporting of gender identity. The Houston Health Department (HHD) initiated a project to investigate data systems' ability to document transgender identification.
Methods: Data on 30 transgender persons of color were extracted from the most comprehensive HIV surveillance database in the Houston, Texas area. The HHD further investigated these individuals for transgender identity in five care systems and one public access database, all of which are used for identifying, locating, and re-linking out-of-care HIV-positive persons into care.
Results: Only three care systems captured transgender identity in pre-defined fields. Three care systems and one public access database only had a field for birth sex; consequently, it often captured birth sex and current gender. Discrepant pairs were assumed to be transgender. Three care systems could record transgender identity in a notes section. Given a total of six data systems and 30 individuals, a total of 180 outcomes were possible. Given variations in data system purpose, individuals were not necessarily found (65 outcomes) in every system. There were 72 outcomes where only birth sex was recorded in a respective data system compared to 39 outcomes where transgender identity was discovered. Four outcomes were inconclusive. Given the multiple fields and/or notes sections per data system for potential transgender identification, including potential aliases, a total of 28 fields and/or notes sections needed to be searched per person to properly assign a transgender outcome. Even then, transgender status could be concluded only 22% of the time.
Conclusions: The current schema of these data systems inadequately identifies transgender persons, limiting the ability to serve this population. These record searches are resource intensive yet necessary to inform HIV prevention programs of a potentially transgender, HIV-positive individual needing critical assistance. More education is needed to clearly define these fields for accurate data collection. Additional cultural training among healthcare workers may encourage transgender persons to disclose their identity, improving documentation and data quality.

WEPEC0990

Consistency in multiple estimates of the population size for persons who inject drugs (PWID) in Hai Phong, Viet Nam

D. Des Jarlais[1], J. Feelemyer[1], K. Arasteh[1], D. Thi Huong[2], K. Thi Hai Oanh[3], P. Minh Khue[2], J.P. Moles[4], H. Thi Giang[2], N. Thi Tuyet Thanh[3], V.H. Vinh[5], R. Vallo[4], C. Quillet[4], D. Rapoud[4], L. Michel[6], T. Hammett[7], D. Laureillard[4,8], N. Nagot[4]
[1]Icahn School of Medicine at Mount Sinai, Baron Edmond de Rothschild Chemical Dependency Institute, New York, United States, [2]Hai Phong University of Medicine and Pharmacy, Haiphong, Vietnam, [3]Supporting Community Development Initiatives, Hanoi, Vietnam, [4]University of Montpellier, Inserm U 1058, Etablissement Français du Sang, Montpellier, France, [5]Viet Tiep Hospital, Department of Infectious and Tropical Diseases, Haiphong, Vietnam, [6]French Red Cross, CESP/Inserm U 1018, Pierre Nicole Center, Paris, France, [7]Consultant to Icahn School of Medicine at Mount Sinai, New York, United States, [8]Caremeau University Hospital, Infectious Diseases Department, Nimes, France
Presenting author email: ddesjarlais@chpnet.org

Background: Good estimates of the sizes of "key populations" are critical for ending concentrated HIV epidemics, particularly in resource-limited settings where efficient allocation of resources is necessary. We conducted two capture/recapture studies to estimate the size of the persons who inject drugs (PWID) population in Haiphong, Vietnam.
Methods: In Sept. 2014, we conducted a respondent driven sampling (RDS) survey of 603 PWID in Haiphong utilizing standard RDS procedures. A fingerprint reader was used to identify unique participants and prevent multiple enrollment. Current injecting drug use was verified through examination of injection marks and urinalysis. In Oct. 2016, 600 uniquely marked lighters were distributed to PWID in drug use "hotspots" in Haiphong. Beginning one week later, we conducted another RDS survey,
N = 1385, following standard RDS procedures. A fingerprint reader was again used to identify unique participants and match 2014 RDS participants with 2016 participants. Questions were added to the 2016 survey to identify PWID who had received lighters. The 2014 RDS survey and the distribution of lighters to PWID served as two separate "captures," and the 2016 RDS survey served as the "recapture" for both "captures." UNAIDS Technical Guidelines capture/recapture formulae were used for estimating population size.
Results: A total of 1385 participants were included in the 2016 RDS "recapture" survey. They were predominantly male (94%), average age was 39 (SD 9); 100% injected heroin (80% daily) and 47% used non-injected methamphetamine. HIV prevalence was 30%, HCV prevalence 70%.
144/603 participants in the 2014 RDS study were "recaptured" in the 2016 RDS study, giving a population estimate of 5799 (95% CI 5016-6581) for the 2014 RDS-2016 RDS capture/recapture. 152/600 PWID who had received lighters were "recaptured" in the 2016 RDS study, giving a population estimate of 5467 (95% CI 4758-6176) for the lighter/2016 RDS capture/recapture study.
Conclusions: Even with a two-year period between RDS surveys and a week between the lighter distribution/RDS survey, the two capture/recapture studies show great consistency in the estimated PWID population size for Haiphong. The lighter recapture method is an inexpensive method for estimating population size when done in conjunction with an RDS survey.

WEPEC0991

Using risk assessment to better identify female sex workers living with HIV in Luanda, Angola

G. Cristino[1], P. Celma[1], A. Lambert[1], M. Goggin-Kehm[1], M.L. Futado[2], C. Coelho da Silva[3], J. Cardao[4], A. Diaz[5]
[1]FHI 360, Washington, United States, [2]Instituto Nacional de Luta contra a SIDA, Luanda, Angola, [3]Cuidados da Infancia, Luanda, Angola, [4]USAID, Luanda, Angola, [5]FHI 360, Luanda, Angola
Presenting author email: mgogginkehm@fhi360.org

Background: In October 2015, the USAID- and PEPFAR-funded LINKAGES project began providing HIV services to female sex workers (FSW) in Luanda, Angola. Early testing data yielded an HIV-positive rate of only 2.91% (57/1956) between November 2015 and May 2016. Limited data are available for FSWs, though one region reported an HIV prevalence rate of 7.2%. As Angola faces periodic stock outs of HIV test kits, HIV programs needed to prioritize HIV testing for those most at risk of being infected with HIV. Risk assessment tools exist nationally but are fully not utilized.
Methods: To better identify FSWs living with HIV, LINKAGES Angola designed a 17-question risk assessment tool that was administered by FSW peer educators with their FSW service beneficiaries from June to December 2016. Risk scores were calculated on three of the 17 questions focusing on age, number of clients per day, and use of condoms. Peers prioritized HIV testing referrals to higher scoring FSWs. All other FSWs, regardless of having had answered the risk assessment or having had obtained a high risk score, were offered HIV testing.
Results: Out of 5,856 FSWs, 5,740 (98%) accepted to take the risk assessment 676 (12%) scored high risk, 2696 (47%) medium, and 2368 (41%) scored lower Twenty-five percent (1433/5740) accepted an HIV test. HIV results by risk group showed HIV rates of 7.61% (21/276), 5.51% (42/762), and 5.82% (23/395), respectively. The overall HIV rate was 6% (86/1,433), an increase of 3.09% compared to the previous period (2.91%) when the risk assessment was not used.
Conclusions: Applying an HIV risk assessment in a resource limited context with FSWs, where little or no data are available, and where there is no culture of asking questions related to risk, LINKAGES Angola was able to improve overall HIV positivity yield within its FSW program. Further analysis of risk data also showed higher rates of HIV in higher risk group. The data showing similar HIV rates for medium- and low-risk FSWs demonstrates the need to further analyze the risk questions to develop a more accurate scoring system that correlates score with elevated risk of HIV infection in FSWs in Angola.

WEPEC0992

Assessing risk for HIV infection among adolescent girls in South Africa: a validation of the VOICE risk score

D. Giovenco[1], J. Hughes[2], E. Piwowar-Manning[3], C. MacPhail[4], K. Kahn[5], R. Wagner[5], A. Pettifor[1]
[1]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [2]University of Washington, Seattle, United States, [3]Johns Hopkins University, Baltimore, United States, [4]University of New England, Armidale, Australia, [5]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa
Presenting author email: dgiovenco@unc.edu

Background: Adolescent girls and young women in sub-Saharan Africa face a disproportionately high risk for HIV infection, accounting for 75% of young people living with HIV. As a result, novel biomedical prevention interventions, such as pre-exposure prophylaxis (PrEP), are being implemented among women at highest risk for infection. In attempts to quantify risk, Balkus et al. (2016) developed and validated a risk assessment tool from the VOICE study and two additional PrEP trials (HPTN-035 and FEM-PrEP) among African women (Mdn age=24-26 years). With implementation trials currently underway investigating PrEP efficacy among adolescent girls under 18-years, this research was aimed at validating the risk score for use in adolescent populations.
Methods: Data from HPTN-068, a 3-year randomized controlled trial to assess the impact of a cash transfer, conditioned on school attendance, on HIV incidence among rural South African adolescent girls (Mdn age=15 years), was utilized for this analysis. The risk score, which incorporates factors such as age, married/living with a partner, partner providing financial or material support, partner having other partners, alcohol use, and HSV2 serostatus, was calculated at baseline for participants who completed at least 1-year of follow-up, with possible values ranging from 0-10. The risk score excluded detection of curable STIs. A proportional hazards model was used in the analysis of baseline risk score and incident HIV infection.
Results: Among the 2318 HPTN-068 participants included in the analysis, there were 105 HIV seroconversions during 4986 person-years of follow-up (2.11% incidence). 74% of the sample received a risk score of 5 (range=2-9). Scores ≥5 identified 79% of incident infections from 88% of the sample, compared to the VOICE sample in which scores ≥5 identified 91% of incident infections from only 64% of participants. With each unit of increase in risk score, participants experienced a greater risk for HIV infection (Hazard Ratio=1.332, 95% CI 1.01 -1.75, p=.041).
Conclusions: Findings revealed that the risk score had limited variability in the HPTN-068 study population, but may still be predictive of HIV incidence. To further inform HIV prevention efforts among adolescents, research is needed to better understand how the unique developmental milestones of adolescence might influence risk.

WEPEC0993

PoCT (point of care) HIV/STI testing at after-hours SOPV (sex on premises venues) theme parties

A. Mullens[1], G. Driver[2], J. Lemoire[2], K. Daken[3]
[1]University of Southern Queensland, Psychology & Counselling, Resilient Regions, Ipswich, Australia, [2]Queensland Positive People, RAPID Clinic, Brisbane, Australia, [3]University of Southern Queensland, Ipswich, Australia
Presenting author email: amy.mullens@usq.edu.au

Background: Sexual 'theme parties' have become more popular among MSM (men who have sex with men) over time. They are typically attended by more 'sexually adventurous' MSM and associated with alcohol/other drug use. These factors may

constitute heightened risks for HIV/STI transmission. Operating a regular, rapid HIV/STI testing service during theme parties (within a high-risk setting), represents a novel approach to health promotion and more accessible testing. This research sought to establish 'proof of concept', and evaluate the uptake and feasibility/acceptability of routine HIV/STI testing for MSM in a novel outreach environment.
Methods: Weekly HIV/STI PoCT (Alere, UniGold) was offered by trained peer-testers on Friday and Saturday nights from 9pm-midnight, in a private room at the venue. Patrons requesting tests were asked to complete an evaluation survey after testing. Verbal consent was provided and ethics approval was obtained for the evaluation. The testing processes were conducted per TGA guidelines.
Results: To date, 122 MSM have participated in PoCT (majority identified as ‚gay'; average age 36, range: 18-66) over a six month period (indicating 4 reactive syphilis tests; nil reactive HIV); recruited via information within the venue and social media). Salient findings indicate: All (100%) participants reportedly felt comfortable with the community outreach testing; 96% reported peer-led testing would increase the frequency of testing; 20% ‚would not have had a test' if the service did not exist; and 34% reported to have 'never had' an HIV test. Further qualitative comments reflecting acceptability included: accessibility; feeling comfortable; easy and quick testing—conducted by friendly and 'relatable' staff members. Secondary analyses regarding socio-demographic features associated with testing patterns, substance use, sexual activity and harm reduction strategies will also be highlighted.
Conclusions: This project has demonstrated acceptability and feasibility within a key MSM sub-group—regarding novel health promotion delivered by a peer-based PLHIV organisation. Implications for further health promotion efforts and future research with sexually adventurous MSM will be discussed in light of main findings. Rapid PoCT technologies foster opportunistic HIV/STI testing uptake amongst MSM in a high-risk setting, and create opportunities for qualitative follow-up; the research will inform the lens through which drug use among gay men and other MSM is contextualised within a sexual context.

WEPEC0994

HIV testing promotion and follow-up with MSM through online dating apps in Cambod

P. Sophat[1], H. Saly[1], R. Channara[1], K. Sothy[2], S. Ratana[1], L. Vanna Seng[3]
[1]HIV/AID Prevention, Phnom Penh, Cambodia, [2]Prevention Innovation in MSM and TG, Phnom Penh, Cambodia, [3]NCHADS, Prevention Innovation in MSM and TG, Phnom Penh, Cambodia
Presenting author email: psophat@fhi360.org

Background: HIV prevalence in Cambodia of men who have sex with men (MSM) is estimated at 2.3% but this low prevalence belies substantial high risk and potentially high HIV incidence in the future. Despite numerous diverse peer outreach and web-based interventions, a majority of MSM report low intervention exposure, thus necessitating more innovative communication channels and behavior change strategies to promote HIV testing.
Methods: We conducted an assessment of on-line application (app) usage among MSM in Cambodia. One MSM-oriented app reported 23,654 unique users, with users in Cambodia accessing the app on average 7.3 times a day and spending 75 minutes each day on the application. Based on this information, we initiated on-line informal counseling or "chats" on two apps with individuals interested in hearing more about HIV, their risk behaviors, and opportunities for HIV testing. Those who expressed interest were referred to community clinics nearby.
Results: Between October-December 2016, 420 MSM were engaged in on-line counseling via the two apps. Among these, 68 (16.19%) MSM were successfully referred to rapid HIV testing at a community clinic. Ten (14.7%) were found to be HIV reactive through Determine rapid test. 7 of these individuals (70%) were successfully referred to confirmatory HIV testing, and all were initiated on ARV treatment within 3 months. During the same period, traditional outreach and peer-drive interventions in the same community reached 1471 MSM, with 945 (64%) accepting an HIV test and 15 (1.6%) of them screening HIV+.
Conclusions: The intervention strongly indicated that MSM-oriented apps can and should be used to reach high-risk and hard-to-reach MSM, in this case reaching a higher percentage of HIV+ MSM than traditional outreach. The results further showed that active case management is needed to ensure that clients are not lost to follow up along the HIV cascade, particularly for confirmatory HIV testing.

WEPEC0995

Social network approaches to locating undiagnosed HIV cases are more effective than RDS recruitment or outreach models

P. Smyrnov[1], L. Williams[2], A. Korobchuk[3], Y. Sazonova[1], G. Nikolopoulos[4,5], B. Skaathun[6], J. Schneider[7], S.R. Friedman[8]
[1]Alliance for Public Health, Kyiv, Ukraine, [2]National Development and Research Institutes, New York, United States, [3]Alliance for Public Health, Odessa, Ukraine, [4]National Development and Research Institutes, TRIP Site, Athens, Athens, Greece, [5]University of Cyprus, Medical School, Nicosia, Cyprus, [6]University of Chicago, Chicago, United States, [7]University of Chicago, Department of Medicine and Center for HIV Elimination, Chicago, United States, [8]National Development and Research Institutes, Institute for Infectious Diseases Research, New York, United States
Presenting author email: friedman@ndri.org

Background: Diagnosing HIV cases is essential for providing health care and for Treatment as Prevention. We hypothesize that social network recruitment is superior both to community outreach testing and respondent driven sampling at case finding in Odessa, Ukraine.
Methods: We compared three studies. Odessa TRIP used network sampling to recruit extended risk networks of Recently-infected and longer-term infected (LTs) seeds in 2013-2016. (Participants were classified as "Recents" if Limiting Antigen Avidity (LAg) assay, past testing history, and viral load data indicated they had been infected in the last 6 months. Other HIV+ participants were classified as LTs). IBBS2013 used respondent driven sampling to recruit people who inject drugs (PWID). SYREX provides data on HIV among PWID tested at community outreach sites, 2013-2016.
Outcomes (percent testing positive who self-reported as previously undiagnosed) were compared between TRIP arms; TRIP vs. IBBS2013; and TRIP vs. SYREX.
Results: TRIP networks contained 1270 men, 344 (21%) women; IBBS2013 328 men, 72 (18%) women; SYREX 9669 men, 4267 (31%) women. TRIP networks had a higher yield of undiagnosed positives (14.6%) than IBBS2013 (5.0%) or SYREX (2.4%); ORs 3.24 (CI 2.06, 5.12) vs. IBBS2013, 7.02 (CI 5.91, 8.34) vs. SYREX. Findings remained significant with odds ratios high when these comparisons were conducted separately by sex and when PWID in TRIP networks were compared with SYREX and IBBS2013. Within TRIP, Recents' networks contained higher rates of undiagnosed positives (14.6%) than LTs' networks (9.3%); OR 1.66 (CI 1.10, 2.49); this remained true among PWID subsets. Both TRIP subsets located significantly higher rates of undiagnosed positives than either IBBS2013 or SYREX. In TRIP Recents' networks, women (20.1%) were more likely to be undiagnosed positives than men (13.3%); OR 1.64 (CI 1.12, 2.40). 36.4% of PWID women in Recents' networks were newly diagnosed positives.
Conclusions: TRIP's network recruiting techniques, and paying particular attention to the networks of the recently infected, should become part of standard case finding and treatment as prevention practice. They may be particularly important for finding undiagnosed women. Research is needed on whether these findings hold in other social and epidemiologic contexts.

WEPEC0996

Screening for PrEP eligibility during rapid HIV testing in high-risk neighborhoods in Philadelphia

M. Felsher[1], A. Roth[1], A. Martinez-Donate[1], E. Gracely[2], Z. Szep[3]
[1]Drexel University, Community Health Prevention, Philadelphia, United States, [2]Drexel University, Epidemiology and Biostatistics, Philadelphia, United States, [3]Drexel University College of Medicine, Division of Infectious Diseases and HIV Medicine, Philadelphia, United States
Presenting author email: maf385@drexel.edu

Background: Daily, oral pre-exposure prophylaxis (PrEP) has been shown to reduce the risk of HIV in diverse populations. While PrEP implementation studies are emerging, few have focused on screening high-risk populations for PrEP eligibility during community-based rapid HIV testing.
Methods: HIV negative individuals, 18 years of age or older, were recruited from 4 community-based rapid HIV testing sites in Philadelphia. We developed a 6-question PrEP eligibility screening tool based on the 2014 CDC PrEP clinical guidelines. The tool was incorporated into a cross-sectional study assessing PrEP knowledge and attitudes among individuals undergoing community-based rapid HIV testing. Descriptive statistics were used to assess PrEP knowledge, eligibility, and intention to use PrEP.
Results: The sample (n=168) is 68.5% male, with race/ethnicity Black (45.2%), Hispanic/Latino (34.5%) and White (15.5%), with mean age of 42. Among participants, 60.7% were heterosexual, 17.9% were men who have sex with men (MSM), 14.9% reported injection drug use, and 11.3% engaged in transactional sex. The majority (74.4%) of participants had not heard of PrEP. Overall, 31% of our total sample was eligible for PrEP: 34.3% of all sexually active heterosexual men and women, 56.7% of MSM, and 64% of persons who inject drugs (PWID). 37.9% of

heterosexual men in comparison to 27.8% of heterosexual women were eligible for PrEP, but this was not statistically significant (p=.30). 64% of PWID were eligible for PrEP in comparison to 25.2% of non-PWID participants (p<0.01). 56.7% of MSM were eligible compared to 25.4% non MSM (p<0.01). Among participants eligible for PrEP, 63.5% indicated that they were somewhat or extremely likely to use PrEP in the future.
Conclusions: We identified a diverse at-risk population through community-based HIV testing and counseling. Most participants were unaware of PrEP, but those who were eligible expressed intention to use PrEP in the future. Having rapid HIV testers screen for PrEP eligibility and educate clients about PrEP is an effective way to increase PrEP awareness and could increase PrEP uptake in diverse, high-risk populations.

WEPEC0997

Reaching the unreachable: the effectiveness of social media networks to recruit hidden MSM populations to an HIV prevention intervention in Kenya

H. Nyongesa-Malava[1,2], N. Njuguna[3], B. Ogwang[3], J. Odada[4], C. Agunga[3], C. Akolo[5,6], R. Wilcher[6], H. Mahler[7]
[1]FHI360, Public Health, Nakuru, Kenya, [2]Ministry of Health, CASCO, Nakuru, Kenya, [3]FHI360, Public Health, Nairobi, Kenya, [4]NYDESO, Public Health, Nakuru, Kenya, [5]FHI360, Public Health, Washington DC, United States, [6]FHI360, Washington DC, United States, [7]FHI360, Global Health, Washington DC, United States
Presenting author email: hmahler@fhi360.org

Background: Despite having significantly higher risk of HIV infection than the general population, men who have sex with men (MSM) in Kenya remain a largely hidden population because of stigmatization and criminalization. Previous interventions driven by health workers exhibited modest success in recruitment and retention of MSM in HIV programs within Nakuru county. The USAID- and PEPFAR-funded LINKAGES program, implemented in Kenya by FHI 360, aimed to accelerate recruitment of MSM to a peer-led comprehensive HIV prevention program using social media.
Methods: Through partnership with a local peer-led community-based organization with preexisting social networks in Nakuru county, we recruited volunteers for peer education training via outreach on a private Facebook page used exclusively by MSM. Volunteers underwent a five-day peer education training on HIV prevention and risk reduction strategies. Peer educators reached out to their peers primarily via WhatsApp with HIV education messages, provided condoms and lubricants, and referred them for HIV testing and screening for sexually transmitted infections (STIs). We used descriptive statistics to summarize recruitment outcomes.
Results: We trained 15 peer educators who subsequently enrolled 371 MSM (82.4% of target) between July and September 2016. Median age was 24 years (IQR: 22-27). Thirty-two (8.6%) tested for HIV and 81 (21.8%) were screened for STIs. Overall prevalence of HIV and STIs was 6.3% and 3.7%, respectively.
Conclusions: Though use of social media was effective in identifying and enrolling MSM in our program, uptake of HIV testing remained low. Leveraging social media networks for HIV programming presents an innovative and cost-effective mechanism for accelerated recruitment of MSM. However, strategies addressing barriers to HIV testing are needed to increase testing uptake.

"Dear Mrembo [Beautiful]": development, testing and finalization of a theory-driven, human-centered mobile phone intervention to prevent pregnancy and HIV/STI among female sex workers in Mombasa, Kenya

K. L'Engle[1], E. Mangone[2], F. Ampt[3,4], C. Mudogo[5], K. Plourde[6], M. Lim[3,4], P. Gichangi[5,7], S. Luchters[3,4], and WHISPER Study Investigators
[1]University of San Francisco, School of Nursing and Health Professions, San Francisco, United States, [2]University of North Carolina, School of Public Health, Chapel Hill, United States, [3]Burnet Institute, Melbourne, Australia, [4]Monash Univesity, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [5]International Center for Reproductive Health, Mombasa, Kenya, [6]FHI 360, Durham, United States, [7]University of Nairobi, Nairobi, Kenya
Presenting author email: klengle@usfca.edu

Background: Female sex workers (FSW) have high unmet need for contraception and high incidence of unintended pregnancy and HIV. Interventions using text messaging -ubiquitous among FSW - can improve sexual and reproductive health (SRH) knowledge and behaviors. Yet, few mobile phone programs target FSW in Africa. This presentation describes the participatory development, usability testing, and final content of a theory-driven mobile phone intervention that is being evaluated in a cluster-randomized controlled trial in Kenya.
Methods: Content was developed and tested for relevancy, actionability, and comprehensibility. Six participatory development workshops (n=42 women) and 12 in-depth interviews were conducted with FSW recruited from sex work hotspots. Participants were 16-44 years old, not currently pregnant, owned a mobile phone, and text messaged. Interview guides covered preferred health topics, wording and language, tone, delivery format and timing, and system usability. Discussions were audio-recorded, translated, and thematically analyzed. Final content was compiled for staged delivery over 12 months.
Results: FSW preferred simple, informational text messages in English with some motivational content in Swahili; and sharing "education-entertainment" role model stories portraying pertinent, tricky situations and health-promoting resolutions (Table 1). Behavioral constructs from stages of change and social cognitive theory resonated with FSW. The resulting intervention alternates 160-character messages delivered three times/week for a month, with a unique role model story delivered in five installments over the next month. The intervention delivers 77 messages and 6 role model stories in total.

Topic	Recommendations	Example Results
Health Content	Pregnancy risk, contraception methods especially long acting, condoms, dual protection, alcohol abuse, violence, STIs, HIV testing, ARVs, PMTCT, rights, partner communication	"I need to be informed on alcohol to make the right decisions when negotiating with a client on the use of family planning or condoms for protection." (Workshop 5) "[Start] with HIV because one has to know her status and how to prevent STI infection using condoms, then family planning messaged on child spacing, then do not drink to avoid drama." (Workshop 4)
Behavior Constructs	Self-efficacy, social support, knowledge, self-evaluation, self-liberation, reinforcement	It has given me information about preventing unplanned pregnancies and [where] I can get services that are near me." (Interview 9) "Send us the messages all the time so that we can remember and feel encouraged." (Workshop 6) "Sex workers should know their rights and also teach other women in the community." (Workshop 4)
Language and Tone	Friendly, caring, some Swahili Simple, fact-based, English content	"Kiswahili can have different meanings for one word while simple English is the best." (Workshop 5) "As sex workers we like to be loved and being called names like ,darling, hi dear'. We should put sweet phrases before the messages ...." (Workshop 3) "The messages are short and link to a place where I can get more information, and it's friendly." (Interview 12)
Format	Text strongly preferred, voice perceived as forgettable Role model stories highly relatable, engaging	"Reading about it now as a text message, you can have time and digest on it unlike when you are taught and can forget." (Interview 12) "This thing [in role model stories] happens to sex workers and it has happened to me, too." (Workshop 3)
Timing	Messages about 3 times/week, sent morning or before work in afternoon	"In the morning so that it can remind me of the choices I should make." (Workshop 2) "I prefer receiving messages on weekdays - Monday, Tuesday and Thursday. Wednesday and weekends I am busy." (Workshop 3)
Usability	High comprehension of mobile phone messages by most FSW On-demand content requires clear instructions and prompts	"It is a very good application and can be understood, the way I have engaged with it gives me alerts and more information." (Interview 9) "Messages are short; language is simple and pull option enables one to get information she wants. It is very interactive." (Interview 10)

[Design recommendations from workshops, interviews]

Conclusions: The final intervention prioritizes contraception and condom information, motivation, service alerts, and role model stories, and also addresses HIV/STIs, alcohol abuse, gender-based violence, and stigma and rights. Messages are sent in a pre-determined order, and participants can text any time for additional SRH content. A staged, social cognitive, and participatory approach to mobile phone intervention design for FSWs may improve intermediate pregnancy and HIV/STI behavior outcomes and biological endpoints.

WEPEC0999

Social media interventions to promote HIV testing, linkage, adherence and retention among key populations: a systematic review and meta-analysis

B. Cao[1,2], S. Gupta[3], J. Wang[4], L. Hightow-Weidman[5], K. Muessig[5], W. Tang[1,2,5], S. Pan[1,2], R. Pendse[3], J. Tucker[1,2,5]
[1]University of North Carolina Project - China, Guangzhou, China, [2]SESH Global, Guangzhou, China, [3]World Health Organization (WHO) South-East Asia Region, New Delhi, India, [4]Jinan University, School of Media and Communication, Guangzhou, China, [5]University of North Carolina at Chapel Hill, Chapel Hill, United States
Presenting author email: caobolin@seshglobal.org

Background: Social media is increasingly used to deliver HIV interventions for key populations (KPs) worldwide. However, little is known about the specific roles and effects of social media in HIV interventions. This systematic review examines the effectiveness of social media interventions to promote HIV testing, linkage, adherence, and retention among KPs.
Methods: We used the PRISMA checklist and Cochrane guidelines and the study was registered on PROSPERO. We systematically searched six databases (without time limits) and three conference websites (2015 and 2016). Search terms were related to HIV, social media, and KPs. We included studies where:
(a) the intervention was created or implemented on social media platforms;
(b) study population included KPs as defined by the WHO; and
(c) outcomes included promoting HIV testing, linkage, adherence, and retention.
Meta-analyses were conducted by Review Manager version 5.3. Pooled relative risk (RR) and 95% confidence intervals (CI) were calculated by random-effects models.
Results: Among 981 manuscripts identified, 27 studies met inclusion criteria. These studies were implemented in ten countries (19 studies from high-income countries). Eight were randomized controlled trials (RCTs) and 19 were observational studies. Twenty-six studies used social media to promote HIV testing among MSM or transgender individuals. Seventeen studies used social media to disseminate HIV test information, 12 to build online interactive communities to encourage HIV testing, and seven to provide HIV self-testing or self-sampling services.
Of the studies providing HIV self-testing/sampling services, 39.6% of participants requested HIV testing kits from social media platforms (95% CI 38.99, 40.13). Existing social media platforms such as Facebook (n=13) and the gay dating app Grindr (n=11) were used most frequently. In the seven RCTs promoting HIV testing, uptake was higher in the intervention arm than the comparison arm (RR 1.55, 95% CI 1.21, 1.99). In the four studies with baseline and post-intervention results, HIV testing uptake increased after social media interventions (RR 1.50, 95% CI 1.28, 1.76).
Conclusions: Social media interventions are effective in promoting HIV testing among MSM and transgender individuals in many settings. Social media interventions to improve HIV services in low- and middle-income countries and among other KPs should be considered.

WEPEC1000

Discordance of self-perceived HIV infection possibility, reported HIV sexual risk-taking, and voluntary HIV testing among social media-using black, Hispanic, and white young-men-who-have-sex-with-men (YMSM)

R. Merchant[1], K. Alexovitz[2], M. Clark[3], T. Liu[2], J. Rosenberger[4], J. Bauermeister[5], K. Mayer[6]
[1]Brown University/Rhode Island Hospital, Emergency Medicine, Providence, United States, [2]Brown University, Providence, United States, [3]University of Massachusetts Medical School, Worcester, United States, [4]Pennsylvania State University, Hershey, United States, [5]University of Pennsylvania, Philadelphia, United States, [6]Fenway Health, Boston, United States
Presenting author email: rmerchant@lifespan.org

Background: Discordance between self-perceived and actual HIV risk may impede efforts to promote HIV testing among young adult men-who-have-sex-with-men (YMSM). Among this higher HIV risk population, we compared YMSM's self-perceived possibility of having an undiagnosed HIV infection against their reported sexual risk-taking and history of voluntary HIV testing.
Methods: HIV-uninfected 18-24-year-old black, Hispanic, and white YMSM were recruited from across the US through multiple social media websites. Participants were queried about their HIV testing history, self-perception of having an undiagnosed HIV infection, and condomless anal intercourse (CAI) history. We assessed the association between self-perceived possibility of being HIV infected and previous CAI. Cochran-Mantel-Haenszel testing was performed to assess if participant self-perception of HIV infection was concordant with their reported history of CAI in relationship to their HIV testing status. Odds ratios (ORs) with corresponding 95% CIs were estimated.

Results:

		Association between self-perceived and reported HIV risk by HIV testing status		
	Association Between Self-Perceived and Reported HIV risk	Previously Voluntarily Tested for HIV	Never Voluntarily Tested for HIV	Mantel-Haenszel Combined
	OR (95% CI)	*OR (95% CI)*	*OR (95% CI)*	*OR (95% CI)*
CAI with any Man	2.10 (1.61-2.73)	2.11 (1.51-2.91)	2.45 (1.49-2.02)	2.21 (1.70-2.87)
___White___	1.95 (1.30-2.88)	2.04 (1.23-3.32)	2.08 (0.97-4.34)	2.05 (1.39-3.02)
___Black___	1.68 (0.91-3.04)	1.69 (0.81-3.45)	2.87 (0.71-11.24)	1.91 (1.07-3.43)
___Hispanic___	2.88 (1.78-4.61)	2.65 (1.46-4.75)	3.50 (1.43-8.45)	2.90 (1.84-4.57)
CAI with Main Male Partner	1.31 (1.06-1.61)	1.46 (1.15-1.85)	1.00 (0.63-1.60)	1.34 (1.10-1.65)
___White___	1.41 (1.02-1.95)	1.68 (1.15-2.44)	0.92 (0.45-1.87)	1.45 (1.06-1.99)
___Black___	1.51 (0.96-2.37)	1.72 (1.05-2.80)	1.18 (0.31-5.08)	1.62 (1.06-2.52)
___Hispanic___	1.07 (0.75-1.52)	1.05 (0.68-1.60)	1.05 (0.50-2.22)	1.05 (0.74-1.49)
CAI with Exchange or Casual Male Partner	1.82 (1.48-2.24)	1.65 (1.30-2.08)	2.94 (1.82-4.78)	1.86 (1.52-2.28)
___White___	1.83 (1.33-2.52)	1.60 (1.10-2.31)	3.54 (1.64-8.02)	1.89 (1.38-2.59)
___Black___	1.52 (0.95-2.42)	1.47 (0.88-2.45)	2.35 (0.61-9.33)	1.58 (1.01-2.47)
___Hispanic___	2.12 (1.49-3.01)	1.89 (1.25-2.83)	3.11 (1.43-6.75)	2.12 (1.51-2.98)

[Main results]

Of the 2,275 18-24-year-old YMSM (19% black, 36% Hispanic, and 45% white), 21% had never been tested for HIV, 87% reported CAI, and 77% believed that it was at least possible they could have an undiagnosed HIV infection. Perception of having an undiagnosed HIV infection was greater for those who reported CAI, yet there were differences by race/ethnicity. Per the Mantel-Haenszel analyses, YMSM who reported CAI with casual or exchange male partners had a greater self-perception of possibly being HIV infected if they had not been tested for HIV. However, this relationship was not observed for CAI with a main male partner.
Conclusions: Self-perception of possibly being HIV-infected was not higher for YMSM who had never been tested for HIV, but was greater for those who reported CAI. However, self-perception, reported HIV risk and testing were not uniformly concordant across sexual partner type and race/ethnicity. Interventions to promote self-realization of HIV risk and translate that into seeking or accepting voluntary HIV testing should be the focus of future interventions.

healthMpowerment: effects of a mobile phone-optimized, Internet-based intervention on condomless anal intercourse among young black men who have sex with men and transgender women

L. Hightow-Weidman[1], S. LeGrand[2], R. Simmons[2], J. Egger[2], S.K. Choi[3], K. Muessig[3]
[1]University of North Carolina-Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]Duke University, Duke Global Health Institute, Durham, United States, [3]University of North Carolina at Chapel Hill School of Public Health, Health Behavior, Chapel Hill, United States
Presenting author email: lisa_hightow@med.unc.edu

Background: In the United States (US), young, black men who have sex with men and transgender women (YBMSM/TW) are the only populations with increasing HIV incidence. healthMpowerment (HMP) is a mobile phone optimized, Internet-based intervention designed to reduce sexual risk behaviors among HIV-positive and HIV-negative YBMSM/TW by providing information, resources, tailored feedback, game-based elements and rewards. The objective of this research was to determine the effect of HMP on self-reported condomless anal intercourse (CAI) at 3 months post-intervention.
Methods: Between 2013 and 2015, 474 YBMSM/TW, age 18-30 years, who lived in North Carolina, and reported having at least one episode of CAI in the past 6 months, were randomized to intervention (HMP) or control (information-only) group in a 1:1 allocation. Participants completed computer assisted self-interviewing assessments at baseline, 3, 6 and 12 months. In intention-to-treat analysis (ITT), a zero-inflated mixed-effects Poisson model was used to estimate the relative rate of CAI in the treatment group compared with controls at 3-months post baseline. The complier average causal effect (CACE) was also estimated with compliance defined as ≥60 minutes of intervention exposure during the 3-month intervention period.
Results: Median time using HMP was 13.5 minutes; 50 participants (25.8%) used HMP for ≥60 minutes between baseline and month 3. In the ITT analysis, those randomized to HMP had a significantly reduced rate of CAI in YBMSM/TW com-

pared to those randomized to the control condition (0.76, 95% CI: 0.69,0.83). In CACE analysis, comparing those compliers in each group, use of HMP led to a 38% reduction in the rate of CAI (0.62, 95% CI: 0.55, 0.70). Notably, individuals in the intervention group with higher CAI rates at baseline also had the highest usage at month 3.
Conclusions: Technology-based interventions can reduce risky sex behaviors and represent a new mechanism for the delivery of HIV prevention interventions. The temporal association between higher CAI and usage of HMP suggests that, when given the choice, individuals do engage with an online intervention in a way consistent with their risk needs. Future research will examine the durability of these findings as well as mediators/moderators of intervention effects.

MSM user preferences for a smartphone app to accompany HIV & syphilis self-testing

I. Balan[1], T. Frasca[1], S. Nayak[2], J. Lopez-Rios[1], C. Lentz[1], C. Dolezal[1], C. Rael[1], S. Sia[2], A. Carballo-Dieguez[1]
[1]Columbia University/NYSPI, HIV Center for Clinical and Behavioral Studies, New York, United States, [2]Columbia University, Department of Biomedical Engineering, New York, United States
Presenting author email: balaniv@nyspi.columbia.edu

Background: HIV self-testing is increasingly used in the US and Europe. Although user acceptability is high, concerns remain regarding proper use, handling of HIV-positive results, and linkage-to-care. Some of these concerns could be mitigated with a designated smartphone app. We report on MSM user preferences for content and capabilities of a smartphone app to accompany HIV and syphilis self-testing.
Methods: MSM who regularly engage in condomless anal intercourse used the SMARTtest, a smartphone-based prototype device to test themselves for HIV and syphilis. Instructions were provided via an app with dual (video and pictorial step-by-step) directions. Participants then completed an in-depth interview that explored their experience using the device and recommendations for additional app content related to instructions, results, information, and linkage-to-care.
Results: To date, 20 participants (total N will be 60) have completed the study. Participants strongly approved of the dual instructions and a results screen that clearly states "positive" or "negative" test results. Almost all participants want the option to save test results on the app for personal reference or to show partners. They also want the option to send results to others, primarily partners but also physicians. A few participants were enthusiastic about widely sharing their HIV-negative test results via social or sexual networking sites. Linking test results to sexual networking sites was seen as offering a verified HIV status versus a self-report. Recommendations on HIV and syphilis information to include focused on symptoms, prevention, and next steps if results were positive. Ideas for how and when the information should be provided ranged from basic text on a separate tab to brief videos embedded into the testing process. Participants strongly recommended providing referrals for follow-up care in case of positive results, ranging from listings of clinics with contact information to geospatial mapping of nearby clinics, and automatic scheduling of clinic appointments. In general, participants of higher socioeconomic status had greater demands for app design, functionality, and interactivity than those of lower status.
Conclusions: Smartphone apps can support HIV/STI self-testing to provide clear instructions and prevention information, assist with linkage-to-care, and facilitate disclosure of results to providers and sexual partners.

WEPEC1003

Feasibility of using Hemaspot dried blood spot kits for at-home collection of blood to quantify viral load among an online sample of U.S. HIV-positive MSM

S. Hirshfield[1], R. Teran[2], M.A. Chiasson[1,2], M. Downing[1], L. Dize[3], C. Gaydos[3]
[1]Public Health Solutions, Research and Evaluation, New York, United States, [2]Columbia University, Epidemiology, New York, United States, [3]Johns Hopkins University, Division of Infectious Diseases, Baltimore, United States
Presenting author email: machiasson@healthsolutions.org

Background: Sub-optimal adherence to antiretroviral therapy (ART) can impede suppression of HIV, which presents a major public health challenge due to the probability of further transmission. U.S. men who have sex with men (MSM) accounted for 70% of new HIV infections in 2014. Recent online studies of MSM have shown relatively high uptake of home collection of biomarker data. Improved home dried blood spot (DBS) collection has been developed (HemaSpot™), streamlining blood collection. The aim of the study was to assess the feasibility of using HemaSpot kits to obtain home-collected blood specimens for quantifying HIV viral load among an online national sample of HIV-positive MSM.
Methods: From 09/01/2016-01/11/2017, HIV-positive MSM completing a 12-month follow-up survey for an online HIV risk reduction intervention were invited to enroll in a study to collect an at-home DBS specimen. Consenting participants were mailed a Hemaspot kit and instructed to return it directly to a laboratory for analysis. HemaSpot samples were eluted in Abbott DBS Elution Buffer and processed using the m2000_1.0ml_HIV_DBS_Quant protocol.
Results: Of 764 MSM who were emailed an invitation, 578 opened the email and visited the study website; of those, 502 (87%) consented to participate. Overall, 69% were White, 15% Black, and 16% Hispanic. Median age was 39; 91% reported being in HIV care; among individuals on HIV treatment (n=464), 51% scored < 90% on ART adherence on the 3-item Wilson adherence scale. Of consenting participants, 474 (94%) received the Hemaspot kit and 308 (65%) mailed it back to a research laboratory. As of 1/11/2017, 166 kits were tested for HIV-1 RNA; of those, 26 had insufficient blood, and 6 had a lab processing error. Of the 134 samples quantified for HIV-1 RNA, 47% had detectable viremia (35% had >832 copies per ml).
Conclusions: HIV-1 RNA quantification of Hemaspot home-collected samples from HIV-positive MSM is feasible. The majority (65%) returned kits, and 81% of laboratory-tested samples were quantifiable. Despite self-reported engagement in treatment and care, 51% had detectable viremia, signaling the need for novel HIV prevention strategies that include biomarker data in order to better engage HIV-positive MSM who struggle with ART adherence.

WEPEC1004

Risk behaviors and HIV prevention perceptions in a national online sample of men who have sex with men (MSM) in Brazil

T. Silva Torres[1], R. Brandini de Boni[1], M. de Vasconcellos[2], B. Hoagland[1], R. Ismerio Moreira[1], V. Gonçalves Veloso[1], B. Grinsztejn[1]
[1]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]Escola Nacional de Ciências Estatísticas, Rio de Janeiro, Brazil
Presenting author email: thiago.torres@ini.fiocruz.br

Background: Although national efforts for prevention, new HIV infections among MSM continue to increase in Brazil, especially among the youngest. Social media apps are becoming the main venue for casual sexual encounters. This study aims to describe risk behaviors and HIV prevention knowledge among MSM using two geosocial-networking apps in Brazil.
Methods: This was a cross-sectional online survey among MSM population from ten Brazilian capitals. The questionnaire was created on SurveyGizmo® website and advertised in two apps for MSM population (Hornett and Grindr). Inclusion criteria included ≥18 years-old, cisgender men and HIV negative.
Results: A total of 5,065 completed the survey: median age was 30.0(IQR:25-26), 3,194(63.1%) were white, 3,106(61.3%) completed at least college and 2,504(49.4%) had ≥5 minimal wage monthly income. Most were homosexual/gay (4,468;88.2%), 1,029(20.3%) reported to have a steady partner. Prevalence of tobacco and marijuana smoke in last 6 months was 32.6% and 33.1%, respectively, while binge drinking was reported by 71.8%. The majority of MSM (3,363;66.4%) had ≥10 points (high risk) on CDC MSM risk index, but only 1,083(21.4%) considered to have 50% or more chances to get infected by HIV in one year. Daily and weekend use of apps for sex was reported by 1,798(35.6%) and 678(13.4%), respectively. Regarding prevention, most MSM (4,488;85.4%) had an HIV test lifetime and 464(9.2%) used PEP in the previous year. The awareness and willingness to use HIV prevention strategies are described on.

	Awareness	Willingness
Condoms	-	3,733(73.7%)
HIV self-testing	1,346(26.6%)	2,589(51.1%)
PEP	2,907(57.4%)	3,325(65.7%)
PrEP (1 pill per day)	2,932(57.9%)	2,653(52.4%)
PrEP (on demand)	-	1,751(34.6%)
PrEP (During short periods or vacation)	-	4,652(91.8%)
PrEP (Injection twice a month)	-	2,405(47.5%)
Would never use PrEP	-	239(4.7%)
Would pay for PrEP	-	2,587(51.1%)

[Table 1]

Conclusions: Considering the CDC index, most of the sample would have an indication for PrEP, but only 57.9% have heard about this strategy. In addition, awareness, willingness and use of PEP - which is available in Brazil since 2009 - were also low. National efforts to increase awareness of prevention strategies are urgently needed and inclusion of PrEP in public health system is very important in the context of combined prevention.

WEPEC1005

Effects of SMS reminders on key population appointment adherence and retention: our success story

R. Kitsao[1], J. Kimani[2], F. Muriuki[1], M. Akolo[1]
[1]SWOP Kenya, Nairobi, Kenya, [2]University of Manitoba, University of Nairobi, Nairobi, Kenya
Presenting author email: ricky.kitsao@gmail.com

Background: The University of Nairobi/University of Manitoba collaboration has been providing services to sex workers for slightly over 30 years. Over the years, a recurring problem has been ensuring adherence to scheduled appointments by clients, as well as a high rate of loss-to-followup (ranging from 32% to 74%). In 2005 we carried out a study on the use of cellphone sms reminders to improve adherence to HAART, the results of which demonstrated a clear link between the two[1]. In the light of this, we decided to widen the scope of the reminders to routine clinic appointments.
[1] Effects of a mobile phone short message service on antiretroviral treatment adherence in Kenya (WelTel Kenya1): a randomised trial.
Methods: Using a home-grown EMR system in the 7 clinics we run in Nairobi, we capture appointment dates prospectively, in addition to client demographic data. We equipped each clinic with a prepaid GSM modem and sms gateway software, enabling the EMR system to send out regularly scheduled coded sms reminders of clinic appointments. The system sends 2 appointment reminders, one 7 days prior and the other a day prior to the appointment date.
Results: We introduced the appointment reminders in the year 2014. In the previous year, out of 5,956 enrolled clients, 1,851 (31%) were still visiting the clinic a year later. After introduction of the reminders, out of 3,478 clients enrolled in the year 2014, 1,925 (55%) were still visiting the clinic a year later. Without attributing the increase solely to the sms reminders, we believe they have had a significant impact.
Conclusions: By improving adherence to clinic appointments (and medication implicitly), sms reminders have proven to be a low-cost way to:
i) Enhance viral suppression
ii) Improve health-seeking behavior
We would recommend the implementation of sms appointment reminders for all programs serving Key Populations in the country as well as further afield in any setting where the usage of mobile telephones is widespread.

WEPEC1006

The demonstrable impact of a new anonymous partner notification tool

A. Menon-Johansson
SXT Health CIC, London, United Kingdom
Presenting author email: anatole@sxt.org.uk

Background: Partner notification (PN) is a key public health strategy than can reduce the cost to diagnose infections. Up to one quarter of partners of HIV index patients are found to have the infection; however, it is difficult to deliver this important work. A new tool was developed to support PN delivery and to capture patient reported outcomes. We therefore tested if this tool could be used to deliver PN for index patients diagnosed with HIV.
Methods: Analysis of the PN tool focused on the number of index patients, total partners, contactable contacts, the number of partners told and tested, either reported by the patient or captured via healthcare worker (HCW) verification using the PN tool. The key performance indicator (KPI) target for STIs has been set as 60 partners seen and tested within four weeks for every 100 index patients (i.e. 0.60), and this was used as a benchmark.
Results: PN data was captured for 105 index patients [58 MSM (36 White, 16 Black or mixed, 8 Asian or other ethnicity), 21 females (15 Black & mixed, 6 White ethnicity), 20 Heterosexual males (13 Black, 6 White, 1 Asian ethnicity) and 6 patients had no demographics captured] with an HIV diagnosis. PN for two or more infections was simultaneously done with 24 (23%) patients and two were diagnosed with Chlamydia, Gonorrhoea, Syphilis and HIV at the same time.
These index patients reported 212 partners and 130 (61%) were contactable; 18 (14%) of these were contacted by the PN tool and not declared to the clinic. Of the contactable contacts told, 65 (50%) were seen and tested [27 (42%) via the PN tool (16 at clinic, 11 reported by the partner) and 38 reported by the patient]. The KPI overall since the launch of the tool is 0.62 for HIV.
Conclusions: The new tool delivers HCW initiated and verified PN and supports providers to simply capture outcomes and achieve the KPI for HIV and other infections. Future developments and research are required to optimize the number of contacts told and support high public health value partners to be seen and tested.

WEPEC1007

Recruitment and enrollment results from a randomized controlled trial of an eHealth, behavioral HIV preventive intervention for HIV-negative male couples in the U.S.

J. Mitchell[1], S.M. Traynor[2], J.-Y. Lee[2], D.J. Feaster[2], P.S. Sullivan[3], R. Stephenson[4]
[1]University of Hawai'i at Manoa, Office of Public Health Sciences, Honolulu, United States, [2]University of Miami, Miller School of medicine, Department of Public Health Sciences, Miami, United States, [3]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States, [4]University of Michigan School of Nursing, Ann Arbor, United States
Presenting author email: jasonmit@hawaii.edu

Background: The use of web-based technologies (i.e., eHealth) and social media (e.g., Facebook) to recruit and enroll male couples into online HIV prevention studies has increased in recent years. However, challenges remain with the online eligibility and enrollment process that could be improved for future eHealth, HIV preventive interventions with this population. To better understand how and where to improve eligibility and enrollment rates for online HIV preventive interventions, the present study uses data collected from a nation-wide, randomized controlled trial (RCT) of an interactive, self-guided, eHealth toolkit aimed to help reduce HIV-negative male couples' risk for HIV.
Methods: Targeted Facebook advertisements were used to recruit the study sample over a period of 5 months. Among the 7,956 individuals who completed the eligibility screener, 28% were ineligible (n=2,191), 69% (n=5,468) were eligible but failed to verify their relationship and/or complete the baseline assessment (i.e., baseline non-completers), and 3% (n=298) were eligible, consented, and verified to represent 149 HIV-negative male couples enrolled into the online RCT (i.e., baseline completers). Comparative statistics, which accounted for the dyadic nature of the data, were conducted to assess differences between ineligible, eligible baseline non-completers, and eligible baseline completers.
Results: For ineligibility, many were disqualified because of living with HIV (41%) or had a partner who was HIV-positive (36%). Compared to those who were eligible, ineligible individuals were more likely to be: older ($p < .0001$); a racial minority ($p < .0001$); Hispanic ($p < .0001$); living in the South ($p < .0001$); non-gay ($p < .001$). Among the eligible participants, baseline completers were more likely to be younger ($p < .0001$), living in the Midwest ($p < .001$), and have a shorter relationship duration ($p < .0001$) yet less likely to live in the Northeast ($p < .0001$) compared to baseline non-completers.
Conclusions: From a primary and secondary HIV prevention perspective, future eHealth HIV preventive interventions should target and include all male couples, irrespective of their HIV serostatus. Broadening this inclusion criteria will help increase enrollment rates among minority couples. Determining whether familiarity of using web-connected devices and the amount of time needed to complete enrollment procedures should also be considered and explored.

WEPEC1008

Alpha and beta testing of a trauma-informed HIV and substance abuse prevention mobile health application for teens who have experienced interpersonal violence: the eHEARTT toolkit

C.K. Danielson[1], Z. Adams[2], A. Franz[3], I. Metzger[3], K. Ruggiero[3]
[1]Medical University of South Carolina, Psychiatry & Behavioral Sciences, Charleston, United States, [2]Indiana University, Indianapolis, United States, [3]MUSC, Charleston, United States
Presenting author email: danielso@musc.edu

Background: Teens who experience interpersonal violence (IPV) are more likely to engage in HIV-sexual risk behaviors and to develop substance use disorders than their non-IPV-exposed counterparts. Prevention of HIV and substance use for IPV-exposed youth may be best addressed from a 'trauma-informed lens'—addressing the overlap in IPV and risk behaviors in the context of trauma-focused treatment.
Prevention-focused m-health tools that can be incorporated into the delivery of evidence-based treatments are low-cost and highly-efficient; readily updated for content; and align with consumer-preferred methods of accessing health information. However, despite the rapid proliferation of HIV oriented web- and smartphone-based interventions, little is known about their effectiveness, and less is known about how they need to be tailored to diverse populations to maximize relevance, reach, and benefit. The purpose of the study was to utilize a qualitative analytic approach to guide the refinement of the eHEARTT application.
Methods: In this NIH-funded study in the US, alpha testing in the format of focus groups and individual qualitative interviews is currently underway with end users (trauma-exposed teens, caregivers, and clinicians) to assess reactions and obtain direct input regarding design, content, and functionality. Alpha testing results are

being used to guide refinements of eHEARTT, resulting in a "beta" version of the tools. Beta testing involves evaluation of the refined tool for functionality.
Results: Through NVivo 9 qualitative analyses software, common themes will be identified through transcriptions of the focus groups and interviews as they relate to the specific toolkit applications and to specific populations. Initial and secondary coding passes will be conducted to identify descriptors of the user's reactions to the tools, to refine theme classifications as they emerge, and to impose a data-derived hierarchy to the nodes identified. Interclass correlation coefficients will be computed across coders. Results will be presented—including how these findings are being used to refine the applications.
Conclusions: eHEARTT is a mobile application that will provide clinicians working with trauma-exposed teens the capacity to deliver state-of-the-art HIV prevention content. The formative research to be presented in this poster is a critical step in ensuring the toolkit is user-friendly and ready for efficacy evaluation in preventing HIV.

WEPEC1009

Pilot testing a social media campaign to increase HIV testing among Indonesian men who have sex with men: a community-based participatory research

A. Nugroho[1,2,3], V. Erasmus[2], R.W. Coulter[4], P.A. Laksmono[1], J.H. Richardus[2]
[1]GWL-INA Network, Jakarta, Indonesia, [2]Erasmus MC, University Medical Center Rotterdam, Department of Public Health, Rotterdam, Netherlands, [3]School of Public Health, Lambung Mangkurat University, Banjarbaru, Indonesia, [4]Graduate School of Public Health, University of Pittsburgh, Center for LGBT Health Research, Pittsburgh, United States
Presenting author email: adie.noegroho@gmail.com

Background: In Indonesia, many men who have sex with men (MSM) avoid HIV testing due to fear of getting an HIV-positive result. To improve HIV testing uptake in this group, we exploited the rapid growth of social media use to develop a social media campaign. This pilot study in an urban setting of Indonesia sought to determine whether such an approach can reach MSM and encourage this hard-to-reach group to undergo HIV testing.
Methods: The ‚Gue Berani' (I am Brave) campaign went online in May 2015. This campaign was developed through community-based participatory research and guided by the Health Belief Model. For a period of ten months, starting from two weeks after the launch, we used a self-administrated questionnaire collected from 1733 MSM who took an HIV test at one of eight clinics. We applied multilevel logistic regression to examine association between participants' characteristics and influence of the Gue Berani (GB) campaign for HIV testing, and to see whether the influence varied by clinic.
Results: Of all participants, 51.8% reported having heard about the campaign. Over a third (31.8%) indicated that information from the GB campaign had brought them for HIV testing. When controlling for age and education, first-time testers had higher odd of getting tested because of the campaign than the experienced testers (AOR=1.34; 95% CI: 1.07-1.69). Getting tested because of the GB campaign were more likely reported among men who felt at risk for HIV than among those who tested due to a curiosity of their HIV status (AOR=1.37; 95% CI: 1.07-1.76). The degree to which this campaign was successful significantly varied across clinics. Similar to information received from peers (32.1%), information provided by the GB campaign appeared to be more successful at encouraging MSM to get tested than other information sources, including outreach workers (25.7%).
Conclusions: This pilot study demonstrates that a social media campaign can indeed reach MSM and refer them to HIV testing, primarily those who had never tested for HIV before. This type of intervention is particularly appropriate for MSM in urban settings who are not being reached through conventional approaches, and who look for HIV information online.

WEPEC1010

Virtual and new physical venues are changing the modes of operation and HIV risk among female sex workers and MSM in sex work in India

S. Ponnusamy Sakthivel[1], V. Chakrapani[2], K. Mariyappan[3], S. Joshi[4], S. Subramaniam[5], K. Krishnan[6], A.K. Agarwal[7]
[1]Public Health Foundation of India, PIPPSE, New Delhi, India, [2]C-SHaRP, Chennai, India, [3]National AIDS Control Organization, National Technical Support Unit, New Delhi, India, [4]PIPPSE-Technical Support Unit, Mumbai, India, [5]PIPPSE-Technical Support Unit, Chennai, India, [6]PIPPSE-Technical Support Unit, Trivandrum, India, [7]PIPPSE, Gurgoan, India
Presenting author email: pssaravanamurthy@gmail.com

Background: In India, targeted HIV interventions among female sex workers (FSWs) and MSM in sex work, are currently hotspot based. The mid-term evaluation of National AIDS Control Programme found a sharp decline in the number of key populations visiting hotspots, and recommended using technology to reach them. To design such newer interventions, PIPPSE of PHFI conducted this rapid assessment to understand the current ways by which FSWs and MSM in sex work meet paying partners.
Methods: In 2016, this exploratory qualitative study was conducted in 6 cities across four states in India: Chennai, Trichur, Pandalam, Mumbai, Santacruz and Margao. We conducted 9 focus groups (N=85 participants) among a purposive sample of 44 FSWs and 41 MSM in sex work, and 9 key informant interviews with leaders/staff of community agencies. Data were explored using narrative thematic analysis.
Results: Participants reported using Internet-based mobile apps (e.g., Whatsapp, Grindr), dating websites (e.g., Planet Romeo), and online classifieds (e.g., Locanto) to meet potential paying partners. Emerging physical venues for meeting paying partners included: certain massage parlors, spas, dance bars, gay parties and gyms. High volume of clients, relative safety and confidentiality, and higher income were stated as the reasons for preferring online over offline venues. Participants felt that the condom use could be relatively better among sex workers who use phones/Internet, when compared to street-based sex workers, because of better negotiation power of the former. However, violence and extortion were reported from paying partners met online. Certain barriers prevent virtual and new physical venues from being used for HIV-related health promotion. For example, phones/apps were seen as useful to get clients, but not to receive HIV-related information.
Conclusions: Emergence of new physical and virtual venues means need for newer strategies (e.g., virtual outreach) to reach sex workers for providing HIV-related information/services. Further research need to focus on HIV risk among sex workers who use smart phones/Internet and testing and scaling up of effective phone-/internet-based HIV prevention interventions, which could augment the traditional hotspot-based interventions.

WEPEC1011

The user experience: perspectives from MCH providers, laboratory providers, and HIV+ mothers enrolled in the HITSystem

M. Brown[1], C. Wexler[1], M. Ochieng[2], E. Muriithi[2], S. Babu[2], E. Muchoki[2], L. Macharia[1], Y. Kamau[1], B. Gautney[3], M. Maloba[3], R. Lwembe[2], K. Goggin[4,5,6], S. Finocchario-Kessler[1], HITSystem Study Team
[1]University of Kansas Medical Center, Department of Family Medicine, Kansas City, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Global Health Innovations, Kansas City, United States, [4]Children's Mercy Hospitals and Clinics, Health Services and Outcomes Research, Kansas City, United States, [5]University of Missouri-Kansas City, School of Medicine, Kansas City, United States, [6]University of Missouri-Kansas City, School of Pharmacy, Kansas City, United States
Presenting author email: skessler2@kumc.edu

Background: The HITSystem is an innovative, web-based system seeking to improve quality and efficiency of early infant diagnosis (EID) services by utilizing algorithm-based electronic alerts for EID providers and text messages for mothers overdue for services. Compared to national data and reported standard of care outcomes, preliminary data at HITSystem sites suggest shorter turnaround times (TAT) for HIV DNA PCR samples, improved retention in care through 18 months, and more rapid ART initiation. This study aims to assess users' (mothers', providers', and lab technicians') experiences with EID services and the HITSystem.
Methods: A trained researcher conducted semi-structured interviews with HIV+ mothers (n=40) and providers directly utilizing the HITSystem (n=4 MCH and n=3 lab providers) at intervention site hospitals (n=3) and central laboratories (n=2) in a randomized controlled trial evaluating the HITSystem. Interviews were recorded, transcribed, and coded into a priori and emergent themes.
Results: Findings emphasized the recognized value of EID services: providing information, support, and conclusive knowledge of infants' HIV status. Participants identified significant barriers to EID (limited resources, opportunity cost of attend-

ing appointments, distance to hospital, stigma, and fear of disclosure). Providers identified HITSystem-driven improvements in EID experience at a systematic level (fewer lost samples, faster TAT for results, result notification, and ART initiation), while mothers identified improvements at the individual level (cues to action for appointment attendance, reduced hospital visits, and reduced anxiety through shorter waiting periods). HITSystem-facilitated communication between hospital and laboratory providers increased collaboration, problem-solving, and motivated performance through enhanced accountability. Participants described increased patient engagement in care as a result of HITSystem-generated text messages, facilitating increased provider-patient communication (notification of result availability and retesting needs) and opportunities for provider and partner support. No unintentional disclosure from HITSystem participation was reported. Provider suggestions for optimizing HITSystem utilization included addressing network challenges, delaying data entry to improve workflow, enhancing report-generating capabilities, and linking with other national EMR systems.
Conclusions: Individual and systemic barriers to EID services remain. Yet, the HITSystem maximizes the benefits of EID by reducing systematic inefficiencies and motivating retention in care. HITSystem adaptation can further address barriers identified.

WEPEC1012

"How do we as young black gay men stand strong?" The healthMpowerment online intervention as a space to engage with stigma related to HIV, sexuality, and race

K. Muessig[1], M. Barry[2], W. Dong[1], D. Pulley[1], N. Blackburn[1], G. Sallabank[3], S. Legrand[4], G. Harper[5], S. Choi[1], L. Hightow-Weidman[6], J. Bauermeister[7]
[1]The University of North Carolina at Chapel Hill, Health Behavior, Chapel Hill, United States, [2]The University of North Carolina at Chapel Hill, Maternal and Child Health, Chapel Hill, United States, [3]University of Michigan, Center for Sexuality and Health Disparities, Ann Arbor, United States, [4]Duke University, Duke Global Health Institute, Durham, United States, [5]University of Michigan, Health Behavior and Health Education, Ann Arbor, United States, [6]The University of North Carolina at Chapel Hill, Institute of Global Health and Infectious Diseases, Chapel Hill, United States, [7]University of Pennsylvania, Family and Community Health, Philadelphia, United States
Presenting author email: kmuessig@med.unc.edu

Background: In the United States, young Black men who have sex with men (YBMSM) experience increased HIV infection. HIV incidence is linked to sexuality, race, and HIV stigma, as stigma may inhibit protective behaviors (condom use, HIV status disclosure) and deter care utilization (HIV testing, pre-exposure prophylaxis use, HIV care). An internet-based HIV risk reduction intervention for HIV-negative and HIV-positive YBMSM included access to online forums where YBMSM could share experiences and garner social support.
Methods: In the healthMpowerment (HMP) randomized controlled trial, intervention arm YBMSM (n=232) read and posted content in three support spaces: a discussion Forum, an HIV physician question and answer area (Ask Dr. W), and a multi-media stories area (Getting Real). Informed by gender and sexuality, race, and HIV stigma theories, we systematically content coded all of participants' posts and then thematically analyzed all stigma-related posts.
Results: Sixty-two participants (mean age 24.4, 28 HIV-positive) contributed 1497 posts, of which 61.1% (n=915) were stigma-related. 80.1% (733/915) contained gender- or sexuality-related stigma, 22.1% (202/915) race-related stigma, and 21.4% (196/915) HIV-related stigma (posts could receive multiple codes). Characterizing stigma, 75.3% (689/915) of posts challenged stigma, 14.5% (133/915) relayed stigma experiences, and 8.9% (81/915) expressed anticipatory stigma. Comparing areas, the Forum had a higher proportion of posts challenging stigma (76.0%, 610/803), while Ask Dr. W had a higher proportion of anticipatory stigma (45.5%, 15/33) posts. 46.9% (429/915) of posts - distributed equally across all three spaces - were coded as perpetuating stigma. YBMSM utilized HMP to respond to stigma in five broad ways: correcting misinformation/stereotypes; seeking information and support; promoting positive norms; interrogating stigmatizing media portrayals; and helping other YBMSM.
Conclusions: HMP fostered dialogue about multiple stigmas. While user posts overwhelmingly challenged stigma, almost half also perpetuated stigma. Social media-based interventions for YBMSM should be attentive to opportunities to challenge stigma, while ensuring that measures to reduce stigma perpetuation are in place. Future studies should examine the efficacy of strategies YBMSM use to challenge stigma in online spaces and test how online support might utilize these strategies to ameliorate the impacts of multiple stigmas on HIV risk.

WEPEC1013

"She thought I instantly had AIDS": how media representation influences perception and stigmatization of race, sexuality and HIV among young black men who have sex with men

G. Sallabank[1], N. Blackburn[2], W. Dong[2], S. Legrand[3], M. Barry[4], D. Pulley[2], L. Hightow-Weidman[5], G. Harper[6], J. Bauermeister[7], K. Muessig[2]
[1]University of Michigan, Center for Sexuality and Health Disparities, Ann Arbor, United States, [2]University of North Carolina at Chapel Hill, Health Behavior, Chapel Hill, United States, [3]Duke University, Duke Global Health Institute, Durham, United States, [4]University of North Carolina at Chapel Hill, Maternal and Child Health, Chapel Hill, United States, [5]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [6]University of Michigan, School of Public Health, Department of Health Behavior and Health Education, Ann Arbor, United States, [7]University of Pennsylvania, School of Nursing, Department of Family and Community Health, Philadelphia, United States
Presenting author email: gsall@umich.edu

Background: Media portrayals of young Black men who have sex with men (YBMSM) may perpetuate racial and homophobic stigma among HIV positive and HIV negative YBMSM, thus heightening experiences of discrimination and HIV disparities. Characterizing how news and social media influence stigma and how YBMSM engage with these portrayals may offer opportunities to confront stigma and develop media-driven stigma reduction interventions.
Methods: Qualitative data were collected from 12 months of user-created posts on an Internet-based HIV intervention aimed at reducing sexual risk behaviors among 474 HIV-positive and HIV-negative YBMSM. Participants posted and commented on a discussion forum, physician question and answer space, and a space for sharing multi-media content (e.g. YouTube videos, newspaper links). Three independent researchers qualitatively coded all participants' posts. All posts with stigma content were identified and coded for race & ethnicity, gender & sexuality, and HIV stigma content. Then thematic content analysis was conducted on all posts with race/ethnicity stigma or intersectional (layered stigmas) codes to identify interactions among YBMSM in relation to shared media.
Results: 62 participants, 28 of whom were HIV positive, contributed 1497 posts. 323 posts were coded with race/ethnicity or intersectional stigma relevant themes. Within these conversations, 59.7% (193/323) of posts contained media content or commentary. Participants engaged highly with these posts discussing the limited presence of YBMSM in popular television shows and sharing examples of LGBTQ portrayals in television and film that were largely positive. Participants also felt that media portrayals reinforced stereotypes, including the perceived interconnectedness of flamboyance, sexuality, AIDS and the experience of coming out. In participants' discussions these portrayals were linked to discrimination within and outside of the gay community.
Conclusions: YBMSM perceived media portrayals as reinforcing and perpetuating stereotypes, which influenced experienced stigma and stigma by association. While this stigma may hinder access to HIV prevention services and engagement with healthcare providers, YBMSM also used social media to challenge stigma, suggesting opportunities to develop media-driven stigma reduction interventions. Structural approaches, including training media on stigma-reduction and HIV advocacy, could lessen perceived and experienced stigma, and ultimately improve the health of YBMSM.

WEPEC1014

Ending HIV through a multi-phased health campaign approach for men who sex with men and the whole of population

D. Russell, M. Warner, J. Avery
HIV Foundation Queensland, Brisbane, Australia
Presenting author email: melissa.warner@hivfoundation.org.au

Background: The END HIV campaign was developed due to rising rates of HIV in Queensland and under the umbrella of the Queensland HIV Strategy 2012-2015. The initial challenge/opportunity for the health promotion campaign was to educate, inform and persuade publics to be actively involved in prevention, testing and treatment of HIV. In 2013, the initial campaign was design as a singular phase.
As the campaign developed, the need for an ongoing response to HIV within Queensland became apparent. Consequently, END HIV was extended and further expanded to be a multi-phased response to HIV in Queensland.
Methods: The campaign was developed to target both men who have sex with men (MSM) and whole of population (WOP). Audience research/insights inform branding, messaging, creative and content and ensure targeting on corresponding platforms and channels. These include stakeholder/community engagement, traditional and digital advertising such as hook up apps i.e. Grindr.
A four-pronged message approach focuses on prevention (condoms, PrEP and PEP), testing, treatment and stigma. Third party formative research and evaluation of the campaign is conducted annually through qualitative and quantitative meth-

ods. Findings from these evaluations are considered and synthesized for ongoing development of strategies and tactics.
Results: The campaign is measured by changes in awareness, attitude and behaviour. Results and findings from 2016 evaluations are divided into MSM and WOP segments. Key findings show 83% of MSM state taking some form of action as a direct result of campaign, compared to 67% in 2013 and includes testing which was undertaken by 43%. Key findings among WOP include 12% talking about HIV with other people, compared to 2% in 2013. And 15% stating being more vigilant about safe sex practises. In addition, behaviour showed a 30% increase in testing in gay friendly GPs and a reduction of 38% new transmissions of HIV in Brisbane since 2014.
Conclusions: The END HIV response to HIV in Queensland showed a direct correlation to awareness, attitude and behaviour change. These findings are supported by data showing an increase in testing and a reduction of new transmissions in Brisbane.

WEPEC1015

To get to zero, we must also get to men: UNAIDS review on men and HIV, eastern and southern Africa regional focus

D. Peacock[1], L. Pascoe[2]
[1]Sonke Gender Justice, Cape Town, South Africa, [2]UC Davis, Davis, United States
Presenting author email: dean@genderjustice.org.za

Background: Men and boys in Eastern and Southern Africa are dying at disproportionately higher rates than their female counterparts because they are underrepresented in HIV testing and are less likely to initiate and adhere to treatment. As part of broader efforts to increase male engagement in the HIV response, UNAIDS commissioned a review to examine effective strategies to increase male engagement in the prevention of and response to HIV.
Methods: An extensive review of available peer-reviewed and grey literature was completed during 2015, informed by additional expert input from UNAIDS, relevant nongovernmental organisations and academic institutions. Evidence presented covers:
(1) the HIV epidemic in Eastern and Southern Africa among men and boys;
(2) men's current use of HIV services;
(3) barriers to men's linkage into the HIV cascade of care;
(4) proven and promising practices to address these gaps; and
(5) a set of recommendations to engage men in HIV prevention and treatment strategies.
Results: Men's low utilisation of HIV prevention and treatment services reflects a combination of factors:
(1) behavioural factors linked primarily to rigid gender norms that discourage uptake of health services;
(2) policy and structural level factors, such as services that are not inclusive of men and boys in all their diversities, and;
(3) insufficient commitment from governments and development partners to fund and implement strategies to scale.
Key recommendations from this review include: development of new policies and policy guidelines that incorporate male engagement as clients and supportive partners; health provider sensitization; mass scale up of male circumcision and male involvement in antenatal care; community-based testing services including self, partner, and workplace testing; extended or varied clinic hours; gender transformative small group and mass media interventions; and community mobilization strategies for uptake of HIV services.
Conclusions: The Fast-Track targets to end AIDS by 2030 outlined in the 2016 Political Declaration on HIV and AIDS cannot be reached unless scaled up and effective strategies to increase male engagement in the HIV response and for gender equality are employed. This review highlights the need for urgent action across multiple levels and sectors, and provides a clear roadmap for how to achieve it.

WEPEC1016

Sex communication at home: parents and health providers as conduits of sexuality-inclusive HIV information for gay, bisexual, and queer adolescent males

D. Flores[1], S. Docherty[2], R. McKinney[3], J. Barroso[4]
[1]University of Pennsylvania, School of Nursing, Philadelphia, United States, [2]Duke University, School of Nursing, Durham, United States, [3]Association of American Medical Colleges, Washington, United States, [4]Medical University of South Carolina, School of Nursing, Charleston, United States
Presenting author email: dalmacio@upenn.edu

Background: Sex communication interventions have been proven to facilitate positive sexual health outcomes with heterosexual adolescent samples. The same has yet to be established for male youth with same-sex attractions, behaviors and identities. Our study aimed to describe the experiences of gay, bisexual and queer-identifying adolescent males with parent-child sex communication, their assessment of parents' efficacy as sex educators and to identify the role the healthcare system can play during these discussions.
Methods: In this descriptive qualitative study, we conducted 30 in-depth semi-structured interviews with a diverse group of 15 to 20 year-old males. Participants varied by sexual orientation (23 gay, 5 bisexual, 2 queer), school level (5 high school, 6 technical school, and 19 college) and race/ethnicity (11 White, 10 Hispanic/Latino, 4 Black, 4 Asian, and 1 multiracial). Interviews lasting 60-90 minutes were transcribed and iteratively coded on NVivo11. Themes were identified using standard thematic and content analysis techniques.
Results: Themes emerged regarding the frequency and content of sex communication, parents´ knowledgability and rating as sex educators, and the role healthcare providers play in initiating and sustaining these talks. Sex communication with parents occurs rarely and is heteronormative in content prior to sons' disclosure as GBQ. After disclosure, parents are reactionary in their approach and provide information to sons based on stereotypes that equate this population with negative health outcomes. The findings are mixed regarding perception of parents' knowledge about GBQ-specific information; more mothers than fathers addressed sex and sexuality with their sons, and both parents were rated poorly as sex educators by their GBQ sons. Healthcare providers were identified as a crucial resource for GBQ sons and their parents, both before and after disclosure.
Conclusions: Sex communication with parents throughout adolescence that excludes GBQ males' same-sex concerns are missed opportunities for targeted HIV risk reduction. There are multiple ways healthcare providers can assist parents to plan age-appropriate, sexuality-inclusive, home-based discussions about sex for this group.

WEPEC1017

Confronting GBV as a barrier to women accessing HIV services including elimination of vertical transmission of HIV in a peri-urban settlement in Lusaka district

B. Chola Muzamindo
Bwafwano Community Home Based Care Organisation, Management, Lusaka, Zambia
Presenting author email: bwafwano@hotmail.com

Background: Bwafwano Integrated Services Organization implemented a project aimed at addressing Gender Based Violence as a barrier to women accessing maternal and child health services and as a factor fueling vertical transmission of HIV. The project sought to eliminate vertical transmission of HIV and provided a platform for improving knowledge, tackling GBV, stigma and discrimination in the community and also improving access to services needed by women living with HIV during pregnancy and delivery.
Methods: This community-based intervention was set in a densely populated peri-urban settlement between 2009 and 2016. 60 men were identified and trained as Champions against GBV and a further 50 Community Volunteers trained in maternal and child health. Working in collaboration with local community leadership, 4,000 men and women were mobilized as couples and engaged through ongoing small group meetings to access information on maternal and child health and to identify barriers to health services among women. A structured questionnaire was also used to identify barriers to services and results analyzed using SPSS. HIV Counseling and Testing services were also provided and 3,798 couples were tested for HIV with 482 being found to be infected HIV with 120 being pregnant.
Results: 82% of the 2,000 women respondents to the questionnaire indicated that they would not disclose their status to their spouses for fear of being divorced while 56% of men felt the same. 120 pregnant women involved in the project gave birth to HIV free babies as compared to 23 babies that contracted HIV in a comparison site which was not targeted under this project. Also, women in this project complied and adhered to treatment compared to those in the comparison site.
Conclusions: Inclusion, GBV is an emerging issue and if not addressed will retard the gains recorded so far in HIV prevention, treatment, care and support especially among women and the implications will be an upswing of vertical transmission despite the availability of OPTION B+.

WEPEC1018

From guideline to implementation of oral pre-exposure prophylaxis for HIV prevention in Taiwan

C.-W. Li[1], W.-W. Ku[2], C.-J. Yang[3], K.-S. Wu[4], H.-S. Toh[5], H.-H. Lin[6], N.-Y. Ko[7]
[1]National Cheng Kung University Hospital, Department of Medicine, Tainan, Taiwan, Province of China, [2]Department of Internal Medicine, Taipei Veterans General Hospital Hsinchu Branch, Hsinchu, Taiwan, Province of China, [3]Far Eastern Memorial Hospital, New Taipei City, Taiwan, Province of China, [4]Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, Province of China, [5]Chi-Mei Medical Center, Tainan, Taiwan, Province of China, [6]E-Da Hospital, Kaohsiung, Taiwan, Province of China, [7]National Cheng Kung University, Tainan, Taiwan, Province of China
Presenting author email: li.cw29@gmail.com

Background: Pre-exposure prophylaxis (PrEP) for prevention of human immunodeficiency virus (HIV) infection was proved to be effective and has been widely implemented worldwide. This article introduced guideline development of PrEP use and the implementation of PrEP use in Taiwan.
Methods: The Taiwan Pre-exposure prophylaxis (TW PrEP) guideline writing group was established by Taiwan AIDS Society in 2015. The writing group searched published randomized controlled trials and global guidelines using keywords as pre-exposure prophylaxis, preexposure prophylaxis, antiretroviral hemoprophylaxis, PrEP, Truvada, tenofovir, HIV, and HIV incident through Medline, PubMed, Cochrane Database, EmBase and ClinicalTrials.gov database. The writing group applied Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to draft TW PrEP guideline. Internal and external reviewers independently evaluated TW PrEP guideline draft using the Appraisal of Guidelines for Research and Evaluation (AGREE II).
Results: Of all, 3 systemic reviews and 26 original articles were reviewed by 2 guideline writers. Final recommendations for PrEP use were stratified by 4 key groups: strong evidence and strong recommendation for men who have sex with men and transgender women, as well as serodiscordant couples, intermediate evidence and weak recommendation for people who inject drugs, while low evidence and weak recommendation for at-risk heterosexual men and women. Taiwan CDC released TW PrEP guideline in May 2016. Following the guideline release, Taiwan Food and Drug Administration (TFDA) approved the indication of PrEP for Truvada® in August 2016 and 41 hospitals in Taiwan further provided the service of PrEP since November 2016. Among them, 5 hospitals were selected as demonstration project sites supported by Taiwan CDC.
Conclusions: Taiwan is the first country in Asia to develop local PrEP guideline and to implement PrEP for population at risk of HIV infection nationwide.

WEPEC1019

The effect of child apprehension on sexual HIV/STI risk negotiation with marginalized women sex workers: possible pathways from trauma to HIV/STIs

K. Kenny[1,2], P. Duff[2], B. Bingham[2,3], M. Braschel[2], M. Thumath[2], R. Abraham[4,5], B. Pence[6], K. Shannon[2,7]
[1]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Department of Maternal and Child Health, Chapel Hill, United States, [2]Gender and Sexual Health Initiative, BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [4]BC Women's Hospital, Fir Square Combined Care Unit, Vancouver, Canada, [5]Sheway, Vancouver, Canada, [6]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [7]University of British Columbia, Department of Medicine, Vancouver, Canada
Presenting author email: kskenny@live.unc.edu

Background: Limited research on sex workers who are mothers show that child apprehension by Child Protective Services (CPS) is a commonly experienced phenomenon. While there is emerging literature identifying child apprehension as a source of trauma and adverse health outcomes in women, there is a paucity of information on the health consequences for sex workers, including HIV/STI vulnerability, and on implications for HIV prevention programs. Building on prior studies showing traumatic events to be predictive of HIV vulnerability, this study examined the potential role of child apprehension in shaping pathways from trauma to HIV/STI vulnerability.
Methods: Analyses drew on a longitudinal community-based cohort AESHA (An Evaluation of Sex Workers' Health Access) of street/off-street sex workers in Vancouver, Canada. We used logistic regression with generalized estimating equations (GEE) to examine the independent effect of child apprehension on client condom refusal among women sex workers who ever had a live birth, as well as potential mediating pathways between child apprehension and HIV/STI risk.
Results: Among 466 women, 180 (39%) had experienced one or more child apprehensions (median =1), with Indigenous women experiencing the highest burden of child apprehension (58%). In a multivariable GEE logistic regression model, women sex workers experiencing child apprehension were 1.70 times more likely (95% confidence interval: 1.06, 2.73) to report client condom refusal. In separate models, there was evidence that drug use may mediate the relationship between child apprehension and HIV/STI risk, and physical or sexual violence may be a partial mediator of this relationship.
Conclusions: This research suggests that child apprehension is a traumatic experience for marginalized women with health consequences evidenced by a direct and possible mediated effect on HIV/STI risk through drug use and violence. There is an urgent need to move away from criminalized approaches to sex worker-led trauma-informed, gender-focused and harm reduction centered policies and programs that respond to the needs of sex workers who are mothers and their families (e.g. family-centered housing). The overrepresentation of child apprehension among Indigenous sex workers highlights the need for decolonizing, cultural and equity-informed approaches to ensure Indigenous women receive tailored supports.

WEPEC1020

The role of violence in migration and displacement patterns, unsafe sexual practices under the influence of non-injected drugs and vulnerability to HIV in the Mexico/Guatemala border region

R. Munoz Martinez
University of California, Family Medicine and Public Health, San Diego, United States
Presenting author email: rubmuma@hotmail.com

Background: In a context of increasing drug trafficking, there has been an increase in local substance use along the Mexico-Guatemala border. The area is also distinguished by migration, towards the United States but also regional circular migration. Among diverse populations around the world, a relationship between use of illicit drugs during sex, unsafe sexual practices, and exposure to HIV/AIDS has been established.
However, the Mexico-Guatemala border region is also distinguished by a context of discrimination of migrants and violations of their human rights, arising from structural, symbolic and direct violence, making migrants particularly vulnerable to acquiring HIV/AIDS or having difficulty in accessing available services.
Methods: This qualitative research is based in a case study in the Mexico-Guatemala border city of Tapachula (Mexico), and embedded within the infrastructure of a mixed methods study, "Crossing Borders". 50 in-depth interviews were conducted, during 2013 and 2016, with a targeted sample of men from Honduras, El Salvador and Guatemala en route to the United States with undocumented status, who have commercial sex with men and/or women under the influence of non-injected drugs use and professionals in migration, drug addiction and HIV fields. Three weeks of field observation were included in 2016.
Results: We analyzed direct, structural and symbolic violence as socio-cultural and economic health determinants, related to migratory/displacement patterns and vulnerability to HIV of study population regarding inconsistent condom use and drug consumption during sexual work, in two public areas of Tapachula. Results highlight four levels of macro and intermediate health determinants:
a) the role of direct violence from organized crime, in origin/transit Central American countries and Mexico, in migratory/displacement mobility.
b) Discrimination and lack of social and economic opportunities as undocumented migrants.
c) Economic extortion and harassment from police and migratory agents, and reduced access to public health services.
d) Praxis and Social-representations through the violence of unequal negotiations of safe encounters, about non-condom and drug use in sexual work transactions.
Conclusions: There is a need to increase understanding and improve local interventions within social, economic and cultural determinants of unsafe sexual praxis under the influence of non-injected drug use in this migratory/displacement context.

WEPEC1021

Feasibility, acceptability, and preliminary efficacy of the bio-behavioral community-friendly health recovery program (CHRP-BB): a combination approach for primary HIV prevention among high-risk drug users

R. Shrestha[1,2], F. Altice[2,3], P. Karki[2,4], T. Huedo-Medina[2,4], M. Copenhaver[2,4]
[1]University of Connecticut Health Center, Community Medicine & Health Care, Farmington, United States, [2]University of Connecticut, Institute for Collaboration on Health, Intervention, and Policy, Storrs, United States, [3]Yale University, Department of Internal Medicine, New Haven, United States, [4]University of Connecticut, Department of Allied Health Sciences, Storrs, United States
Presenting author email: roman.shrestha@uconn.edu

Background: Despite unequivocal evidence supporting pre-exposure prophylaxis (PrEP), few - if any - researchers have reported incorporating it into an existing HIV prevention program, particularly among people who use drugs (PWUD). Based on our formative work, we integrated the biomedical component (PrEP) into the evidence-based behavioral intervention (Community-friendly Health Recovery Program: CHRP). Moreover, we incorporated specific behavioral strategies (e.g., mHealth technology, cognitive remediation tools) within the new combination approach - now called CHRP-BB - to accommodate those with neurocognitive impairment such that primary prevention benefits - including PrEP adherence and HIV risk reduction - can be maximized among PWUD. Here, we report the feasibility, acceptability, and preliminary efficacy of the CHRP-BB intervention among high risk PWUD in methadone maintenance program (MMP).
Methods: Using a within-subjects pre/post/follow-up design, we implemented the CHRP-BB intervention within a group of high risk, HIV-negative MMP clients who had started taking PrEP in the past week (n=23). Participants completed four 50-minute intervention sessions, and reported on demographic, behavioral, and psychosocial characteristics at baseline, immediately post-intervention, and 1-month post-intervention. Furthermore, following the completion of the intervention phase, we administered a process measure among treatment providers and administrators (n=12) at the MMP clinic.
Results: Our pilot study affirmed feasibility, acceptability, and preliminary efficacy of the CHRP-BB intervention. We assessed feasibility based on participant engagement (e.g., attending groups and completing assessments), which was outstanding, with 100% retention through the 1-month post-intervention follow-up. The mixed methods data analysis showed that participants were highly satisfied and perceived the CHRP-BB intervention as valuable and acceptable (82.7%). Post-intervention feedback also indicated that the content delivered in the group sessions, during the mHealth text messaging, and the overall CHRP-BB intervention was helpful in addressing PrEP adherence and HIV risk reduction. In terms of efficacy, PrEP adherence, PrEP-related knowledge and behavioral skills, drug-related risk behaviors, and demonstrated HIV risk reduction skills improved significantly from Pre- to Post-intervention, and the improvement persisted at the 1-month post-intervention Follow-up point.
Conclusions: This pilot study argues for the potential of the new CHRP-BB approach to increase adherence to PrEP and reduction in HIV risk behaviors among high risk PWUD in treatment.

WEPEC1022

Combination prevention in key populations' social venues: a Brazilian experience in partnership with NGOs

T. Dourado de Miranda Lobo, C. Habckost Dutra de Barros, A.R. Pati Pascom, A. Schwartz Benzaken
Ministerio da Saude, IST, AIDS e Hepatites Virais, Brasilia, Brazil
Presenting author email: tainah.lobo@aids.gov.br

Background: To address the many determinants of HIV epidemic, a multisectoral response is required, operating in individual, social and programmatic levels. The 'Live Better Knowing' project, characterized by the association of HIV prevention interventions targeted at the most at-risk groups, has been considered an assertive combination HIV prevention strategy. This study aims to provide a snapshot of key populations' HIV prevalence and prevention behaviors based on data collected by the strategy.
Methods: The project offers rapid oral fluid HIV testing (DPP HIV-1/2 Bio-Manguinhos/Fiocruz), counseling, prevention education, supplies distribution, referral to PEP and monitored linkage to health services for treatment and care. Testing is free and held in social venues where key populations meet. The targeted population reached by the initiative between June 2015 and October 2016 was also invited to answer a structured questionnaire containing sociodemographic data and information about their risk and prevention behaviors.
Results: Among the 54.476 participants, 62% were nonwhite and 60.3% aged 20 to 40 yo. 61.9% reported drug use and 16.9% drug use and commercial sex combined. 51% reported condom use at last sexual intercourse and 9% reported STI symptoms in the last 12 months. Overall, 47.3% had been tested for HIV at least once before the strategy. The general HIV prevalence found was 1.6%. Among cis-women, transvestites, transsexual women, transsexual men, MSM and heterosexual men it was 0.9%, 6.8%, 5.3%, 1.5%, 3.5%, and 0.9% respectively.
Conclusions: Transvestites and transsexual women constitute a high-risk population for HIV in urgent need of responses able to tackle the vulnerabilities related to the HIV acquisition in these groups. The participation of the key populations, composing the NGOs teams, in the execution of the strategy was crucial to impact structural variables in addition to improve the uptake of prevention technologies trough biomedical and behavioral interventions.

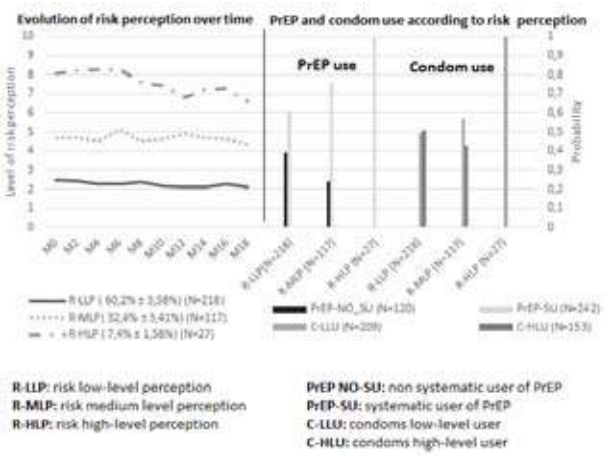
Impact of risk perception trajectory on PrEP and condom use among men who have sex with men during the open-label-extension of the ANRS-IPERGAY trial

M. Di Ciaccio[1,2,3], L. Sagaon-Teyssier[1,3,4], M. Suzan-Monti[1,3,4], B. Mmadi-Mrenda[1,3,4], E. Cua[5], G. Pialoux[6], N. Leturque[7], V. Foubert[7], M. Préau[1,2], J.-M. Molina[8], B. Spire[1,3,4], ANRS IPERGAY Study Group
[1]INSERM, UMR_S 912, Sciences Economiques & Sociales de la Santé et Traitement de l'Information Médicale (SESSTIM), Marseille, France, [2]Groupe de Recherche En Psychologie Sociale (GRePS), Université Lyon 2, Lyon, France, [3]Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [4]Aix Marseille Université, UMR_S 912, IRD, Marseille, France, [5]Hospital Archet 1, Department of Infectious Diseases, University Hospital, Nice, France, [6]Hospital Tenon, Department of Infectious Diseases, Assistance Publique Hôpitaux de Paris, Paris, France, [7]NSERM SC 10 US 19, Villejuif, France, [8]Hospital Saint-Louis, Department of Infectious Diseases, Assistance Publique Hôpitaux de Paris, Paris, France
Presenting author email: marion.di-ciaccio@inserm.fr

Background: First results of the Open-Label-Extension (OLE) of the ANRS-IPERGAY trial showed greater use of PrEP than condoms. We assessed whether participants' risk perception trajectories impacted PrEP and condom use during the OLE.
Methods: Two-monthly follow-up was performed during ANRS-IPERGAY OLE (M0 to M18) and included online questionnaires focusing on sexual behaviours, condom use, risk perception and PrEP uptake at most recent anal intercourse encounter. A longitudinal multi-trajectory model was implemented for three outcomes: level of risk perception (10-point scale), PrEP use (correct/suboptimal versus no PrEP) and condom use for anal sex (yes versus no). Dual trajectory models helped estimate probabilities of PrEP and condom use according to risk perception.
Results: Data for 362 participants were analysed. Three trajectories of risk perception (low, R-LLP; medium, R-MLP; and high, R-HLP; see left-side figure below), two trajectories of condom use (low-level, C-LLU; high-level, C-HLU), and two trajectories of PrEP uptake (systematic, PrEP SU; non-systematic, PrEP No-SU) were identified. The R-HLP trajectory declined over time. Dual models (see right-side figure below) showed that condom use probability decreased with increased risk perception level: 50% of R-LLP, 40% of R-MLP, and 0.2% of R-HLP were high-level condom users. Estimated PrEP uptake probabilities highlighted that

greater PrEP use compensated for low-level use of condoms, with probabilities increasing with increased risk perception. Specifically, 60% of R-LLP, 75% of R-MLP, and 100% of R-HLP were systematic PrEP users.
Conclusions: In the ANRS-IPERGAY OLE, risk perception contributed to explain PrEP uptake levels. Systematic PrEP users appeared to be less worried about risk over time. Psychosocial factors might explain the barriers to condom use and the success of PrEP uptake. To reduce HIV infection, special attention must be paid to understand factors influencing risk perception and accordingly PrEP uptake.



[Risk perception trajectory and duals model]

WEPEC1024

Men who have sex with men (MSM) in Egypt: high-risk sexual and injecting behaviors

S. Elkamhawi[1], Y. Elkei[1], M. Abdel Malak[1], C. Khoury[1], W. Elbeih[2], H. Ramy[3], E. Elkharrat[4], N. Elkott[5], N. Sanan[6], S. Kozman[7], C. Soliman[1]
[1]FHI 360, Cairo, Egypt, [2]Drosos Foundation, Cairo, Egypt, [3]Ain Shams University, Cairo, Egypt, [4]Freedom, Cairo, Egypt, [5]Hayat, Cairo, Egypt, [6]Befrienders, Cairo, Egypt, [7]YAPD, Cairo, Egypt
Presenting author email: selkamhawi@fhi360.org

Background: In Egypt, Key Populations (KPs) especially Men who have Sex with Men (MSM) face severe discrimination from the society. In 2013, FHI 360, with support from the Drosos and the Ford foundations, established the Network of Associations for Harm Reduction (NAHR) to provide KPs with a comprehensive package of HIV/AIDS prevention and harm reduction services through the Comprehensive Care Centers (CCCs).
Methods: Street-based outreach was used to refer MSM to six NAHR CCCs where they received voluntary, anonymous and free of charge harm reduction services promoting safe sex and safe injection. Socio-demographic and behavioral data addressing the sexual and injecting behaviors were collected and analyzed between March 2013 and September 2016 in Greater Cairo and Alexandria.
Results: A total number of 12492 males visited the CCCs, of which 4523 (36.2%) were MSM. Almost half of them (47.3%) were in the age group of 16-24 years, about 44.4% received some university education, more than half of them (52.6%) were employed and 13.0% were currently married. Condom use at last sex was reported by 13.4% with a non-steady partner and 11.2% with a steady partner. About 91.0% were willing to use condom in the future. More than one quarter (27.7%) of MSM ever injected drugs and Heroin injection in the last month was reported by 41.0%. Among injecting MSM, more than half (51.2%) shared needles, 59.2% shared syringes, and 46.1% shared paraphernalia in the last month. Moreover, about 6.0% of MSM exchanged sex for drugs and 17.2% had sex with a sex worker in the last year. The HIV prevalence among MSM was 8.7%.
Conclusions: The comprehensive care package of services provided in NAHR CCCs succeeded is addressing the overlap of risky behaviors among MSM. Replicating the Egyptian integrated model with an adapted harm reduction approach may offer an attractive and practical solution to reaching MSM in similar conservative societies.

WEPEC1025

Use of HIV services increases with targeted HIV campaigns among adolescent girls and young women in a multicountry survey in sub-Saharan Africa

O. Gbadamosi[1], L. Klazinga[2], A. Kayongo[3], J. Gonzalez Perez[4], P. Iutung Amor[3], K. Ssamula[3]
[1]AIDS Healthcare Foundation, Abuja, Nigeria, [2]AIDS Healthcare Foundation, Durban, South Africa, [3]AIDS Healthcare Foundation, Kampala, Uganda, [4]AIDS Healthcare Foundation, Kigali, Rwanda
Presenting author email: kate.ssamula@aidshealth.org

Background: Adolescent girls and young women (AGYW) have one of the highest HIV incidence rates globally. Lack of access to health services, including Sexual and Reproductive Health (SRH) and HIV testing and low condom use have been indicated among the reasons to explain this situation. In April 2016, AIDS Healthcare Foundation (AHF) commissioned a multi-country survey among AGYW to better understand specific challenges facing this group and identify interventions to address them.
Methods: The survey, among female 16-24 years-old in Uganda, Nigeria and South Africa, used Short Message Service (SMS) technology and comprised of 50 questions covering access to health services, sexual behavior, family planning, HIV testing and information on HIV. Independent covariates of access to HIV related services and condom use were assessed by multivariate logistic regression analysis.
Results: Overall 1,600 participants were included in the survey, 62 % were sexually active, 76 % had used condom in the last sexual intercourse and 81 % claimed to know their HIV status. 72 % of the participants have visited a health facility for HIV or SRH related services. In the multivariate analysis, consistent condom use was higher in those that knew their HIV status and lower in married AGYW (Adjusted Odds Ratio [aOR]: 0.3, 95%Confidence Interval [95%CI]: 0.1-0.6). Access to HIV and SRH services increased with age and onset of sexual activity, and was higher in those whose main source of information was family (aOR: 1.4, 95%CI: 1.2-1.5) versus school and in participants that had recently seen HIV messages/campaigns relevant to them (aOR: 2.6, 95%CI: 1.8-3.9) and decreased when distance to the closest facility was more than 5km (aOR: 0.6, 95%CI: 0.5-0.6).
Conclusions: We found a higher than expected use of health services and uptake of HIV testing. It is also significant that those that received messages on HIV that were relevant to them had more than double the odds to seek HIV health services, highlighting the importance of tailored communication strategies for this group. Regarding condoms, the lower use reported in married AGYW (with the existing evidence of ongoing HIV transmission) calls for new prevention efforts in this context.

Attitudes about PrEP among physicians who participated in the open-label extension of the ANRS-IPERGAY trial: a qualitative study

M. Di Ciaccio[1,2,3], M. Suzan-Monti[1,3,4], C. Chidiac[5], C. Bernaud[6], A. Cheret[7], G. Pialoux[8], E. Cua[9], M. Saouzanet[10], E. Netzer[10], B. Spire[1,3,4], J.-M. Molina[11], M. Préau[1,2], ANRS IPERGAY Study Group
[1]INSERM, UMR_S 912, Sciences Economiques & Sociales de la Santé et Traitement de l'Information Médicale (SESSTIM), Marseille, France, [2]Groupe de Recherche En Psychologie Sociale (GRePS), Université Lyon 2, Lyon, France, [3]Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [4]Aix Marseille Université, UMR_S 912, IRD, Marseille, France, [5]Hospital Croix Rousse, INSERM U 1052, Department of Infectious Diseases, Lyon, France, [6]University Hospital, Department of Infectious Diseases, Nantes, France, [7]University Hospital, Department of Infectious Diseases, Lille, France, [8]Hospital Tenon, Department of Infectious Diseases, Assistance Publique Hôpitaux de Paris, Paris, France, [9]Hospital Archet 1, Department of Infectious Diseases, University Hospital, Nice, France, [10]NSERM SC 10 US 19, Villejuif, France, [11]Hospital Saint-Louis, Department of Infectious Diseases, Assistance Publique Hôpitaux de Paris, Paris, France
Presenting author email: marion.di-ciaccio@inserm.fr

Background: The ANRS-IPERGAY trial recruited physicians to prescribe PrEP. No scientific data currently exists about physicians' specific experience of prescribing medical HIV prevention treatment.
Methods: A novel, original psychosocial sub-study examined the subjective experience of prescribing physicians during the trial. Between March and June 2016, data were collected during an open-label extension study through interviews with physicians (9 generalists, 7 infectologists and 2 internists). Interviewees came from all participating ANRS-IPERGAY centres. The standard interview grid collected information on experience of PrEP prescription, attitudes about PrEP, treatment of seronegative people and the physician-patient relationship. Text analysis was performed using IRaMuteQ, an open-source automated statistical software package.
Results: Analysis of 18 interviews highlighted that attitudes about PrEP were based

on: i) medical and scientific knowledge (side effects, protocol, impact on public health), which comprised 35% of physicians' discourse, and;
ii) personal experiences with PrEP users and with participating volunteers from the HIV patient association AIDES (personalized support, PrEP use in real life, sex practices, drug use), comprising 65% of their discourse.
The ANRS-IPERGAY experience impacted physicians' practices. They became more favourable to promoting risk reduction practices (39% of interviewees). They also changed their consultation style, becoming more attentive to their patients' needs and opinions. They were required to be more benevolent and non-judgemental, given the delicate nature of the themes discussed (55.5% of interviewees). The physician-patient relationship was a central element for successful PrEP consultation as was the relationship with AIDES' volunteers (for 72% of interviewees). Globally, physicians' participation in ANRS-IPERGAY led to a positive change in their personal representations of PrEP and its users.
Conclusions: This novel study highlights the positive outcome of the ANRS-IPERGAY trial on participating physicians. They gained in-depth knowledge about the MSM community, risk-taking behaviours, PreP users' concerns, and more generally, related public-health issues. The feedback from this trial will help to draw-up guidelines for future professionals prescribing PrEP.

WEPEC1027

Brisbane, capital city of Queensland is the first Australian city to see a significant drop in HIV diagnoses due to new prevention methods

D. Russell[1], J. Gow[2], M. Warner[3]
[1]HIV Foundation Queensland and Cairns Sexual Health Clinic, Fortitude Valley, Australia, [2]HIV Foundation Queensland and University of Southern Queensland, Brisbane, Australia, [3]HIV Foundation Queensland, Brisbane, Australia
Presenting author email: melissa.warner@hivfoundation.org.au

Background: Brisbane is the first Australian city to report a significant reduction of HIV notifications in 2016. Data reports HIV notifications have decreased by 38% since 2014, following a period where HIV diagnoses had doubled over the 10 previous years. In response, the Queensland HIV Strategy 2012-2015 provided strategic direction focusing on 4 key pillars: comprehensive preventative approach; increase voluntary testing; increase treatment uptake; and addressing stigma and discrimination. With Government commitment to work towards the virtual elimination of HIV and achieving the UN 90-90-90 targets in Queensland, a multi-pronged approach was implemented. The HIV Foundation Queensland was established and tasked with providing leadership, coordination and support to the HIV public health response.
Methods: Stakeholders and partnerships with community, clinicians and academics were mobilised. A peer-led HIV rapid testing clinic and outreach services were established and the growth of Queensland led innovative research and programs was supported. International partnerships with British Columbia were developed and treatment as prevention strategies implemented to promote and improve access to early HIV treatment, PrEP and PEP. The END HIV campaign was launched and demonstrated a shift from one off campaigns to a multi-phased approach.
Results: The peer led HIV rapid clinic and outreach services were well received by MSM and quickly became the busiest testing service in the city with 99% client satisfaction ratings. Gay friendly General Practices also reported significant annual increases (30%+) of HIV testing. Evaluations of forums with community, health professionals, academics and policy makers demonstrated significant shifts in understanding treatment as prevention strategies and willingness to promote and prescribe early treatment, PrEP and PEP. There was an increase in PEP prescriptions and it is estimated that approximately 300 + people at risk of HIV in Brisbane were accessing PrEP through a small demonstration project and self-importation.
Conclusions: Political commitment, clear strategic direction and the mobilisation of all stakeholders and partnerships to work towards the common goal of ending HIV laid the foundation for implementation of innovative strategies. Brisbane is yet to see the full benefit of PrEP, which means the current data present an even more promising outlook for Brisbane.

WEPEC1028

Evaluating HIV testing strategies: a randomized trial of Opt-out versus Opt-in testing among at-risk women in Russia

T. Balachova[1], A. Shaboltas[2]
[1]The University of Oklahoma Health Sciences Center, Oklahoma, United States, [2]St. Petersburg State University, St. Petersburg, Russian Federation
Presenting author email: tatiana-balachova@ouhsc.edu

Background: Young women are disproportionately affected by HIV which is a major concern in countries with increasing HIV incidence, such as Russia. Testing is a promising prevention strategy particularly for young women who intend to become pregnant or may have limited control over condom use. However, evidence to support effective testing remains low with majority of studies utilizing pre/post or cross-sectional design and data on Russian women are lacking.
The objective of this study was to evaluate Opt-in vs. Opt-out testing among at-risk Russian women.
Methods: The study was conducted in primary care setting in Russia and utilized a mixed methods adaptive design that included a two-arm randomized clinical trial followed by a survey. A total of 868 women of childbearing age were screened; 200 at-risk women who had not completed HIV testing in 12 months were recruited and assigned to either Opt-in or Opt-out testing conditions. Laboratory tests included a rapid HIV screening test and, in Opt-out condition, a multi-health screening (cholesterol, hemoglobin, and blood glucose). Immediately after the trial procedures, participants completed a face-to-face health risk survey. Testing was available after the survey for testing non-acceptors. The outcomes of interest were modeled using Generalized Estimating Equations and Generalized Linear model.
Results: Participants had mean age of 23.5 and 23.4 years in Opt-in and Opt-out groups, respectively. Testing acceptance rates were 86% (Opt-in) and 90% (Opt-out). After participating in the survey, additional 4% (Opt-in) and 6% (Opt-out) accepted testing, totaling to 90% of participants in Opt-in and 96% in Opt-out groups. Education, age, and having children had significant effect on testing behavior. The odds of accepting testing were lower for those who were younger, had any children, and had higher education. When controlling for these characteristics, the odds of acceptance of HIV testing were 3.8 times higher in Opt-out group compared to Opt-in group (OR=3.779, 95% CI:1.169, 14.795, p=0.036).
Conclusions: Removing barriers and offering HIV rapid testing is an effective strategy to increase HIV testing uptake. The specific effect of Opt-out vs. Opt-in testing on testing acceptance provides information necessary to estimate effects of scaling up HIV testing among at-risk women in Russia.

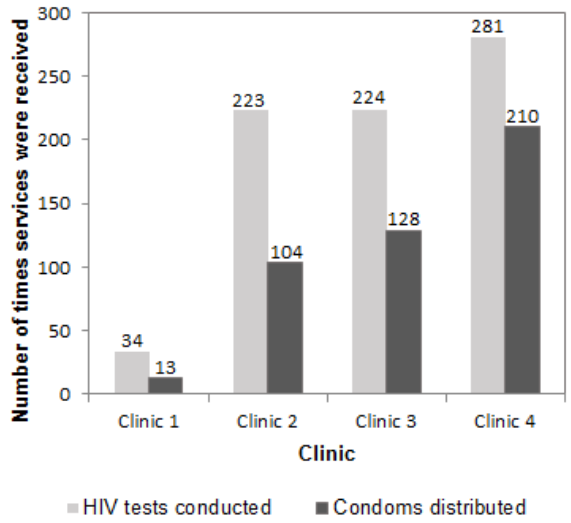
WEPEC1029

Evaluating the impact of combination HIV prevention approaches on service uptake among adolescent girls and young women in Lilongwe, Malawi

N.E. Rosenberg[1,2], A. Pettifor[1], T. Phanga[2], B. Maseko[2], D. Vansia[2], N. Bhushan[1,2], A. Kachigamba[3], J.H. Tang[2,4], M.C. Hosseinipour[2,4], L.G. Bekker[5]
[1]University of North Carolina at Chapel Hill, School of Public Health, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, UNC Project-Malawi, Lilongwe, Malawi, [3]District Health Office, Lilongwe, Malawi, [4]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, [5]University of Cape Town, Desmond Tutu HIV Foundation, Cape Town, South Africa
Presenting author email: nora_rosenberg@unc.edu

Background: Although multi-level combination HIV prevention has been promoted for adolescent girls and young women (AGYW) in sub-Saharan Africa, there is limited evidence on how clinical, behavioral, structural, and multi-level interventions compare to one another and to no intervention.
Methods: Girl Power is a study assessing four different models of service delivery for AGYW in Lilongwe, Malawi:
1) standard of care (no intervention),
2) youth-friendly health services (YFHS) (clinical intervention),
3) YFHS + empowerment (clinical + behavioral interventions),
4) YFHS + empowerment + cash transfer (clinical + behavioral + structural interventions).
Four comparable public sector clinics were selected and randomly assigned to one model of service delivery. During the six-month enrollment period, the four clinics were compared for uptake of HIV testing and counseling (HTC) and condom uptake (number of times a participant received any condoms). Number of times services were received per 100 AGYW were calculated and compared across clinics.
Results: 250 AGYW 15-24 years old were enrolled in each clinic (N=1000 total). Median age was 19 years. Rates of HTC uptake were 14, 89, 90, and 113 per 100 AGYW at clinics 1, 2, 3, and 4, respectively (p<0.001); rates of condom uptake were 5, 42, 51, and 84 per 100 AGYW in clinics 1, 2, 3, and 4, respectively (p<0.001). Uptake was higher in clinic 2 than clinic 1 for both HTC (p<0.001) and condoms (p<0.001).

Uptake was similar at clinics 2 and 3 for both HTC (p>0.999) and condoms (p=0.116). Uptake was higher in clinic 4 than clinic 3 for both HTC (p=0.009) and condoms (p<0.001).



[Figure 1. Number of times services were received]

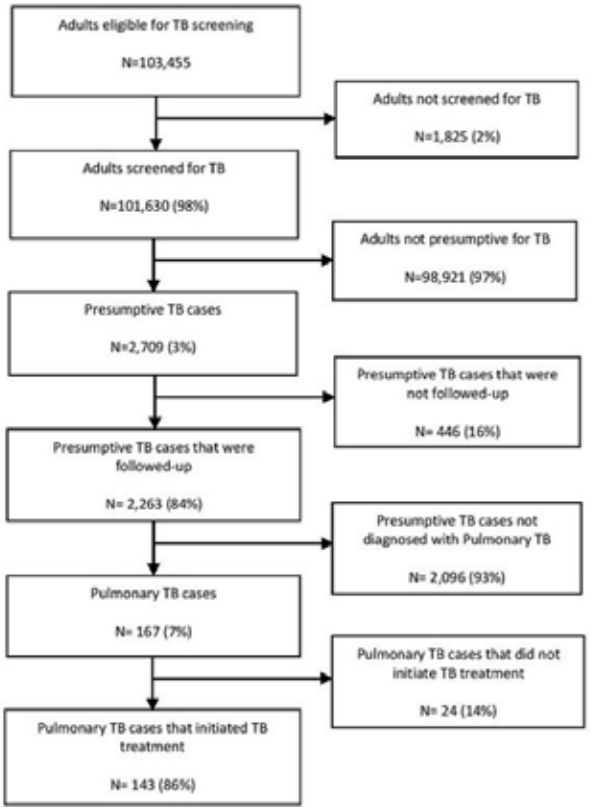
Conclusions: A YFHS clinical package contributed to high rates of HTC and condom uptake. A cash transfer contributed further. For AGYW in sub-Saharan Africa, combination prevention programs can substantially impact HIV service uptake.

WEPEC1030

Feasibility, uptake and yield of household-based tuberculosis active case finding within the combination prevention package in the HPTN 071 (PopART) intervention in high TB/HIV burden communities in South Africa

B. Yang[1], S. Floyd[2], S. Griffith[3], R. Dunbar[1], P. Bock[1], H. Ayles[4,5], S. Fidler[6], R. Hayes[2], N. Beyers[1], R. Sloot[1,7]
[1]*Desmond Tutu TB Centre, Stellenbosch University, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa,* [2]*London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom,* [3]*Family Health International 360, Durham, United States,* [4]*Zambia AIDS Related Tuberculosis Project, University of Zambia, Lusaka, Zambia,* [5]*London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom,* [6]*Imperial College, Department of Infectious Disease Epidemiology, London, United Kingdom,* [7]*Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands*
Presenting author email: bliay@sun.ac.za

Background: HPTN 071 (PopART) is a community-randomised trial of a combination HIV prevention intervention, which includes home-based HIV counselling and testing and tuberculosis (TB) screening, delivered in four annual rounds by Community HIV-care Providers (CHiPs) in Zambia and South Africa. We evaluated the feasibility, uptake and yield of household-based TB active case finding (ACF) within a combination HIV prevention intervention.
Methods: We report data from the second annual round (06/2015-08/2016) from six South African communities. Adults (≥18 years) that consented to participate were eligible for TB screening if not on TB treatment. CHiPs administered electronic TB screening questionnaires (weight loss, cough ≥2 weeks, night sweats) and enquired about persons with TB in the household or at work. Two sputum specimens were collected from adults with presumptive TB (≥1 symptom or in contact with TB). Diagnosis of bacteriologically confirmed pulmonary TB (PTB) was based on Xpert MTB/RIF®, smear microscopy, or culture. PTB cases were referred to the local health care facility for treatment. Multivariable logistic regression was used to determine the association of sex and age with different outcomes within the TB cascade of care.
Results: 103,455 adults were eligible for TB screening. 101,630/103,455 (98%) adults received TB screening (43% males, median age 31 years). 2,709/101,630 (3%) were presumptive TB cases. 2,263/2,709 (84%) were followed up. 167/2,263 (7%) were PTB cases. 143/167 (86%) initiated TB treatment (See Figure 1). Adults aged ≥55 were more likely to be presumptive TB cases compared to younger age groups (P-value <0.01). Females were less likely to be presumptive TB cases (aOR 0.78, 95%CI 0.72-0.84) and less likely to be diagnosed with PTB (aOR 0.67, 95%CI 0.49-0.93) compared to males.



[Figure 1: Flowchart for TB active case finding]

Conclusions: ACF through household TB screening within a combination HIV prevention intervention is feasible. CHiPs were able to identify undiagnosed cases in the community and refer adults for treatment.

WEPEC1031

HIV testing strategies as opportunities to identify new and long-standing HIV infections: implications for linkage to care

M. McNulty[1], D. Pitrak[1], N. Benbow[2], J. Schneider[1]
[1]*University of Chicago Medicine, Infectious Diseases and Global Health, Chicago, United States,* [2]*Feinberg School of Medicine, Northwestern University, Chicago, United States*
Presenting author email: moira.mcnulty@uchospitals.edu

Background: Multiple HIV testing recruitment strategies have been endorsed as effective by the US CDC, including social network strategies and routine clinical based testing, but it is unknown how each strategy performs in engaging patients in the care continuum. This study aims to evaluate HIV testing strategies and downstream care continuum metrics.
Methods: We evaluated two HIV testing programs operating in Chicago between 2013-2015 that utilize routine testing (RT) and the social network strategy (SNS). For each method, we determined seropositivity rate of new and existing HIV diagnoses, linkage to care and time to linkage to care for new HIV diagnoses using programmatic and Department of Public Health data.
Results: RT performed 31,921 HIV tests in 30,225 individuals, with 203 total positive tests and 81 new HIV diagnoses for a new seropositive rate of 0.27%, while SNS tested 508 individuals with 208 positive tests and 38 new HIV diagnoses for a new seropositive rate of 7.5% (χ^2 (1, N = 30,733) = 673.7, p<0.001). Of new cases diagnosed by RT, 56 (69.1%) were male and 71 (87.7%) were African American (AA) with a mean age of 31.8 years. In RT, median CD4 count and viral load at diagnosis were 279/μL and 4.91 log units, respectively. New diagnoses in SNS were 92.1% male and 100% AA with a mean age of 24 years. In SNS, median CD4 count and viral load were 400/μL and 4.69 log units. Median time to linkage to care was 22 days for RT and 41 days for SNS.
Conclusions: HIV elimination will require identifying approaches that engage individuals in HIV care and prevention. In this analysis, SNS had a higher seropositivity rate, while RT had a faster time to linkage to care. Multiple integrated testing approaches may be necessary to identify individuals with HIV and at risk for HIV. Next steps will be to determine downstream metrics in the continuum of care, including retention in care and viral suppression.

WEPEC1032

PrEP cohort results from MP3 youth combination HIV prevention pilot study

I. Inwani[1], J. Buttolph[2], A. Kawango[3], C. Cleland[2], J. Kiarie[1], J. Kinuthia[1], L. John[4], A. Kurth[5], J. Lizcano[4,5]
[1]University of Nairobi, Nairobi, Kenya, [2]New York University, New York, United States, [3]Impact Research and Development Organization (IRDO), Kisumu, Kenya, [4]Ministry of Health, Nairobi, Kenya, [5]Yale University, New Haven, United States

Background: Young women remain at high risk of HIV in sub-Saharan Africa. PrEP is an effective biomedical intervention for HIV prevention in combination with behavioral and structural interventions, to reduce the risk of HIV among young women. The MP3 youth pilot provides real-world evidence on delivering PrEP to young women in Kenya as part of an age-sex-HIV risk combination HIV prevention package.
Methods: Eligible girls were offered PrEP (TFV-DP) for 12 months. Eligibility included clinical and behavioral criteria (HIV-negative, not-pregnant, 18-24, not enrolled in school, met risk criteria). Enrolment was during mobile events and follow-up was in-person and via SMS survey, monthly for the first 6 months, and 3-monthly for the next 6 months. Adherence was measured by refill visits, self-report, and having >600 fmol/punch of TFV-DP in a dried blood spot (DBS) sample.
Results: Based on eligibility, 40 girls were screened and 28 were enrolled. Participant retention was high in month one (92%), and decreased by month 9 (64%). Ninety-three percent of participants returned at month 9 for endline sample collection. Self-reported adherence was high (87.7%) and congruent with drug levels. Based on DBS drug levels, most girls were adherent (67% (14/21)) at month 2, and even more adherent (78% (7/9)) at month 9. There were no HIV seroconversions and no serious adverse events. Three pregnancies occurred.
Conclusions: PrEP can be initiated in the field after a clinical assessment. Girls need high interaction during follow-up for good retention. The majority of the participants who were non-adherent to PrEP were identified in month one. PrEP may not be the solution for all, but 50% of girls in the study took PrEP consistently, with high levels of adherence. Girls continued to engage in unprotected sex, as evidenced by the pregnancies. Additional research is needed to identify PrEP retention strategies.

WEPEC1033

Participatory package for improving HIV and reproductive health knowledge of HIV-infected and affected adolescents in Myanmar

K.-M. Htut[1], M.-M. Mon[1], H.-N. Oo[2]
[1]Ministry of Health and Sports, Department of Medical Research, Yangon, Myanmar, [2]Ministry of Health and Sports, National AIDS Program, Nay Pyi Taw, Myanmar
Presenting author email: 84kyawminhtut@gmail.com

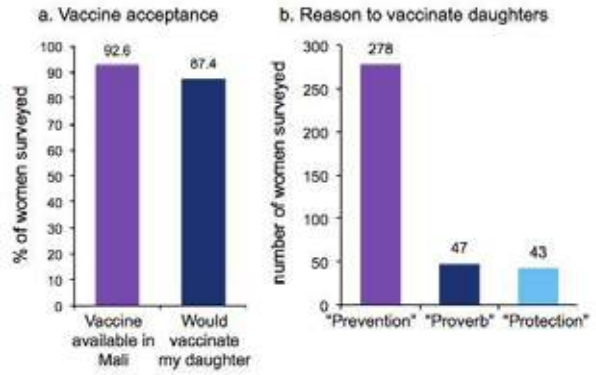
Background: Comprehensive knowledge on HIV and reproductive health (RH) is essential for HIV infected and affected adolescents in order to prevent them from adopting RH risk behaviours. Applying participatory package could be more beneficial for young adolescents to learn health knowledge than usual way of providing health education.
Methods: Pre and post intervention design was applied to assess the effectiveness of participatory discussions on HIV and RH among HIV infected and affected adolescents. Participatory package comprising body mapping, two-way discussion using case scenarios and meditation practice were applied during the 3 months intervention period. Baseline and post assessment at 3 months after the intervention were conducted using both quantitative and qualitative research methods.
Results: A total of 80 HIV infected and affected adolescents included in the study. Mean age of the adolescents was 12.8±1.9 years and ranged from 10 to 16 years. Nearly one-fourth (23.7%) of the adolescents were currently out of school, 36.2% stayed with extended family members and 76.2% were either single or double orphans.
At the start of intervention, body mapping exercises were conducted separately for male and female where reproductive organs and puberty changes were discussed. Although the adolescents were aware of puberty changes for their respective gender, most of them could not mention about the opposite gender. Many of them did not know the connection between menstrual cycle and conception. Improvement in knowledge scores on RH regarding puberty changes (2.7±1.3 vs. 4.2±0.7, p<0.05), adolescent pregnancy and consequences (4.0±1.0 vs. 5.0±0.5, p<0.05), contraceptive measures (3.2±1.4 vs. 4.1±0.8, p<0.05) and STI (3.0±1.1 vs. 4.1±0.8, p<0.05) were seen at post-intervention assessment.
Increase in HIV knowledge scores was also seen among the adolescents (4.0±0.9 vs. 5.0±0.5, p<0.05). Overall knowledge scores on RH was significantly increased (18.1±3.4 vs. 22.0±2.3, p<0.001).
Furthermore, majority of the adolescents could apply the knowledge gained from the intervention package and could highlight the adverse consequences of HIV/STI and adolescent pregnancy during group discussion on case scenarios.
Conclusions: Improving in knowledge of RH and HIV/STI among HIV infected and affected young adolescents were achieved by applying such kind of participatory package.

WEPEC1034

Community-led education interventions for human papillomavirus vaccination: a model for future HIV vaccination campaigns?

K. Tounkara[1], I. Teguété[2], E. Squibb[3], B. Aboubacar[1], K. Sangare[4], S. Beseme[3], O. Koita[4,5], A.S. De Groot[3,6,7]
[1]GAIA Vaccine Foundation, Bamako, Mali, [2]Gabriel Touré Teaching Hospital, Bamako, Mali, [3]GAIA Vaccine Foundation, Providence, United States, [4]Laboratory of Applied Molecular Biology, Bamako, Mali, [5]University of Bamako, Department of Biology, Faculty of Sciences, Bamako, Mali, [6]Epi, Providence, United States, [7]University of Rhode Island, Institute for Immunology and Informatics (iCubed), Providence, United States
Presenting author email: gaiavfdirector@gmail.com

Background: HPV-associated cervical cancer is one of the major causes of morbidity for HIV-infected women, worldwide. Existing HPV vaccines are safe and effective and increasingly accessible in developing world settings. The success of the local community-based intervention on HPV knowledge, desire for CC screening and HPV/CC vaccine uptake described here suggests that a similar approach could be employed for HIV vaccine campaigns.
Methods: Beginning in April 2015, GAIA launched a 6-month campaign using community outreach workers dressed in a West African-style printed cloth with a pattern specifically designed to illustrate the connection between HPV and CC. Outreach workers and midwives led weekly education sessions in 4 neighborhoods and 5 clinics. Women seeking CC screening at the clinics were offered a survey to determine effectiveness of this and other (radio-based) communication methods on knowledge about HPV and CC and willingness to permit their daughters to be vaccinated with HPV vaccine.
Results: 13% of the 500 survey participants knew what HPV was, but 75% knew about CC. 87.4% wanted their daughter HPV/CC vaccinated, when asked why, 84% quoted "Prevention", "Protection", or cited the Malian proverb that was used in the design of the cloth "It is better to prevent than to cure". 38% indicated that their knowledge was derived from clinic-based education sessions, while 8% of participants reported radio and 9% reported national TV ads as a source. During the 6-month campaign, CC screening rates increased 5-fold at the clinics, and a total of 3,271 women received free screenings.



Desire for vaccination is high. (a) Result from a survey where women answered whether they wanted the vaccine available in Mali and if they would vaccinate their daughters. (b) Number of women who wrote in specific reasons for vaccinating their daughters

[Desire for Vaccination]

Conclusions: Community-led education proved more effective than TV and radio outreach. This community-based approach could similarly be applied to HIV prevention, by linking education efforts to testing and treatment services. Community-based education is a successful means of increasing disease awareness and may also improve vaccine coverage when used in conjunction with the introduction of novel vaccines.

WEPEC1035

Risks, benefits and sustained change associated with participating in a social network-based community-level HIV risk reduction intervention for crack users: participant perspectives

B. Suro Maldonado, J. Lechuga, C. Prieto, K. Melo, B. Quiñones
Lehigh University, Education, Bethlehem, United States
Presenting author email: bms416@lehigh.edu

Background: In the realm of HIV prevention, research indicates that HIV risk reduction behavioral interventions that only target individual behavior change have failed to reduce the rate of new HIV infections (Coates, Richter, & Caceres, 2008; Vermund, 2010). Experts have made a call for the implementation and testing of combination biomedical and behavioral multi-level interventions at the level of the community. The objectives of the project are to understand the motivations of research participants to participate in a social network-based community-level combination HIV risk reduction intervention, their experiences as research participants and drawbacks to research participation.
Methods: Eighty participants were recruited to take part in a survey and 20 to take part in a semi-structured interview. The mean age of participants was 33.08 years (SD = 12.83, range 18 to 64 years). The median monthly income reported was $85.00. Approximately 54% did not have a stable residence, 87.2% reported to be heterosexual and 6.4% reported to be HIV Positive. Participants answered a survey after participating in the last session of a risk reduction behavioral intervention. In addition, the survey assessed reactions to research participation, motivations to participate in research, mistrust of research, mistrust of the health care system, health care access, internalized drug use and HIV stigma.
Results: Participants were motivated to participate in the research for a variety of reasons including feeling part of a community and receiving advice from the research staff. Regarding associations, the following correlations were significant: Motivation to participate to help others and substance use (r = .29, p = .01); Positive attitudes towards research and personal satisfaction of participating in the study (r = .40, p = .001); and positive attitudes towards research and HIV and Crack use stigma (r = -.23, p = .01).
Conclusions: Participants were motivated to participate for a variety of reasons, reactions to research participation indicated few drawbacks and benefits at the personal and group level, and importantly, particulars of the research context were significantly associated with motivation, reactions, and effectiveness. The significant associations point to the potential importance of considering the particulars of the research context by researchers and ethics boards.

WEPEC1036

Evaluation of a training aimed at building capacity for outreaching to men who have sex with men and transgender women in Indonesia

A. Nugroho[1,2,3], R.W. Coulter[4], V. Erasmus[2], T.S. Mihari[1], J.H. Richardus[2]
[1]GWL-INA Network, Jakarta, Indonesia, [2]Erasmus MC, University Medical Center Rotterdam, Department of Public Health, Rotterdam, Netherlands, [3]School of Public Health, Lambung Mangkurat University, Banjarbaru, Indonesia, [4]Graduate School of Public Health, University of Pittsburgh, Department of Behavioral and Community Health Sciences, Pittsburgh, United States
Presenting author email: adie.noegroho@gmail.com

Background: High turnover of outreach workers (OWs) can hamper the effectiveness of HIV outreach programs. Yet this problem might be overcome if programs offer comprehensive, consistent training to new OWs. This study aimed to develop, implement, and evaluate a training package for increasing OWs' knowledge and skills for outreaching to men who have sex with men (MSM) and transgender women.
Methods: Using a one-group pretest-posttest study design, we evaluated an OW-informed training program aimed at helping OWs execute their job responsibilities. We analyzed longitudinal data from 75 OWs from seven Indonesian cities using one-way within-subjects ANOVA to examine the effects of the training program on participants' knowledge and perceived skills over time.
Results: Average overall knowledge among participants increased from pretest to immediate posttest ($p < 0.001$) and from pretest to 2-month posttest ($p < 0.001$), especially in the following knowledge areas: HIV and STIs; condoms and lubricants; sexual and reproductive health and rights; sexual orientation and gender identity and expression; and stages of behavior change. Average overall perceived skills increased significantly from pretest to 2-months posttest ($p=0.018$), especially in the following areas: creating innovative outreach approaches; building effective teamwork; and coordinating with healthcare providers.
Conclusions: This training package increased knowledge and perceived skills among outreach workers, and may help organizations overcome the negative consequences of frequent OW turnover.

WEPEC1037

Stigma, shame and despair as drivers of low HIV testing among transgender women in Lima, Peru

A. Silva-Santisteban[1], J. Klausner[2], M.J. Bustamante[1], X. Salazar[1]
[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]UCLA, Los Angeles, United States
Presenting author email: alfonsoss@upch.pe

Background: Globally, transgender women (TW) are 50 times more likely to acquire HIV vs. the general population. In Peru, TW are the population most affected by HIV, with 30% prevalence. Only 50% of TW are aware of their HIV status. Limitations of the Peruvian and Latin American public health system regarding the offer, delivery, and quality of prevention strategies for TW have been previously described. However, there is a to understand the drivers at the individual level that decrease TW´s access to prevention strategies and services.
Methods: Between 2015-2016 theoretical sampling was used to recruit participants to a qualitative study consisting of 15 in-depth interviews and a brief demographic survey. Peers invited participants according to demographic patterns that emerged from the ongoing collected information. Audio files were transcribed verbatim and analyzed using grounded theory, to describe pathways linking TW experiences regarding HIV to the outcome (reduced access to testing).
Results: TW had a mean age of 27 years, 64% had migrated to Lima from the Amazonian region, and 42% reported sex work as their primary source of income. TW conceive HIV as something that will occur at some point in their lives. Through jokes that signal HIV positive peers, messages associated with fear of disease and death are spread within the community. At the same time, the shame about being HIV positive (regarding their families, friends or partners) reduces TW´s agency to decide to get tested and becomes a deterrent for status awareness. Thus, TW don´t internalize existing prevention and treatment options as options available for themselves.
Conclusions: Misinformation linked to HIV stigma, shame and despair are deeply rooted among Peruvian TW, decreasing their ability and willingness to access HIV testing. Peruvian public health prevention strategies designed for key populations are currently dissociated from TW´s understanding of the HIV epidemic. Biomedical interventions with demonstrated efficacy need to urgently add behavioral components (such as HIV stigma reduction) to reach TW and to decrease HIV transmission among this population.

WEPEC1038

Cognitive testing of an instrument to evaluate acceptability and use of PrEP products among women

S. Zissette[1], M. Atujuna[2], E.E. Tolley[1], A. Adimora[3], HIV Prevention Trials Network - Women at Risk Committee
[1]FHI 360, Social & Behavioral Health Sciences, Durham, United States, [2]Desmond Tutu HIV Centre, Cape Town, South Africa, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States
Presenting author email: millicent.atujuna@hiv-research.org.za

Background: As diverse HIV prevention products (i.e., oral pills, vaginal rings, injections and gels) are developed to meet women's needs, a standardized tool could facilitate comparisons of product acceptability and use across geographic, trial and user contexts. We developed a draft instrument to assess product use and trial experience. We conducted a cognitive evaluation of the instrument to assess comprehensibility, salience and completeness of items and domains, and revised the instrument in accordance with our findings.
Methods: We conducted three rounds of interviews in English and isiXhosa among 28 South African women who had recently participated in clinical trials of injectable/oral PrEP and vaginal rings. Participants responded to each question and then described how they determined their response. They were invited to provide alternative wording for questions and response options. Following each round, the study team identified items with low response variability and unclear, embarrassing, or difficult-to-answer questions/response options. The questionnaire was successively modified to reflect participant input until smooth administration was achieved.

Reason for change	n	Examples
Response variability	1	"How easy is the product to use?" → "How difficult..."
Unclear wording		
Question	7	"stigmatized" → "that people looked at you differently"
Responses	8	Rarely, Frequently → Less than half the time, More than half the time
Embarrassment	4	"The last time you had vaginal/anal sex..." → Two separate questions
Difficult to answer		
Question	4	"How many times did you use..." → "How often did you use..."
Responses	4	"Did you use a male/female condom..." Yes/No → Yes, male/Yes, female/No
Administrative	16	Skip patterns, framing throughout

[Table 1. Changes to items]

Results: The final instrument contained 41 items, including five new items that improved construct validity; 22 items were modified for clarity. See Table 1 for types of changes made.
Conclusions: This rapid, low-cost cognitive interview study provided valuable insight into participants' understanding of PrEP acceptability questions, enabling us to further refine the instrument for use in the South African setting. Further validation of the instrument in other geographic settings will improve our ability to examine and compare women's preferences and needs for PrEP across multiple contexts.

WEPEC1039

Integrating microenterprise and behavioral economics for HIV prevention in U.S. urban poor young adults: study design and intervention development of the EMERGE project

L. Jennings[1], N. Glass[2], S. Linnemayr[3], M.W. Johnson[4], F. Ssewamala[5], J. Merrill[1], A. Labrique[6], C. Latkin[7], S. Gaonkar[8], EMERGE Study Group
[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]Johns Hopkins University School of Nursing, Department of Community Public Health, Baltimore, United States, [3]RAND Corporation, Santa Monica, United States, [4]Johns Hopkins University School of Medicine, Department of Psychiatry and Behavioral Sciences, Baltimore, United States, [5]Columbia University School of Social Work, International Center for Child Health and Development, New York, United States, [6]Johns Hopkins Bloomberg School of Public Health, Global mHealth Initiative, Department of International Health, Baltimore, United States, [7]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior, and Society, Baltimore, United States, [8]Johns Hopkins Carey Business School, Baltimore, United States
Presenting author email: ljennin6@jhu.edu

Background: Economic vulnerability contributes to HIV risk among racial and ethnic minorities in the U.S. who are disproportionately infected. Yet, low-income U.S. young adults are largely excluded from HIV-focused economic empowerment initiatives. This presentation discusses the protocol and preliminary findings for study design and intervention development of the EMERGE Project, a microenterprise intervention with integrated behavioral economic text messages to prevent HIV in homeless, out-of-school, and unemployed (HOU) African-American young adults.
Methods: Three formative research methods were used to inform the design and development of the EMERGE project. One, we conducted a systematic review of intervention materials of prior successful HIV-focused microenterprise models, most of which were conducted in low-income countries. This enabled us to identify gaps in study measurement and implementation needs for economics-based prevention science. Secondly, we developed a conceptual framework of the potential effects of an HIV-focused microenterprise intervention, drawing on literature from traditional behavior change models as well as traditional and behavioral economic theory. Thirdly, to include participant perspectives in the study and intervention design, we conducted formative in-depth interviews with HOU youth on perceived gains and losses of engaging in HIV-preventive behaviors using a traditional and behavioral economics perspective.
Results: The EMERGE study will be designed to encourage micro-business start-up, financial self-sufficiency, and positive sexual behaviors to prevent HIV in HOU African-American young adults, aged 18 -24. We will use training workshops, start-up grants, business mentoring, and text messages. An integrated conceptual framework of the hypothesized causal pathways will be presented. We will also discuss the use of text messages to address a current gap in study designs of repeated, longitudinal measurements of sexual and economic outcomes. We will conclude with an overview of the integration of behavioral economic concepts (delay discounting, loss aversion and endowment effect) in HIV-focused microenterprise curriculum and text messages to address study gaps in this area.
Conclusions: The design and implementation of HIV-focused microenterprise interventions, most of which have been conducted in low-income countries, may be informed by experiences working with economically-disadvantaged U.S. youth. Expanding prevention science studies to include behavioral economic theory and text-based longitudinal measurement may also prove beneficial.

WEPEC1040

Research ethics capacity of selected health institutions involved in HIV/AIDS counseling and testing, treatment and research in Nigeria

A.K. Adeneye[1], A. Adesanmi[2], M.A. Sulyman[1], A.Z. Musa[3], M.A. Mafe[1]
[1]Nigerian Institute of Medical Research, Public Health Division, Lagos, Nigeria, [2]Nigerian Institute of Medical Research, Microbiology Division, Lagos, Nigeria, [3]Nigerian Institute of Medical Research, Monitoring and Evaluation Unit, Lagos, Nigeria
Presenting author email: oakadeneye@yahoo.co.uk

Background: Research Ethics Committees (RECs) should review, approve and monitor HIV/AIDS research to ensure the rights, safety and integrity of vulnerable groups are protected. This abstract highlights the institutional capacities for ethical review of and oversight for HIV/AIDS treatment/care interventions and research in Nigeria given: the HIV/AIDS epidemic and increasing HIV/AIDS research and care programmes; that research is one of the major mandates of all Federal and State Ministries of Health (FMoH/SMoH) departments, agencies, and other tertiary health institutions (THIs); and many HIV/AIDS researches target groups vulnerable to abuse and exploitation.
Methods: A cross-sectional study of 41 institutions including FMoH/SMoH, THIs and local government (LGAs) departments of health involved in HIV/AIDS counseling and testing, treatment and research was conducted in 7-randomly selected States and Abuja, the Federal Capital Territory of the country, using semi-structured questionnaires. Data were analysed using SPSS version 20.
Results: Of 41 institutions surveyed, oversight for health research was lacking in many (61.0%) of the institutions. Only 39.0% have established and functional RECs [FMoH (100.0%); States (62.5%); THIs (100.0%); LGAs (4.3%)]. Reasons for non-existent of RECs in the States and LGAs included: perceived non-involvement in research (36.0%); unawareness of need for RECs (20.0%); no provision for RECs (16.0%); and lack of staff with research ethics knowledge/skills (12.0%). Only 1.2% of 8,349 staff of studied institutions have had research ethics training. Such trainings in the 16 established RECs were mostly received at workshops/seminars (68.8%), in-house/hands-on (18.8%), online course (12.5%) and as degree course (12.5%). Only 9 (22.0%) of studied institutions have ever obtained ethical clearance for researches conducted internally. Sources of proposals for ethical review by those having RECs included: researchers/lecturers/health professionals (93.8%); students (68.8%); government agencies (18.8%); development partners (12.5%); and non-government organisations (12.5%).
Conclusions: Most institutions studied lack functional RECs for effective research oversight. The need to address identified capacity gaps is critical in strengthening RECs operations in Nigerian health institutions particularly at State and LGA levels in safeguarding research participants' rights/welfare and harnessing research for evidence-informed policies and sustaining science integrity as well as public confidence in research and standard of care on HIV/AIDS to achieve the 90-90-90 goal.

A community-based program to end HIV criminalization, promote public health and defend human rights

L. Liz
COCQSIDA, LAW, Montreal, Canada
Presenting author email: liz.lacharpagne@cocqsida.com

Background: The Supreme Court of Canada requires that people living with HIV (PLHIV) disclose their HIV-positive status to their sexual partners before sexual acts that pose a "realistic possibility" of transmission which means, for the Court, that viral load is low (< 1500 Copies/mL) or undetectable (< 40 Copies/mL) **and** a condom is used. Although there is no evidence that criminalization is effective in preventing transmission, criminal law is often used in the name of public health. Convinced that criminalization could in contrary harm prevention and human rights (Supreme Court decisions are hardly compatible with scientific advances which demonstrate that treatment prevents transmission, increases discrimination against PLHIV and can lead to rights violations), COCQ-SIDA Human Rights Program (the "Program"), in collaboration with other organisations, conduct advocacy strategies to end criminalization.
Methods: The program is part of a Working group on criminalization which includes representatives of Public Health, Justice and Security Departments which advise government in the light of scientific data and legal principles. The program also organises workshops for PLHIV and service providers, plus training for lawyers and prosecutors. Finally, the Program tracks Criminalization cases and provides individual support to defense lawyers and people charged in Quebec.
Results: The Program has written a policy statement on criminalization, which represents COCQ-SIDA member's position and has been calling for prosecutorial guidelines to limit the impact of criminalization. Also, it has participated in three cases at the Supreme Court, given individual support in fifteen files as well as track-

ing all of the various prosecutions throughout Quebec. The Program has given more than one hundred workshops for PLHIV and service providers in addition to two trainings for lawyers and prosecutors.

Conclusions: The Program will continue its different actions and develop new advocacy strategies especially to demonstrate that criminalization could harm prevention and human rights if in contradiction with scientific advances and public health prevention messages. As the impact of the Program's actions on the prosecutions and the decisions reached is difficult to evaluate, the development of a formal evaluation is in process.

HIV and access to rights for sub-Saharan immigrants in France: results from the ANRS Parcours Survey

A. Gosselin[1], A. Ravalihasy[1,2], F. Lert[1], N. Lydié[3], A. Desgrées du Loû[1,2], Parcours Study Group

[1]CEPED (Paris Descartes University-IRD), Paris, France, [2]Institut de Recherche pour le Developpement (IRD), Marseille, France, [3]Santé Publique France, National Agency for Public Health, Saint-Maurice, France

Presenting author email: anne.gosselin@ceped.org

Background: In France, HIV-positive foreigners can obtain a residence permit for medical reasons (RPHR) (a 1-year renewable permit). However, associations for immigrants' rights have claimed that RPHR holders had more difficulty to access long-term permits than other immigrants although they are entitled to them. In this study we assess whether HIV-positive persons are discriminated in the access to long-term permits because of their holding RPHR.

Methods: We use data from the ANRS Parcours quantitative survey which was led in 2012-2013 among 1705 randomly-sampled Sub-Saharan immigrants living with HIV/Aids or Hepatitis B in Paris area. This biographical survey allows us to reconstitute the entire history of residence permits. With discrete-time logistic models, we study the determinants of the access to long-term permits and the effect of RPHR on this access. Control variables are included to take the instruction level, the reason of migration, the period of arrival and length of stay into account.

Results: The RPHR has a negative impact on the access to long-term residence permits (aOR between 0.15 and 0.27 according to the group, p<0.01), thus RPHR holders are discriminated in their access to long-term permits in France. Additionally, our results reveal an increasing difficulty to access long-term permits since 2005 (aOR= 0.16 [0.07-0.41] for men in the Hepatitis group, same tendency in other groups), reflecting the hardening of migratory policy in the last decade.

	HIV		Hepatitis B	
	Men N=185 (2094 p.years)	Women N=320 (2791 p.years)	Men N=238 (2682 p.years)	Women N=90 (635 p.years)
	aOR[CI95%]	aOR[CI95%]	aOR[CI95%]	aOR[CI95%]
Period of arrival in France				
Before 1996 (ref)	-	-	-	-
1996-2004	0,54 [0,28; 1,04]	0,52 [0,27; 1,00]	0,35 [0,20; 0,61]	0,90 [0,25; 3,32]
2005-2013	0,57 [0,26; 1,26]	0,70 [0,42; 1,18]	0,16 [0,07; 0,41]	0,26 [0,06; 1,17]
Length of stay (t)*	1,06 [0,99; 1,13]	1,07 [1,02; 1;13]	1,05 [0,99; 1,10]	1,16 [1,01; 1,32]
Has had a resident permit for health reasons	0,20 [0,11; 0,36]	0,19 [0,13; 0,28]	0,15 [0,07; 0,32]	0,27 [0,11; 0,66]

[Table 1. Factors associated with the access to 10-year residence or French nationality, year by year, per sex and study group. Odds ratios in bold are significant at 5%. (adjusted on age, region of origin, to have been diagnosed or not, having a child a given year, level of instruction and reason for coming to France) Source : ANRS Parcours Survey 2012-2013]

Conclusions: These results quantitatively measure the discrimination in access to long-term permits towards Sub-Saharan immigrants holding a permit for health-care reasons and they claim for a sustainable legal status for ill foreigners in Europe.

WEPEC1043

Ethical and human rights considerations for inclusion of minors who sell sex in epidemiological, prevention, and other research: evidence from female sex workers in Abidjan, Côte d'Ivoire

A. Grosso[1,2], C. Lyons[2], D. Diouf[3], B. Liestman[2], R. Ezouatchi[3], M. Thiam-Niangoin[4], K. Abo[4], F. Drame[3,5], A. Bamba[3], J. Tety[6], E. Obodou[7], I. Ba[8], S. Baral[2]

[1]Public Health Solutions, Research and Evaluation, New York, United States, [2]Johns Hopkins University Center for Public Health and Human Rights, Epidemiology, Baltimore, United States, [3]Enda Santé, Dakar, Senegal, [4]Programme National de Lutte Contre le SIDA, Ministere de la Lutte Contre Le SIDA, Abidjan, Cote D'Ivoire, [5]Gaston Berger University, Department of Geography, School of Social Sciences, St. Louis, Senegal, [6]Blety, Abidjan, Cote D'Ivoire, [7]Office National de la Population, Ministère d'Etat, du Plan et du Développement, Abidjan, Cote D'Ivoire, [8]Institut National de la Statistique de la Côte d'Ivoire, Abidjan, Cote D'Ivoire

Presenting author email: grossoas@gmail.com

Background: Parental permission may not be appropriate or feasible for research with minors less than 18 years old who sell sex, who are understudied and at high risk for HIV acquisition, particularly in sub-Saharan Africa. Research with adult female sex workers (FSW) who started selling sex as minors can illustrate ethical and human rights issues related to parental consent for epidemiological and prevention research with this vulnerable group.

Methods: FSW >17 years old recruited through respondent-driven sampling in Abidjan, Côte d'Ivoire completed an interviewer-administered survey that included a question asking the age at which they first sold sex. This variable was dichotomized to assess the prevalence and correlates of selling sex under age 18 through multivariable logistic regression using Stata 14/SE. The Johns Hopkins School of Public Health Institutional Review Board and the Comite National d'Ethique et de la Recherche in Côte d'Ivoire approved the study.

Results: Specific numeric results are presented in the tables. Over one quarter (27.9%, 130/466) of participants started selling sex before age 18. Those who sold sex as minors were more likely than those who started as adults to have given birth before age 18 and been orphaned before age 18. They were more likely to have been raped by anyone before age 18 and raped or physically assaulted by a family member ever. Those who sold sex as minors were more likely to report that a parent or family member knew they sold sex but also more likely to report stigma from their family due to selling sex.

Age of start of selling sex	Tested positive for HIV in the study	Gave birth before age 18	One or both parents died before participant was 18 years old	Ever told one or both parents they sold sex	Someone in their family knew they sold sex though they did not voluntarily disclose
Under 18	12.6% (16/127)	33.9% (44/130)	47.3% (61/129)	10.1% (13/129)	45.7% (59/129)
18+	10.4% (34/326)	22.2% (74/333)	32.9% (109/331)	4.2% (14/334)	29.5% (99/336)
Age-Adjusted Odds Ratio (95% Confidence Interval)	2.0 (1.0-4.1)	2.2 (1.4-3.5)	1.7 (1.1-2.5)	2.4 (1.1-5.5)	2.2 (1.4-3.4)

[Correlates of selling sex as a minor in Abidjan]

Age of start of selling sex	Was raped before age 18	Ever told family they were raped (among those raped before age 18)	Was ever raped by family member	Was ever physically assaulted by family member	Ever felt excluded from family gatherings due to selling sex	Ever felt family members spoke badly of them, made discriminatory remarks or gossiped about them because they sold sex
Under 18	43.9% (57/130)	36.8% (21/57)	6.9% (9/130)	17.7% (23/130)	15.4% (20/130)	43.1% (56/130)
18+	6.6% (22/335)	40.9% (9/22)	2.4% (8/336)	9.2% (31/336)	6.0% (20/336)	14.9% (50/336)
Age-Adjusted Odds Ratio (95% Confidence Interval)	10.0 (5.7-17.6)	0.9 (0.3-2.5)	3.5 (1.3-9.7)	2.3 (1.2-4.2)	2.9 (1.5-5.8)	4.5 (2.8-7.3)

[Violence/stigma correlates of selling sex <18]

Conclusions: Women who started selling sex as minors experienced substantial health and social risks for HIV acquisition before age 18. Obtaining parental consent for participation in research about selling sex under age 18 for this population would likely be unreasonable due to parents' death, lack of disclosure of sexual violence or sex work, and violence or stigma from family.

"I think the parent should be there because no one was born alone": Kenyan adolescents' perspectives on parental involvement in HIV research

A.K. Groves[1], D.D. Hallfors[2], B.J. Iritani[2], S. Rennie[3], F.S. Odongo[4], D. Kwaro[4], N. Amek[4], W.K. Luseno[2]

Presenting author email: aligroves@drexel.edu

Background: AIDS is the leading cause of death among African adolescents. Yet there are substantial gaps in knowledge of how to curb the epidemic among adolescents, in part because they are persistently underrepresented in HIV research. Further, ethical guidance for conducting research among youth under 18 is lacking. One ethical issue is the degree to which parents should be involved in the research process. Much of the existing discourse is theoretical and focuses on negative consequences of parental involvement, particularly in sexual health research. We use empirical data to describe Kenyan adolescents' perspectives on parental involvement in consent and disclosure of HIV test results in a research study context.
Methods: We conducted two rounds of focus group discussions with 40 adolescents (15-19 years old) in Western Kenya. Half of the adolescents were female and one-fifth identified as HIV-positive. We used semi-structured guides to ask hypothetical questions about minor adolescent participation in HIV research and parental involvement. We analyzed data using codes and matrices.
Results: Kenyan adolescents were largely in favor of having their parents involved during the research process. More than half of all participants, and a majority of HIV-positive participants, who spoke about permission felt minors must seek their parents' permission to participate in HIV research. Further, an overwhelming majority of adolescents felt that parents of minors should be present for part or all of HIV testing and disclosure, even among those who felt conflicted about or against mandatory parental permission for minors. Youth primarily wanted to have their parents present during HIV testing and disclosure because they wanted their support. Such support was perceived as particularly important for youth receiving an HIV-positive diagnosis.
Conclusions: Our findings depart from existing discourse and provide an important contextualized perspective from Kenyan youth on benefits of parental involvement. From this perspective, involvement of parents in research extends beyond obtaining their permission to participate to providing essential support for youth, regardless of HIV status, during and beyond the course of research. Ethical guidelines that prioritize adolescent autonomy in research must take into account reasons to involve parents considered important by adolescents themselves, particularly in low-resource settings.

Ignoring the ban: blood donation among young adult MSM at risk for HIV

A. Wentz[1], R. Merchant[1,2], M. Clark[3], T. Liu[1], J. Rosenberger[4], J. Bauermeister[5], K. Mayer[6]
[1]*Brown University School of Public Health, Providence, United States,* [2]*Rhode Island Hospital, Providence, United States,* [3]*University of Massachusetts Medical School, Worcester, United States,* [4]*Pennsylvania State University, Hershey, United States,* [5]*University of Pennsylvania, Philadelphia, United States,* [6]*Fenway Health, Boston, United States*
Presenting author email: anna_wentz@brown.edu

Background: In the US, men who have sex with men (MSM) were banned from donating blood from 1983 to 2015 in effort to prevent transfusion transmitted HIV infection. In December 2015, the US FDA replaced the ban, permitting MSM to donate if they reported no sex with another man in the prior year. Qualitative evidence suggests that MSM who choose to donate blood despite the ban likely base this decision on self-perceived risk, although data on this topic are limited. We aimed to identify blood donation practices and their relationship with HIV risk in a population of young adult MSM (YMSM) believed to be at higher risk for HIV who previously donated blood.
Methods: In 2014, 18-24-year-old black, Hispanic, and white, HIV-negative YMSM were recruited from across the US through multiple social media platforms to complete an online survey. The survey queried about blood donation history, HIV testing history, self-perceived HIV risk, and sexual behavior, particularly condomless anal intercourse (CAI). Among YMSM who ever donated blood, we conducted a multivariable logistic regression analysis estimating the odds of donating blood in the past year, adjusting for age, race/ethnicity, geographic region, education, and if they had a primary care provider.
Results:

	Total (n=1,093) aOR (95% CI)	Black (n=195) aOR (95% CI)	Hispanic (n=385) aOR (95% CI)	White (n=513) aOR (95% CI)
Never had CAI	1.84 (1.24-2.73)	2.81 (1.16-6.85)	3.41 (1.65-7.05)	1.20 (0.69-2.09)
No CAI in the last 12 months	1.16 (0.84-1.60)	1.74 (0.82-3.69)	1.49 (0.86-2.57)	0.93 (0.58-1.49)
Perceived likelihood of having HIV "Not possible at all"	1.57 (1.14-2.16)	1.61 (0.74-3.50)	1.80 (1.07-3.01)	1.55 (0.97-2.49)
Had HIV test in last 12 months	1.23 (0.90-1.67)	1.59 (0.68-3.71)	1.45 (0.86-2.43)	0.97 (0.63-1.48)

[Adjusted odds of donating blood in the past year]

Of the 2,261 YMSM surveyed (19% black, 36% Hispanic, 45% white), 49% had previously donated blood, and 13% had donated blood within the past year. Among YMSM who ever donated blood, past year blood donation was more likely among those who never had CAI and had a lower perceived likelihood of being HIV infected. Past year blood donation was related to ever having had CAI, self-perceived HIV infection likelihood, and past year HIV testing for black and Hispanic but not white YMSM.
Conclusions: Black, Hispanic and white YMSM donated blood with a surprisingly high frequency despite the ban in the US. Although the choice to donate for some YMSM was congruent with HIV risk, white YMSM in particular appeared to donate despite self-perceived HIV risk, sexual behavior, and HIV testing utilization.

WEPEC1046

'From one pill a day to no pill a day': perceptions of HIV cure research among people living with HIV: qualitative findings from focus groups in 4 U.S. cities

K. Dube[1], L. Sylla[2], D. Evans[3,4], J. Taylor[5], D. Palm[6], A. Gilbertson[7], J.D. Tucker[8,9], J. Auerbach[10]
[1]*The University of North Carolina at Chapel Hill, UNC Gillings School of Global Public Health, Public Health Leadership Program (PHLP), Chapel Hill, United States,* [2]*defeatHIV Community Advisory Board (CAB), Seattle, United States,* [3]*Delaney AIDS Research Enterprise (DARE) CAB, Los Angeles, United States,* [4]*Project Inform, Los Angeles, United States,* [5]*Collaboratory of AIDS Researchers for Eradication (CARE) CAB, Palm Springs, United States,* [6]*Collaboratory of AIDS Researchers for Eradication (CARE) CAB, Chapel Hill, United States,* [7]*UNC Social Medecine Department, Chapel Hill, United States,* [8]*UNC Project China, Guangzhou, China,* [9]*UNC Institute of Global Health and Infectious Diseases (IGHID), Chapel Hill, United States,* [10]*University of California San Francisco (UCSF), San Francisco, United States*
Presenting author email: karine_dube@med.unc.edu

Background: Biomedical HIV cure research is advancing in the United States and elsewhere around the world. Little is known, however, about perceptions and acceptability of various HIV cure research strategies or willingness to participate in studies to test these strategies among people living with HIV.
Methods: We undertook focus group discussions with people living with HIV at four (4) Martin Delaney collaboratory HIV cure clinical research sites in the United States: Seattle, WA; Los Angeles, CA; San Diego, CA and Durham, NC. We conducted 10 focus group discussions January - June 2016 and subsequent thematic analysis.
Results: 76 individuals (60.5% males, 35.5% females, 2.6% transgendered individuals, 1.3% non-binary/queer) participated. The sample was ethnically diverse (40.8% Caucasian/White, 39.5% African American/Black, 9.2% Hispanic/Hispanic descent, 10.5% other). Main narratives centered on meanings of HIV cure (e.g. not having to take medications and not being able to infect sexual partners) and deterrents and motivators to participation in HIV cure research. There was a preference for a sterilizing cure (eradication) compared to a functional cure (remission) across all 4 sites. Participants expressed anxiety with interrupting HIV medication in the context of HIV cure research and preferred knowing that they were controlling the virus at all times. Further, there were concerns about potential clinical side effects of HIV cure strategies. Participants who experienced several HIV treatment regimens to become undetectable appeared less willing to take part in risky cure studies. One thread that emerged was the impact of stigma, and the belief that a sterilizing cure would be the only way to eradicate stigma. Additional narratives focused on expectations of HIV cure biomedical investigators, recruitment of special populations - including women, and practical issues involved in the conduct of HIV cure studies. Some anxieties were expressed around being cured, including losing disability insurance (financial burden). The need for better education around HIV cure research emerged as a strong theme.
Conclusions: This community participatory project begins to fill a gap around perceptions of HIV cure research among people living with HIV. Qualitative results can help inform a patient-centered HIV cure research agenda.

WEPEC1047

What would an HIV cure mean to you? Ascribing meaning through an HIV cure tree

L. Sylla[1], M. Louella[1], D. Evans[2,3], J. Taylor[4], D. Palm[5], R. Jefferys[6], K. Dubé[7]
[1]defeatHIV, Community Advisory Board, Seattle, United States, [2]Delaney AIDS Research Enterprise (DARE) Community Advisory Board, Los Angeles, United States, [3]Project Inform, Los Angeles, United States, [4]Collaboratory of AIDS Researchers for Eradication (CARE) Community Advisory Board, Palm Springs, United States, [5]Collaboratory of AIDS Researchers for Eradication (CARE) Community Advisory Board, Chapel Hill, United States, [6]Delaney AIDS Research Enterprise (DARE) Community Advisory Board, Melbourne, Australia, [7]University of North Carolina Gillings School of Global Public Health, Chapel Hill, United States
Presenting author email: lauzie1@live.com

Background: Interest and investment in HIV cure research has been increasing since the apparent cure of Timothy Brown 10 years ago through a bone marrow transplant from a donor homologous for the CCR5-delta 32 mutation. While his experience has not yet been replicated and is still not fully understood, it spawned the burgeoning field of HIV cure research. An HIV cure holds the possibility of being transformative societally as well as medically. Little has been explored about the meaning and value individuals ascribe to a cure.
Methods: Volunteers from the Community Advisory Board (CAB) of the Martin Delaney Collaboratory (MDC), a US National Institutes of Health initiative funding multiple HIV cure research collaboratories created an "HIV Cure Tree" at the 2016 IAS Conference Global Village in Durban, South Africa. MDC CAB volunteers asked a convenience sample of Global Village attendees from around the world to write on paper leaves their answers to the question, "What would an HIV Cure Mean to You?" Respondents included clinicians, researchers, people living with HIV, activists, and others. Leaves were later sorted into themes.
Results: We collected 244 leaves. The two dominant themes that emerged were freedom and hope. Freedom was a stand-alone concept, and also included multiple sub-themes, such as freedom from taking medication, freedom from stigma, freedom from worry, and freedom to enjoy making love. Other significant themes clustered around personal meanings, such as, "My precious time with my children-LIFE," and "All my dreams come true," while others were more societally focused, such as, "An AIDS-free generation" and, "A world full of happy people." Some saw a cure as "Victory" or an end, while others saw it as a new beginning. Other significant themes that emerged included no more stigma, happiness, fulfillment, a better future, ending suffering, love, prosperity and relief.
Conclusions: People see an HIV cure as liberating for both individuals and societies. Many perceive it as the best route to ending stigma and a key element contributing to ending AIDS. Cultural context contributes to the meanings people ascribe to a cure. There is significant global support for continuing to search for an HIV cure.

WEPEC1048

Adolescent girls´ understanding of consent and views on waiver of parental consent regarding HIV self-testing

K. Agot[1], G.-N. Wango[1], S.H. Masters[2], L. Oluoch[1], M. Omoya[1], N. Ounda[1], H. Thirumurthy[2]
[1]Impact Research and Development Organization, Kisumu, Kenya, [2]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, United States
Presenting author email: mamagifto@yahooo.com

Background: Adolescent girls (AGs) aged <18 years are often omitted from biomedical research because of requirements for parental consent. Thus, there is paucity of knowledge regarding whether interventions that are effective in adult women also work for AGs. We assessed if AGs ages 15-17 years can understand a consent document and explored their views regarding waiver of parental consent.
Methods: We conducted a mixed-methods study with AGs accessing HIV testing services in western Kenya. After enrollment, a study staff administered a second consent for a planned study in which AGs would be offered multiple HIV self-tests for use with their sexual partners. A second staff asked participants 22 multiple-choice questions to assess understanding of various aspects of the second consent, including: purpose, eligibility, procedures, risks and benefits, confidentiality, voluntarism, and rights. We also used semi-structured interviews to explore participant´s views on waiver of parental consent. Participants' response were audio-taped, coded, and analyzed.
Results: We interviewed 33 sexually-active HIV-negative AGs. Sixteen had some primary education and 17 had some secondary education. The proportion of participants who understood each question was ≤25% for 2 questions, 26-50% for 3 questions, 51-75% for 10 questions, >75% for 7 questions. Questions on ,who to contact if rights are violated' and ,IRB with ethical oversight over the study' scored lowest while sample size, age eligibility, voluntary participation, benefits, and reasons for contacting researchers scored highest. Thirty-two participants preferred the consent document read to them, and most felt that parental consent should not be waived when the study is about HIV generally (77%), HIV testing (83%), STIs (77%), pregnancy (83%), contraceptives (67%) and ART (90%). However, when informed that the consent document for studies on these topics could mean that their parents learn of their sexual activity, 64% preferred waiver of parental consent and another 31% preferred that the mother should provide consent.
Conclusions: AGs can understand consent documents fairly well and believe parental consent should not be a requisite for their participation in research if their sexual behavior could be involuntarily disclosed. There is need to also get views from ethics bodies and parents regarding waiver of parental consent.

Presenting author email: clyons8@jhmi.edu

Background: Female sex workers (FSWs) face high burdens of gender-based violence (GBV) and associated HIV risk globally. Depression is consistently associated with both GBV and HIV risk behaviors in other populations, yet remains poorly understood or researched among FSWs. We examined the relationship between GBV and mental health for FSWs, and how the relationship may mediate consistent condom use with clients.
Methods: We analyzed data from Cameroon-based FSWs (n=2,265), recruited via respondent-driven sampling across five sites in 2016. Eligible participants were aged 18 and over, and had to report having sold sex within the past year. The women were given tablet-based structured interviews, which included questions about violence, condom use, and the Patient Health Questionnaire 9 (PHQ9) to screen for depression. Survey respondents were linked to HIV tests conducted on site.
Results: HIV prevalence was 24% (548/2,250) and inconsistent condom use with clients was 28% (508/1,841). Violence was prevalent; 25% (561/2,261) reported physical violence and 33% (739/2,263) reported sexual violence. Forty-five percent (934/2,059) of respondents scored a 5 or higher on the PHQ9 scale, signaling some level of depression. Sexual violence was significantly associated with inconsistent condom use among both casual (p=0.009) and regular clients (p=0.000). The PHQ9 depression levels were significantly associated with condom use, with higher PHQ9 depression scores associated with inconsistent condom use (regular clients: p=0.007, casual clients p=0.002). PHQ9 depression levels were significantly inversely associated with experiencing sexual violence (p=0.000).

	Total, N/N	Total, %	inconsistent condom use, reg client, N/N	inconsistent condom use, reg client, %	Chi squared p-value	inconsistent condom use, casual client, N/N	inconsistent condom use, casual client, %	Chi squared p-value

[Condom Use, Violence, and Depression Among FSW]

Conclusions: Both sexual violence and depression are prevalent and shape condom use with clients among FSW in Cameroon. The large proportion of FSW with reported depression is highly connected both to sexual violence and inconsistent condom use. This highlights the need for interventions to address the structural- and individual-level mental and physical impacts of GBV for FSWs to reduce HIV acquisition and transmission among FSW.

A videogame intervention for sexual risk reduction in minority adolescents: a randomised controlled trial

L. Fiellin[1,2], K. Hieftje[1], T. Pendergrass[1], T. Kyriakides[1], L. Duncan[3], J. Dziura[1], B. Sawyer[4], L. Mayes[1], C. Crusto[1,5], B. Forsyth[1,5], D. Fiellin[1]
[1]Yale University, New Haven, United States, [2]Yale Child Study Center, New Haven, United States, [3]McGill University, Montreal, Canada, [4]Digitalmill, Freeport, United States, [5]University of Pretoria, Pretoria, South Africa
Presenting author email: tyra.pendergrass@yale.edu

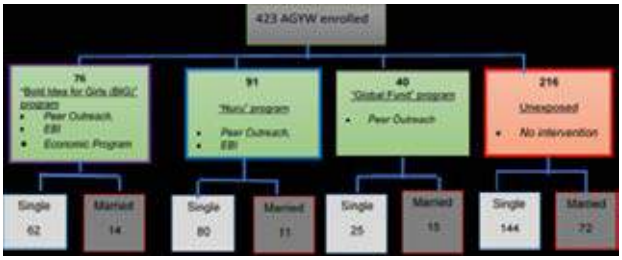
Background: HIV disproportionately impacts minority youth. Interventions to decrease HIV sexual risk are needed. We hypothesized that an engaging theory-based videogame intervention, would improve sexual health outcomes in adolescents.
Methods: Randomised controlled trial in 12 community programs. Participants were randomised 1:1 to up to 16 hours of the intervention videogame or attention/time control videogames over six weeks. Assessments were conducted at six weeks, three, six and 12 months. Primary outcome was delay of initiation of vaginal/anal intercourse. Secondary outcomes included delay of initiation of sexual activities (composite of vaginal/anal intercourse, oral sex, and touching), sexual health attitudes, knowledge, and intentions. We examined outcomes by gender and age. Analyses of 24-month outcomes are underway and will be presented.
Results: Between February 26, 2013 and May 16, 2014, we randomised 333 participants to play intervention (n=166) or control games (n=167): 90% were racial/ethnic minorities, 53% were boys, and the mean age was 13 years. At 12 months: for the 258 (84·6%) participants with available data: 122/129 (94·6%) in the intervention group vs. 123/129 (95·4%) in the control group delayed the initiation of intercourse (p > 0·99). Eighty-seven percent of participants in both groups delayed the initiation of sexual activities (p > 0·99). We have just completed 24-month follow-up and analyses are underway. This longer duration of follow-up in this age group may demonstrate higher event rates in the initiation of sex. Over 12 months, the intervention group, compared to the control group, demonstrated: improved sexual health attitudes overall (p=0·04), in boys (p=0·01) but not in girls (p=0·63) (treatment by gender interaction, p=0·09), in younger participants (p=0·009) but not in older participants (p=0·97) (treatment by age interaction, p=0·06); increased sexual health knowledge overall (p < 0·001), in boys, girls, younger (≤12 years) and older (> 12 years) participants (p < 0·01 for all comparisons); no differences in intentions to delay the initiation of intercourse or other sexual activities between the two groups (p= 0·59).
Conclusions: A videogame intervention improves sexual health attitudes and knowledge in minority adolescents.

WEPEC1051

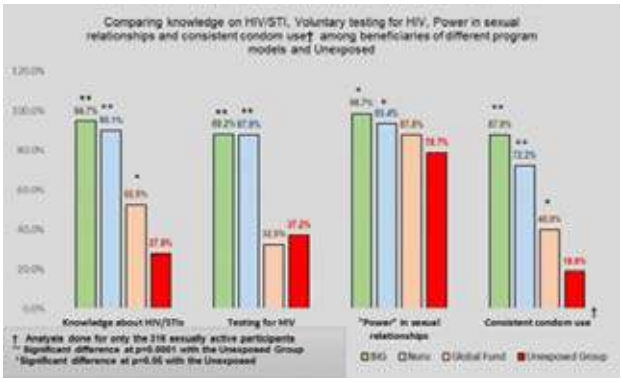
Impact of integrating evidence-based behavioral interventions (EBIs) and economic empowerment into HIV/STI prevention programs for slum-dwelling adolescent girls and young women in Kenya

J. Njathi Nguku[1], F. N. Mbai[2], E. W. Mwaniki[1]
[1]Technical University of Kenya, Community and Public Health, Nairobi, Kenya, [2]Technical University of Kenya, Biomedical Sciences and Technology, Nairobi, Kenya
Presenting author email: njathi.wambui@gmail.com

Background: Slum-dwelling Adolescent Girls and Young Women (AGYW) are highly vulnerable to HIV infection. Almost 7,000 new infections occur among AGYW in Eastern and Southern Africa. There is inadequate evidence on which health promotion models elicit sustainability of required behaviors. The objective of the study was to assess Knowledge, Attitude and Behavior (KAB) of AGYW residing in Mukuru Slums, Nairobi who had previously (2011-2014) participated in three different HIV/STI prevention programs. The study shows the potential sustainability of the interventions after three years.
Methods: A total of 423 AGYW were identified through stratified random sampling and enrolled into this retrospective cohort study. These included 207 former beneficiaries of the three different program models and another 216 who had not participated in any HIV Prevention program. The figure below shows those enrolled and the components of the different program models.



[Number of AGYW Enrolled]



[Comparing KAB aspects among programs' beneficiaries]

Conclusions: Integrating EBIs and economic empowerment aspects in HIV/STI prevention programs for slum dwelling AGYW seems to have efficacy in sustaining knowledge, attitude and protective behaviors.

WEPEC1052

"It's almost like gay sex doesn't exist." The nature of sex communication according to sexual minority adolescent males

D. Flores[1], S. Docherty[2], R. McKinney[3], J. Barroso[4]
[1]University of Pennsylvania, School of Nursing, Philadelphia, United States, [2]Duke University, School of Nursing, Durham, United States, [3]Association of American Medical Colleges, Washington, United States, [4]Medical University of South Carolina, School of Nursing, Charleston, United States
Presenting author email: dalmacio@upenn.edu

Background: Forty years of research on sex communication between parents and children in the home has led to empirically-based HIV and STI prevention interventions. Minimal research on this process prevents the formulation of similar interventions that would benefit adolescents with same-sex attractions, behaviors and identities. We sought to describe the perspectives of gay, bisexual, and queer (GBQ) adolescent sons on how sex communication with parents was initiated and their reactions to these conversations. These data will be inform future home-based HIV and STI intervention work for this population.
Methods: We conducted 30 semi-structured interviews with 15-20 year-old male youth from September 2015 to March 2016. Our participants included 23 gay, 5 bisexual, and 2 queer males. The transcribed data were analyzed iteratively on NVivo11 using standard thematic and content analysis techniques.
Results: We identified four central themes focused on how sex communication was experienced by these adolescent males: Prompts and triggers (when sons initiate the conversations, when parents observe signs of sons' physical maturation or social milestones, when family stories are being shared, and talks that evolve from teachable moments), parents' approaches (informing, lecturing, bargaining or joking), sons' reactions (compliant, mortified, dismissive, isolated, or offended), and the underlying functions they assigned to sex communication (to seek answers to questions of a sexual nature, to gauge parental opinion and acceptance, to keep parents informed, to educate parents, and to maintain a relationship for future support). We describe similarities to sex communication with mostly heterosexual samples and highlight intervention points for the sexuality-sensitive education of sons with same-sex attractions, behaviors, and identities.
Conclusions: Gay, bisexual, and queer males' informational needs about sex are not adequately addressed in the home. Parents are in an opportune position to provide sexuality-sensitive information because of the premium sons place in the parent-child relationship. Parents can be sources of reliable sexual health information and may be leveraged for future HIV/STI risk reduction interventions.

WEPEC1053

The feasibility and acceptability of a technology-based HIV preventive intervention in an urban youth-centered community health clinic in the United States

D. Cordova[1], F. Mendoza Lua[1], J. Ramsey[2], J. Bauermeister[3], B. Castillo[1], K. Fessler[2], A. Kasten[1], N. Adelman[2], M. Brown[2], T. Neilands[4], T.Y.L. Council[2], C. Boyer[4]
[1]University of Michigan, School of Social Work, Ann Arbor, United States, [2]The Corner Health Center, Ypsilanti, United States, [3]University of Pennsylvania, School of Nursing, Philadelphia, United States, [4]University of California, Center for AIDS Prevention Studies, San Francisco, United States
Presenting author email: cordovad@umich.edu

Background: HIV among youth remains a significant public health concern in the United States. HIV testing among adolescents is underutilized despite federal recommendations to screen adolescents for HIV infection and risk behaviors. Efficacious technology-based interventions aimed at improving HIV testing and preventing and reducing HIV risk behaviors among adolescents in clinic settings are limited. To fill this gap, we developed Storytelling 4 Empowerment (S4E), a theory-driven, culturally congruent, technology-based HIV preventive mobile application (app) for delivery in the clinic setting.
Methods: Employing a multi-method research design, we examined the feasibility and acceptability of S4E among clinicians and adolescents in an urban youth-centered community health clinic. S4E aimed to improve clinician-adolescent HIV communication and self-efficacy. Once adolescents completed the intervention, clinicians were provided adolescent risk behavior scores via the S4E app, aimed at facilitating adolescent-clinician HIV risk communication, and link adolescents to care and prevention services. We recruited 5 clinicians and 20 adolescents from an urban youth-centered community clinic to test the feasibility and acceptability of the intervention. Quantitative data were analyzed by computing mean scores and qualitative analyses followed the tenets of content analysis.
Results: Among eligible participants, 86.9% of adolescents and 85.7% of clinicians enrolled in the study, suggesting the feasibility of recruiting participants from the targeted clinic. Among the clinicians, 83% identified as non-Hispanic white and 66.7% female. Among the adolescents, 70% identified as non-Hispanic white, 30% African American, 50% female, and the mean age was 19.6 (SD=1.5, Range= 16-21). Findings indicate the participants' high acceptability of S4E (CSQ-8 mean sum= 25.2, SD= 4.8, Range= 17-29). Qualitative themes revealed that participants perceived the S4E app prepared them to discuss HIV risk and reduced their feelings of discomfort associated with initiating HIV communication, facilitated targeted and tailored HIV prevention services, and assisted with linkage to care.
Conclusions: Findings demonstrate the feasibility and acceptability of S4E in an urban community-based clinic setting. A next important step is to examine its efficacy in improving HIV testing and preventing and reducing risk behaviors among adolescents.

WEPEC1054

Participants' perceptions of the extended repeat HIV testing and enhanced counseling (ERHTEC) intervention for primary HIV prevention of pregnant and lactating women in Uganda

F. Bannink Mbazzi[1], R. King[2], Z. Namukwaya[3], A. Amone[3], F. Ojok[4], J. Etima[3], J. Matovu[3], E. Katabira[3,5], M.G. Fowler[3], J. Homsy[2], PRIMAL Study Team
[1]Ghent University, Faculty of Psychology and Educational Sciences, Ghent, Belgium, [2]University of California, Global Health Sciences, San Francisco, United States, [3]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [4]AVSI Foundation, Kampala, Uganda, [5]Makerere University, College of Health Sciences, School of Medicine, Kampala, Uganda
Presenting author email: femke.bannink@ugent.be

Background: The ‚Primary HIV Prevention among Pregnant and Lactating Ugandan Women' (PRIMAL) study aimed to assess an extended HIV testing and enhanced counseling (EHRTEC) strategy among 820 HIV-negative pregnant and lactating women aged 18 to 45 years and 410 of their male partners to address the first pillar of the World Health Organization global strategy for the prevention of mother-to-child HIV transmission (PMTCT).
Methods: We carried out qualitative research to evaluate the acceptability of ERHTEC and understand its effect on risk reduction, couple communication and support. We conducted 6 focus group discussions and 44 key informant interviews involving health care providers, pregnant/lactating women and their male partners in Mulago, Uganda's National Referral Hospital in urban Kampala, and in a rural hospital in Kitgum, Northern Uganda between July and September 2015. We used Nvivo10 for coding and thematic analysis.
Results: In both sites, participants mentioned that counselling had been helpful in risk reduction. The majority of participants enrolled as couples felt counselling had improved understanding, faithfulness, and support within their relationship. Another counselling benefit frequently mentioned was improvement of couple communication and negotiation for decision making for daily matters as well as sexual issues, family planning and condom use. Most participants felt the information provided on HIV prevention, family planning, and nutrition had supported them to remain HIV-negative and take better care of their children. Participants appreciated the combination of regular HIV testing and counselling, and were helped by the frequent reminders to come for quarterly follow-up. Some participants explained community members approached them for advice on HIV prevention and marital problems. They stressed the importance of providing counselling to all couples, and providing these services at village level. In Kitgum, participants felt couple counselling was the best way to address risk-reduction. In Kampala, participants recommended individual sessions in addition to couple counselling, in order to address personal challenges and concerns.
Conclusions: This study shows how an enhanced repeat testing and counselling PMTCT program with a focus on HIV risk reduction, couple communication, family planning and nutrition can support risk reduction, and improve support, communication and decision-making about sexual and reproductive health in HIV-uninfected mothers.

WEPEC1055

The effect of schooling on partner age difference and number of sexual partners among young women in rural South Africa enrolled in HPTN 068

M.C.D. Stoner[1], J.K. Edwards[1], W.C. Miller[1,2], A.E. Aiello[1], C.T. Halpern[1], A. Julien[1], A. Selin[1], J. Hughes[3,4], J. Wang[4], F.X. Gomez-Olive[5], R.W. Wagner[5], C. MacPhail[6], K. Kahn[5,7], A.E. Pettifor[1], HPTN 068
[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]Ohio University, Athens, United States, [3]University of Washington, Seattle, United States, [4]Fred Hutchinson Cancer Research Center, Seattle, United States, [5]MRC/Wits Rural Public Health and Health Transitions Unit CRS, Agincourt, South Africa, [6]University of New England, Biddeford, United States, [7]University of Witwatersrand School of Public Health, Johannesburg, South Africa

Background: Attending school may prevent sexually transmitted infections among young women as they may belong to safer sexual networks, manifested by fewer sex partners who are closer to their own age. In this paper we investigate this hypothesis using longitudinal sexual behavior data on young women.
Methods: We used data from the HIV Prevention Trials Network (HPTN) 068 randomized controlled trial in Agincourt, South Africa. We used "having a partner five or more years older" and "number of partners in the last 12 months" as outcomes. We measured the association of these outcomes with three different schooling situations: women attending >=80% of school days versus < 80%; women in school versus women who had dropped out; and women ever repeating a grade versus never repeating. We used inverse probability of exposure weighted Poisson models with generalized estimating equations. For the binary outcome, a Poisson model was used to approximate the binomial model.
Results: Of the 2,360 young women age 13 to 23 with a follow-up visit, 5.4% (N=270) attended less than 80% of school days and 3.8% (N=190) dropped out of school over the study period. Young women with low attendance had a higher one-year risk of having a much older partner (RD: 13.0%; 95% CI: 6.3%, 19.7%) and more partners (RD: 18.1%; 95% CI: 7.2%, 29.1%) than women with high attendance. Young women who dropped out of school had a higher risk of having a much older partner (RD: 13.7%; 95% CI: 5.1%, 22.3%) and more partners (RD: 36.1; 95% CI: 21.4%, 50.9%). Grade repetition was not associated with either behavior.
Conclusions: Young women who stay in school or attend more days of school have partners closer to their own age and fewer partners than young women who attend less school or drop out. The lack of association with grade repetition suggests that the effect of school on sexual behaviors is more strongly related with frequency of time spent in a school environment than with educational success.

WEPEC1056

Adapting an evidence-based HIV prevention curriculum for native american adolescents

M.C. Lee[1], C. Dodge-Francis[2]
[1]University of California, Global Center for Children & Families, Los Angeles, United States, [2]University of Nevada, School of Community Health Sciences, Las Vegas, United States
Presenting author email: crystal42lee@gmail.com

Background: Native American (Native) adolescents are at risk for HIV infection attributed to various biological, economic, and social factors, and high-risk behavioral factors. The lack of substantive and culturally appropriate HIV evidence-based prevention interventions for Native youth is evident within the literature. Effective

scientific prevention methods require tailoring fundamental interventions to respond to both immediate risks and underlying causes of vulnerability for Native adolescents. This article presents a feasibility study that adapted and modeled an existing HIV evidence-based preventive intervention for Native adolescents.
Methods: Becoming A Responsible Teen (BART) is a community-level, education and behavior skills training designed to reduce risky sexual behaviors and improve safer sex skills among African American adolescents. This adolescent HIV evidence-based prevention curriculum; was adapted in three phases for Native adolescents:
1) ascertaining feedback and guidance from a Native Advisory Board (N=5 experts);
2) modifying the BART curriculum and creating an adolescent workbook to be culturally appropriate and consistent with Native ideologies, language, symbols, practices, and pedagogy; and
3) conducting the BART prevention curriculum to test for both efficacy and effectiveness, with 14 urban inter-tribal Native adolescents.
Examination of acceptability and cultural congruence between the adapted intervention and the youth's culture was captured with Likert-scale ratings and qualitative focus group narratives. A pre-post HIV knowledge survey was conducted to measure HIV knowledge gains.
Results: The adolescents consistently rated each session has highly acceptable. There was difference in pre-survey (M=13.93, SD=3.08) and post-survey (M=17.14, SD=2.25) conditions; t(13) = 4.166, p <0.0005. Qualitatively respondents preferred the Native cultural content and activities as a curriculum format in assisting and clarifying their individual HIV knowledge, sexual ideals, and decision-making practices.
Conclusions: Few HIV evidence-based prevention feasibility studies have been developed, adapted, and/or evaluated for Native adolescents. This study demonstrates that an adapted BART curriculum would be culturally appropriate for dissemination or implementation beyond the population and modalities in which it was originally created and studied.

WEPEC1057

Sharing circles with indigenous women: understanding perceptions of HIV to inform the scale-up of behavioural change strategies in Quebec, Canada

C. Martin[1], D. Peltier[2], N. O'Brien[3,4], A. Kaida[5], M. Becker[6], C. Bourassa[7], S. Bruce[8], M. Loutfy[9], A. de Pokomandy[3,4], on behalf of the CHIWOS-PAW Team
[1]Native Women's Shelter of Montreal, Montreal, Canada, [2]Canadian Aboriginal AIDS Network, Dartmouth, Canada, [3]McGill University, Family Medicine, Montreal, Canada, [4]McGill University Health Center, Chronic Viral Illness Service, Montreal, Canada, [5]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [6]University of Manitoba, Centre for Global Public Health, Winnipeg, Canada, [7]First Nations University of Canada, Indigenous Education, Regina, Canada, [8]University of Manitoba, Community Health Sciences, Winnipeg, Canada, [9]Women's College Hospital, Women's College Research Institute, Toronto, Canada
Presenting author email: carrie.nwsm@gmail.com

Background: As a result of historical and structural processes, Canadian Indigenous women are disproportionally affected by the HIV epidemic. Although Indigenous women (First Nations, Métis, Inuit), are 4.3% of the Canadian female population, they represent 30.6% of new female diagnosis. Counter to national trends, available data suggests that the HIV-epidemic among Indigenous women in Quebec is not as widespread.
This research was undertaken to better understand Quebec Indigenous women's perceptions of HIV, and prevention and care services. The overall goal is to identify innovative, culturally safe behavioural intervention for HIV prevention specific to Indigenous women in Quebec.
Methods: This research is embedded within the Canadian HIV Women's Sexual and Reproductive Health Cohort Study - Prioritizing the Health Needs of Positive Aboriginal Women (CHIWOS-PAW). From December 2015 to December 2016, four full-day research retreats were conducted with 14 Indigenous women, led by Indigenous researchers in Quebec. Drawing on Indigenous Methodologies, and under the guidance of an Indigenous Elder, sharing circles, reproductive justice-based sexual health workshops, and arts-based behavioural change strategies were conducted. Research participants then collaboratively interpreted and confirmed the findings in an interactive closing circle.
Results: Fourteen Indigenous women, 24-74 years of age, participated. Inuit, Métis and First Nations were represented from 12 different communities, and seven distinct languages were spoken. Self-reported HIV-status included HIV-positive, HIV-negative, and HIV-status unknown. In the sharing circles, emphasis was placed on root causes of HIV, including gendered violence, unequal relationships, and intergenerational trauma. Recommendations for improving prevention and care included ensuring safe spaces for women to meet, share, and learn from one another, with peer and youth led programming. Strategies to ensure confidentiality within health care settings, and when seeking risk reduction services should be improved. Education regarding HIV must also be prioritized to communicate transmission risks, to dispel persisting HIV misconceptions, and to reduce stigma and discrimination. During the circles, women also shared self-care strategies and tools for building self-esteem as part of overall health.
Conclusions: Peer-led design and delivery of HIV-prevention and care programs are key to ensuring a response that meets Indigenous women's needs, including addressing structural factors which impact their health and healthcare seeking.

WEPEC1058

Unsuccessful behavioral risk reduction contributed to HIV seroconversion as well as high STI incidence among newly diagnosed HIV-positive MSM and TG in a facility-based Test and Treat cohort in Thailand

N. Phanuphak[1], P. Chamnan[2], P. Pathipvanich[3], S. Thongpaen[4], S. Nonenoy[1], J. Jantarapakde[1], S. Pengnonyang[1], N. Teeratakulpisarn[1], M. Kongkabpan[1], D. Trachunthong[1], T. Sungsing[1], K. Parasate[2], S. Seneewong Na Ayutthaya[3], K. Trairat[4], T. Poorisri[5], C. Lertpiriyasuwat[5], S. Akksilp[5], P. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Sanpasitthiprasong Hospital, Ubonratchathani, Thailand, [3]Lampang Hospital, Lampang, Thailand, [4]Mahasarakham Hospital, Mahasarakham, Thailand, [5]Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand

Background: Facility-based Test and Treat model for Thai MSM and TG has proved successful in identifying and linking new HIV cases to ART. However, long-term behavioral risk patterns among these HIV-negative and HIV-positive MSM and TG are unknown.
Methods: Thai MSM and TG aged ≥18 years were recruited through 4 clinics/hospitals. Self-administered questionnaires and HIV testing were performed at baseline and every 6 months. Syphilis, gonorrhea and chlamydia were screened at baseline and every 12 months. We studied risk behaviors over a 24-month period among participants diagnosed HIV-positive, seroconverted, or remained HIV-negative. Factors were modeled by Cox proportional hazard for HIV incidence.
Results: Of 696 MSM and 112 TG enrolled, HIV prevalence was 16.4% and HIV incidence was 5.3 per 100 person-years. 85% initiated ART within a median (IQR) time of 8(4-22) days. HIV RNA was < 40 copies/mL in 80.4%, 93.4%, 94.8% and 97.2% at months 6, 12, 18 and 24 after ART, respectively.
Newly diagnosed HIV-positive participants significantly reduced, from baseline to months 6, 12, 18 and 24, unprotected sex (76.4% to17.3%, 14.0%, 13.5%, 15.1%, p<0.001), having multiple partners (60.9% to32.3%, 31.2%, 34.0%, 31.4%, p< 0.001), and amphetamine-type stimulants (ATS) use (10.9% to5.8%, 2.0%, 2.1%, 1.5%, p<0.001). Participants who remained HIV-negative also reduced unprotected sex (50.5% to 34.7%, 32.9%, 35.4%, 29.2%, p<0.001) although not to the level of HIV-positive participants. HIV seroconverters, however, remained practicing unprotected sex (79.1% to 62.8%) and having multiple partners (61.9% to 69.7%) from baseline until seroconverted, and increased ATS use at seroconversion (7.0% to 11.6%). Unprotected sex (HR 3.15, 95%CI 1.31-7.57, p=0.01) and having baseline STIs (HR 2.08, 95%CI 1.10-3.91, p=0.02) increased risk of HIV seroconversion.
HIV-positive participants had higher STI incidence (per 100 person-years) than HIV-negative participants: syphilis (13.4 vs. 1.6, p<0.001), gonorrhea (16.4 vs. 6.0, p<0.001), and chlamydia (18.1 vs. 5.7, p<0.001).
Conclusions: Behavioral risk reduction was not always successful. Continued risks contributed to HIV seroconversion and STI incidence which could affect the ending AIDS goal. Integrating effective use of pre- and post-exposure prophylaxis and regular STI screening into programs for populations with high-risk behaviors are urgently needed.

WEPEC1059

Addressing issues impacting safe and consistent use of an HIV prevention intervention: development of a social benefits-harms (SBH) tool

E.E. Tolley[1], S. Zissette[1], T. Palanee-Phillips[2], F. Mathebula[2], S. Tenza[2], M. Hartmann[3], E. Montgomery[4]
[1]FHI 360, Behavioral and Social Science Research, Durham, United States, [2]Wits Reproductive Health and HIV Institute, University of the Witswatersrand, Johannesburg, South Africa, [3]RTI, Women's Global Health Imperative, Cape Town, South Africa, [4]RTI, Los Angeles, United States
Presenting author email: btolley@fhi360.org

Background: In HIV prevention trials, male partners have influenced women's ability to safely and consistently adhere to trial products, including vaginal rings as demonstrated in the MTN 020/ASPIRE trial. Validated scales can be useful tools to systematically measure complex constructs, such as those related to male partner engagement. Building onto an open-label microbicide vaginal ring trial called MTN025/ HOPE, the CHARISMA intervention tailors HIV prevention and em-

powerment counseling to study participants' relationship contexts and monitors the social benefits and harms (SBH) of the intervention on women's agency to use microbicides. Part of the intervention involved development of a SBH tool.
Methods: Based on a literature review and conceptual framework, we identified and refined 127 potential items representing intimate partner violence, agency and social support. A structured survey (n=309), including SBH items among other variables was administered to former microbicide trial- and non-trial participants. We conducted exploratory factor analyses (EFA), examining solutions for three to nine factors, to identify a reduced set of constructs and items to screen women who might experience social harms or benefits related to vaginal ring use. We examined associations with other survey variables to assess content and construct validity.
Results: Several EFA solutions produced conceptually relevant factors with good to strong reliability. We retained five constructs with particular theoretical relevance for the tool. They included:
Traditional Values (13 items, α=.84);
Partner Support (10 items, α=.81);
Partner Abuse and Control (9 items, α=.81);
Partner Resistance to HIV Prevention (5 items, α=.80);
and HIV Prevention Readiness (5 items, α=.68).
The SBH tool is currently being piloted at the Johannesburg MTN 025/ HOPE site; after further validation, rollout to other African sites is anticipated. Administered electronically, women whose scores indicate low partner support and/or high resistance or abuse are identified as potential recipients of tailored counselling and/or referrals.
Conclusions: Our brief, electronically-administered tool assists trial providers to assess women's perceptions of partner support or opposition to using HIV prevention products, including the risk of IPV. Beyond trial settings, such a tool could assist clinic staff to efficiently tailor risk reduction, empowerment and adherence counseling for microbicides and other services.

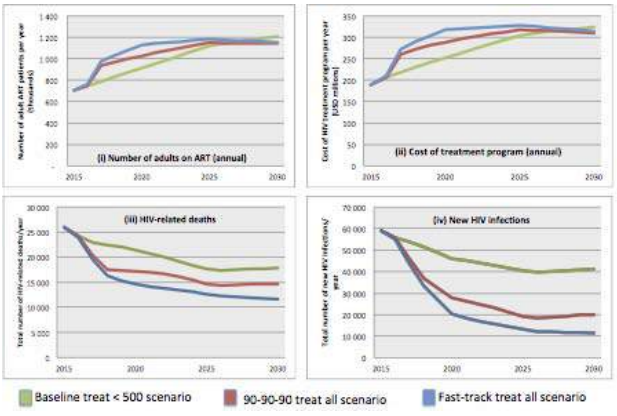
The cost and effectiveness of achieving universal HIV treatment coverage in Africa: a modeling analysis of scaling up "treat all" in Zambia

T. Guthrie[1], C. Moyo[2], A. Kinghorn[3], C. van Rensberg[4], J. Kuenhle[5], W. Kaonga[2], L. Hehman Soares[6], M. Kamanga[7], G. Sinyangwe[5], J. Stover[8], L. Long[4], S. Rosen[9]
[1]Health Economics and Epidemiology Research Office, WITS University, Johannesburg, South Africa, [2]Ministry of Health, Zambia, Clinical Services, Lusaka, Zambia, [3]WITS University, Perianatal HIV Research Unit, Johannesburg, South Africa, [4]WITS University, Health Economics & Epidemiology Research Office, Johannesburg, South Africa, [5]USAID, Lusaka, Zambia, [6]CHAI, Lusaka, Zambia, [7]EQUIP, Lusaka, Zambia, [8]Avenir Health, Washington, United States, [9]Boston University, Boston, United States

Background: To achieve "90-90-90" targets, many countries have adopted "treat all" with no eligibility threshold for ART. We modeled the impact of adopting treat all in Zambia on total cost and HIV incidence and mortality, to inform policy choices and resource mobilization.
Methods: We used existing Zambian Spectrum AIM and GOALS models and new data on HIV program coverage, ART effectiveness, and current local unit costs to estimate the impact and costs of implementing treat all under three scale-up scenarios:
(1) "baseline" (500 CD4 threshold for ART eligibility, treatment coverage of 70% by 2020 and 82% by 2030);
(2) "90-90-90" (treat all, reaching 81% in 2020 and 90% in 2030);
(3) "Fast Track" (treat all, reaching 90% in 2020 and 95% in 2030, with scaled-up prevention interventions).
Results: Figure 1 presents resulting changes in:
(i) ART patient numbers,
(ii) costs,
(iii) HIV-related deaths, and;
(iv) HIV infections.
Adult patient numbers increase by 45% and 60% by 2020 in scenarios 2 and 3, respectively. New infections and deaths both decline under scenarios 2 and 3, averting 3,000-5,000 more deaths per year and 20,000-30,000 more new infections per year than scenario 1 by 2030. Treatment costs rise from $261 million/year in 2015 to $398 million, $411 million or $443 million by 2020 in the three scenarios, respectively. Annual costs for scenarios 2 and 3 plateau around 2025 and then fall below baseline due to reduced transmission. Compared to baseline, the incremental cost per infection averted over the period was $281 for Fast Track and (-$466) (cost saving) for 90-90-90.



[Zambian Cost & Effectiveness of Treat All scale-up]

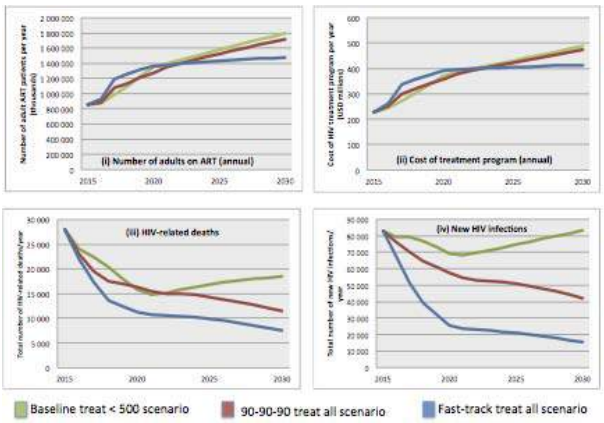
Conclusions: Scaling up treat all in Zambia has the potential to save thousands of lives and reduce new infections, but costs will increase dramatically. Domestic and international financing initiatives will need to be explored, with greater efforts to ensure sustainability.

WEPED1346

Uganda: the cost and effectiveness of achieving universal HIV treatment coverage. A modeling analysis of scaling up "treat all"

T. Guthrie[1], C. Zikusooka[2], J. Musinguzi[3], W. Kirungi[3], S. Dejene[4], B. Nabukalu[2], S. Kanoowe[2], S. Lagony[2], S. Balyejjusa[5], J. Stover[6], L. Long[7], S. Rosen[8]
[1]Health Economics and Epidemiology Research Office, WITS University, Johannesburg, South Africa, [2]Health Net Consult, Kampala, Uganda, [3]Ministry of Health, Kampala, Uganda, [4]USAID Uganda, Kampala, Uganda, [5]Ministry of Health, QPPU, Kampala, Uganda, [6]Avenir Health, Washington, United States, [7]WITS University, Health Economics and Epidemiological Research Office, Johannesburg, South Africa, [8]Boston University, Boston, United States

Background: To achieve "90-90-90" targets, many countries have adopted "treat all" guidelines with no eligibility threshold for ART. We modeled the impact of adopting treat all in Uganda on cost, HIV incidence and mortality.
Methods: We used existing Ugandan Spectrum AIM and Goals models and new data on HIV program coverage, ART effect on incidence, and current local unit costs to estimate the impact and costs of implementing treat all under three scenarios: (1) "baseline" (500 CD4 threshold for ART eligibility, treatment coverage of 70% by 2020 and 82% by 2030); (2) "90-90-90" (treat all, coverage of 81% in 2020 and 90% in 2030); (3) "Fast Track" (treat all, coverage of 90% in 2020 and 95% in 2030, plus expanded prevention interventions).
Results: Figure 1 presents resulting changes in (i) ART patient numbers, (ii) costs, (iii) HIV-related deaths, and (iv) HIV infections. Adult ART patient numbers increase by 49% and 59% by 2020 in scenarios 2 and 3, respectively. New infections and deaths both decline under scenarios 2 and 3, averting 2,000-6,000 more deaths per year and 20,000-50,000 more new infections per year than scenario 1 by 2030. Treatment costs rise from $228 million/year in 2015 to $372 million, $358 million or $391 million by 2020 in the three scenarios, respectively. Annual costs for scenarios 2 and 3 decline around 2025, while the Fast Track costs could fall below baseline due to reduced transmission. Compared to baseline, the incremental cost per infection averted over the period was $1,022 for Fast Track and (-$281) (cost saving) for 90-90-90.



[Cost and effectiveness of "Treat All" in Uganda]

Conclusions: Treatment costs in Uganda will increase steadily regardless of scenario, but the 90-90-90 and Fast Track scenarios have the potential to avert thousands more deaths and new infections. Sustainable financing opportunities will be needed for treatment program expansion to achieve the benefits of the treat-all scenarios.

WEPED1347

Global fund funding transition readiness in middle-income countries

A. Sharp[1], R. O'Hagan[1], J. MacAllister[2], B. Honermann[1], S. Blumenthal[1], G. Millett[1]
[1]amfAR, Washington, United States, [2]International AIDS Society, Washington, United States
Presenting author email: alana.sharp@amfar.org

Background: In the Global Fund's (GF) new funding model, countries become ineligible for support as their economies grow or disease burden decreases. This loss of funding may constitute significant operational and budgetary challenges. This analysis evaluates the domestic capacity to provide HIV services, particularly for key populations (KPs), in countries expected to graduate from GF funding by 2025.
Methods: We analyzed eleven countries projected by GF to lose eligibility for HIV funding by 2025. GF support as a share of country resources for HIV was taken from the first year of support listed in each country's most recent GF funding application, stratified by module. Data on civil society organizations' (CSO) program implementation were compiled from UNAIDS National Commitment and Policy Instruments. Criminalization data for same-sex acts, sex work and illicit drug use and evidence of extralegal action were taken from country criminal codes and monitoring organizations.
Results: GF support constitutes on average almost one-third of total HIV budgets in the eleven nations expected to transition to country ownership by 2025. All of these nations have concentrated HIV epidemics in KPs. On average, 35% of GF grant budgets were designated for KP-specific activities, ranging from 0-67%. Services for KPs are largely provided by CSOs, which implement more than 75% of HIV services for at least one KP in six countries. Despite this critical role, six countries have imposed legal barriers on CSO funding and activities, and government harassment of CSOs has been reported in at least three countries. Criminalization of same-sex sexual acts, sex work, or illicit drugs is common.
Conclusions: GF is a major funder of HIV services, particularly for KPs, in this group of middle-income countries. CSOs are important implementers of KP programs, but are dependent on international funding and experience significant barriers to operation in the majority of these countries. In preparation for transition, GF and governments must improve CSO operational and funding environments as well as strengthen advocacy to remove the legal obstacles to sustaining the progress that has been achieved in reducing HIV in these nations.

WEPED1348

Beyond Global Fund: transitioning to sustainable funding for HIV prevention: the case of harm reduction programs in Eastern Europe

I. Varentsov[1], G. Shaw[2], D. Parsons[3]
[1]Eurasian Harm Reduction Network, Vilnius, Lithuania, [2]Independent Consultant, Cambridge, United Kingdom, [3]AIDS Projects Management Group, Sydney, Australia

Background: After the Global Fund's new approach to resource allocation was introduced in 2014, there was a decrease in funding available for middle-income countries with concentrated epidemics. Discussions took place on how to ensure the successful transition and sustainability of HIV programs from Global Fund support to national funding, especially interventions that targeted key populations.
In 2016, the Eurasian Harm Reduction Network conducted 5 case studies in Albania, Bosnia & Herzegovina, Macedonia, Montenegro and Romania to evaluate the readiness for transition of harm reduction services, analyse the transition-related processes and possible consequences for the sustainability of such services.
Methods: A standardized approach was used to analyze the situation in each country. The Transition Readiness Assessment Tool (TRAT) was developed. Experts were hired to use the tool to conduct a comprehensive transition readiness assessment which included collection of quantitative and qualitative data through a desk review and interviews with key informants to assess and score benchmarks for each indicator in each thematic area of transition. TRAT was updated based on the results of this field-testing.
Results: In the majority of countries, transition planning processes didn't take place at all or started too late to have any impact. Mostly, governments had neither a tenable plan, nor sufficient human and/or financial resources in place to maintain its HIV program. Governments did not prioritize HIV prevention programs among people who inject drugs. As a result, programs that deliver services for key populations have no resources to continue their work after the end of Global Fund support and, in most cases, collapse.
Conclusions: The transition processes should begin well in advance of the Global Fund's withdrawal, at least 2 allocation periods beforehand. Services delivered by NGOs are at special risk of termination within the transition period, especially without the existence of state mechanisms for contracting NGOs to provide HIV prevention services.

WEPED1349

Sustainable integrated collection logistics management information system reports: collecting HIV/AIDS and malaria LMIS reports using local government area officers and roll back malaria focal persons in Nasarawa State, Nigeria

C. Okolo[1], S. Umaru Mohammed[2]
[1]Nigeria Supply Chain Integration Project, HIV/AIDS and Other Integrated Programmes, Nasarawa, Nigeria, [2]State Ministry of Health, Logistics Management Coordinating Unit (LMCU), Lafia, Nigeria
Presenting author email: pamelanonye@gmail.com

Background: Uninterrupted service delivery for any programme is achieved by Commodity Security/availability and this can only be attained by a sustainable timely submission of quality Logistics Management Information System (LMIS) reports. Previously in Nasarawa State, LMIS reports were collected using cluster review meetings. This method of report collection was donor driven and as such not sustainable. This is because of the number of supported facilities and cost of paying individual program focal persons for HIV and Malaria.
Methods: Twenty eight (28) Local Government Area (LGA) officers and Roll Back Malaria (RBM) focal persons representing 13 Local Government areas were recruited to collect both HIV and Malaria LMIS reports.
This group comprised of eight (8) females and twenty (20) males. The selected focal persons were oriented on the LMIS report collection tools used by both programs. This was to enable them validate reports collected from health facilities. At the end of the orientation exercise, the 28 officers were provided with all LMIS tools for report collection, list of facilities offering both services to clients at their LGAs and the names of their focal persons. They were mandated to collect Malaria and HIV/AIDS LMIS reports from the listed facilities. The timelines for usual collection and submission of LMIS reports; first week of each reporting month, was also shared with them.
Results: The cost for integrated collection of HIV and Malaria LMIS reports reduced from twelve thousand eight hundred and five US Dollars (12,805 USD) using the cluster review meeting mechanism to three thousand four hundred and eighteen US Dollars (3,418 USD) using the LGA officers mechanism. In addition, these LMIS reports were collected timely and used to inform resupply of HIV and malaria commodities to health facilities.
Conclusions: Integrated collection of LMIS reports for all program areas using Local Government Area and Roll Back Malaria officers mechanism is a cheaper and more sustainable method of LMIS data collection which can be transitioned to State governments.

WEPED1350

Standing on our own feet: reducing donor dependence and ensuring self sufficiency and self reliance

T. Narendran
Vrutti, Resource Mobilization, Bangalore, India
Presenting author email: narendran31@gmail.com

Background: Community Organisations (COs) of key populations in India are witnessing a substantial decrease in funding from Government and donor agencies for HIV/AIDS works. The future of this funding is not certain in the years to come due to various reasons, including change in priorities of Government, shift in focus of donor agencies and growing competition between local NGOs and COs for limited funding opportunities. Long term sustainability of COs and the community's agenda is possible only if they are able to raise resources locally. Most of them are not strong enough to sustain on their own due to limited skills and knowledge of key staff and board members about resource mobilization.
Methods: Swasti, Vrutti and CMS manages the Avahan Phase III initiative (2014-2017), funded by Bill & Melinda Gates Foundation, and supports 74 COs on resource mobilization for their long term sustainability. The project covers about 121,000 key populations (FSW, MSM & TGs) across 5 states of India. Capacities of key leaders and staff of COs is built to raise resources. COs are provided handholding support to implement a range of context (and capacity specific) activities to raise resources, which include conducting cultural events, lucky draws, selling

products and seeking donations. They are also equipped to raise resources in kind and also reduce their costs through a range of cost cutting measures. Standing on own feet, a tool to calculate total yearly core cost estimate and choose strategies for achieving the same has been developed and have been tracked on a monthly basis.
Results: Substantial efforts on resource mobilization have started yielding results, with 74 Organizations raising USD 370,462 cumulatively since April 2014. Systematically planned and organized methods of resource mobilization can result in enhanced fundraising required for sustainable HIV/AIDS prevention program.
Conclusions: With right tools, capacity building, facilitation and local leadership, it is possible to mobilize local resources, and this is vital for success of HIV/AIDS prevention and vulnerability reduction programmes. Crises are also opportunities to bring in a sense of urgency. Raising local resources also tests the connect with the Community and relevance of Community services.

WEPED1351

The hidden costs of HIV: what about costs to users?

A. LeFevre[1], A. Dia Lou[2], K. Ouattara[2], D. Mohan[3], G. Furlane[4], S. Stender[5]
[1]Johns Hopkins School of Public Health, International Health, Cape Town, South Africa, [2]Jhpiego, Abidjan, Cote D'Ivoire, [3]Johns Hopkins School of Public Health, Baltimore, United States, [4]Jhpiego, Baltimore, United States, [5]Jhpiego, Cape Town, South Africa
Presenting author email: angeline.dialou@jhpiego.org

Background: Côte d'Ivoire, like many PEPFAR supported countries, has mandated that antiretrovirals, clinical tests, consultation and other fees related to HIV testing, care and treatment, be provided free of charge to patients. In practice, however, patients incur substantial out of pocket costs directly and indirectly related to HIV care and treatment.
This analysis explores the economic consequences of ill-health amongst people living with HIV (PLHIV) in Cote d´Ivoire.
Methods: From July-September 2016, a phone survey was administered to 320 PLHIV recruited from 16 health facilities in N'zi-Ifou and Indenie Djuablin regions of Cote d´Ivoire. The survey included modules on socioeconomic and demographic characteristics, HIV, facility-based services (including direct and indirect costs), equity and financial risk. Data entry occurred using RedCAP and data were analyzed using Stata 13.0.
Results: A total of 317 interviews were completed: 196 (61%) from urban health centers and 124 (39%) from hospitals. 62% of respondents were female; 76% were 35 years of age or older; 55% were married or lived together; 34% reported not having had any education; and 44% were shopkeepers or vendors. 45% of respondents incurred $0.00 cost for their most recent visit to the health facility. Amongst the 55% that incurred a cost, the median cost was US$1.91 and comprised primarily of transportation costs (median $1.61). Transportation costs were significantly higher amongst women, individuals in higher socioeconomic strata, and those receiving care at hospitals. Wages lost and informal payments to be seen first were reported by 9% and 2% of patients, respectively. Direct costs for clinical services were reported by 5% of respondents and included consultation fees and clinical exam fees. Amongst the sub-sample (61%) who received clinical exams during their last visit, 6% incurred costs for blood tests (median $4.04), TB sputum (median $11.20), and/or chest x-rays (median $8.07).
Conclusions: Finding highlight the importance of understanding the consequences of indirect costs to households of PLHIV, including transportation. Strategies which promote community-based distribution of ARTs are likely to reduce indirect costs to patients and lesson the burden on providers. Costs for tuberculosis tests, while infrequent, were high amongst those incurring any cost.

WEPED1352

The fast track to achieve the 90-90-90 target: a review of a costed national plan and expenditure in Nigeria from 2013-2015

I. Ezirim, F. Agbo
National Agency for the Control of AIDS, Strategic Knowledge Management Department, Abuja, Nigeria
Presenting author email: send2teyin@yahoo.com

Background: Despite the progress made in addressing the epidemic, the pace at which new HIV infections is declining globally and in Nigeria is slow. It is globally accepted that achieving the 90-90-90 targets is a step towards ending AIDS . The 2017- 2021 Nigeria National Strategic Framework (NSF) was developed to provide direction towards ending AIDS in Nigeria by 2030.As such priorities for achieving the 90-90-90 target in Nigeria have been identified in the NSF. To reach the 90-90-90 target, it is important to look at a previous national plan so we can avoid the pitfalls from past years.
Methods: This paper reviews the goals and estimated cost for attaining these goals in the President Comprehensive Response Plan for HIV/AIDS (PCRP) 2013-2015. It compares the estimated cost in the PCRP with what was spent during the period. HIV/AIDS expenditure was obtained from National AIDS Spending Assessment (NASA) 2013- 2014.
Results: The estimated cost in the PCRP for providing 80 million Nigerians with access to HCT for the 2013-2015 period was 640,202,344USD. NASA revealed that only 44,001,049USD was spent in 2013 and 2014 on HCT. So from 2013-2014 only 7% percent of the estimated HCT cost was spent. In addition only 4,077,663 and 6,716,482 persons respectively were tested in 2013 and 2014 (13% of the target). Also it was estimated that it will cost 181,518,583USD to reach 4million young people and 500,000 MARPS with combination prevention for the 2013-2015 period. NASA however showed that 49,397,478USD (27% of the estimated cost) was spent on sexual prevention within the same period.
Conclusions: The huge funding gap significantly slowed down progress in the implementation of national targets in the past. The goal of 2017-2021 NSF will suffer similar set back if this gap is not addressed. Therefore the fast track to attaining the 90-90 -90 target in the current NSF is dependent on Nigeria's ability to provide cost efficient programs and mobilize resources to bridge this gap.

WEPED1353

Individual and healthcare supply-related barriers to ART initiation in HIV-positive patients followed up as part of the Cameroonian antiretroviral treatment program (ANRS-12288 EVOLCam survey)

P.-J. Coulaud[1], K. Ndiaye[1], L. Sagaon-Teyssier[1], G. Maradan[1], C. Laurent[2], B. Spire[1], L. Vidal[1], C. Kuaban[3], S. Boyer[1], The EVOLCam Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]TransVIHMI, IRD UMI 233, INSERM U 1175, Université de Montpellier, Montpellier, France, [3]Faculté de Médecine et de Sciences Biomédicales, Université de Yaoundé, Yaoundé, Cameroon
Presenting author email: bruno.spire@inserm.fr

Background: The increasing demand for HIV services and the reduction of international financial support observed in the last decade compromise the sustainability of antiretroviral therapy (ART) programs in developing countries. This translates into limited patient access to ART and reduced capacity of HIV services to promptly initiate treatment. We aimed to investigate whether individual and healthcare supply-related factors were associated with the time of ART initiation (ART-I) in patients eligible for ART within the context of the Cameroonian ART program.
Methods: We used data from a cross-sectional survey conducted among 2141 HIV-positive adults attending 19 HIV services in Cameroon (EVOLCam ANRS 12288). Socio-behavioural, psychosocial, medical and facility-related data were collected. The analysis was carried out on the 1727 (81%) patients eligible for ART at the time of HIV-diagnosis, according to national guidelines. The time elapsed between diagnosis and ART-I was the main outcome. A multi-level Cox model was implemented to investigate healthcare supply and individual factors associated with the time of ART-I.
Results: Among the 1727 patients (women 73%, median age 40 years [Interquartile Range (IQR) = 34-48]), median time elapsed between HIV diagnosis and ART-I was 2.4 months ([IQR= 0.7-12.3]) with large variability across HIV services ([min-max = 0.7-10.6] months). ART-I was slower for patients followed up in the Littoral region (Hazard Ratio (HR): 0.76, 95% Confidence Interval (CI) [0.62-0.90]), in private HIV services (HR [95% CI]: 0.79 [0.67-0.92]) and in HIV services with a higher number of ART patients per medical staff member (HR [95%CI]: 0.99 [0.99-1.00]). Conversely, faster ART-I was associated with the availability of health education activities (HR [95%CI]: 1.83 [1.63-2.04]). With regard to individual factors, having a CD4 count ≥100cells/mm^3 (HR [95%CI]: 0.85 [0.73-0.98]), being HIV-diagnosed without presenting medical symptoms (HR [95%CI]: 0.63 [0.51-0.76]) and having a history of tuberculosis (HR [95%CI]: 0.86 [0.74-0.98]) were all associated with a slower ART-I.
Conclusions: Our findings suggest that health system constraints may delay ART initiation, thereby compromising the second target of the 90-90-90 objective. The development of educational interventions is necessary but insufficient to improve linkage to treatment, and should be complemented with global strengthening of health-based human resources.

WEPED1354

Trends in healthcare expenditure among individuals with HIV/AIDS in the United States: 2002-2011

T. Ritchwood
Medical University of South Carolina, Public Health Sciences, Charleston, United States
Presenting author email: ritchwoo@musc.edu

Background: While previous studies have examined HIV cost expenditures within the United States, the majority of these studies focused on data collected prior to or shortly after the advent and uptake of antiretroviral therapy, focused only on a short time frame, or did not provide cost comparisons between HIV/AIDS and other chronic conditions. It is critical that researchers provide accurate and updated information regarding the costs of HIV care to assist key stakeholders and decision-makers with economic planning, policy development and adjustments, and resource allocation.
Methods: We used data from the Medical Expenditure Panel Survey-Household Component for the years 2002-2011, which represents a nationally representative U.S. civilian non-institutionalized population. Using generalized linear modeling, we estimated the adjusted direct medical expenditures by HIV/AIDS status after controlling for confounding factors.
Results: Data were from 342,732 people living with HIV/AIDS. After adjusting for socio-demographic factors, comorbidities and time trend covariates, the adjusted incremental cost of total direct expenditures for HIV/AIDS was increased by $31,147 (95% CI $23,645-$38,648) when compared to those without HIV/AIDS. Based on the adjusted mean, the aggregate incremental cost of HIV/AIDS was approximately $10.7 billion higher than the costs for those without HIV/AIDS.
Conclusions: Our estimates of cost expenditures associated with HIV care over a 10-year period show a financial burden that exceeds previous estimates of direct medical costs. There is a strong need for financial investment and comment to socio-structural interventions to reduce the financial burden on those most impacted by HIV and facilitate longer and healthier lives.

WEPED1355

Methods for standardizing sector-wide health budgets to improve allocative efficiency and government ownership in the HIV response: lessons from Malawi

G. Manthalu[1], M. Ferng[2], G. Hadley[2], A. Kallarakal[2], A. Gunda[2]
[1]Ministry of Health, Department of Planning and Policy Development, Lilongwe, Malawi, [2]Clinton Health Access Initiative, Lilongwe, Malawi
Presenting author email: gmanthalu@gmail.com

Background: Achieving 90-90-90 depends on the availability and efficient allocation of limited resources. In many developing countries, fragmentation and information asymmetry constrain governments' ability to coordinate resources across the HIV response.
Malawi is one of the poorest and most donor-dependent countries in the world; in FY2015/16, 99% of all HIV resources financed by donors. In 2012, the Government of Malawi, supported by CHAI, set out to test the hypothesis that annual standardization of health budget data could improve allocative efficiency and optimize the use of HIV resources.
Methods: Developing the annual resource mapping database requires all donors and implementers to complete individual Excel-based submissions with detailed forward-looking budget data, which are consolidated into a single sector-wide database. The data is disaggregated by intervention category, project, activity, financing source, geographical area, cost category, and fiscal year.
Results: Since initiation, resource mapping has repeatedly been used for investment planning, resource mobilization, and coordination of Malawi's diverse HIV investments. Leveraging estimations of the available budget, the Ministry and its partners have been able to:

- Conduct detailed gap analyses to mobilize and allocate new funding. Comparing planned resources against the costed HIV National Strategic Plan, an activity-based gap analysis identified ARVs as experiencing the most severe funding shortfalls. This led to over US$360M in targeted donor investments toward ART.
- Identify and address allocative inefficiencies caused by poor coordination and lack of transparency. By listing funders and implementers of each NSP intervention, resource mapping helped identify duplication of VMMC activities between donors and informed reprogramming of US$15M to 18 underfunded districts.
- Identify technical inefficiencies in planned spending caused by fragmentation. Resource mapping evidence estimated the inefficiency of Malawi's parallel supply chains at US$11M per year. The quantified need for harmonization informed a decision by DFID to channel funding through the national system, saving up to US$3M annually.

Conclusions: Since 2012, resource mapping has become an indispensable tool to ensuring efficiency in Malawi's national HIV response. By enabling comprehensive analysis of HIV commitments over the next five years, resource mapping has increased transparency and country ownership, equipping country stakeholders with evidence for investment planning, coordination, and resource mobilization.

Health Systems Strengthening

WEPED1356

Improved implementation of policies pertaining to antiretroviral therapy access between 2013 and 2016 in six sub-Saharan African countries

J. Ambia[1], J. Renju[1], P. Mee[1], A. Wringe[1], E. Geubbels[2], J. Nakiyingi-Miiro[3], M. Urassa[4], T. Lutalo[5], M. Crampin[6], D. Kwaro[7], C. Kyobutungi[8], N. Chimbindi[9], X. Gomez-Olive[10], M. Tlhajaone[11], B. Njamwea[8], B. Zaba[1], J. Todd[1]
[1]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [3]MRC/UVRI, Entebbe, Uganda, [4]NIMR, Mwanza, Tanzania, United Republic of, [5]Rakai Health Sciences, Kampala, Uganda, [6]MEIRU, Lilongwe, Malawi, [7]KEMRI-CDC, Kisumu, Kenya, [8]APHRC, Nairobi, Kenya, [9]AHRI, Durban, South Africa, [10]University of the Witwatersrand, Johannesburg, South Africa, [11]Imperial College, London, United Kingdom
Presenting author email: jennyrenju@yahoo.co.uk

Background: Revisions in World Health Organisation (WHO) guidelines on use of antiretroviral therapy (ART) are aimed at increasing ART uptake and improving treatment outcomes among people living with HIV. As many African countries adopt "test and treat", it is essential to assess their progress in implementing previous WHO recommendations, at the facility level. We assessed changes in the implementation of policies influencing ART provision and other service delivery indicators from 2013-2016.
Methods: Two cross-sectional surveys were conducted in health facilities located within 10 Health and Demographic Surveillance Systems in Uganda, Kenya, Tanzania, Malawi, Zimbabwe and South Africa. Standardised questionnaires were administered to in-charge personnel in 2013/2015 (round 1) and 2015/2016 (round 2). We used descriptive statistics to compare these indicators across the rounds.
Results: Overall, 145 facilities were surveyed in both rounds. The proportion of facilities providing ART services increased between rounds, with most providing ART free of charge (97% in round 1 and 96% in round 2). The proportion of facilities providing ART within two weeks of initiating TB treatment remained over 90% in both rounds.
In 2013, WHO recommended ART initiation with a CD4 count of < 500 cells/μL, and this was implemented in 12% of the facilities in round 1, ranging from 0% in Uganda, Kenya and Malawi to 41% in South Africa. In round 2, the proportion of facilities implementing this recommendation increased to 68%, with 91% implementation in South Africa. In Zimbabwe, the proportion of facilities that did not require laboratory testing to initiate ART increased from 27% to 63% across rounds, whereas overall increase was from 22% to 32%. The proportion of facilities that provided recommended first line WHO 2013 ART regimen increased from 42% in round 1 to 87% in round 2. Occurrence of stock-outs of this regimen decreased from 19% in round 1 to 12% in round 2. However, proportion of facilities providing same-day ART initiation remained low in both round 1 (5%) and 2 (8%).
Conclusions: The sustained reductions in ART stock-outs and an increased adoption of revised WHO ART regimens and ART eligibility criteria signifies an apparent readiness to implement test and treat approach.

WEPED1357

Enhancing ownership of the HIV response in a devolved system of governance: lessons learnt from Kenya

I.B. Okiya[1], N. Kilonzo[2], R. Ombam[3], J. Kamigwi[1]
[1]National AIDS Control Council, Policy, Monitoring and Research, Nairobi, Kenya, [2]National AIDS Control Council, Office of Director, Nairobi, Kenya, [3]National AIDS Control Council, HIV Investments, Nairobi, Kenya
Presenting author email: okiyabryan@gmail.com

Background: The Constitution of Kenya 2010 fundamentally changed the governance framework for the multi-sectoral HIV response. Unlike the other three plans which were designed and implemented in the old constitutional dispensation, the current Kenya AIDS Strategic Framework (KASF) 2014/15-2018/19 is aligned to the Constitution and takes cognizant of the devolved system of governance.

KASF is the strategic guide for the country's response to facilitate universal access to comprehensive HIV prevention, treatment and care services. The development of the Strategic Framework was highly consultative and evidence informed. Forty Seven counties have since developed county specific HIV plans guided by this framework with a focus on diseases burden, population and geographical disparities of the counties.
Methods: The process involved the following: Consultation with leadership at the Ministry of Health and Council of Governors; Involvement of other key stakeholders across sectors and levels of government including development partners; Development and dissemination of the KASF; Development of 47 County HIV and AIDS Strategic Plans; Mainstreaming of HIV and AIDS in other key policy and strategic documents and establishment of effective coordination, Monitoring and Evaluation structures at national and county levels.
Results: By implementing KASF, the following key results have been realized between 2013 and 2015;

- 24% Reduction in new HIV infections among the population with 49% decline among children (less than14 years).
- 37% Increase in number of people who received ART treatment.
- 38% Reduction in AIDS related deaths.
- 8% Increase in domestic financing of HIV response; Counties have funds earmarked for sustainable HIV programming through the Medium Term Expenditure Framework.
- Better HIV programming and enhanced ownership of the HIV response by government leaders and implementers; HIV and AIDS activities have been mainstreamed in key Sector and County documents.

Conclusions: Strategic planning, prioritization, effective political engagement, partnership and inclusion of key stakeholders is indispensable in achieving ownership of the HIV response through defining of local priorities for investment, establishment of accountability and enhancing efficiency for sustainability.

WEPED1358

Opt-out HIV testing in out-patient setting

G. Tam[1], D. Chan[2], G. Lui[3], S. Wong[1], B. Yip[1], F. Ho[1], T.Y. Wong[1]
[1]The Chinese University of Hong Kong, JC School of Public Health and Primary Care, Hong Kong, Hong Kong, [2]The Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Hong Kong, Hong Kong, [3]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong
Presenting author email: gretatam00@gmail.com

Background: Under-diagnosis of HIV is often linked with barriers to HIV testing, including tedious informed consent in some settings, lengthy counseling and stigma associated with selection for HIV screening. Opt-out approach can overcome these barriers, but such practice has not been integrated into the healthcare system. In addition, previous studies in hospitals reported acceptance rates as low as 21%, with most patients excluded due to severe illness. Our study attempts to overcome these barriers by using an outpatient setting where extra venipuncture is unnecessary. We aim to evaluate the feasibility and acceptance of opt-out HIV testing in this patient population.
Methods: This is a cross-sectional study. All adult patients attending a selected specialist clinic in Hong Kong over a 7 month period were offered HIV test during routine blood-taking. Patients were surveyed for collecting their demographics and reasons for refusing HIV testing. Factors associated with HIV test refusal were analyzed by multiple logistic regression.
Results: Between June 2015 and January 2016, 963 out of 1069 subjects enrolled in the study with a response rate of 90.1%. Of 952 patients included in the analysis, 361 were females and 591 were males. Acceptance rate was 62.0% (590/952). Of the remaining patients who refused, the most common reason was perceived low risk of infection (57.8%). A small proportion of patients declined because they did not want to know test result (3.7%), fear of venipuncture (2.8%) or fear of stigma (1.8%). The remaining 33.9% declined due to other factors, such as inconvenience. Factors significantly associated with refusing HIV test included older age (58-77 years old) and birth in Mainland China, while males were associated with accepting HIV test. All blood tests showed HIV-negative results.
Conclusions: Pilot data from our study shows that opt-out HIV testing in an outpatient setting is feasible and acceptable to most patients.

WEPED1359

Monitoring delays in adopting WHO HIV treatment guidelines in low- and middle-income countries

S. Gupta[1], R. Granich[2]
[1]International Association of Providers of AIDS Care, New Delhi, India, [2]International Association of Providers of AIDS Care, Washington, United States
Presenting author email: somyagupta17@gmail.com

Background: Countries use the World Health Organization (WHO) HIV treatment guidelines to revise their national policies. We quantify the time in the adoption of the October 2009, June 2013, and September 2015 WHO guidelines in low- and middle-income countries (LMICs).
Methods: International Association of Providers of AIDS Care's (IAPAC) website www.hivpolicywatch.org includes 326 published national policies from 122 countries. Using the site database, we abstracted date of publication and antiretroviral therapy (ART) eligibility criteria from 215 policies from 91 LMICs (92% of 2015 global HIV burden). We excluded nine countries that have reported moving to WHO 2009, 2013 or 2015 guidelines but their latest policies are not available. Numbers of months taken to adopt the WHO 2009, 2013, and/or 2015 guidelines were calculated for the remaining 82 countries (91% burden) to determine the average time lag in adoption of the WHO guidelines.
Results: Of 82 countries, 17 (39% burden) recommend the new WHO 2015 ‚treatment for all' recommendation, 38 (39% burden) recommend ART at WHO 2013 CD4 criteria (≤500 cells/mm^3), and 27 (13% burden) at WHO 2009 CD4 criteria (≤350 cells/mm^3). The average time lag to WHO 2009 guidelines adoption in the countries was 12 months (n=68 countries). The countries that have adopted WHO 2013 guidelines took an average of 8 months (n=53 countries), a number that will increase to 19 months assuming the remaining countries move to CD4 ≤500 cells/mm^3 or earlier by December 2016. On average, the 17 countries recommending 'treatment for all' adopted this recommendation 3 months before the release of WHO 2015 guidelines in September 2015. The average time lag in adoption of the WHO 2015 guidelines was the highest in sub-Saharan African region.
Although the time to adoption of the 2015 guidelines appears accelerated, if the trajectories for the adoption of WHO 2009 and 2013 guidelines are followed, it may take many years for the new WHO 2015 guidelines to become national policies, especially for high burden countries.
Conclusions: There is an urgent need to shorten the time lag in adoption and implementation of the new WHO guidelines recommending ‚treatment for all' to achieve the 90-90-90 target by 2020.

WEPED1360

Accessing drug abuse treatment for PLHIV in the Philippines: attitudes of HIV care providers and drug abuse treatment providers

C. O'Connor[1,2], G. Binay[3], R.L. Bona[4], M.I. Feria[3], P.B. Fiarod[3]
[1]Sustained Health Initiatives of the Philippines (SHIP), Manila, Philippines, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]NoBox Transitions Foundation, Manila, Philippines, [4]Sustained Health Initiatives of the Philippines, Manila, Philippines
Presenting author email: coconnor@ship.ph

Background: The Philippines has one of the fastest growing HIV epidemics in the world. Recreational drug use is common among HIV patients. The combination of substance abuse and HIV/AIDS poses special challenges for medical providers. There are currently no services in the Philippines catering to the needs of PLHIV who use drugs. Compounding this issue, the Philippine President declared an "all-out war on drugs" and more than 7,000 drug-related extrajudicial killings occurred between July 2016 and January 2017, prompting international concern for human rights.
Methods: A survey of HIV care and drug abuse treatment providers collected data about provider attitudes toward HIV, drug use, and harm reduction. The survey was distributed by email and social media to more than 140 organizations/facilities nationwide; 47 responses were received.
Results: The majority of respondents opposed aspects of the "war on drugs": 91% disagreed or strongly disagreed with the statement that people who use drugs should be killed, and 63% opposed imposing harsher penalties for drug use. 54% of respondents disagreed or strongly disagreed that health care providers should report patients' illicit drug use to law enforcement. 75% of respondents agreed that health care providers should provide sterile needles and syringes to HIV patients who use drugs. Opposition to needle provision was higher among drug rehab providers (22% opposed) than it was among HIV care providers (8%). 65% of respondents agreed or strongly agreed that health care providers should inform people who use drugs about safer practices for the use and administration of drugs.
Conclusions: There is a need to capacitate HIV care and drug abuse treatment providers about harm reduction practices. An issue of concern is that a significant proportion of providers (46%) either supported reporting or were unsure about

whether they should report their patients' illicit drug use to law enforcement. This raises concerns for the safety of patients who access treatment related to their drug use and may discourage them from disclosing illicit drug use to their HIV primary care providers. It is a priority to create a network of providers who can provide safe spaces and high quality care for PLHIV who use drugs.

WEPED1361

'Yes' to recreational drugs but 'no' to life-saving medications: unpacking paradoxical attitudes about HIV treatments

A. Mey[1], D. Plummer[2], S. Anoopkumar-Dukie[1], G. Rogers[3], J. Gow[4], Griffith Health
[1]Griffith University, School of Pharmacy, Gold Coast, Australia, [2]James Cook Univeristy, School of Medicine, Townsville, Australia, [3]Griffith University, School of Medicine, Gold Coast, Australia, [4]HIV Foundation Queensland, Gold Coast, Australia
Presenting author email: a.mey@griffith.edu.au

Background: Recent research into motivations and barriers to ART uptake and adherence uncovered a puzzling phenomenon: despite the well-known life-preserving benefits of ART, some people are declining potentially life-saving treatment while still being prepared to use potentially dangerous recreational drugs. Unpacking and understanding this paradox will provide insights into core beliefs regarding antiretroviral medication and will enable better models of care to be created.
Methods: In-depth interviews were conducted with adults living with HIV in the Gold Coast region of Australia. Interviews explored perspectives of living with HIV and the role of medical and non-medical treatments, supplements and other substances (including recreational drugs). Data were audio recorded, transcribed and analysed using a 'grounded theory' approach.
Results: This study reports data collected from 27 participants (phase 1 of the study). The majority of participants were gay, male, 40 years or older and contracted HIV through unprotected sex. Participants had been living with HIV from 1 month to 23 years and were currently receiving ART. Eleven participants who reported current recreational drugs use; all used prior to diagnosis; the majority reported increased use after diagnosis. Participants spoke of the benefits of non-medical treatments: relief from stress of living with HIV; potential health benefits of CAM without side effects; self-control as being able to influence disease progression. Participants also expressed concerns regarding ART toxicity, and financial, emotional and physical burdens imposed by treatment. The burden of treatment appears to be a strong motivator for declining, while positive views towards recreational drugs appear to justify use, particularly for mitigating negative states-of-mind.
Conclusions: Decisions regarding living with HIV are complex and appear to be influenced by internal factors such as beliefs about ART, CAM and recreational drugs as well as external factors such as the communities within which they live. Optimal models of care for people with HIV must take into account treatment reservations and people's desires to go beyond what orthodox medicine currently offers.

WEPED1362

Examining Malawi's rollout of universal treatment: policy implementation and provider perceptions

M. Mphande[1], K. Phiri[1], M. Chivwara[1], M. Nyirenda[1], A. Schooley[1,2], R. Thomas[1], R. Hoffman[1,3], K. Dovel[1,3]
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California Los Angeles, Department of Infectious Disease, Los Angeles, United States, [3]University of California, Department of Infectious Disease, Los Angeles, United States
Presenting author email: mphandemisheck@gmail.com

Background: In July 2016, Malawi implemented universal treatment for all adults (Test and Treat) with no baseline CD4 cell count. We summarize early experiences with the rapid implementation of Test and Treat in 4 districts in Malawi 3 months after the policy change. Provider perceptions of successes and challenges are shared.
Methods: A facility-level survey was conducted at 53 mid- and large-level health facilities across central and southern Malawi. The facility in-charge, lead HIV testing and counseling (HTC) provider, and lead antiretroviral therapy (ART) provider at each site completed a survey. Twelve focus group discussions were completed with providers across 6 health facilities (n=79).
Results: The majority of providers were informed about Test and Treat through a Ministry memo and briefings by facility supervisors. Three months after policy implementation, 96% (n=51) of facilities offered Test and Treat. Two sites had not started because providers felt they had inadequate training. Ninety-one percent (n=48) of Test and Treat sites offered same-day initiation for adult clients. Seventy-seven percent (n=41) of providers reported improved client flow due to the elimination of CD4 count; however, 68% (n=36) experienced heavy workloads due to the increase in ART initiates. Forty-percent (n=21) believed asymptomatic HIV+ clients were not ready to initiate ART. Only 15% (n=8) felt the policy was confusing for clients because it contradicted previous messaging about ART eligibility.
In focus group discussions, providers reported that the policy was easy to implement because it simplified initiation protocols. Providers were concerned that healthy clients were not ready to start ART due to fear of stigma, the burden of taking ART for life, and being unaware of the new policy before testing. While same-day start was believed to be critical for initiation, providers raised concern about increased defaulter rates among healthy clients who initiated ART before feeling ready.
Conclusions: Three months after national rollout, nearly all facilities surveyed provided Test and Treat, with most offering same-day initiation. Data indicate that minimal training and supervision are needed to implement this new policy. Monitoring of provider workload will be needed as patient numbers increase. More research is needed to understand barriers to engaging healthy clients.

WEPED1363

Countrywide epidemiology of B, C and Delta hepatitis in Burkina Faso: the ANRS 12270 clustered cross-sectional study

N. Meda[1,2], E. Tuaillon[3,4,5], D. Kania[2], A. Kiendrebeogo[6], A. Pisoni[4,5], S. Zida[2,5], K. Bollore[5], I. Meda[7], D. Laureillard[5,8], J.P. Moles[5], N. Nagot[3,4,5], Y. Nebie[1,9], P. Vande Perre[3,4,5], P.F. Dujols[3,4,5]
[1]University of Ouagadougou, Ouagadougou, Burkina Faso, [2]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [3]Montpellier University, Montpellier, France, [4]Montpellier University Hospital, Montpellier, France, [5]UMR 1058, Montpellier, France, [6]INSD, Ouagadougou, Burkina Faso, [7]Health Ministry, Ouagadougou, Burkina Faso, [8]Nimes University Hospital, Nimes, France, [9]CNTS, Ouagadougou, Burkina Faso
Presenting author email: draka3703@yahoo.fr

Background: At a time when control tools for hepatitis B (vaccination) and C (direct antiviral agents) are available, reliable data of the hepatitis epidemiology are mandatory to inform local health policies and resource allocation. We present the results of a nationwide clustered cross-sectional survey on hepatitis B, C and Delta in the adult population of Burkina Faso.
Methods: Data of the 2010 Burkina Faso Demographic and Health Survey (DHS) were merged to the results of serologic hepatitis assays on 14,886 dried blot spot samples collected during this survey for HIV testing and stored at -20°C. Hepatitis prevalence were estimated, for the general community and for each gender, according to demographic and geographic parameters. Hepatitis prevalence confidence intervals accounted for the multistage clustered design of the study.
Results: The HCV estimated prevalence was 3.6% (95%CI 3.3-3.8) overall, 3.9% (95%CI 3.4-4.5) among males and 3.2% (95%CI 2.8-3.7) among females. HCV prevalence age-class distribution was increasing on males (40-44yrs group: 6.0%, 95%CI 4.0-8.0) suggesting an ongoing HCV epidemic. The HBsAg prevalence was 9.1% (95%CI 8.5-9.7) overall, 10.5% (95%CI 9.6-11.4) among males and 7.8% (95%CI 7.1-8.6) among females. HBV prevalence age-class distribution was decreasing suggesting that HBV infection is mostly acquired at birth, during infancy or horizontally in early childhood. Among HBsAg carriers the Delta hepatitis prevalence was 1.1% (95%CI 0.6-1.6) overall. Strikingly high HCV prevalence (13.2%, 95%CI 10.6-15.7) and HDV prevalence in HBsAg carriers (8.7%, 95%CI 2.5-15.0) were identified in the South West region.
Conclusions: This very large, nationwide study classify Burkina Faso as high endemic for HBV and low-intermediate for HCV and identified an high HCV epidemic in a region of the country which deserves further epidemiological investigation. This study illustrates the very added value of DHS surveys with viral hepatitis immune markers on DBS to obtain precise countrywide and intra-country prevalence estimates for epidemic follow-up, prevention and care programs and evaluation of national health policies.

The DRIVE Project to "End the HIV Epidemic" among people who inject drugs in Haiphong, Vietnam: importance of the evolving policy environment

T. Hammett[1], T. Nguyen[2], O. Khuat[3], H. Nguyen[4], G. Le[2], H. Duong[5], N. Nagot[6], D. Des Jarlais[7]
[1]Abt Associates/Consultant to Icahn School of Medicine at Mount Sinai, Cambridge, United States, [2]Hanoi Medical University, Hanoi, Vietnam, [3]Supporting Community Development Initiatives, Hanoi, Vietnam, [4]Abt Associates, Hanoi, Vietnam, [5]Haiphong University of Medicine and Pharmacy, Haiphong, Vietnam, [6]University of Montpellier, Montpellier, France, [7]Icahn School of Medicine at Mount Sinai, New York, United States
Presenting author email: ddesjarlais@chpnet.org

Background: The DRIVE project aims to "end the HIV epidemic" among people who inject drugs (PWID) in Haiphong, Vietnam through public health-scale HIV and substance use treatment. Vietnam's HIV epidemic is concentrated among PWID and other key populations. Like other countries, Vietnam is experiencing reductions in donor support for its HIV/AIDS response and changing its approach to substance use treatment so DRIVE will provide a useful test case. Its success depends on two policy pillars:
1) shift from donor-funded HIV outpatient clinics (OPC) to public facilities and expansion of health insurance (HI) for PLHIV; and
2) implementation of the government's "Renovation Plan" for substance use treatment.
Methods: We describe DRIVE's policy baseline, drawing on interviews and focus group discussions with key stakeholders, policy documents, and data on OPCs.
Results: 52% of ART patients in Haiphong receive care in donor-funded OPCs and 48% in public facilities; 53% of ART patients have HI. All patients will have to move to public clinics when donor-funded OPCs close. Public facilities may be more convenient for some patients but the care is perceived to be inferior. In addition, many patients have difficulty meeting the requirements for free or subsidized HI and producing the ID papers needed to obtain HI cards and receive care in public clinics.
The Renovation Plan aims to transition Vietnam from compulsory drug detention to voluntary, community-based treatment. In Haiphong, compulsory center population has dropped sharply (7300 in 2013 to 200 in 2016) and the number of methadone maintenance treatment (MMT) clinics and patients has increased (currently 12 clinics with 4,000 clients).
However, powerful interests still oppose the Renovation Plan and some conflicting policies persist. Some MMT patients have difficulty making required copayments and dropout rates are substantial. Voluntary treatment besides MMT is very limited. No treatment is available for amphetamine type stimulant (ATS) use, which has surged in Vietnam.
Conclusions: Both policy transitions are underway but face challenges and the policy environment is fluid. DRIVE will monitor the policy environment and its effects on project implementation and outcomes and advocate for improvements in policies and programs based on project data.

WEPED1365

Legal and policy regulatory barriers to effective health and HIV services for key populations in the East African community region

M. Atela
University of Nairobi, Public Health, Nairobi, Kenya
Presenting author email: m.atelah@googlemail.com

Background: Evidence suggests that vulnerable and key populations (KPs) are disproportionately affected by HIV and AIDS and other health challenges. Many of these communities remain under-served, particularly along cross-border zones. While anecdotal evidence have mainly implicated unfavourable legal and regulatory frameworks that criminalise activities of these populations, the evidence remains weak. As part of a larger project to support harmonisation of policies across the East African Community (EAC) region, this study reviewed the legal and regulatory frameworks and identified the key barriers to effective and efficient health, HIV and AIDS service delivery for KPs in EAC.
Methods: A critical structured review of key government documents - laws, policies, strategic and investment plans, and monitoring and evaluation frameworks - of five EAC states together with published technical reports on HIV and health services provision for cross border KPs. A predefined structured search criteria guided literature search. Analysis was guided by ‚Decision Model' framework focusing on five core domains targeting KPs: policy and legal framework; budgets and planning for services, community partnerships for service delivery, legal environment and the design of intervention, access, and implementation of policies and programs for KPs.
Results: Major gaps exist in EAC partner states' legal and policy commitment and implementation with regard to services for key populations. Contradictions in legal and policy provisions hamper service providers' ability to respond to the needs of key populations. For instance, in cases where same-sex sexual relations and sex work have not been formally criminalized, public health authorities and policymakers have largely ignored the needs of KPs and detainees.
Conclusions: Although there are improvements in the policy and regulatory framework for health and HIV service provision for KPs, significant gaps remain that hinder effective service delivery towards meeting UN 90-90-90 global goals. EAC bloc countries have committed to harmonising these laws and policies. This process should be hastened to ensure KPs enjoy standard health rights. Harmonisation will also reduce conflicts within laws and curb criminalization of HIV transmission in some member state laws. Finally, the development of regulatory frameworks should ensure full involvement of KPs.

WEPED1366

Who, where, and how? Developing scenarios for the rollout of oral PrEP in Zimbabwe

N. Bhavaraju[1], K. Muther[2], M. Dunbar[3], D. Nhamo[4], I. Mahaka[4], J. Murungu[4], Z. Mukandavire[5], K. Torjesen[6]
[1]FSG, Washington, United States, [2]FSG, Boston, United States, [3]Pangaea Global AIDS, Oakland, United States, [4]Pangaea Global AIDS, Harare, Zimbabwe, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]FHI 360, Durham, United States
Presenting author email: neeraja.bhavaraju@fsg.org

Background: As Zimbabwe plans for oral PrEP introduction, questions remain about how to rollout PrEP across districts and populations. While epidemiological and cost-effectiveness modeling traditionally guide decisions, these analyses often require significant time and resources. New rapid analytical methods can complement modeling to accelerate implementation planning, product introduction, and impact.
Methods: We reviewed district-level data and Spectrum model estimates on HIV incidence, population demographics, and demonstration projects to identify districts with greatest impact and cost effectiveness potential for oral PrEP roll-out.
Results: This analysis identified 8 scenarios for oral PrEP rollout in Zimbabwe - 4 scenarios defined by HIV incidence and 4 scenarios defined by target populations (see chart below). The four scenarios targeting high incidence districts range from rollout in 13 districts (adult population 1.6M) covering 39% of new HIV infections to rollout in 38 districts (adult population 6.0M) covering 85% of new infections. The scenarios defined by target populations would prevent significantly fewer new infections, but could leverage existing delivery channels to reach sero-discordant couples (22% of adult new infections) or sex workers, farmworkers, mineworkers, and truck drivers (~15% of new infections).

[Oral PrEP Rollout Scenarios]

The analysis showed that while HIV is not highly geographically concentrated in Zimbabwe, focusing on districts with highest HIV incidence and/or new HIV infections (Scenarios 1-4) will likely be most impactful. Between these scenarios, greater resources available for PrEP will enable greater coverage of new infections. Rollout limited to key populations would cover far fewer new infections than a general rollout in the highest incidence districts and should be pursued only if limited resources demand this approach.
Conclusions: Rollout scenario analyses using existing data can inform oral PrEP implementation planning in Zimbabwe. While this approach does not replace the need for further modeling, it provides timely guidance that can inform planning while more robust analyses are developed.

WEPED1367

Use of residual bio-specimens in research: guidance for Zimbabwe

M.E. Shana[1,2], K. Moodley[2]
[1]Medical Research Council of Zimbabwe, Research Oversight, Harare, Zimbabwe, [2]University of Stellenbosch, Centre for Medical Ethics and Law, Cape Town, South Africa

Background: Residual bio-specimens are an invaluable resource in improving health care, scientific advancement focused on patient care and research on HIV. However, regulations on secondary use of bio-specimens collected in clinical settings are not explicit or are non-existent in most African countries. It is unclear who determines the fate of such specimens. As such, secondary use of residual bio-specimens has been steeped in legal and ethical controversies, which can be detrimental to research and the advancement of medicine. Explicit guidance should be given internationally and nationally.
Methods: A descriptive desktop review of journal articles, guidelines and legislation on secondary use of bio-specimens was conducted, i.e. Google scholar, Pubmed, JSTOR, Hinari and also Ministry of Health websites were accessed. Journal articles focusing on secondary use of residual bio specimen, including consenting, privacy, confidentiality, bio-banking and ownership were selected and analyzed to determine existence of uniformity or concordance in the recommendations. Guidelines and legislation on secondary use of residual bio specimen collected from clinical and research settings were also searched for, an assessment of areas covered, recommended type of consent and uniformity in guidance given by developed and developing countries. Also an assessment of the common areas addressed by the guidelines was also carried out. The outcome of the analysis was used as grounds for the researcher to make recommendations on the position that could be adopted by regulators and policy makers in Zimbabwe, with regards to secondary use of bio-specimens.
Results: There is a paucity of guidelines that are specific to use of residual bio-specimens. Locally and internationally, an all-encompassing guideline on the collection, ownership, use and storage of residual bio-specimens does not exist. There is also lack of sufficient information on the recommended type of informed consent to be given for such use.
Conclusions: Residual bio-specimens are a valuable resource in medical research, HIV research and health care. There is a need for uniform guidelines that regulate secondary use of residual bio-specimens as international collaboration in research and sharing of bio-specimens is on the rise. Zimbabwe needs specific guidance on secondary use of bio-specimen collected in clinical settings.

WEPED1368

Additional yield of HIV cases through provider initiated testing and counselling in RNTCP in Telangana State, India

C. Chatla[1], S. Chakramahanty[2], K. Guguloth[2], J. Prabakaran[1], J. Kurada[1], R. Bandi[3], R. Deshmukh[4], S.A. Nair[4]
[1]World Health Organization, Public Health, Hyderabad, India, [2]State TB Cell, Public Health, Hyderabad, India, [3]Telangana State AIDS Control Society, HIV, Hyderabad, India, [4]World Health Organization, Public Health, New Delhi, India
Presenting author email: chatlachakri@gmail.com

Background: According to the national framework for TB/HIV coordination in India, all the diagnosed TB cases must be tested for HIV. In 2013, the concept of PITC (provider initiated testing and counselling for HIV) has been introduced in the country. Telangana, a high HIV prevalence state, initiated PITC meticulously through successful state, district and field level coordination with National AIDS Control Programme. This study attempts to find out the utility of PITC in field.
Methods: PITC is implemented since Jan 2013 in all the districts of Telangana State, India through all ICTC (Integrated Counselling and Testing Centres) across the state. Towards this all the lab technicians in RNTCP (Revised National Tuberculosis Control Programme) were trained on HIV testing and co-location of ICTC and DMC services was ensured.
Results: Of 39,072 registered TB patients were tested for HIV among the total of 41,827 (93.4%) in year 2013 and 41,672 were tested among 42,661 (97.7%) in year 2014. This resulted in identification of 2,763 (7.1%) and 2,571 (6.2%) HIV +ve cases in year 2013 and 2014 respectively.
A total of 1,43,127 presumptive TB cases (which includes diagnosed TB patients) were tested for HIV as part of PITC among the total of 1,91,081 (75%) in year 2013 and 1,96,494 were tested among 2,21,000 (89%) in year 2014. The analysis demonstrated that there is an additional yield of 6,502 (2.4 times) HIV cases in year 2013, of 10,972 (4.3 times) in 2014, of 8,239 (4.0 times) in 2015 and of 3,561 (2.0 times) in 9 months of 2016 as a result of implementation of PITC.
Conclusions: Provider initiated testing and counselling must be implemented in all high HIV prevalent settings and can contribute to early detection of HIV cases which can help in early initiation of Co-trimoxazole prevention therapy and Antiretroviral therapy to those diagnosed and thus reduce morbidity and mortality among PLHIV. This can in turn contribute to reduction in transmission of TB as the risk of getting TB is very high in PLHIV.

WEPED1369

Challenges faced by transgender/hijra community in public and private health care set up in India

D. Baruah[1], A. Dange[1], S.M. Rawat[1], S. Banik[2], B. Horton[3], V.R. Anand[1]
[1]The Humsafar Trust, Research, Mumbai, India, [2]Baldwin Wallace University, Public Health and Prevention Sciences, Ohio, United States, [3]Brown University, Anthropology, Rhode Island, United States
Presenting author email: dicky.hst@gmail.com

Background: In India, the Transgender and Hijra communities are marginalized population vulnerable to stigma and discrimination in the Health care sector, which has been identified as a significant barrier to effective HIV prevention, care, treatment and support. Health Care Providers are positioned to respond with needed services and treatment, however prejudicial, ignorant, and discriminatory attitudes coupled with lack of knowledge of trans-issues acts as a barrier toward providing adequate care and services.
Objective: To understand the experiences faced and to address myths, misconceptions and barriers stated by Transgender/Hijra Community in seeking health-care services across Public and Private health care settings in Mumbai.
Methods: In 2013, Five Key Informant interviews and Seven Focus Group Discussions were conducted with Transgender/Hijras Community people. Focus groups and interviews were transcribed and analyzed thematically using NVIVO.
Results: Transgender/Hijra reported experiencing varying levels of stigma and discrimination in Public as well as Private Healthcare settings e.g. Outing of their HIV status (writing their report in red ink, mentioning the status on the file), lack of awareness of Transgender/Hijra anatomy, hesitation in performing physical check-ups, issues with allocation of space if hospitalized, and sex of the examining health-care practitioner affecting the interaction etc. Transgender/Hijra also perceived a differential and biased attitude towards them by the healthcare professionals in government settings based on the language and tone employed along with the long waiting hours. However, Transgender/Hijra also preferred public health settings for its affordability and for addressing their "major" health concerns and local clinics/private practitioners in their areas for other minor health concerns. Transgender/Hijra reported accessing over-the-counter hormonal treatments from chemists and compounders in unlicensed clinics and being over-charged for the services in private health care set up as compared to the general population.
Conclusions: Despite experiencing Stigma and Discrimination, in health care set up, Transgender/Hijra will continue to access Public as well as Private health care set up. The lack of knowledge and training on Transgender/Hijra healthcare issues among the HCPs and Institutions calls for enhanced level of training and awareness among the Health Care Providers from Public and Private health care institutions to address Transgender/Hijra health care needs.

Georgia's path towards HCV elimination

L. Sulaberidze, I. Chikovani, M. Uchaneishvili, N. Shengelia
Curatio International Foundation, Research Unit, Tbilisi, Georgia
Presenting author email: l.sulaberidze@curatio.com

Background: Hepatitis C (HCV) infection represents a major public health concern globally and especially in Eastern Europe and Central Asia. HCV is hyper-endemic in People Who Inject Drugs (PWID) throughout the world, with 60-70% chronically infected. HCV prevalence among PWID is in the same range in Georgia. Latest Bio-Behavioural Surveillance Survey among PWID reveals that HCV prevalence among HIV-infected individuals equals to 91%. In 2015, the Government of Georgia introduced a new initiative, that entails provision of HCV treatment free of charge to the the entire population with completed HCV diagnostic testing. Ongoing monitoring of program implementation and awareness on facilitators and barriers to diagnosis and treatment services is necessary to assure success of the program.
Methods: We conducted a qualitative study to investigate individual, societal and health system barriers and facilitators of HCV testing and treatment among PWID in Georgia in 2016. In depth semi-structured interviews were held with key informants, service providers and 40 program beneficiaries purposively selected from 6 main cities to with different HCV testing and treatment status. Data analysis was performed in NVivo-11.
Results: The program had high political support that resulted in smooth management and uninterrupted implementation of the program that was accompanied by public awareness campaign. Risk perception and knowledge about the disease, free

access to expensive treatment, that was previously unavailable in the country, triggered PWID to seek the treatment services. Unavailability of treatment services in some geographic areas, requirement of co-financing for diagnostics prior to inclusion in the program, skepticism about new drugs negatively affected decision to seek treatment. Facilitators to adherence to HCV treatment were supportive environment from family and friends, conducive physical infrastructure and caring staff in treatment facilities, successful treatment experience from peers and short course of treatment with quick recovery. Some factors that hindered decision to seek and adhere to treatment were continuously resolved during the program implementation.
Conclusions: Although the HCV elimination program is underway, the study showed more facilitators rather than barriers to program services among beneficiaries. The study revealed important individual, societal and health system factors supporting program effective implementation that might be useful information for other countries.

WEPED1371

Expanding access to HIV treatment services, the role of government policy in Akwa Ibom State, Nigeria

Y. Ogundare[1,2], M. John[3], E. Okpongkpong[4], E. Xavier[5]
[1]Akwa Ibom State Ministry of Health, HIV/AIDS Unit, Uyo, Nigeria, [2]FHI360 SIDHAS Project, Program Management, Abuja, Nigeria, [3]Akwa Ibom State Ministry of Health, Uyo, Nigeria, [4]Akwa Ibom State agency for the control of AIDS, Monitoring and Evaluation, Uyo, Nigeria, [5]State Ministry of Health, HIV/AIDS Unit, Uyo, Nigeria
Presenting author email: yemisiogundare@gmail.com

Background: Expanding access to HIV treatment and care services for HIV positive individuals in rural communities of Akwa Ibom State remains fundamental to reducing the spread and impact of the virus. HIV positive clients identified within the rural communities through outreaches are referred to government owned facilities where registration fees are required for positive clients before enrollment into care. The poverty level of most positive living HIV (PLHIV) limits their ability to afford registration fees before commencement of treatment, these constitute a barrier to treatment services.
Methods: Akwa Ibom has experienced expansion in comprehensive treatment centers from 4 in 2010 to 61 as at 2016 through support from USAID and Global fund. State government developed policies to support treatment uptake; in 2013 a government policy of free health care for pregnant women and children under five years was adopted and in 2015 a government policy for free registration fees for poor PLHIV who are either pregnant women or children under 5 years and cannot afford registration fees at health facilities was also introduced. An assessment of this policy on treatment uptake across health facilities were evaluated using desk review of program data in the State.
Results: : Of the 42,982 (as at June, 2016) PLHIV currently on ARV in the State, more than 60% could not afford registration fees in health facilities at first visit in 2015. Between 2014 and 2015 after adoption of the policy waiver by government, about 48% of those enrolled in care were poor and could not afford registration fee in secondary health facilities. Also percentage of pregnant women who access HTC services at antennal clinics increased by 80% in 2015 from 37% in 2010, infection rate for children deceased from 8% 2010 to 5% in 2015. Overall this contributed to more PLHIVs and their dependents accessing treatment care and support services through enabling government policies.
Conclusions: HIV program implementer to extend evidence based advocacy interventions to host government leaders in Africa and faith based institutions for adoption of enabling policies to improve access to ART services in State and Nigeria.

Recommendations for the rapid expansion of HIV self-testing in fast track cities

R.M. Granich[1], J. Nkengasong[2], A. Abimiku[3], M. Isbell[4], J. Zuniga[5], IAPAC ASLM Expert Writing Committee
[1]IAPAC, Chief Technical Officer, Washington, United States, [2]CDC, Atlanta, United States, [3]ASLM, Addis Ababa, Ethiopia, [4]Independent Consultant, New York, United States, [5]IAPAC, Washington, United States
Presenting author email: rgranich@iapac.org

Background: Globally, 40% of people living with HIV were unaware of their status in 2015. Cities are heavily impacted by HIV and, by necessity, have served as first responders to the epidemic. Accelerated access to HIV self-testing is critical to closing the diagnosis gap in high HIV burden Fast-Track Cities worldwide.
Methods: IAPAC and ASLM convened an expert Advisory Panel from Africa, Asia, Europe, South America, and North America. The U.S. Centers for Disease Control and Prevention systematically searched for articles from 2000 to 2016 using multiple search terms in two areas: (i) HIV descriptors and (ii) self, home, or rapid testing (5542 citations). The recommendations were drafted by the co-chairs and technical writing team, and reviewed, revised, and approved by the Advisory Panel.
Results: The Panel developed nine recommendations for Fast-Track Cities and their stakeholders:
1) support access to HIV self-tests for use at home and/or in assisted settings;
2) ensure quality-assured, affordable HIV self-tests for everyone, especially for vulnerable populations;
3) lower the price of HIV self-test kits through price reductions, market diversification, pooled procurement, price transparency, market forecasting, and subsidized pricing or for free;
4) monitor expansion of HIV self-tests as part of achieving the UNAIDS 90-90-90 targets by 2020;
5) accelerate regulatory and supply chain processes by identifying and addressing obstacles;
6) support monitoring and evaluation measures to assess individual barriers to HIV self-testing;
7) develop communication, educational and marketing efforts designed to encourage HIV self-testing;
8) optimize service delivery self-refer after HIV self-testing
9) remove government technical and administrative barriers to improve access to HIV self-testing.
Conclusions: apid implementation of HIV self-testing in Fast-Track Cities requires changing HIV policy and regulations, smart programming to increase uptake, and ongoing programmatic adaptation. The recommendations will assist high HIV burden cities to realize the potential of self-testing to achieve the 90-90-90 target and end AIDS as a public health threat.

Stock-outs of HIV testing and treatment resources in Eastern Zimbabwe: a longitudinal analysis from 2013 to 2015

M. Tlhajoane[1], R. Rhead[1], R. Schaefer[1], A. Takaruza[2], R. Maswera[2], C. Nyamukapa[1,2], S. Gregson[1,2]
[1]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe
Presenting author email: m.tlhajoane14@imperial.ac.uk

Background: Great progress has been achieved in scaling-up national HIV care programmes in Zimbabwe. However, the capacity of local health systems to cope with the increasing number of patients requiring services is of increasing concern, as eligibility for antiretroviral treatment (ART) is expanded through the adoption of WHO's ‚test and treat' policies.
Methods: Between August 2013 and July 2015, two rounds of a survey of thirty-six (36) purposively sampled health facilities were completed in two districts in Eastern Zimbabwe. Data were collected on health facility characteristics, including human resources, and both the frequency and duration of stock-outs in HIV test-kits, first-line ART drugs and prophylactic treatments for opportunistic infections (OIs). Trends in demand for and stock-outs of testing and treatment resources were determined. Facility-level factors were examined for associations with stock-outs.
Results: A large proportion of facilities reported at least one stock-out of HIV test-kits, although this number fell slightly from 69% in 2013 to 61% in 2015. Stock-outs were primarily prominent amongst large district hospitals who reported a notable increase in the mean number of HIV tests conducted over the prior 3 months from 508 in 2013 to 1326.5 in 2015. Amongst facilities that reported stock-outs of HIV test-kits, the mean duration was reduced from 54.5 days in 2013 to 17 days in 2015. Despite the expansion in ART eligibility and expected rise in demand for first-line drugs, no facilities reported experiencing stock-outs of ART drugs in 2015, compared to 1 facility in 2013. Larger facilities and district hospitals were more likely to have experienced a stock-out of prophylactic drugs for OIs, however, no significant difference in the frequency or duration of these stock-outs was found across the two study rounds.
Conclusions: While the impact of changing ART guidelines on ART stock outs could not be directly evaluated, there have been significant improvements in test kit availability over time despite a rise in demand. This may indicate improved supply chain management and an increase in the provincial availability of resources for HIV testing as more initiatives are developed to improve linkage to care.

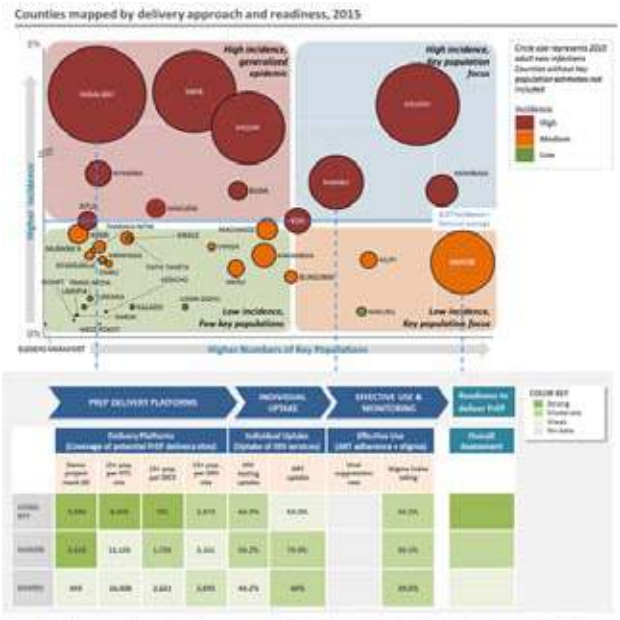
Who, where, and how? Developing scenarios for the rollout of oral PrEP in Kenya

N. Bhavaraju[1], K. Muther[2], M. Kiragu[3], P. Jeckonia[3], W. Mukoma[3], K. Kripke[4], A. Bershteyn[5], M. Larson[6], E. Gardiner[7], S. Masyuko[8]
[1]FSG, Washington, United States, [2]FSG, Boston, United States, [3]LVCT Health, Nairobi, Kenya, [4]Avenir Health, Washington, United States, [5]Institute for Disease Modeling, Bellevue, United States, [6]FHI360, Durham, United States, [7]AVAC, New York, United States, [8]Kenya Ministry of Public Health and Sanitation - NASCOP, Nairobi, Kenya
Presenting author email: neeraja.bhavaraju@fsg.org

Background: As Kenya plans for oral PrEP (PrEP) introduction, questions remain about how to rollout PrEP across counties and populations. While epidemiological and cost-effectiveness modeling traditionally guide decisions, new rapid analytical methods can complement modeling to help accelerate planning, product introduction, and impact.
Methods: We analyzed existing county-level data on HIV incidence, population demographics, demonstration projects, and uptake of HIV testing, ART, and contraception to assess counties for potential impact and cost of PrEP and develop multi-county scenarios for PrEP rollout.
Results: Counties in Kenya vary greatly by HIV incidence and concentration of key populations. Together, these dimensions define several delivery approaches for PrEP - high-priority general population rollout, high-priority key population rollout, and targeted/limited rollout (see graphic below).
In addition, analysis of county capacity to deliver PrEP along a five-factor value chain suggests that readiness to rollout PrEP effectively varies by county. Counties with high capacity across these factors (e.g., Homa Bay) may be early PrEP adopters while those with lower capacity (e.g., Kiambu) may require additional investment before introducing PrEP.



[Kenya Rollout Analysis]

Promising scenarios included rollout to four highest incidence counties to leverage high existing delivery capacity and meet a great need (~45% of new infections) and rollout to seven counties with the most new HIV infections (~60% of new infections) with general population rollouts in three counties and key population-focused rollouts in four counties. Rollout to all nineteen counties with above-average incidence would have greater impact (covering ~85% of all new infections) but require significantly larger investments, while rollout limited to key populations would reach only ~15% of new infections.
Conclusions: Rollout scenario analyses using existing data can inform oral PrEP implementation planning in Kenya. While this approach does not replace the need for further modeling, it provides timely guidance that can inform planning while more robust analyses are developed.

WEPED1375

Predictors of social security disability benefits use in HIV-infected adults

M. Ali[1], T. Crook[2], M. Witmer[2], J. Zurlo[2]
[1]Penn State Milton S. Hershey Medical Center, Division of Infectious Disease, Hershey, United States, [2]Penn State Milton S. Hershey Medical Center, Hershey, United States
Presenting author email: mali6@hmc.psu.edu

Background: The proportion of adults living with HIV receiving social security disability benefits (SSDB) is considerably higher compared to general population. We aimed to investigate the predictors of SSDB use in our adult HIV population.
Methods: A retrospective cohort study was conducted among our HIV+ adult population followed at Penn State Milton S. Hershey Medical Center. The study population comprised all patients seen between January 1st 2014 to December 31st 2015. Patients' employment status was determined by reviewing each patient's profile individually. Demographic and clinical data were obtained from our patient database that included basic demographics, recent CD4+ cell counts, year of HIV diagnosis, cardiac disease, cardiac disease risk factors (diabetes, hypertension, hyperlipidemia, tobacco use, and family history of cardiac disease), chronic hepatitis C infection, history of injection drug use, history of AIDS defining complication(s), county of residence (rural vs. urban), bronchodilator use, opioid use, psychiatric medication use (antidepressants, antipsychotics), and mood stabilizing agent use was obtained to identify risk factors for SSDB use among these patients.
Results: Of the total 866 patients analyzed, 357 (41.2%) were working full-time or part-time, and 313 (36.1) were receiving social security disability benefits. Employment/SSDB could not be determined for the remaining 196 patients. Predictors of SSDB use were Hispanic ethnicity (odds ratio [OR], 3.66; 95% confidence interval [CI], 1.95-6.87), psychiatric medications use (OR, 2.94; 95% CI, 1.96-4.40), African - American race (OR, 2.44; 95% CI, 1.53-3.9), rural county residency (OR, 2.34; 95% CI, 1.40-3.89), history of AIDS defining complication(s) (OR, 2.02; 95% CI, 1.30-3.12), tobacco use (OR, 1.82; 95% CI, 1.24-2.67), injection drug use (OR, 1.81; 95% CI, 1.18-2.77), and older age (OR, 1.03; 95% CI, 1.01-1.05). SSDB use was not related to CD4+ cells counts and other non-tobacco use cardiac risk factors, chronic hepatitis C infection, and cardiac disease.
Conclusions: In our adult HIV population SSDB use was more among racial and ethnic minorities, rural population, smokers, injection drug users, those with a history of AIDS defining complication(s) and older age. Specific interventions may be required to promote return to work for people with HIV/AIDS whose health has been restored by antiretroviral therapy.

WEPED1376

The relation of HIV stigma to satisfaction with health service: a lesson learnt in HIV task-shifting pilot project in Thailand

M.N. Aung[1], S. Moolphate[2], T. Kitajima[3], Y. Siriwarothai[4], P. Takamtha[4], C. Katanyoo[2], H. Okamura[3], M. Field[3], O. Noyama[5], P. Wannakrairot[6], V. Klinbuayaem[4]
[1]Faculty of Medicine, Chulalongkorn University, WHO Collaborating Center for Medical Education, Bangkok, Thailand, [2]Chiang Mai Rajabhat University, Chiang Mai, Thailand, [3]Kyorin University, Tokyo, Japan, [4]Sanpatong Hospital, Chiang Mai, Thailand, [5]Tokyo Kasei University, Tokyo, Japan, [6]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand
Presenting author email: dr.myonyeinaung@gmail.com

Background: The task-shifting of HIV services to primary health care is a global strategy that aims to expand access to anti-retroviral therapy (ART). This represents one of the national goals in Thailand the country with the highest HIV-burden in Southeast Asia. In Thailand, health care workers usually say "close to the house, close to the heart", yet this is not really the case for people living with HIV (PLHIV). PLHIV are afraid of becoming known within their community as being infected with HIV. This stigma forms a barrier to the provision of ART within the primary care setting. This study aimed:
(1) to explore the levels of ‚perceived stigma' in PLHIV attending district hospitals and primary care units (PCUs), and;
(2) to find out the relation between HIV stigma and the satisfaction of patients with their health service.
Methods: In this cross-sectional study, two matched PLHIV receiving routine health care service were recruited for every PLHIV attending a PCU. A total sample of 198 participants was recruited with informed consent. The levels of the participants ‚perceived stigma' and ‚internal shame' were measured applying validated Thai version instruments. The level of the participants' satisfaction was measured applying the Patient Satisfaction Questionnaire 18 (PSQ18). The relationship between the PLHIV's satisfaction with their health service and their ‚perceived stigma' and ‚internal shame' was examined using multivariate robust regression models. Levels of ‚perceived stigma' and ‚internal shame' were measured using two different instruments and analyzed using two different regression models.

Results: 'Perceived stigma' and 'internal shame' levels did not differ significantly between task-shifted PCUs attendants and the district hospital HIV clinic attendants (P>0.05 MANOVA). However, a higher level of patient satisfaction was independently associated with a lower level of 'perceived stigma' (β -5.9, 95% confidence interval (-7.7 to -4.1)) and a lower level of ,internal shame' (β -5.7, 95% CI (-8.3 to -3.2). (P< 0.001)) among PLHIV.
Conclusions: PLHIV's satisfaction with their ART service may serve to relieve their 'perceived stigma' and 'internal shame' regardless of where the ART is received. Health professional education improving HIV services and patient's satisfaction may minimize the HIV related stigmata.

Addressing clinician-induced barriers to INH prophylaxis for persons living with HIV in South-Eastern Nigeria

O. Onyedinachi[1], P.O. Anyanwu[1], A. Eyo[2], M. Odeyale[3], C. Onyegbado[4]
[1]Excellence Community Education Welfare Scheme, Clinical Services, Abuja, Nigeria, [2]Excellence Community Education Welfare Scheme, Programs, Uyo, Nigeria, [3]Excellence Community Education Welfare Scheme, Monitoring and Evaluation, Abuja, Nigeria, [4]Excellence Community Education Welfare Scheme, Clinical Services, Enugu, Nigeria
Presenting author email: okezie@ecews.org

Background: The HIV/AIDS epidemics in Nigeria is complicated by the high tuberculosis (TB) burden. Nigeria ranks 9th among the 22 high-burden TB countries in the world and one in four incident TB cases are co-infected with HIV. Despite these facts, only 57% of HIV-positive registered cases in Nigeria were screened for TB in 2010; while 4712 (2.5%) out of the 185,708 individuals newly enrolled ART in 2013 started Isoniazid Preventive Therapy (IPT). The 2014 Nigeria GLOBAL AIDS RESPONSE Country Progress Report (GARPR) also included reluctance of Clinicians to initiate HIV positive patients on IPT due to perceived fear of Isoniazid (INH) resistance and difficulty with diagnosing active TB in HIV setting as some of the barrier that limit access to TB preventive services for PLHIV.
Methods: Review of INH uptake at HIV treatment centres showed poor access to IPT services. Clinicians were provided with targeted technical assistance (TA) to address the barriers hindering access to IPT for PLHIVs. This include continuous medical education, hands-on mentoring, monthly data feedback and quarterly review of program performance. Excel and Statistical Package for the Social Sciences were used to analyze IPT data captured at the supported treatment centres.
Results: The rate of INH uptake ranged from 0%, to 61% between Jan-Dec, 2014. Targeting 70% of eligible clients (3092); after intervention IPT uptake increased from 11% (348) in Jan, 2015 to 110% (2,356) in Dec 2015.
Conclusions: The TA given to the clinician resulted in sustained increased in the rate of IPT uptake at the HIV treatment sites; relative to achievement in 2014. It is therefore recommended that continuous engagement of the fore front clinicians should encouraged to sustain INH access for eligible clients

WEPED1378

Expanding the provider base: HIV and hepatitis C clinical preceptorships in New York State

N. Harris, T. Wilder, J. Steinke, R. Walsh, A. Urbina
Mount Sinai Institute for Advanced Medicine, HIV/AIDS Education and Training, New York, United States
Presenting author email: terri.wilder@mountsinai.org

Background: In 2014, New York State (NYS) Governor Cuomo announced a three-point plan to end the AIDS epidemic by 2020. The subsequent blueprint outlined several recommendations highlighting the important role of clinicians. Recent advances in Hepatitis C (HCV) treatment have emerged making it possible for patients to be cured. Despite these developments, there is a dearth of competent HIV and HCV clinicians in many counties throughout NYS, impacting access to quality care. There is a need for experience based medical education for clinicians practicing in at-risk communities.
Methods: From October 2015 to November 2016, three preceptorship programs were held (two on HIV, one on HCV) in New York City. These programs combined didactic presentations, case-based discussions, clinic observations, and support materials. Interested clinicians completed an application. Acceptance criteria included NYS region, intention to improve HIV/HCV care services, and current HIV/HCV knowledge and confidence. Applicants from the upstate regions were provided financial assistance. At the conclusion of the program, attendees provided reflective notes of their clinic observations and completed an exit survey.
Results: Over 200 NYS clinicians applied and 31 clinicians were selected including 12 nurse practitioners, 7 physicians, 7 registered nurses, and 5 physician assistants. More than half (58%) practiced in upstate NYS. The majority of accepted attendees had limited knowledge or were somewhat confident in HIV/HCV treatment and prevention. Reflective notes revealed that clinic observations included screening potential PrEP candidates, HIV resistance testing, HCV treatment selection, and drug-drug interactions. Of exit survey respondents, 100% either "agreed" or "strongly agreed" that they could apply the information learned. The majority of attendees indicated enhanced knowledge and/or confidence in managing newly diagnosed HIV/HCV patients as well as prescribing treatment.
Conclusions: This program provided a needed resource and may be a tool to identify and support future HIV/HCV clinical leaders. Challenges include limited number of participation spots, coordination of preceptor schedules, and long-distance travel for upstate attendees. Long-term impact of this program on workforce capacity is unclear until additional evaluation measures are taken. As advances in HIV/HCV prevention and treatment emerge, programs will need to be revised and resources identified in order to stay relevant and sustainable.

WEPED1379

PrEP implementation in New York State: challenges and solutions in clinical practice

C. Ferraris, J. Steinke, T. Wilder, N. Harris, R. Walsh, A. Urbina
Mount Sinai Institute for Advanced Medicine, New York, United States
Presenting author email: christopher.ferraris@mountsinai.org

Background: Despite the evidence that pre-exposure prophylaxis (PrEP) is an effective HIV prevention option, it remains underutilized given the estimated 1.2 million people in the United States for whom PrEP is indicated. Healthcare provider perceptions are often a barrier to implementation. More research is needed to understand the challenges and barriers perceived by healthcare providers and to identify potential solutions to educate and support them in implementing PrEP. New York State (NYS) is uniquely situated to lead PrEP scale-up, given Governor Cuomo's three-point plan to end the AIDS epidemic by 2020 includes point three: provide access to PrEP for high-risk persons to keep them HIV-negative.
Methods: Five PrEP implementation workshops were held throughout NYS with a large sample of interdisciplinary healthcare providers (n=137). A regional and agency-level ,SWOT' (strengths, weaknesses, opportunities, threats) analysis of PrEP implementation was conducted at each workshop. Researchers performed a preliminary conventional content analysis of this data to identify major themes discussed by participants.
Results: Initial results from this conventional content analysis fall into two large regional and agency-level categories (weaknesses/threats; strengths/opportunities). Consistent themes cited by healthcare providers as weaknesses or threats to PrEP implementation include: clinician willingness and knowledge, funding/reimbursement, patient access and knowledge, clinic protocols, staff buy-in, stigma, and organizational capacity. Themes classified as strengths or opportunities include interagency networking, NYS progressive policies, outreach, utilizing multidisciplinary teams, and marketing opportunities.
Conclusions: As PrEP awareness increases, healthcare organizations will need to create or scale up their PrEP programs. This analysis examining healthcare provider perceptions of PrEP implementation demonstrates that many clinical settings do not have key elements necessary to deliver PrEP (e.g. policy and procedure, staff buy-in). Findings from this analysis also show that insurance navigation concerns, clinical capacity, and a lack of ongoing support are hindrances to implementing PrEP. However, we also see that healthcare providers in NYS are able to identify, and feel bolstered by, strengths and opportunities. The level of information sharing and resources provided during the workshops has enabled them to think strategically about providing PrEP services. Disseminating results from these workshops may help other healthcare settings purposefully and effectively develop their own PrEP programs.

WEPED1380

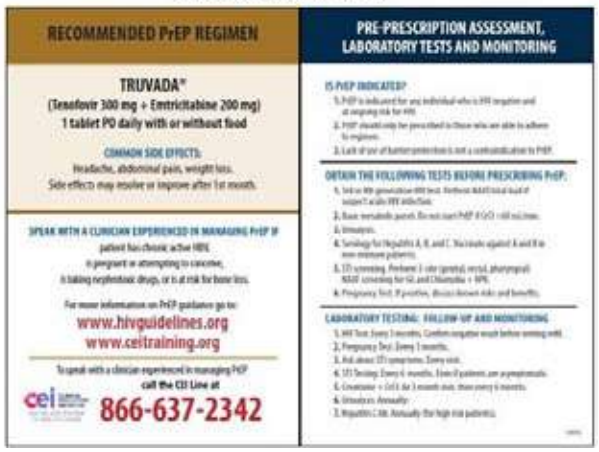
PEP and PrEP clinical cards: translating New York State (NYS) clinical guidelines into practical tools

T. Wilder, N. Harris, A. Urbina, J. Steinke
Mount Sinai Health System, Institute for Advanced Medicine, New York, United States

Background: Pre- and post-exposure (PrEP, PEP) clinical guidelines are tools to assist clinicians with HIV preventive care. While this information exists online, clinicians have limited time to review and process lengthy documents during patient visits. PEP/PrEP should be offered by all clinicians; however, many are hesitant due to perceived difficulty in understanding guidelines. PrEP and PEP clinical cards offer a way to disseminate guidelines while providing a portable quick reference.
Methods: PrEP and PEP clinical cards were designed based on the NYS clinical guidelines and included the recommended regimens, lab tests, evaluation, clinician help line, and the NYS guidelines and Clinical Education Initiative websites. Each

card is the size of a credit card and can be attached to a clinician's name tag. Cards were distributed free of charge via online mail order, during clinical conferences/trainings, and preceptorship programs. Due to their clinical content, cards were intended only for physicians, physician assistants, nurses, nurse practitioners, dentists, and pharmacists.

PrEP Card (front and back)



[PrEPClinicalCard]

Results: From August 2015 - January 2017, over 26,000 cards were distributed (12,915 PEP cards and 13,258 PrEP cards). In the first ten months of distribution, over 9,000 PEP and PrEP cards were simultaneously distributed to clinicians practicing in a number of settings including community clinics, hospitals, local health departments, and private practice. Qualitative data suggests strong favorability of the cards and content presented.
Conclusions: As we move toward ending the AIDS epidemic by 2020, it is critical that NYS clinicians have PEP/PrEP guidelines easily available. Clinical cards fill a gap in guideline access and could be used to address other topics including HIV and Hepatitis C screening. Barriers include delivery to the wrong address, torn envelopes, and cards being taken by non-clinicians. While highly popular, future cards will need to be updated when guidelines change and distribution expanded in order to reach clinicians across NYS.

WEPED1381

Strengthening governance, leadership and managerial capacity of district and regional health managers to improve health service delivery in Uganda

V. Gwokyalya[1], J. Matovu[1], R. Wanyenze[1,2], C. Isabirye[3], S. Byakika[4], D. Serwadda[2]
[1]Makerere University School of Public Health, MakSPH-CDC Fellowship Program, Kampala, Uganda, [2]Makerere University School of Public Health, Department of Disease Control and Environmental Health, Kampala, Uganda, [3]Ministry of Health, Human Resource Division, Kampala, Uganda, [4]Ministry of Health, Planning, Kampala, Uganda
Presenting author email: gwokyalyav@gmail.com

Background: Inadequate management competences among lower level managers is a major challenge to healthcare delivery in low- and middle-income countries. Capacity strengthening initiatives for managers are still limited and primarily focused on individual competences, with limited attention to the governance challenges faced by managers. In this paper we share experiences implementing a District Capacity Building Program that utilizes a team approach to equip local government managers with skills in governance, leadership and management to improve service delivery.
Methods: We implemented a **9-months** work-based, action learning Fellowship for **health managers** that offered trainees short workshops with mentorship at their work stations. Trainees enrolled as teams and as part of training, each team implemented a project addressing governance, leadership and management challenges affecting service delivery at their workplace. Teams introduced changes including; establishing reporting systems, quality improvement structures, coordination structures, community engagement platforms, and staff performance management systems to improve service delivery. A total 134 managers (52 teams) were enrolled: 33 District Health Officers, 67 Regional Performance Monitoring Teams, 30 Regional Referral Hospital managers and 4 Principal Medical Officers of Urban Authorities.
Results: Within 6 months, weekly epidemiological surveillance reporting in 10 districts improved from an average 55.1% to 90.5%; completeness, accuracy and timely reporting of data in 29 facilities improved from 49% to 91.3%, 36% to 81.5%, and 64% to 100% respectively; Measles and DPT3 immunization coverage in 5 districts improved from 58% and 55% to 90% and 94%, respectively; and retention of HIV infected mothers in care at 15 facilities improved from 48% to 63%. Linkage of HIV positive clients to care in 2 districts improved from 55% to 95% and TB case notification in 2 districts improved from 46% to 55%. Managers acquired competences in motivating teams to produce results, data analysis and use for decision-making, strategic planning, negotiation, resource mobilization, and coordination of partners.
Conclusions: Developing governance leadership and management skills of managers empowers them to create organizational change that improves service delivery. The work-based, action learning training model that situates the training in the local context facilitates application of concepts in real life situations and creates immediate improvements in service delivery.

WEPED1382

Workforce development with an innovative HIV training program for nurse practitioners

K. McGee[1,2], J. Harmon[2]
[1]Duke University Medical Center, Division of Infectious Diseases, Durham, United States, [2]Duke University School of Nursing, MSN Program, Durham, United States
Presenting author email: kara.mcgee@duke.edu

Background: In order to achieve the 90-90-90 targets set forth by UNAIDS in 2014 and achieve the U.S. National HIV/AIDS Strategy goal of increasing access to care and improving health outcomes for people living with HIV (PLWH), there needs to be an adequate workforce of providers who are skilled in HIV medical care. To address the potential shortage of HIV primary care providers in the U.S., the Health Resources and Services Administration (HRSA) issued a funding opportunity to establish nurse practitioner (NP) and physician assistant (PA) HIV/AIDS primary care education programs designed to train NPs and PAs in HIV/AIDS care and treatment.
Methods: The Duke University School of Nursing (DUSON) developed a distance-based HIV training program for NPs who wish to provide primary medical and HIV specialty care to PLWH in the U.S. A 12-credit HIV specialty concentration was designed and implemented in the fall semester of 2014. Students enrolled in the specialty complete online didactic instruction in HIV epidemiology, pathogenesis; HIV pharmacology; and HIV psychosocial, political, legal and ethical issues, followed by a clinical management course and 392 hours of supervised clinical practice in an HIV treatment center. Online instruction is complemented by two on-campus learning intensives with an inter-professional focus.
Results: Since inception of the program in August 2014, 43 degree-seeking students, and 4 licensed nurse practitioners have enrolled in the specialty. Most are women (68%), and white (68%) though there is representation from various ethnic groups including Filipino American, African, Cuban American, African American and Hispanic. Thus far 16 degree-seeking students and 3 licensed nurse practitioners have successfully completed the program; of these, 11 (58%) are employed in HIV specific settings providing primary and HIV specialty care and/or sexual health care to PLWH in the U.S., including 5 graduates who are employed in resource limited settings. Four recent graduates are currently seeking employment in HIV specific clinics.
Conclusions: The DUSON has developed and implemented an innovative and replicable HIV training program for NP students. The school has graduated NPs with expertise to provide primary HIV medical care and substantially contributed to the expansion of the HIV workforce.

WEPED1383

An innovative preceptor education training program for nurses and midwives to promote clinical competencies for accelerated scale-up of HIV treatment in Malawi

P.M. Sakanda[1], A. Khawja[2], R. Sutton[2], S. Michaels-Strasser[2]
[1]ICAP at Columbia University, Global Nursing Capacity Building Program, Lilongwe, Malawi, [2]ICAP at Columbia University, Global Nursing Capacity Building Program, New York, United States
Presenting author email: ps2848@cumc.columbia.edu

Background: In 2013, ICAP at Columbia University developed the Preceptor Education Training Program (PETP) as part of its Nursing Education Partnership Initiative (NEPI). PETP was designed to enhance nursing education by improving the mentorship skills of preceptors at clinical teaching sites linked to nursing schools in Malawi. The six-week PETP included didactic and clinical training to equip nurse-mentors with student-centered clinical teaching competencies and enable them to model competent clinical skills, attitudes and evidence-based practice, with a focus on nurse-initiated and managed antiretroviral treatment (NIMART). In 2016, we assessed the skills of PETP-trained mentors and solicited feedback from nursing students regarding their mentors' performance.

Methods: 126 nurses completed the PETP between 2013-2015. In 2016, trained evaluators observed 25 purposively sampled PETP trainees using a standardized patient and clinical scenario to evaluate clinical teaching competencies in six NIMART domains. In each domain, teaching performance was assessed via a five-point-scale from "not-at-all descriptive" (1) to "very descriptive" (5). In addition, 50 students were randomly selected to complete a self-administered online survey. They were asked if their preceptors demonstrated teaching competencies in 23 domains, using a five-point scale from "disagree" (1) to "agree" (5). They were also asked to assess their preceptors' contribution to their learning, using a five-point-scale from "did not contribute" (1) to "contributed a great deal" (5). Data were analyzed in EXCEL™.
Results: The 25 observed PETP trainees received a median score of 4.0/5.0 for their teaching performance. 53% were "very descriptive" in teaching clinical principles, and 59% were "very descriptive" in teaching key steps in ART initiation. 44 nursing students (88%) completed the online survey, giving their preceptors' teaching competencies a median score of 3.7/5.0 for the 23 domains. 31 students (70%) felt their preceptors contributed to their acquisition of NIMART competencies.
Conclusions: PETP-trained mentors performed well, receiving high scores from trained observers. The majority of students felt their preceptors contributed to their mastery of NIMART competencies. Lessons learned will inform improvements to the PETP curriculum, to ensure production of competent preceptors able to build clinical skills and HIV/AIDS competencies of the next generation of nurses and midwives.

WEPED1384

The road to excellence: journey of the first public health laboratory in West Africa to achieve International Organization for Standards (ISO) 15189 and 15190 accreditation

P.A. Diaw[1], F. Jones[2], M. Diop[3], M. Sarr[2], S. Mboup[1]
[1]CADU RARS IRESSEF, Dakar, Senegal, [2]Westat, Rockville, United States, [3]CADU RARS, Dakar, Senegal

Background: The Laboratory of Virology (LBV) at Cheikh Anta Diop University (CADU) in Dakar, Senegal, is a National Reference Laboratory for Human Immunodeficiency Virus (HIV). LBV offers specialized testing for HIV, including HIV serology, CD4, viral load, and early infant diagnosis (EID). LBV also currently serves as a regional provider of external quality assessment (EQA), offering HIV related proficiency testing (PT) services for many laboratories.
In 2010, with assistance from the International Laboratory Brach (ILB) at the Centers for Disease Research and Prevention (CDC) and Westat; LBV began making preparations for achieving international ISO15189 accreditation. After 5 years, through implementation of a quality man- agement system (QMS) for laborato- ry services and carefully addressing identified gaps and deficiencies, the laboratory successfully achieved its goal. In October 2015, LBV was of- ficially recognized by the Institute of Quality Management in Healthcare (IQMH) as one of the first public health laboratories in West Africa to achieve ISO15189 accreditation.
Methods: LBV first initiated efforts to implement a laboratory QMS in the immunology molecular biology, and virology units in 2011. In 2012, the CDC ILB supported training on the World Health Organization (WHO) Stepwise Laboratory Improvement Process Towards Accreditation (SLIPTA) program. Continued internal and external audits based on ISO15189 technical and management requirements were also conducted which identified additional gaps and areas for improvement from which corrective action plans were developed and tracked to ensure compliance.
Results: Baseline SLIPTA assessments scores ranged from 55-64% (Level 0/1); and increased to 85-94% (indicating Level 4 status) within the first 2 years of implementation. Follow up assessments were conducted based on ISO15189 checklist; which included detailed requirements for technical and management compliance under ISO15189. After addressing areas in need of improvement, the labo- ratory submitted an application for ISO15189 accreditation to IQMH.
Conclusions: The road to ISO15189 accreditation is a major challenge for public health laboratories, and in particularthose within resource limited settings. Key factors for success include management commitment, team effort, mentorship, and financial resources to support infrastructure improvements, service contracts for equipment preventative maintenance and calibration, and procurement of needed equipment and supplies.

WEPED1385

Nurturing community-based organizations of MSM, transgender and hijra (MTH) communities to take ownership in reducing vulnerability to HIV and AIDS

S. Mane[1], V. Raj Anand[2], Murugesan. S[1], D. Tripathi[1]
[1]The Humsafar Trust, Mumbai, India, [2]The Humsafar Trust, CEO, Mumbai, India

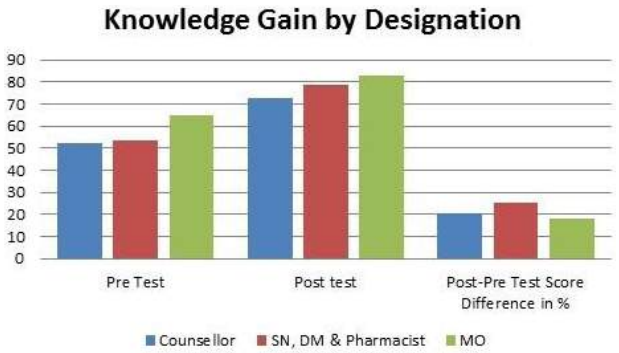
Background: Since October 2010, The Humsafar Trust (HST), a community based organization (CBO) in Mumbai, has been implementing a GFATM-fund program (Round 9), Pehchan (Identity) across five states in west/central India. Pehchan is unique in its design and approach because it is community-driven and focuses on advocacy and capacity building to create an enabling environment for MSM, TG and Hijra (MTH) populations in unreached districts to access services.
Methods: In addition to strengthening existing organizations, Pehchan focused on setting-up CBOs in districts without HIV interventions. HST worked in 34 districts with low or no visibility of the MTH community due to stigma and discrimination. The project with support from a community advisory board identified community members from various districts, conducted the proto-CBO meetings and provided technical assistance to the members to form and register a CBO. These organizations were then provided with classroom and field level training to deliver the projects effectively.
The program has been able to register 73442 new MTH populations, 47327 have been tested for HIV of which 714 tested positive. Advocacy sessions were conducted with various stakeholders to strengthen their work and conducted 20 community based activities such as TG/ Hijra Habba, Solidary events, state level consultations which provided a platform for the community to mobilize together and also interact with state level stakeholders. A crisis response team comprising of lawyers, doctors, and community leaders helped address 700 crisis situations majority of which were reported post the Supreme Court judgement recriminalizing homosexual acts.
Results: Communities take ownership when there is a platform available.
Sustainability comes with experience and efforts. Advocacy when used as a tool can bring the social pillars of Judiciary, Law enforcement, Media, and Health to stand with the community in crisis situations.
Conclusions: Newly-nurtured CBOs have successfully accessed unreached MTH populations, motivated them to access health services, and empowered the community to fight stigma and discrimination. Strengthened capacities of these organizations has ensured sustainability of HIV programme for MTH population.

WEPED1386

Collaborative capacity building initiatives by two national programs through conventional and distance learning seminars for effective roll out and optimal uptake of services

R. S. Gupta[1], N. Kadyan[1], V. Purohit[2], S. Singh[1], N. Garg[1], M. Sebastian[1]
[1]National AIDS Control Organisation, Ministry of Health & Family Welfare, Delhi, India, [2]World Health Organisation, New Delhi, India
Presenting author email: nishakadyan@gmail.com

Background: TB is one of the most common opportunistic infections and causes of morbidity and mortality in PLHIV. Assessment and field visits suggested a need to strengthen infection control practices at the ART center. National AIDS Control Organisation(NACO) and Central TB Division(CTD)approved the provision of daily Anti-TB Treatment(ATT), and measures of Intensified Case finding(ICF) for TB, provision of Isoniazid Preventive Treatment(IPT), implementation of Airborne Infection Control(AIC) practices(3I's) at treatment centersto strengthen TB infection control practices.
It was necessary to build the capacity of the staff at service delivery sites for optimal implementation at HIV care settings.
Methods: Standardized training package was developed based on the principles of adult learning followed by one Training of Trainers(TOT) and 21 down training batches over a period of three months June to September 2016. The master trainers comprised of officials from both the HIV and TB programs, clinicians and state level program officials.
Distance learning seminars in local languages were used to train the staff on comprehensive guidelines for prevention and management of TB at ARTCs with detailed guidance on the activities and measures to identity TB in PLHIV, initiate early ART/ATT, and implement 3I´s.
Results: 956 ARTC staff including 429 doctors and 527 Nurses & Counsellors were trained from 510 ARTCs.The pre test scores under all category confirmed a limited baseline knowledge of the participants and there was a 25-30% increase in post test evaluations.



[Knowledge gain by designation]

In 40 distance learning session 3714 staff were oriented about the new guidelines. Post training, the roll out picked well within 3 months with 12 states have started dispensing daily ATT drugs, 6 states have rolled out provision for IPT, 17 states have all their centers linked to CBNAAT facilities and 508 centers havestarted doing 4S screening.
Conclusions: Collaborative and focussed capacity building by HIV and TB programs has positive impact on implementation.

WEPED1387

Reducing viral load sample rejection rates in health facilities of Kabarole district of western Uganda through onsite mentorships and coaching

I. Namuleme Ddumba[1], I. Baganzi[2], P. Ajuna[3], A. Kekitiinwa[3]
[1]Baylor College for Medicine, Children Foundation Uganda, HIV/AIDS Care and Traitment, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Monitoring and Evaluation, Kampala, Uganda, [3]Baylor College of Medicine Children's Foundation, Care and Treatment, Kampala, Uganda
Presenting author email: ddumbaimmaculate@yahoo.com

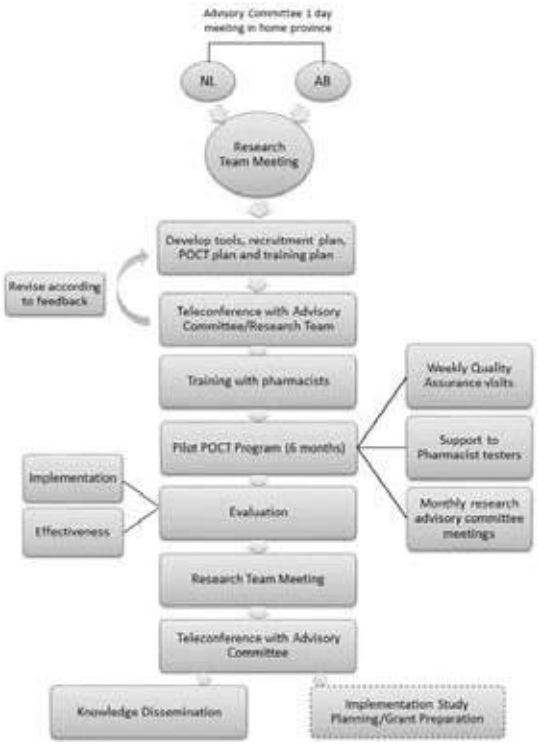
Background: To attain the third 90 in line with the UNAIDS strategy, Uganda has scaled up the use of Viral load monitoring for all ART patients however VL sample rejection remains one of the major hindrances to the achievement of VL coverage. Kabarole district in western Uganda registered a high rejection of VL samples. Poor quality of samples and incomplete filing of the sample requisition form for VL were the leading causes for sample rejection. A project was started to reduce the rejection rate of VL samples through mentorship and coaching of health workers. The project set out to build the capacity of health workers to collect quality samples and correctly fill in the requisition forms to reduce the rejection rates.
Methods: 15 sites with VL rejection rates above 5% were selected for the project, a team of competent clinical mentors in VL monitoring were identified and teamed up with the 15 health facilities. A total of 5 teams each comprising of a clinician and a laboratory technician were formed. The mentors worked with health facility staff providing mentorship and coaching for three days for each round of mentorship. Each facility received 4 rounds of mentorship, 2 for each quarter. Health facility staff were monitored by the mentors attached to the sites. Data on the rejection rates were reviewed quarterly for 9 months.
Results: There was a decline in the rejection of VL samples in all 15 health facilities, however the decrease is gradual over time. Health workers were more competent in sample collection and VL sample requisition. Non laboratory health care workers were able to do DBS phlebotomy which reduced client waiting time at the ART clinics. An increase in the rejection rates was observed in some of the sites when new staff attempted to do DBS VL phlebotomy for the first time, however this improved with more coaching and mentorship.
Conclusions: Mentorship and coaching is critical to building skill in the collection of VL samples using DBS and filing of the sample requisition VL form. Follow up of is critical to the effectiveness of the mentorship and acquisition of skill.

WEPED1388

The importance of community: development of a novel pharmacy-based HIV POCT program (the APPROACH study)

D. Kelly[1], J. Kielly[1], C. Hughes[2], S. Hancock[1], APPROACH study team
[1]Memorial University of Newfoundland, School of Pharmacy, St. John's, Canada, [2]University of Alberta, Faculty of Pharmacy and Pharmaceutical Sciences, Edmonton, Canada
Presenting author email: dvkelly@mun.ca

Background: Approximately 21% of HIV-infected Canadians are unaware of their status. In smaller provinces and rural communities, barriers include lack of access to testing, privacy concerns, and stigma. The availability of HIV point-of-care testing (POCT) is limited and variable across Canada. Pharmacists are well-positioned to address these barriers by offering HIV POCT and facilitating linkage to care (LTC).
Methods: The APPROACH study uses a type II hybrid Implementation-Effectiveness design to build a pharmacy-based HIV testing model to assess the acceptability, feasibility, and effectiveness in reaching at-risk individuals. In each province, we created provincial advisory committees (PAC) comprised of stakeholders from community-based organizations (CBOs), health providers, provincial laboratories, and policy/decision makers. PAC consultations informed selection of testing sites, client recruitment strategies, and local resources to support LTC plans in each region.



[APPROACH study - Team Development and Governance]

Results: PAC consultations have identified system and policy gaps including regional disparity in access to testing, which will impact LTC plans. We have devised creative solutions to provide client support using existing resources, including CBO and provincial mental health support lines. LTC plans are tailored for each testing site making best use of existing community and healthcare resources. PAC members facilitated client input and feedback on recruitment materials. PAC members are championing this multifaceted project and are vital to its implementation and sustainability.
Conclusions: Stakeholder engagement has proven critical to ensure the testing model developed is appropriate and responsive to each community's needs. Even in these initial stages of the project, PAC involvement has identified issues of importance beyond this specific study that will impact policy decisions, such as scope of practice and systemic barriers to HIV/STI testing in rural areas. When the testing program begins, PACs will play a critical role in supporting ongoing client recruitment and interpreting study results in the local context of communities.

WEPED1389

South Africa HIV and TB implementation research: a national agenda setting process

S. Smith, South Africa HIV and TB Implementation Research Advisory Committee Members
Office of Global Affairs, U.S. Department of Health and Human Services, Pretoria, South Africa

Background: South Africa (SA) has the largest HIV epidemic, the sixth largest TB burden, and the highest prevalence of HIV/TB co-infection in the world[i],[ii]. The SA government has adopted UNAIDS 90-90-90 goals for HIV and is committed to strengthening its TB program. In order to provide guidance the SA National Department of Health (NDoH) convened a SA HIV/TB Implementation Research (IR) Advisory Committee consisting of experts from the government, WHO, academia, program implementers, and healthcare providers. The Committee developed a list of national priority HIV/TB IR questions.
Methods: In January 2015 NDoH convened the IR Advisory Committee to advise on IR goals outlined in the National Strategic Plan on HIV, STIs and TB (NSP). The Committee developed an IR Agenda through this process:
· A list of IR questions submitted by stakeholders was assembled with over 300 questions focused on HIV Prevention, HIV Care and Treatment, Tuberculosis, Health Systems Strengthening, and Strategic Information, Laboratory, and Civil Society. Questions were ranked as "High Priority", "Priority", "Not a Priority".
· February 2016: The Advisory Committee developed a Scorecard with 8 Criteria ranked on a 4 point scale: Burden, Impact, Cost and Cost Effectiveness, Sustainability, Scalability, Available Research, Research Resources, and Policy Alignment. The Committee disseminated the scorecard of "High Priority" and "Priority" questions to over 100 experts in Microsoft Excel and Google Forms formats. The average score for each question was calculated.
· April 2016: The Advisory Committee convened a workshop with 80 stakeholders to clarify, support or dispute results from the exercise.
Results: Experts at the workshop endorsed the high priority IR questions and acknowledged that the highest ranking questions reflect priority HIV/TB IR topics. Participants noted that some questions could be addressed in multiple studies that investigate a larger topic. They recommended that HIV/TB IR also focus on findings and lessons learned from underperforming implementation efforts.
Conclusions: The list of IR questions reflects and complements SA HIV/TB priorities. The SA government and the Committee will continue to pursue related objectives of broader dissemination and capacity building for IR. This includes the use of IR findings for improved effectiveness and efficiency of SA's HIV/TB programs.

WEPED1390

Effect of community-led vulnerability reduction intervention on condom use among female sex workers in India

E. Daniel[1], R. Narayanan[2], S. Karkal[3], P. Patel[4], S. Kumar[5], P. Mathew[1], S. Syam[1]
[1]Swasti Health Resource Centre, Monitoring, Evaluation and Learning, Bangalore, India, [2]Catalyst Management Services Private Limited, Bangalore, India, [3]Swasti Health Resource Centre, Sexual and Reproductive Health, Bangalore, India, [4]Catalyst Management Services Private Limited, Performance Enhancement, Bangalore, India, [5]Swasti Health Resource Centre, Bangalore, India
Presenting author email: daniel@swasti.org

Background: Implementation Research Study was conducted under Avahan Phase III (April 2014 - September 2017) program as a part of BMGF supported India AIDS Initiative, to examine the impact of Combined vulnerability Reduction Intervention Coverage Index (CVRICI) on risk behavior among FSWs, and answer the research questions, whether vulnerability reduction increases Consistent Condom Use (CCU)? what is its contribution? and what is the pathway through which vulnerability reduction may impact CCU?
Methods: A systematic process of Member Engagement and Communication was conducted by Field Workers in their respective intervention areas using existing lists available with Community Organizations (COs) and Targeted Intervention Programs, as a part of social network including peer network, and conventional snowball method during April - September 2015, covering 109,366 FSWs across 71 COs from 47 districts of high risk states, Andhra Pradesh, Karnataka, Maharashtra, Tamil Nadu and Telangana.
Variables such as CVRICI, potential mediator CO Bonding Index (COBI) and outcome indicator, CCU with clients were operationally defined and measured using composite scales. SPSS V22.0 was used for Multiple Regression Analysis to explore whether CVRICI was associated with outcome indicator CCU and with mediator variable, COBI. Pathway analysis conducted by testing mediation, explored the degree to which effects could be attributed to CVRICI.
Results: FSWs with high level of CVRICI were more likely to report CCU with clients, AOR = 1.74, 95% CI = 1.66 - 1.81. Similarly, they were more likely to report high degree of COBI, AOR 2.30, 95% CI = 2.17 - 2.45. COBI was epidemiologically associated with CCU, AOR = 1.80, CI = 1.71 - 1.89. Pathway analysis conducted through Multiple Regression suggested that CVRICI acted above and beyond COBI to increase CCU, attributable to CVRICI leading to prevention of STI and HIV.
Conclusions: Findings reveal that vulnerability reduction interventions focusing on social protection, financial security, safety, security, justice among FSWs and institutional development support to community led organizations have both direct and indirect effect on increasing CCU beyond that of community mobilization (CO bonding) as potential mediator. Holistic approach of integrated vulnerability and risk reduction interventions may contribute to the sustainability of accelerated HIV Prevention program.

Monitoring and Evaluation

WEPED1391

Geo-prioritisation of HIV services: a direction for future interventions in Mumbai, India

S. Acharya[1], A. Palkar[1], M.S. Setia[2], P. Keskar[1]
[1]Mumbai Districts AIDS Control Society, City AIDS control, Mumbai, India, [2]Consultant, Dematologist & Epidemiologist, Mumbai, India
Presenting author email: acharyashrikala@gmail.com

Background: HIV prevention and care services including targeted interventions should be easily accessible to communities. We designed the present study to examine the association between geographical locations of intervention programmes and HIV infected individuals in Mumbai, India.
Methods: We categorised the 24 wards in Mumbai into high (A), medium (B), and low (C) based on the proportions of key population (KP), bridge population (migrants and truckers), current HIV infected individuals, and slums in each ward. We used the Poisson Regression Model for count data for estimating the association.
Results: Fifteen wards were categorized as A, seven as B, and two as C respectively. The mean proportion of HIV infected individuals (total and active), HRGs, and slums was significantly different across these categories of wards (Table 1). In general, the median number of HIV-related services was highest in Category A wards; however, the median number of bridge population targeted interventions (TIs) was highest in Category C (Table 2). In the poisson regression models, we found that a unit increase in the proportion of KPs across wards was associated with a 10% increase in the number of KP TIs; this association was statistically significant (Rate Ratio [RR]: 1.10, 95% Confidence Intervals [CI]: 1.03, 1.18; p=0.008). Furthermore, a unit increase in the proportion of bridge population was associated with 5.7% increase in the number of Bridge Tis; however, this was not statistically significant (RR: 1.05, 95% CI: 0.98, 1.16, p=0.22).

Group	Total HIV %	Active HIV %	Key population %	Bridge population %	HIV/TB co-infection %	Slum %
	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)
A (15)	5.03 (1.36)	5.03 (1.36)	5.45 (3.62)	5.55 (7.21)	4.17 (2.10)	4.78 (2.74)
B (7)	3.18 (0.94)	3.29 (0.97)	2.38 (0.82)	2.32 (3.40)	4.87 (3.62)	4.05 (3.26)
C (2)	1.15 (0.54)	0.76 (0.36)	0.77 (0.95)	0.27 (0.38)	1.68 (0.00)	0.14 (0.20)
p value	< 0.001	< 0.001	0.04	0.35	0.33	0.03

[Table 1: Proportion of select variables]

Categories	HIV testing centres	PPTCT centres	ART centres	STI centres	KP TIs	Bridge population TIs
	Median (IQR)	Median (IQR)	Median (IQR)	Median (IQR)	Median (IQR)	Median (IQR)
A (15)	3 (2, 3)	3 (2, 3)	1 (1, 2)	2 (1, 2)	3 (1, 3)	0 (0, 1)
B (7)	2 (1, 3)	1 (1, 3)	1 (1, 1)	1 (1, 2)	2 (0, 3)	0 (0, 1)
C (2)	0 (0, 0)	0 (0, 0)	0 (0, 0)	0 (0, 0)	1 (1, 1)	0.5 (0, 1)
p value	0.28	0.09	0.18	0.53	0.28	0.88

[Table 2: Median number of Service Centres across t]

Conclusions: Even though, the number of KP TIs increased with a higher proportion of KPs in the wards, this pattern was not observed for the Bridge population. Thus, it will important to relocate some of the Bridge population TIs or add new services in wards with a high proportion of bridge population.

WEPED1392

Understanding pregnant women´s uptake and retention in mother to child prevention of HIV transmission in Papua, the most HIV-affected province of Indonesia

C. Lumbantoruan[1], M. Kelaher[1], M. Kermode[2], A. Giyai[3], A. Ang[3]
[1]The University of Melbourne, Centre for Health Policy, Melbourne, Australia, [2]The University of Melbourne, The Nossal Institute, Melbourne, Australia, [3]Provincial Health Office, Papua, Indonesia
Presenting author email: christina.dolarosa@gmail.com

Background: Papua is the most affected province in Indonesia with an HIV prevalence of 2.3% (IBBS, 2011) among the general population, most infected through unprotected heterosexual sex. Treatment for the prevention of mother to child transmission (PMTCT) of HIV is available in Papua, but results are suboptimal following five years of implementation. There is evidence of increased coverage of women received PMTCT treatment, but little is known about determinants for (not) uptake and (not) retention. This research investigated facilitators and barriers to PMTCT uptake and retention of HIV-positive women in Jayapura, Papua.
Methods: In-depth interviews were conducted toward 20 HIV-positive women, and 20 health workers providing PMTCT service. Women participants were registered in ANC care between January 2015 and August 2016; half completed PMTCT uninterrupted and the remainder had interrupted program. PMTCT completion is defined as ART adherence until infant HIV status is established.
Results: All women interviewed accepted PMTCT program at first offer for personal and infant health reason; expectating to have HIV-uninfected child and to maintain physical health to take care of their children. However, during the pregnancy course, some women discontinued the treatment and returned again approaching childbirth, while some others diligently followed the recommendation until HIV status of the baby was declared. All women in both groups had good knowledge of HIV, ARV, and PMTCT. For women completing PMTCT, health gains following ARV treatment and belief in efficacy of ARV helped overcome barriers such as lack of support from partner, risk of unwanted HIV status disclosure, financial burden, geographical challenge, as well as stigma and discrimination. Meanwhile, PMTCT interruption in the second group was mainly due to fear of HIV status exposure; it occurred among women who were not fully motivated to uptake PMTCT since the beginning.
Conclusions: Results suggested that PMTCT success is dependent upon women's personal belief on ARV effectiveness and the strength of her motivation to stay healthy and to have a HIV-negative child. Further research is needed to understand how HIV-positive pregnant women's existing knowledge could be transform into belief that drives compliance behaviours in order to improve retention in PMTCT program.

WEPED1393

Designing a monitoring and evaluation system for oral PrEP in South Africa

H. Subedar[1], S.Y. Jenkins[2], C. White[2], Y. Pillay[1]
[1]South Africa National Department of Health, Pretoria, South Africa, [2]Clinton Health Access Initiative, Pretoria, South Africa
Presenting author email: sjenkins@clintonhealthaccess.org

Background: In late 2015 the South African National Department of Health (NDoH) undertook development of policy and guidelines for oral Pre-Exposure Prophylaxis (PrEP) implementation to prevent HIV acquisition for groups at high risk. This was in line with WHO guidance and following Medicines Control Council (MCC) approval of Truvada for use as PrEP. Development of a comprehensive monitoring and evaluation (M&E) framework, tools and templates was a critical part of this effort.
Methods: PrEP M&E development undertook a two-pronged approach. Standardized clinical forms were designed to support longitudinal, cohort-based client management and intrinsically linked to the design of a standard system to support routine data collection. The M&E system was planned with a limited, carefully-considered set of data elements and indicators. Additional operational metrics were included in routine monitoring to support program evaluation. Three M&E trainings have been conducted, in addition to individual site visits to support M&E. Formalized trainings and site visits drove adjustments to existing tools to improve client management and routine reporting.
Results: On 1 June, 2016, oral PrEP implementation began at ten sites in South Africa that work largely with sex workers. By December 2016, twelve sites were implementing oral PrEP, all using the developed M&E tools. From June through December, 2016, the 12 implementation sites initiated management of 729 individuals using the developed M&E tools, representing 235 client-years of data. Program data has informed adjustments to the M&E tools, including capture and management of missed appointments and program evaluation, including assessment of why/how certain sites have maintained higher rates of uptake and retention.
Conclusions: PrEP program design and services were comprehensively and proactively designed with intrinsic considerations for M&E. This has led to robust data availability from program inception. The data have supported adjustments to the M&E approach and evaluation of PrEP services, enabling the program to adjust in near real-time. Inclusion of additional operational metrics, as part of the two-pronged approach, has identified areas of focus for further programmatic and M&E evaluation. This allowed for critical review of data elements required for longer-term M&E where the quantity of data captured will be further limited.

Remaining causes of mother to child HIV transmission (MTCT) in Thailand: barriers to achieving an MTCT rate of <1%

C. Tonpudsa[1], R. Lolekha[2], P. Pavaputanondh[3], T. Puthanakit[4], P. Kosalaraksa[5], W. Petdachai[6], T. Borkird[7], R. Hansudewechakul[8], A. Rojanawiwat[9], T. Samleerat[10], S. Boonsuk[1], M. Martin[2], S. Ongwandee[3]
[1]Ministry of Public Health, Department of Health, Nonthaburi, Thailand, [2]Thailand Ministry of Public Health-U.S. CDC Collaboration (TUC), Division of Global HIV and TB, Nonthaburi, Thailand, [3]Ministry of Public Health, Bureau of AIDS, TB and STIs, Nonthaburi, Thailand, [4]Chulalongkorn University and HIVNAT, Thai Red Cross AIDS Research Center, Bangkok, Thailand, [5]Srinagarind Hospital, Khon Kaen, Thailand, [6]Phrachomklao Hospital, Petchburi, Thailand, [7]Hat Yai Hospital, Songkla, Thailand, [8]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [9]Ministry of Public Health, Department of Medical Sciences, Nonthaburi, Thailand, [10]Chiang Mai University, Department of Medical Technology, Faculty of Associated Medical Sciences, Chiang Mai, Thailand
Presenting author email: chawee_phd@yahoo.co.th

Background: Thailand validated the elimination of mother-to-child transmission (MTCT) of HIV in June 2016 (meeting WHO target < 2%). Thailand's National HIV strategy aims to reduce MTCT rate to < 1% by 2020. To understand current causes of MTCT and better focus prevention activities, we analyzed data from an established national prevention of MTCT active case management network (ACC).
Methods: A Department of Health (DOH) case manager is notified when an HIV-infected infant is reported to the ACC. The case manager sends a standardized case investigation form to the Hospital Director where the HIV-infected infant was identified to assess potential causes of MTCT. We analyzed data collected from August 2014 to December 2016. Infants at high risk for MTCT were defined as infants whose mothers had viral load (VL) >50 copies/mL at gestational age >36 weeks or received antiretroviral therapy (ART) for < 4 weeks prior to delivery.
Results: A total of 168 HIV-infected infants were reported. Of these, 102 (61%) infant case investigation forms were completed. Among the 102 HIV-infected mothers, mean age was 26 years with mean CD4 count 466 cells/mm^3. Only 28 (27%) had VL testing near delivery. Mean gestational age at first antenatal visit was 21 weeks and at delivery was 37 weeks.
Among the 102 HIV-infected infants, 82 (80%) were classified as high risk for MTCT. Mean age at first positive PCR was 86 days. Potential maternal risk factors for MTCT reported included presentation at ≥32 weeks or no antenatal care 35 (34%), poor antiretroviral adherence or suspected viral resistance 28 (27%), incident HIV infection (e.g., a woman who seroconverts to HIV-positive late in pregnancy or post-partum) 15 (15%), poor service delivery (e.g., delayed ART initiation) 13 (13%), lost to follow-up 7 (7%), and others 4 (4%).
Conclusions: To reduce MTCT rate to < 1%, Thailand should identify pregnant women with a high risk of MTCT by increasing uptake of VL monitoring prior to delivery, provide ART intensification for mothers with high VL and late-presenters, promote couples HIV testing and counseling to identify HIV discordant couples, and support HIV-infected pregnant women to adhere to ART and remain in care.

Assessment of the effectiveness of PMTCT program in service delivery points in North-Central Nigeria

O.O. Oleribe[1,2,3], E. Enenche[4], E. Ekom[5], D. Udofia[5], S.D. Taylor-Robinson[6,7]
[1]Excellence and Friends Management Care Centre (EFMC), Executive Office, Dutse, Nigeria, [2]Royal College of Physicians (RCP), M-PACT Project, London, United Kingdom, [3]West African College of Physicians (WACP), M-PACT Project, Lagos, Nigeria, [4]Excellence and Friends Management Care Centre (EFMC), Programs Unit, Dutse, Nigeria, [5]Excellence and Friends Management Care Centre (EFMC), Health Systems Strengthening, Dutse, Nigeria, [6]Royal College of Physicians (RCP), London, United Kingdom, [7]Imperial College London, St Mary's Hospital Campus, Faculty of Medicine, Norfolk Place, United Kingdom
Presenting author email: obinna.oleribe@expertmanagers.org

Background: Prevention of mother-to-child transmission(PMTCT) is essential in HIV/AIDS control as mother to child transmission account for the majority of Paediatric HIV infections. Despite over 12 years of HIV programming in Nigeria, there is a paucity of data as to the effectiveness of PMTCT programs in Nigeria. We executed this study to explore the effectiveness of PMTCT in selected sites in Nigeria.
Methods: We conducted a secondary data analysis at eight of supported Service Delivery Points in Abuja and Nassarawa States. Ethical review was received, and all identified PMTCT cases from 2012 - 2016 were included in the study. Mother-infant pairs data were extracted and analyzed using a tailored data collection tool. Data on early infant diagnosis(EID), final outcome and relevant test results were reviewed. We also examined the predictors of HIV transmission from mother-to-child in these centers. SPSS V23 and OpenEpi were used for data analysis.
Results: We retrieved 1,454 mother-infant-pair data from eight centers, but 83% (1207) were from secondary level facilities. While 89.5% (1302) positive pregnant women (PPW) and 92.2% (1340) of HIV-exposed infants received antiretroviral prophylaxis/treatment and 88.4% (1285) were breastfed with 32.5% still on breast milk as at the time of DBS collection. EID-PCR positivity rate was 3.5% (range: 0.0 - 11.1%). Facility of delivery (X=24.99, p<0.00), mother on ARV (X=48.8, p<0.00), mother received ARV prophylaxis (X=89.59, p<0.00), infant received ARV prophylaxis (X=58.56, p<0.00) and baby received cotrimoxazole (X=55.24, p<0.00) were all significantly related to positive EID-results. However, mode of delivery, place of delivery and breastfeeding were not significantly associated with positive EID results.
Conclusions: PMTCT services minimized the transfer of HIV from infected mothers to HIV exposed infants(HEI). To eliminate HIV in our generation and achieve zero new infections, every HIV-positive pregnant woman should receive ARV prophylaxis and supported post-delivery to prevent transfer of infection to the new born. Also, HEI should receive timely ARV and cotrimoxazole prophylaxis.

Evaluation of the South African national female condom programme: overview of key findings in the progress of female condom rollout in the public and non-public sector

M. Beksinska[1], Z. Mabude[1], P. Nkosi[1], J. Smit[1], J. Mantell[2], R. Greener[1], B. Zulu[1], M. Kubeka[1], L. Phungula[1], E. Marumo[3], T. Chidarikire[3]
[1]Match Research Unit (MRU) University of The Witwatersrand, Obstetrics and Gynaecology, Durban, South Africa, [2]HIV Center, Columbia University and New York State Psychiatric Institute, New Yoork, United States, [3]National Dept of Health, HIV Prevention, Pretoria, South Africa
Presenting author email: mbeksinska@matchresearch.co.za

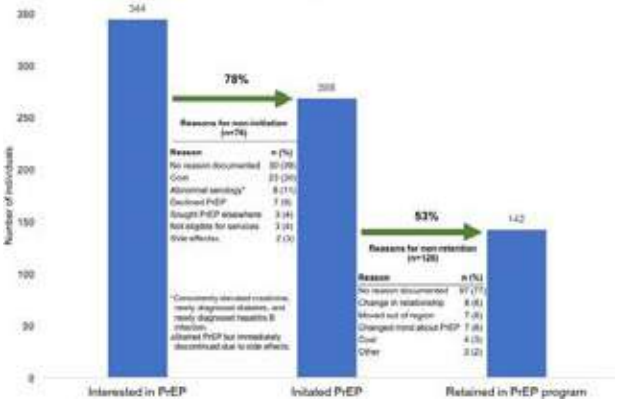
Background: South Africa (SA) has one of the largest and best-established, national public-sector male and female condom (MC and FC) programmes worldwide. The first comprehensive evaluation of the FC programme has recently been completed, with the primary objective of describing and evaluating FC distribution and promotion approaches.
Methods: This multi-component evaluation included a national survey in public and non-public health sectors, including interviews with providers (n=278) and female clients who had ever used the FC (n=424), and an anonymous female and male client survey (n=4442); review of District Health Information System data; key informant interviews with policy and programme managers; and 12-month follow-up of new FC users (n=598) and a sub-set of their male partners. The existing National STI sentinel site surveillance sample was used for the public-sector evaluation.
Results: Nationally, 256 public and 28 non-public sector facilities participated in the evaluation. Between 2014-2016, FC distribution more than doubled to over 27 million, exceeding the 2016 target of 25 million. All surveyed sites reported ever having distributed FCs, with 4.8% reporting a stock-out on the day of assessment. The anonymous client survey indicated that nearly 90% of women and men had heard of the FC, around 20% had ever used it, and two-thirds knew that FCs were available at their facility. Three-quarters of providers had been trained in FC provision and viewed introduction of new FC products (three FC types available in SA) favourably. Distribution across sites differed widely, with some sites distributing <50 FCs per month while others distributed over 10,000. A third of sites distributed FCs to other sites (e.g. taverns, NGOs, garages). HIV-positive women were well represented in both the cross-sectional client data (30%) and cohort (42%) data. Cohort data indicated that condom use at last sex using either an FC or MC increased from 56% to almost 90% from baseline to one year.
Conclusions: Distribution is increasing year on year, however varies significantly between sites, and around a third of clients are unaware of FC availability in their local facilities. Information that the FC is now available along with MCs in the programme is a priority to ensure access.

WEPED1397

The PrEP cascade: initiation of pre-exposure prophylaxis (PrEP) and retention in care in a clinic-based cohort of men who have sex with men (MSM)

J.C. Hojilla[1], P.-C. Crouch[2], G.-M. Santos[1,3], D. Vlahov[1], R. Grant[2,4], K. Freeborn[1,2], C. Hall[2], C. Dawson-Rose[1], A. Carrico[5]
[1]University of California, School of Nursing, San Francisco, United States, [2]San Francisco AIDS Foundation, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States, [4]University of California, School of Medicine, San Francisco, United States, [5]University of Miami, Department of Public Health Sciences, Miami, United States
Presenting author email: carlo.hojilla@ucsf.edu

Background: Addressing the PrEP cascade is crucial to optimize its clinical and public health benefits. In a community-based clinic serving MSM, this study characterized key steps of the PrEP cascade (i.e., seeking services, initiating PrEP, and retention in care) and identified predictors of non-retention.
Methods: Between November 2014 and August 2015, MSM were enrolled in a PrEP clinic in San Francisco. Follow-up visits were one month after enrollment and quarterly thereafter. Baseline sexual risk (i.e., self-report and STI diagnoses), stimulant use in the last 12 months (i.e., cocaine, crack, methamphetamine), and binge drinking (i.e., ≥ 5 drinks on one occasion) in the last month were assessed. PrEP initiation was verified at the 1-month follow-up. Non-retention was defined as failure to return within 30 days of a scheduled follow-up after initiating PrEP without evidence of transferring care.
Results: Among the 344 patients who sought PrEP services, most (95%) reported condomless sex and 14% were diagnosed with an STI (i.e., syphilis, rectal gonorrhea or rectal chlamydia). At enrollment, half reported binge drinking (50%) and one-fourth (27%) reported stimulant use. Of those who sought PrEP services, 268 (78%) initiated PrEP. Cost was the most commonly cited reason for not starting PrEP (see Figure). Among patients who initiated PrEP, median follow-up time was 389 (range 112-488) days. Cumulative incidence of non-retention at 13 months was 38%. Men with an STI diagnosis at enrollment had a 79% greater rate of non-retention (Adjusted Hazard Ratio [aHR]=1.79, 95%CI=1.06-3.01). Binge drinking (aHR=1.07, 95% CI=0.73-1.57) and stimulant use (aHR=1.00, 95% CI=0.64-1.56) were not associated with non-retention.



[Figure 1. PrEP cascade: proportion of individuals who sought PrEP, initiated care, and were retained in care]

Conclusions: Barriers to PrEP initiation among MSM are multifactorial, and cost remains a key concern. Non-retention is also prevalent. Although some PrEP discontinuations may be appropriate, expanded efforts are needed to support retention of those with STI diagnoses such as syphilis that increase risk for HIV seroconversion.

Near real-time tracking of PMTCT gaps in three districts of KwaZulu Natal province, South Africa

F. Moyo[1,2], A. Haeri Mazanderani[1], S. Bhardwaj[3], O.B. Mhlongo[4], T. Kufa-Chakezha[1], K. Ng'oma[3], B.A. Smith[3], G.G. Sherman[1,2]
[1]National Institute for Communicable Diseases, Centre for HIV & STIs, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Paediatrics and Child Health, Johannesburg, South Africa, [3]UNICEF South Africa, Pretoria, South Africa, [4]Department of Health, Province of KwaZulu Natal, Pietermaritzberg, South Africa
Presenting author email: faithmo@nicd.ac.za

Background: Over the past decade South Africa's prevention of mother-to-child transmission (PMTCT) of HIV programme has seen significant reduction in early-infant transmission from >20% to < 2%. Understanding PMTCT gaps that continue to fuel transmission rates will fast-track the last mile to elimination of mother-to-child transmission (eMTCT) of HIV and mobile health technologies hold the key to rapidly identifying gaps for intervention.
We describe findings from an operational follow-up study that investigated in near real-time, PMTCT gaps among HIV-infected infants aged < 18 months in KwaZulu-Natal Province.
Methods: Between May-September 2016, PMTCT co-ordinators from eThekwini, uMgungundlovu and uMkhanyakude districts received daily email notifications of all HIV PCR-positive results in their district, including patient identifying details. Co-ordinators reviewed facility records for each infant to answer five questions to identify gaps in PMTCT care (maternal age, timing of maternal HIV diagnosis, maternal treatment history, maternal viral load (VL), infant prophylaxis). Data was submitted via cellphone short-message-service using Rapid Pro technology and analyzed in STATA 14.
Results: 400 infants tested HIV PCR-positive during the study period and 367 (91.8%) had data for analysis. 258 (70.3%) were from eThekwini, 58 (15.8%) from uMgungundlovu and 51 (13.9%) from uMkhanyakude. Data was received within a median of 12.5 days (interquartile range [IQR]: 6-23). Median maternal age was 25 years (IQR 22-30) with no significant difference in PMTCT gaps observed between 48 teenage (15-19 years) and 293 older (20-34 years) mothers. 220 (60.0%) mothers were first diagnosed prior to conception or at their first antenatal clinic (ANC) visit and 127 (34.6%) at or after delivery. 137 (37.3%) women transmitted despite receiving >12 weeks cART with 48.9% diagnosed prior to conception. 257 (70.0%) women had no VL result documented, despite 62 (24.1%) being on cART for >12 weeks. Amongst 110 women with a documented VL, 75 (68.2%) received cART for >12 weeks with 35 (46.7%) virologically suppressed. No statistically significant differences in PMTCT gaps were observed between districts.
Conclusions: Findings highlight the need to improve services during ANC, prevention of maternal infections postpartum and prioritization of maternal VL monitoring. We intend using improved technology to streamline data collection and reporting towards eMTCT.

What is the benefit of the Basic Care Package (BCP) in the era of test and treat of all people living with HIV?

H. Kaula[1], P. Buyungo[1], B. Lukwago[1], D. Balaba[2]
[1]PACE, Research, Kampala, Uganda, [2]PACE, Programs, Kampala, Uganda
Presenting author email: kaula.henry@gmail.com

Background: Uganda has the highest prevalence of HIV in East Africa (7.3%) with about 2363 persons getting infected every week (UNAIDS 2013). Uganda aims to have at least 90% of persons diagnosed with HIV are enrolled on ART by 2020. The question is whether it's necessary to complement ART with BCP. PACE implemented the Positive Living Project (PLP) from 2010-2015 to provide BCP which was a combination of items (water treatment, mosquito net, and condoms) and messaging to People Living with HIV (PLHIV) enrolled in care and their families to adopt a Positive Living Life style (PLL). The goal was to reduce HIV transmission, opportunistic infections. Over 580,000 BCP kits were distributed accompanied with messaging about the PLL. An evaluation was done to establish the effect of complementing ART with BCP on incidence of OIs.
Methods: A retrospective review of clinical records to compare incidence of OIs for three categories of PLHIV i.e.
i) Enrolled on BCP but not on ART
ii) enrolled on ART but not enrolled on BCP, and
iii) Enrolled on both ART and BCP.
Patient records for 12 months after enrollment into each group were reviewed. The achieved samples for the 3 groups were 1110, 1676 and 1815 respectively.
Results: Key findings: In the 12 months follow-up period, a higher proportion of patients on ART-only reported OIs compared to those on both BCP and ART, 41% vs 29%, p value = 0.0002. Similarly, those on BCP-only reported OIs compared to those on both BCP and ART, 34% vs 29%, p value = 0.002. Overall incidence of OIs during the 12 months of follow-up was higher significantly in the ART-only group than other groups. All the 3 interventions have immediate reduction of incidence of OIs within the first three months which wanes by the end of the sixth month to similar levels.
Conclusions: The BCP is critical in the reduction of OIs in the first six months. A combination of both BCP and ART should be prioritized in the first six months of enrollment on ART for effective results.

Challenges and innovations in monitoring HIV prevention programs for key and priority population

D. Damba
Baylor College of Medicine Children's Foundation, Strategic Planning and Monitoring & Evaluation, Kampala, Uganda
Presenting author email: ddamba@baylor-uganda.org

Background: Integration of HIV prevention programs targeting key and priority populations (KP and PPs) has been advocated and implemented globally. However, the M&E system used to monitor its performance is constrained by a number of issues. This abstract presents key challenges faced and innovations in the M&E system for KP/PP programs implemented in Eastern and Western Uganda.
Methods: Between 2014 and 2016, Baylor Uganda is implementing HIV prevention programs in Eastern and Western Uganda targeting key and priority population including female sex workers, MSM, truckers, sero-discordant couples and adolescents among others. As part of the program, we designed appropriate M&E tools including the framework, data collection and reporting tools, longitudinal registers. Mapping of KPs and PPs was done; Focal persons at all service delivery points received appropriate training and mentorship in data management. Routine support supervision and action plans developed to address identified gaps. A computerized information system was designed and records assistants oriented on using the system. On quarterly basis, data coordination meetings and facility based meetings are conducted to review performance, share experiences and develop work plans. Additionally, quality improvement projects were initiated based on specified gaps. We reviewed data for 34 sites providing KP and PP services and interviewed focal persons on M&E issues; experience, challenges and innovations.
Results: A total of 5,767 KPs and PPs were served including; female sex workers (17%), MSM(1%), fisher folks(63%), truckers (6%) and sero-discordant clients (13%). Key innovations were; the development of new data systems which improved program performance tracking; Use of innovative staffing patterns and KP peers in providing prevention services and updating registers; Collaboration and partnership between stakeholders including project staff, health workers, KP/PP peer groups strengthened the continuity and quality of services. Key challenges included: Transportation of health workers at night for moonlight activities; lack of unique identifiers leading double counting; unreliable Internet connectivity; Lack of tracking system for mobile KPs/PPs leading to missing longitudinal data;
Conclusions: HIV Programmers need to adopt innovative M&E strategies for improved monitoring of the KPs and PPs programs; Standardize and integrate Prevention M&E tools in national M&E system; design a web-based and unique identifier system.

WEPED1401

Predictors of mother to child transmission in women on ART: results from a national evaluation of Malawi's PMTCT program

B. Tippett Barr[1], M. Landes[2,3], M. van Lettow[4], J.J. van Oosterhout[4,5], E. Schouten[6], R. Nyirenda[7], A. Auld[8]
[1]Centers for Disease Control and Prevention, CGH/DGHT, Harare, Zimbabwe, [2]University of Toronto, Toronto, Canada, [3]Dignitas International, Toronto, Canada, [4]Dignitas International, Blantyre, Malawi, [5]University of Malawi, College of Medicine, Blantyre, Malawi, [6]Management Sciences for Health, Blantyre, Malawi, [7]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [8]Centers for Disease Control and Prevention, CGH/DGHT, Lilongwe, Malawi

Background: In 2016, high ART uptake in HIV infected pregnant women was documented by the National Evaluation of Malawi's PMTCT Program (NEMAPP), and early infant transmission reduced to less than 2% in women on ART. Understanding factors associated with infant transmission in women on ART becomes increasingly important as countries seek to reach virtual elimination of mother-to-child transmission (eMTCT).
Methods: NEMAPP was implemented at 54 health facilities in 10 districts. A stratified cluster sampling design was used to identify a nationally representative sample of 4-12 week old infants. Mothers were consecutively consented and screened for HIV while attending an under-5 clinic, and all identified HIV-exposed infants underwent HIV-1 DNA testing. Structured interviews collected data on sociodemo-

graphic and clinical characteristics. Complex weighted survey design analysis was conducted using STATA.

Results: Of the 2125 HIV-infected women enrolled, 1,865 (88.5%) were on ART at the time of enrollment. Early infant transmission was lower in mothers who started ART prior to pregnancy in comparison to those who started in pregnancy (2.3% vs 3.5%, p=0.014) and women who disclosed their status to their partners (5.8% vs 2.0%, p=0.008).

In multivariable analysis for the subgroup of woman on ART, early infant transmission was almost twice as likely if a woman started ART during compared to before their pregnancy (aOR 1.9;p=0.032). Additionally, partner's HIV status disclosure to mother was significantly protective against early infant transmission (aOR 0.39; p=0.011), although maternal disclosure to spouse was not. Maternal self-reported health status, mother's self-reported missed ART, exclusive breastfeeding and infant receiving nevirapine syrup were not associated with early transmission in this sub-group of women on ART.

Conclusions: Women who have not openly discussed their partner's HIV status are more likely to transmit the virus to their child, indicating that disclosure between partners may mediate the effectiveness of PMTCT, potentially through the mother's adherence to antiretrovirals. This is the first time HIV status disclosure between partners has been documented to affect vertical transmission at national level.

Sexual health clinics successfully improve efficiencies and increase access to HIV testing among gay and bisexual men

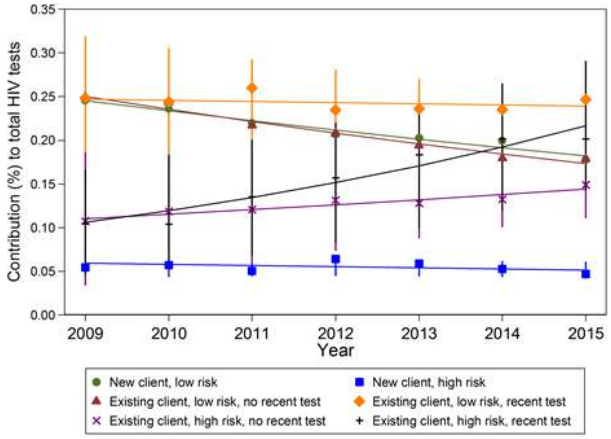
M.S. Jamil[1], H. McManus[1], D. Callander[1,2], G. Prestage[1], H. Ali[1], V. Knight[1,3], T. Duck[4], C.C. O'Connor[1,5,6], M. Chen[7,8], A.M. McNulty[3], P. Keen[1], N. Medland[7], M. Hellard[9], A.E. Grulich[1], D.A. Lewis[10,11], J.M. Kaldor[1], C.K. Fairley[7,8], B. Donovan[1,3], R.J. Guy[1]

[1]The Kirby Institute, UNSW Sydney, Sydney, Australia, [2]Centre for Social Research in Health, UNSW Sydney, Sydney, Australia, [3]Sydney Sexual Health Centre, Sydney Hospital, Sydney, Australia, [4]NSW Ministry of Health, Sydney, Australia, [5]Sexual Health Service, Community Health, Sydney Local Health District, Sydney, Australia, [6]Central Clinical School, Sydney University, Sydney, Australia, [7]Melbourne Sexual Health Centre, Melbourne, Australia, [8]Monash University, Melbourne, Australia, [9]Centre for Population Health, Burnet Institute, Melbourne, Australia, [10]Western Sydney Sexual Health Centre, Sydney, Australia, [11]Westmead Clinical School, University of Sydney, Sydney, Australia

Presenting author email: mjamil@kirby.unsw.edu.au

Background: In the past 5 years, public-funded sexual health clinics (SHCs) in New South Wales (NSW) have introduced a range of largely information-technology initiatives to improve efficiencies in their existing services including express-clinics, online booking, self-registration and SMS reminders. We analysed temporal trends in HIV testing among gay and bisexual men (GBM) attending SHCs in this period and if testing was targeted to high-risk GBM.

Methods: We used retrospective data from 32 SHCs in NSW participating in a sexual health surveillance network. HIV-negative GBM were categorised based on client type (new or existing), risk status (using partner numbers and/or recent rectal sexually transmitted infection), and recent HIV testing (past 6 months for high-risk, past 12 months for low-risk GBM). We used repeated measures Poisson regression to assess trends in testing and contribution to total tests by GBM categories.



[Proportional contribution to HIV tests by category]

Results: From 2009-2015, 58,377 HIV tests were done, 74% in existing clients and 35% in high-risk clients. The number of HIV tests increased 2.5-fold (4,779 in 2009 to 12,173 in 2015) with significant increase in all categories and the greatest increase in high-risk existing clients. Over time, high-risk existing clients with recent (past 6 months) testing had an increasingly larger contribution to total tests (13% annual increase, 95%CI: 8-18%, p< 0.001). There were no changes in contribution by other high-risk categories. There was a simultaneous annual decline in contribution to total tests by low-risk new clients (5% annual decline, 95%CI: 2-7%, p< 0.001), and low-risk existing clients with no recent (past 12 months) testing (6% annual decline, 95%CI: 5-7%, p< 0.001; see Figure).

Conclusions: Sexual health clinics in NSW have successfully increased HIV testing among GBM, with testing remaining targeted to high-risk men. Strategies to improve efficiencies in existing clinics, rather than establishing new ones, should be adopted more widely.

WEPED1403

Data for decision making to increase HIV testing among MSM in Kiambu county, Kenya: the Kuja clinic campaign

A. Olawo[1], S. Kuria[2], P. Mwaura[2], C. Agunga[1], B. Ogwang[1], N. Njuguna[1], C. Akolo[3]

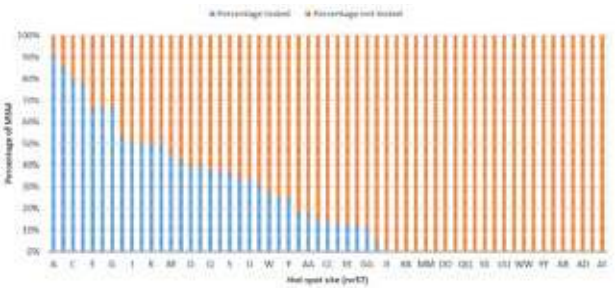
[1]Family Health International, Nairobi, Kenya, [2]Mamboleo Peer Empowerment Gruop, Nairobi, Kenya, [3]Family Health International (FHI 360), Washington DC, United States

Presenting author email: cakolo@fhi360.org

Background: Men who have sex with men (MSM) in Kenya are at high risk of HIV and are a priority population for HIV interventions, including HIV testing. However, MSM underutilize testing services due to stigmatization and discrimination. Through the USAID- and PEPFAR-supported LINKAGES project, we used routinely collected data from the project's efforts in Kiambu County, Kenya to identify gaps in HIV testing among MSM and implement an individualized HIV testing outreach intervention, the Kuja Clinic campaign.

Methods: MSM were recruited into the LINKAGES program through peer-led outreach and referred for HIV testing at community-based centers. At enrollment, all participants were assigned a unique identifying number and were assigned to the peer educator who identified them. We reviewed routine program data, including the number of hot spots from which MSM were recruited, number of MSM enrolled, and number of MSM who did not test for HIV. Data were disaggregated by hot spot to allow for individualized tracking of participants. We used descriptive statistics to summarize HIV testing gaps within the program.

Results: We enrolled 533 MSM from 63 hotspots between July and November 2016. Overall, 361 (68%) MSM spread across 57 hot spots did not test for HIV. HIV testing gaps across hot spots ranged widely from 9-100% (Figure 1). Hot spots with >75% testing gap (n=34) were prioritized for more intensive follow up of MSM through outreach by peer educators.



[Testing Gaps]

Conclusions: Analysis of routine program data revealed gaps in testing by hot spot and allowed for individualized HIV testing mobilization by peer educators. The ongoing Kuja Clinic campaign demonstrates the need for data-driven targeted HIV responses for strategic planning in KP programming to optimize service uptake in resource constrained settings.

WEPED1404

HIV testing strategies in primary health care centres: Indicator condition, risk-based or universal offer. Which strategy is the best?

M. Pichiule-Castañeda[1], M.F. Domínguez-Berjón[1], M.D. Esteban-Vasallo[1], C. Cevallos-García[1], J. Verdejo-Ortés[1], M.C. García-Riolobos[1], M. Morán-Arribas[1], S. Ruiz-Alonso[2], M. Hernández-Pascual[2], M.C. García-Valverde[2], I. Gonzalez-García[2], O.L. Martínez-Manglano Parra[2], M.P. Alonso-Martín[2], M.D. Prieto-Barbosa[2], C. Villanueva-Sanz[2], M.C. Álvarez-Castillo[1], J. Astray-Mochales[1], ESTVIH Study Group
[1]Pub, Madrid, Spain, [2]Pri, Madrid, Spain
Presenting author email: myrian.pichiule@salud.madrid.org

Background: Primary health care centres are a key piece to reduce the amount of people who don´t know their HIV status. The aim was to describe the effectiveness of three HIV testing strategies: Indicator condition, risk-based and universal offer in primary care centres.
Methods: Quasi-experimental multicenter study in primary care in the Community of Madrid (Spain). Study population were 18-64 years old patients attending health care centres. We selected centres using a multi-stage cluster sampling from HIV high incidence areas. We randomly assigned one strategy by centre. In 30 centres three strategies were implemented (10 centres by each strategy).
HIV test was indicated according each strategy:
1. Indicator condition offer (IO): in people with HIV indicator disease according 'HIV in Europe platform' recommendations, reminders in the electronic clinical record of patients were implemented.
2. Risk-based offer (RO): focus on the most-at-risk behaviours and vulnerable populations (men sex men, migrants, multiple sex partners, no condom use).
3. Universal offer (UO): for everyone for whom a blood analysis is requested.
We analyzed, by strategy: HIV test uptake, new HIV diagnosis and effectiveness (new HIV diagnosis/ HIV test uptake) with 95% confidence interval (CI).
Results: The study was completed in August 2016, one year after strategies implementation. In 30 centres, 320 professionals (family physicians and nurses) indicated HIV test to 4,044 patients. According strategies, the largest number of tests was performed in UO: 2,358 HIV tests (895 tests in IO and 791 in RO). There were 13 new HIV diagnosis, 9 of these patients with CD4>350 cell/µl. Global effectiveness: 0.32% (95%CI: 0.14-0.51). The most effectiveness strategy was IO: 0.78% (95%CI: 0.15-1.42), followed by RO: 0.51% (95%IC: 0.14-1.29) and finally UO: 0.08% (95%CI: 0.01-0.31).
All new HIV diagnosis had history of indicator disease in the last five years.
Conclusions: Although with routine offer strategy it is possible to carry out many HIV tests, indicator disease offer was the most effective strategy to new HIV diagnosis in primary care centres. So it would be necessary the strengthening of this strategy to reduce HIV hidden infection.

WEPED1405

Afro-Caribbean community HIV rapid testing in France: an opportunity for untested population?

P. Piron[1], F. Limousi[1], R. Mbiribindi[2], N. Lydié[1]
[1]Santé Publique France, Unité Santé Sexuelle, Saint Maurice, France, [2]Afrique Avenir, Paris, France
Presenting author email: nathalie.lydie@santepubliquefrance.fr

Background: Community-based HIV testing initiatives has been launched in France since 2010. They target most-at-risk populations, including the afro-caribbean community. We aimed to evaluate how a mobile programme promoting and offering rapid HIV testing in outdoor can attract untested persons.
Methods: Between 2014 and 2015, the programme served 6565 persons in the Paris metropolitan area. Each participant answered to an anonymous questionnaire about sociodemographic characteristics, sexual behaviour and history of HIV testing. Characteristics of untested and already tested persons were compared by Chi-squared or Fisher tests for qualitative variables and by t-tests for quantitative variables. All analyses were stratified by sex. Analyses were conducted using STATA 13.
Results: 1829 participants (28%) had never undergone an HIV test before, more men than women (30.0% vs 23.4%). For both sex, undergoing a first HIV test was associated with younger age (< 25 years), being born in France metropolitan and not having health insurance (22.1% vs 15.9% for women and 27.0% vs 17.2% for men). Men tested for the first time declared less often having multiple partners in the past year and unprotected sex with casual partner.
Men and women declared more often to have decided to be tested when they passed by the programme than those who have ever been tested (15.1% vs 9.1% for women and 16.3% vs 7.9% for men).
Among all participants 40 had an HIV rapid test positive (positivity rate: 0.6%). Among them, 16/40 were tested for the first time (positivity rate among first time testers: 0.9%): 9 were men, 12 were born in sub-Saharan Africa and 8 did not have health insurance. Positivity rate between first time testers and people already tested was slightly different (0.9 % vs 0.5%).
Conclusions: This community programme attracted a substantial number of persons who have never been tested probably because it offers multiple and more attractive, accessible and convenient testing locations than conventional healthcare settings. It may increase access to HIV testing by persons unaware of their HIV serostatus and particularly those without health insurance.

WEPED1406

Distributing HIV self-test kit by vending machines to raise serostatus awareness among high-risk populations in Taiwan: a pilot study in 2016

Y.-F. Huang, H.-Y. Huang, H.-Y. Lo, J.-S. Chu, C.-C. Lee, S.-T. Huang
Taiwan Centers for Disease Control, Division of Chronic Infectious Diseases, Taipei, Taiwan, Province of China
Presenting author email: gaky@cdc.gov.tw

Background: According to the surveillance data in Taiwan, up to 90% all new HIV cases are attributed from unsafe sexual behaviors. High-risk sero-unaware individuals with concerns about venue-based testing might benefit from novel private, self-testing methods such as In-Home HIV Test. The purpose of the study was to evaluate the feasibility for distributing the HIV self-testing kit in Taiwan and the HIV-positive rate among users.
Methods: From September-December 2016, we undertook a pilot study to examine the feasibility for HIV self-testing kit targeting vulnerable populations in Taiwan. Taiwan Centers for Disease Control applied for special permission to distribute HIV self-testing kit at NGOs or health stations, through vending machines at LGBT health centers, health stations, and gay sauna. Besides, only Hualien county provided extra route that pay-at-pickup services provided by chained convenient stores (only at Hualien County). Clients paid 6 US dollars to get the kit, and could receive full redeem after logging their test results online. Also, they could join a lottery activity for convenient store coupons (3 US dollars) after completing a questionnaire.
Results: In total, 4,812 kits were sold: 2,526(52.5%) through vending machines, 1,990(41.4%) distributed by LGBT health centers and health stations. At Hualien County, 88.1% (296/336) kits were distributed through pay-at- pickup services provided by chained convenient stores. Of 2,249(46.7%) who logged their test results anonymously on the website, 22 (1%) of respondents reported being newly tested HIV-positive. Of 1,341 who completed the questionnaire, 1,170(87.3%) were males, and 688(51.3%) reported being homosexuals, 179(13.4%) being bisexuals; 521(38.6%) reported that this was their first time to do HIV testing. About the satisfaction survey, 1,203(89.7%) claimed it was convenient to get the kit, 1,253(93.4%) said the service price was acceptable or cheap. For future access to the kits, 883(65.9%) said they'd like to get the kit from vending machines, 559(41.7%) through pay-at- pickup services at convenient stores.
Conclusions: The two novel delivery services were well-accepted and led to a substantial proportion of first-ever HIV testing. Both distributing methods were feasible to facilitate HIV self-testing and their access should be expanded in the upcoming programs.

WEPED1407

Low rates of HIV testing and multiple barriers to care in a large online sample of MSM across India: implications for scale-up of treatment and prevention

V.V. Patel[1], A. Dange[2], S. Rawat[2], C. Pina[1], J.H. Arnsten[1], S.A. Golub[3], J. Harrison-Quintana[4], Y. Ning[1], K.H. Mayer[5,6]
[1]Albert Einstein College of Medicine, Montefiore Health System, Medicine, Bronx, United States, [2]The Humsafar Trust, Mumbai, India, [3]Hunter College, City University of New York, Psychology, New York, United States, [4]Grindr, Grindr for Equality, Washington, United States, [5]The Fenway Institute, Fenway Health, Boston, United States, [6]Beth Israel Deaconess Medical Center, Harvard Medical School, Infectious Diseases, Boston, United States
Presenting author email: vpatel@montefiore.org

Background: HIV serostatus awareness is a critical initial step to optimize treatment and prevention. Because little is known about current HIV related behaviors in Indian MSM, we sought to determine factors associated with HIV-testing in a national online sample.
Methods: In January 2017, sexually-active MSM, aged 18 years or older, recruited via social-media and MSM mobile dating sites across India, completed an online-survey in English or Hindi, assessing HIV testing and sexual behaviors, and sociodemographics. We used summary statistics and multivariable logistic regression to identify factors associated with HIV-testing.

Results: The 3,637 (59%) MSM completing the survey, came from all states, 17% from rural areas; 18% responded in Hindi. Their median age was 26, most (82%) completed college, and 15% were categorized as being in poverty and 21% in lower class; 49% identified as homosexual, 47% as bisexual, and 4% as heterosexual; 43% had not disclosed their sexual-identity to anyone, and most (77%) had never disclosed same-sex behaviors to any healthcare provider. In the past year, 31% had used drugs/alcohol during sex and 7% were diagnosed with an STI. In the past six months, participants had a median of 5 sexual partners and 42% had condomless anal sex (CAS). Overall, 46% had never had an HIV test and 47% among those reporting CAS (n=1,520), Among those previously tested (n=1,964), 5.4% were HIV positive, and 25% last tested over 12months ago; 59% tested at a private lab or clinic, 23% at a public-hospital, and 8% at a testing-counseling center. Among those never tested, reasons for not testing included not being at risk (43%), feeling scared (20%), and not knowing where to test (14%). In multivariable analysis, never being HIV-tested was associated (p<0.01) with younger age, lower income, less education, CAS, not using drugs/alcohol, lacking access to comfortable testing-sites, non-disclosure of their sexual-identity, and never disclosing same-sex behaviors to any healthcare provider.
Conclusions: In a large demographically diverse Indian MSM sample, large proportions were at-risk and unaware of their HIV status, particularly those engaging in CAS. Local and national programs need to increase access to culturally-competent, non-judgmental services and increase educational outreach to MSM online.

WEPED1408

Implementation of routine HIV testing program in University Infectious Diseases Centre: four-year analysis

R. Matulionyte, K. Žagminas, G. Gaižutyte, E. Balciunaite, R. Paulauskiene, A. Bajoriuniene, A. Jelinskaite, A. Ambrozaitis
Vilnius University Hospital, Infectious Diseases Centre, Vilnius, Lithuania
Presenting author email: raimonda.matulionyte@santa.lt

Background: HIV transmission remains of major concern in Eastern Europe, and too many people are diagnosed late. Expanded testing strategies and early and appropriate access to care are required. Infectious diseases departments might be a target for expanded HIV testing owing to intense passage of people belonging to key populations and carrying indicators for HIV disease.
Objectives: To describe implementation and outcomes of integrated nontargeted opt-out rapid HIV screening program in an urban teaching Infectious Diseases Hospital.
Methods: A retrospective cross-sectional study was conducted from October, 2010, through December, 2014, in Vilnius University Hospital Infectious Diseases Centre. The program was divided into two periods:
(1) from October 2010 to December 2012 (pilot study), and
(2) from January, 2013, to December, 2014.
The pilot study consisted of routine HIV screening of patients aged 18-55, hospitalized in one inpatient department. In the second period the decision to enlarge eligibility for screening was made with indication to test all inpatients aged 18-65. Physician-directed testing was conducted in the second inpatient department during the pilot study and in the outpatient department during both periods.
Results: During the pilot study, 2203 patients were hospitalized, 1314 (59.6%) were eligible, 954 (72.6%) were tested, 3 (0.31%) were HIV positive. In the second period, 4911 patients were hospitalized, 3727 (75.9%) were eligible, 3303 (88.6%) were tested, 7 (0.21 %) were HIV positive.
A total of 2800 physician-directed tests (10.1% out of 27 673 admitted/consulted patients) were performed, and 4 (0.14%) found HIV positive. All 14 diagnosed patients were linked to care in the centre.
Comparing cumulative groups of routine (n=4257) and physician-directed testing (n=2800), the HIV prevalence was 0.23% vs. 0.14%, p=0.40. HIV prevalence (0.23%) was above the cost-effectiveness threshold of 0.1 % (p=0.012). A lower proportion of advanced disease (CD4 < 200/mm^3) was found in the routinely tested group (2/10 vs. 4/4, p=0.015).
Conclusions: Routine HIV testing in Infectious diseases admissions is acceptable, feasible, sustainable, and cost-effective. Routine testing helped to discover more patients in earlier stages, compared to physician-directed testing. Furthermore, expanded testing in infectious diseases settings is favourable for linkage to care process.

WEPED1409

Integrated surveillance for HIV, syphilis, HBV & HCV in pregnant women attending ANC sentinel surveillance sites in Eritrea, 2016

A.B. Mesfin[1], H. Ahmed[2], M. Asrat[2], T. Asfaha[1], N. Tesfamichael[1]
[1]*Ministry of Health, Communicable Diseases Control Division, Asmara, Eritrea,* [2]*National Statistics Office, Asmara, Eritrea*
Presenting author email: araiabm@gmail.com

Background: Countries monitor their HIV epidemic using ANC sentinel surveillance sites. Though, HIV surveillance in pregnant women is well advanced, surveillance on Hepatitis B and C is far behind. To determine prevalence and distribution of these infections, HBsAg and Anti-HCV testing were nested in the HIV surveillance.
Methods: A cross-sectional, anonymous and unlinked sentinel surveillance survey was conducted in Dec. 2015-Feb 2016. It covered a total of 46 health facilities from urban and rural areas. Pregnant women, 15-49 years old, attending ANC for their first visit in current pregnancy were consecutively recruited and interviewed followed by drawing blood for HIV, Syphilis, HCV and HBV testing at the National Reference Laboratory.
Results: A total of 5019 pregnant women with 62% from urban and 38% from rural ANC sites were enrolled. Majority (57%) were in the age group 20-29 with the median age of 27 years. Almost all (94%) were married with 87% of them house wives. The overall prevalence of HIV, syphilis and HBV was 0.84% [95%C.I: 0.6, 1.1], 0.56% [CI: 0.4%, 0.8%] and 3.01% [95%CI: 2.6%, 3.5%], respectively. Multivariate analysis showed that age, residence, marital status and occupation of respondents were the most important variables that determined HIV infection. HIV peaked in the age group 25-29 and was more common in urban, in those not married and unemployed. Unlike HIV, HBV and syphilis were more common in rural. Though, region, age and marital status determined syphilis prevalence, region was important factor that determined HBV infection. Anti-HCV was negative in all the pregnant women tested, while co-infection was not evident from the study.
Conclusions: The integrated surveillance showed that the overall prevalence of HIV, syphilis, HBV and HCV is low in Eritrea. However, these infections were relatively higher in some regions and population groups and with no co-infection. Relatively higher prevalence in some regions, age groups and occupations may indicate presence of practices that expose these pregnant women. Therefore, in-depth researches are recommended to understand why certain sub-groupsare more vulnerable to these infections. Moreover, existing HIV sentinel surveillance sites can be used to monitor HBV and HCV infections, generate important data for decision making.

Coverage of HIV testing among HIV-exposed infants in the context of option B+ in Malawi

T. Henry Tchereni[1], J. Joseph[2], A. Gunda[1], V. Mwapasa[3]
[1]*Clinton Health Access Initiative, PRIME Study, Lilongwe, Malawi,* [2]*Clinton Health Access Initiative, Applied Analytics, Denver, United States,* [3]*University of Malawi, College of Medicine, Faculty of Public Health and Family Medicine, Blantyre, Malawi*
Presenting author email: ttchereni@clintonhealthaccess.org

Background: Early infant diagnosis is critical for the survival of HIV-Exposed Infants (HEI), yet testing rates remain low in resource-limited countries. Malawi recommends testing of HEIs by HIV Polymerase Chain Reaction (PCR) by two months and by HIV rapid antibody test (RT) at 12 and 24 months or after cessation of breastfeeding. This analysis estimated the proportions of HEIs tested for HIV at 2, 12 and 24 months in the context of option B+.
Methods: Data were analyzed from the "Promoting Retention among Infants and Mothers Effectively (PRIME)" study, a 3-arm cluster randomized trial assessing the effectiveness of service integration and SMS-reminders on HEIs and maternal retention. The trial was conducted from 2013 to 2016 in 30 health facilities in southern Malawi. HEIs were enrolled at birth and followed up to 24 months. Data on HIV tests, deaths and transfer-outs were extracted from routine health facility records. Infants were considered censored if they did receive the full 24 months of follow-up.
Results: Figure 1 illustrates the testing coverage at 2, 6, 12, 18, and 24 months. A total of 1085 HEIs were enrolled, of whom 369 (34%) received PCR testing by 2 months, 433 (42%) and 130 (16%) receiving 12 and 24 month RT tests, respectively. A total of 59 (8%) received all three recommended tests. Twenty-seven infants (2%) tested HIV-positive; 24 (2%) died, and 50 (5%) transferred-out. A total of 207 (19%) were never tested.
Conclusions: Low coverage was found at all testing points, and PCR testing was notably conducted late. Additionally, very few infants were re-tested, despite continued exposure via breastfeeding. Continual follow-up of HEIs is necessary to ensure testing at all time points is conducted. Though transmission rates were low, interventions targeting longer follow-up of HEIs through the end of breastfeeding are needed to avoid post-natal transmission.

	2 Months (DNA PCR Test Required)	6 Months	12 Months (Rapid Test Required)	18 Months	24 Months (Rapid Test Required)
Censored	0	0	0	156	221
Died	12	5	5	1	1
HIV-Positive	8	5	8	2	4
Transferred-out	13	7	16	10	4
Not tested	708	783	570	747	482
Rapid tested	0	0	433	101	130
PCR tested	369	264	24	0	0

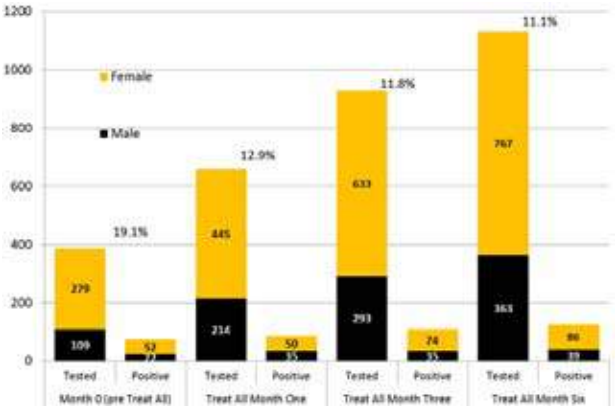
Treat All and the 1st 90: exploring changes in HIV test rates and yields among adults following implementation of test and treat in Bulilima district, Zimbabwe

K. Webb[1], V. Chitiyo[1], S. Page-Mtongwiza[1], J. Murungu[2], P. Mbetu[1], T. Maphosa[1], B. Engelsmann[1]
[1]Organisation for Public Health Interventions and Development, Harare, Zimbabwe, [2]Ministry of Health and Child Care, AIDS & TB, Harare, Zimbabwe
Presenting author email: bengelsmann@ophid.co.zw

Background: At 22.3%, Matebeleland South Province has the highest HIV prevalence in Zimbabwe. The impact of test and treat strategies on demand and uptake for HIV testing are unknown in high prevalence, resource-limited settings. Our objective was to explore changes to HIV test rates and test yields among clients accessing facility-based care in Bulilima District, Matebeleland South Province, following start of Treat All.
Methods: We conducted a retrospective cohort analysis of clients accessing HIV testing services after Treat All implementation. All clients accessing HIV testing services at 11 purposively selected health facilities in Treat All inception district, Bulilima, from May 2016 (month 0) and 1, 3 and 6 months after Treat All implementation were traced through multiple registers to document HIV test results disaggregated by age, sex and entry point.
Results: Among 3,101 individuals tested for HIV over the period of interest, the majority tested were women (68%). A significant 290% increase in HIV test uptake was observed from pre-Treat All to Month 6. While HIV test yields decreased (19-11%), the absolute number of new positives identified increased by 68% due to increased test rates.



[HIV test rate, new positives and yield (%)]

Within age groups, young women aged 15-19yrs and 20-24yrs had significantly higher test yields than men of the same age (8% vs 2.2%; p=0.02 and 14.5% vs 8%; p=0.04 respectively). Adult men aged 25-49 had the highest test yield (23.2%).

Conclusions: We observed increased HIV test rates and number of new positives identified following implementation of Treat All. Tests rates remained low among men compared to women. In high prevalence settings such as Zimbabwe, our findings highlight the value of offering HIV testing to all individuals with unknown HIV status presenting to health facilities. Evidence-based differentiated models of care to increase testing uptake among high yield groups (young women, older men) are required to reach the 1st 90.

WEPED1412

The test of time: An interrupted time series analysis of HIV testing following service changes at a community-based rapid HIV testing service in Melbourne, Australia

K. Ryan[1,2], A. Wilkinson[1], P. Locke[3], D. Leitinger[3], A. Pedrana[1,2], M. Hellard[1,2,4], M. Stoove[1,2]
[1]Burnet Institute, Centre for Population Health, Melbourne, Australia, [2]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [3]Victoria AIDS Council, Melbourne, Australia, [4]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia
Presenting author email: kathleen.ryan@burnet.edu.au

Background: PRONTO!, a peer-led community-based rapid HIV testing service, was established in Melbourne, Australia in 2013 to increase testing frequency among gay and bisexual men (GBM). In response to evaluation data attributing low return-testing rates to the lack of integrated STI testing, STI (gonorrhoea, chlamydia, syphilis) testing and SMS reminders were implemented. Using a quasi-experimental design, we quantified changes to return-testing following these service-level interventions.
Methods: Implementation of STI testing and SMS reminders occurred in February 2016. Return HIV testing rates were compared between pre-intervention (January 2015-January 2016) and post-intervention (February 2016-December 2016) periods. All HIV tests between 01 July 2014 and 31 December 2016 were included in analyses (2014 tests allowed six months of lead time to assess returning). Using monthly aggregate data a segmented linear regression assessed changes in the percentage of tests per month with a previous test within 91 days (3m return testing) and 182 days (6m return testing). We report regression coefficients: percentage of 3m and 6m return tests at baseline (January 2015, β0), return-testing trend (pre-intervention slope, β1), and return-testing trend from pre-to post-intervention (change in slope, β3). A change in slope (β3) p<0.05 was considered a significant change in return testing.
Results: Over 24 months, 4959 HIV tests were conducted among 3339 individuals (median tests/month=201, range 178-243). Post-intervention, ~100 SMS reminders were sent per month and 60% of clients accessed STI testing. Overall, 3m and 6m return testing increased by approximately 50% in the ten months post-intervention. At baseline, 3m return testing was estimated at 12% (β0), decreasing by 0.4% per month (β1) during the pre-intervention period. Post-intervention, 3m return testing increased an average of 0.8% per month (β3, 95%CI:0.3-1.3, p<0.01), from 7% to 15%. Baseline 6m return testing was estimated at 23% (β0), remaining stable pre-intervention (β1=-0.2%). Post-intervention, 6m return testing increased an average of 1.1% per month (β3, 95%CI:0.7-1.6, p<0.01), from 22% to 35%.
Conclusions: Implementation of STI testing and SMS reminders increased frequent testing. However, less than one in five clients were testing quarterly post-intervention, well below recommended frequencies. Despite improved convenience in this client-centred testing service, compliance with high frequency risk-based HIV testing guidelines remains a significant challenge.

WEPED1413

Pooled PCR testing of dried blood spots (DBS) for HIV early infant diagnosis is cost-efficient and accurate

J. Maritz[1,2], C. van Schalkwyk[3], G.U. van Zyl[1,2], W. Preiser[1,2], A. Welte[3]
[1]University of Stellenbosch, Medical Virology, Cape Town, South Africa, [2]National Health Laboratory Service, Cape Town, South Africa, [3]South African Centre for Epidemiological Modelling and Analysis, University of Stellenbosch, Stellenbosch, South Africa
Presenting author email: maritzj@sun.ac.za

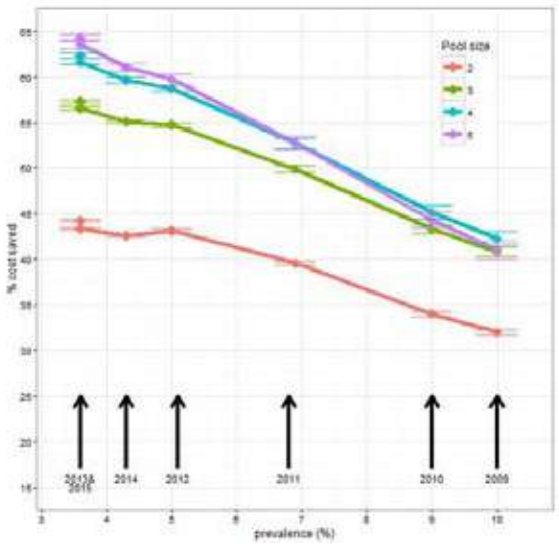
Background: Access to qualitative HIV PCRs for early infant diagnosis (EID) is restricted in resource limited settings due to cost. We hypothesised that pooling of dried blood spot (DBS) samples, defined as combining multiple patient samples in a single assay run with subsequent individual testing of positive pools, would be cost saving while retaining acceptable clinical accuracy compared to individual patient whole blood testing.
Methods: Cost savings: A model was developed to simulate reagent and consumable cost saving of pooled compared to individual sample testing. The number of pools requiring deconvolution (individual testing) was set to the expected number

of positive pools based on a binomial distribution. To validate the model, daily sample/result data and reagent costs of a public health laboratory in South Africa for the period January 2009 to July 2015 were used.
Clinical sensitivity: 1,170 patient samples were tested in pools of five 50µl DBS. Negative pools comprised 5 DBS previously tested in single reactions; positive pools included 1 positive sample. All tests were performed with the Roche CAP/CTM Qual assay.
Results: Overall sensitivity of pooled testing was 98.8%; 100% for strongly reactive pools (Table 1). One pool tested false positive but would not impact clinical specificity as individual patient testing is performed prior to reporting.

		Pooled samples result, n (%), 5 samples per pool		
		Positive	Negative	Total
Whole blood reference result	Positive pools	149 (100)	0	149
	Low positive pools	16 (89)	2 (11)	18
	Negative pools	1 (1.5)	66 (98.5)	67
	Total	166	68	234

[Table 1. Clinical performance of pooled testing]

Pooling would have resulted in saving 65% of laboratory EID costs in 2015 (Figure 1). The model is published as an R-based web tool, into which the user enters sample/positivity estimates and workflow management parameters to obtain cost saving estimates at an optimal pool size.



[Figure 1. Cost savings by pool size / prevalence]

Conclusions: Pooled PCR testing for EID remains accurate and dramatically reduces costs in settings with moderate to low prevalence rates.

WEPED1414

Scale-up of HIV care and ART use over a decade for children in 4 African countries

C.A. Teasdale, C. Wang, R. Fayorsey, M. Hawken, Z. Melaku, A. Mussa, W.M. El-Sadr, E.J. Abrams, Identifying Optimal Models of Care in Africa Study
ICAP-Columbia University, New York, United States
Presenting author email: eja1@columbia.edu

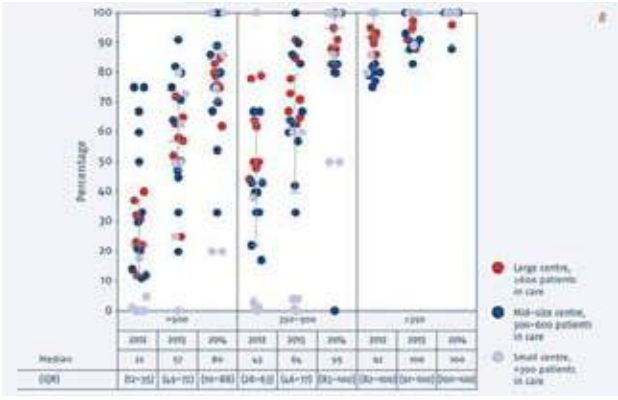
Background: Expanding access to HIV care and treatment for children has been critical to combating the HIV epidemic. We report attrition pre and post-ART among children enrolled in care at 349 health facilities in Ethiopia, Kenya, Mozambique and Tanzania over 10 years.
Methods: We describe characteristics of children (0-14years) enrolled in care at PEPFAR-funded ICAP-supported clinics in four countries 2005-2014. We report proportions of children starting ART by year and estimate attrition (loss to follow-up(LTF) and death) pre-ART initiation using competing risk estimators (ART as competing risk) and post-ART initiation with Kaplan-Meier. LTF was defined as no visit within 12 months for pre-ART and 6 months post-ART start. We compared outcomes by year using Cochran-Armitage tests, Kendall Tau coefficients, log rank tests and unadjusted sub-distributional hazards models.
Results: From 2005-2014, 72,120 children were enrolled at 349 facilities: median age 4.1 years[IQR 2-8], 10.4% were < 1year and 46.9% were >=5years; 41.6% were WHO stage3/4 and median CD4+ count for children 5-14years was 362cells/mm³[IQR146-654](51.5% missing). Overall, 43,255 (60.0%) children started ART at median age of 4.9 years[IQR 2-8.7]; 53.0% were WHO stage3/4. The proportion of children starting ART increased from 53.1% in 2005-06 to 72.9% in 2013-14(p<0.0001); for children < 1year, the proportion starting ART increased from 24.3% in 2005-06 to 86.7% in 2013-14 (p<0.0001).
Median CD4+ for children 5-14years at enrollment was 240[104-414] in 2005-06 and increased to 439[193-724] in 2013-14(p<0.0001); median CD4+ at ART start was 197[77-351] in 2005-06 and 314[139-550] in 2013-14(p<0.0001).
Pre-ART attrition overall at 12 months was 27.1%(95%CI 26.7-27.4); it decreased from 34.3%(33.3-35.3) in 2005-06 to 15.5%(14.4-16.6) in 2013-14 (p<0.0001).
Attrition post-ART at 12 months was 22.3%(21.9-22.7) and increased from 15.8% (14.8-17.0) in 2005-06 to 28.4%(26.9-30.1) in 2013-14 (p<0.0001).
Conclusions: Over 10 years, more than 72,000 children enrolled in care and 60% started ART. Over time, a higher proportion of children in care initiated ART and at higher CD4+ count. Attrition decreased among pre-ART patients and increased among those on ART, the latter may reflect higher LTF among children who initiated ART at higher CD4 counts. Innovative efforts are needed to enhance retention among children on ART.

WEPED1415

Initiation of cART: a nationwide overview of variation between HIV treatment centres in the Netherlands

T.S. Boender[1], C. Smit[1], K. Brinkman[2], J.M. Prins[3], F.P. Kroon[4], S.E. Geerlings[3], P. Reiss[1,3,5], on behalf of the ATHENA national HIV cohort
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]OLVG, Amsterdam, Netherlands, [3]Academic Medical Centre of the University of Amsterdam, Department of Internal Medicine, Amsterdam, Netherlands, [4]Leids Universitair Medisch Centrum, Leiden, Netherlands, [5]Academic Medical Centre of the University of Amsterdam, Amsterdam Institute for Global Health and Development & Department of Global Health, Division of Infectious Diseases, Amsterdam, Netherlands
Presenting author email: s.boender@amc.nl

Background: We explored variation in combination antiretroviral therapy (cART) initiation between all 26 acknowledged HIV treatment centres in the Netherlands.
Methods: We assessed the annual proportion of HIV+ adults starting cART within 6 months after entering care, according to CD4 count at entry into care and centre size (>600,300-600,< 300 people in care). We used logistic regression adjusted for CD4 count at entry into care, calendar year and socio-demographic differences between patients at centres (sex, age, HIV-transmission route, region of origin, socio-economic status).
Results: In 2012, 2013 and 2014, 957, 942 and 784 people, respectively, entered into care and had ≥6 months follow-up. A median 62% of the people who entered into care in 2012 started cART within 6 months, increasing to 76% in 2013, and 91% in 2014. Starting cART within 6 months was significantly more likely after entering in 2014 compared to 2012: aOR 5.47; 95%CI 4.22-7.10; p< 0.0001.
People with < 350 CD4 cells/mm³ when entering into care initiated cART earlier, compared to those with ≥350 CD4 cells/mm³ (figure). This difference decreased in 2014, although considerable variation between centres remained, particularly for patients with >500 CD4 cells/mm³.



[Initiation of cART]

People at small centres were less likely to initiate cART within 6 months compared to those at large centres, also after adjusting for CD4 count, socio-demographic differences and calendar year (aOR 0.68; 95%CI 0.48-0.96; p=0.028). People with 350-500 CD4 cells/mm³ entering into care in small centres were less likely to initiate cART within 6 months, compared to those in large centres (aOR: 0.49; 95%CI 0.27-0.90, p=0.005).

Conclusions: Following guideline recommendations, increasing numbers of HIV+ people initiated cART within 6 months. However, differences between centres of different size were observed. Patients with 350-500 CD4 cells/mm^3 entering care in small centres were less likely to start cART within 6 months compared to large centres.

WEPED1416

Persistent high burden of advanced HIV disease in South Africa: data from a longitudinal nationwide laboratory cohort

S. Carmona[1], J. Bor[2,3,4], C. Nattey[2], B. Maughan-Brown[5], M. Maskew[2], M.P. Fox[2,3,6], D.K. Glencross[1], N. Ford[7], W. Macleod[2,3,4]
[1]WITS University - NHLS, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]Health Economics and Epidemiology Research Office, Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]Boston University School of Public Health, Department of Global Health, Boston, United States, [4]Center for Global Health and Development, Boston University School of Public Health, Boston, United States, [5]University of Cape Town, Southern African Labour and Development Research Unit, Cape Town, South Africa, [6]Boston University School of Public Health, Epidemiology, Boston, United States, [7]World Health Organization, HIV/AIDS, Geneva, Switzerland
Presenting author email: sergio.carmona@nhls.ac.za

Background: The South African national HIV programme has achieved substantial coverage of antiretroviral therapy (ART) over the last decade, supported by policy changes allowing for earlier ART initiation. However, individual clinic reports suggest the proportion of patients entering care with advanced (< 200 cells/mm^3) and very advanced (< 100 cells/mm^3) HIV disease has remained constant in recent years. We assessed this using nationwide laboratory data.
Methods: We constructed a cohort utilizing nationwide laboratory records containing CD4 counts from 2004-2015. Using standard linkage methods, we determined first CD4 cell count at entry to care. We estimated numbers and proportions of adult patients with first CD4 in the following categories: < 100, 100-199, 200-349, 350-499 and ≥500 cells/mm^3.
Results: In total, 8,4 million first CD4 count tests were identified. From 2004-2011, the % patients with CD4 count < 200 cells/mm^3 entering into care declined from 50% to 35% of all tests (Figure 1). However, from 2011 onwards the % patients entering ART care with low CD4 counts has remained relatively unchanged. In 2015, over 230,000 patients entered care with advanced HIV disease, of whom around 120,000 had very advanced HIV disease. The proportion of men entering care with advanced HIV disease was nearly twice that of women.
Conclusions: The proportion of patients presenting with advanced HIV disease remains consistently high despite ART scale up, representing a large avoidable burden of HIV morbidity, medical costs, and onward transmission. Testing campaigns focused on early HIV-diagnosis and linking patients to ART care should be prioritised, particularly among men. CD4 testing for patients presenting with advanced disease, including rapid ART initiation and screening and prophylaxis for opportunistic infections remains critical.

WEPED1417

Ten-year treatment outcomes of a cohort receiving comprehensive HIV care at Newlands Clinic, Zimbabwe (TENART cohort)

T. Shamu[1], C. Chimbetete[1], S. Shawarira-Bote[1], T. Mudzviti[1,2]
[1]Newlands Clinic, Research, Harare, Zimbabwe, [2]University of Zimbabwe, School of Pharmacy, Harare, Zimbabwe
Presenting author email: tineis@newlandsclinic.org.zw

Background: Data on long term outcomes of patients receiving antiretroviral therapy (ART) in resource limited settings are important but few, particularly in Sub-Saharan Africa. We describe 10 year outcomes of patients enrolled into the Newlands Clinic cohort between 2004 and 2006 and received comprehensive care including psycho-social and adherence support.
Methods: In this retrospective cohort study, data collected during routine care of patients were accessed from an electronic medical record using Microsoft SQL Server Studio 2012 and analysed using Stata version 12.1. We describe baseline characteristics, virological and clinical outcomes, attrition rates, and treatment adverse effects after 10 years from enrollment. We defined virological suppression as HIV viral load < 50 copies/ml and virological failure as >1000 copies/ml after ≥6 months of ART.
Results: Between 2004 and 2006, 605 patients were enrolled into comprehensive care and commenced on ART, 404 (67%) being female and 161 (27%) < 24 years old. Baseline characteristics are listed in Table 1.

Characteristic	Male n (%)	Female n (%)	Total n (%)
Study Participants	201 (33.2)	404 (66.8)	605 (100)
Baseline Age (years) - Median (IQR)	34 (12-40)	35 (27-42)	34 (17-42)
WHO Stage			
Stage 1	10 (5.0)	38 (9.4)	48 (8.0)
Stage 2	55 (27.4)	113 (28.0)	168 (27.8)
Stage 3	107 (53.2)	191 (47.4)	298 (49.3)
Stage 4	29 (14.3)	61 (15.1)	90 (14.9)
Baseline CD4 Count - Median (IQR)	114 (47-200)	131 (63-211)	121 (57-195)

[Baseline demographic and clinical charact]

Patients were followed up for 5823 person-years (median:10.7 years, IQR:10.1-11.4). At enrollment, 129 (21.3%) patients had a history of pulmonary tuberculosis (PTB) and 66 (11%) developed PTB, and 24 (4%) developed extrapulmonary tuberculosis while in care. During follow up, 385 (63.6%) patients experienced ≥1 treatment adverse event, the most frequent being stavudine-induced peripheral sensory polyneurophathy (n=252, 41.7%). After a median ART duration of 10.8 years (IQR:10.5-11.6), 474 (78.3%) patients were still in care, 428 (90.3%) being virologically suppressed, and 21 (4.4%) virologically failing. While 483 (79.8%) remained on first line, 122, (20.2%) were switched to second line ART. Fifty-nine patients (9.8%) were transferred to other ART facilities, 45 (7.4%) were lost to follow up, 25 (4.1%) died, and two stopped ART.
Conclusions: Comprehensive HIV care can result in low mortality, high rates of retention in care and virologic suppression in resource limited settings.

WEPED1418

Adherence to antiretrovirals in Medicaid-insured patients living with HIV: predictors and economic consequences

K. Dunn[1], M.-H. Lafeuille[2], X. Jiao[1], H. Romdhani[2], B. Emond[2], K. Woodruff[1], J. Pesa[1], N. Tandon[1], P. Lefebvre[2]
[1]Janssen Scientific Affairs, LLC, Titusville, United States, [2]Groupe d'analyse, Ltée, Montréal, Canada
Presenting author email: kdunn1@its.jnj.com

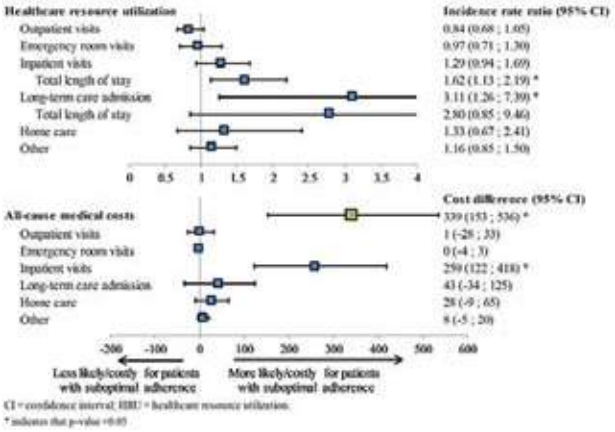
Background: Adherence to antiretrovirals (ARVs) is critical to achieving durable virologic suppression and preventing drug resistance. This study assessed predictors of adherence in Medicaid beneficiaries living with HIV initiating ARVs, and compared healthcare resource utilization (HRU) and costs between patients with suboptimal and optimal adherence.
Methods: Multi-state Medicaid administrative data (05/2012-03/2015) was used to identify adults with HIV-1 who initiated commonly used ARV regimens (index date) and had ≥6 months of observation pre- and post-index. Adherence was measured using proportion of days covered (PDC). A multivariable logistic regression was used to assess risk factors of poor adherence (PDC< 80%) at 6 months post-index. HRU and costs were compared between patients with suboptimal (80%≤PDC< 95%) and optimal (PDC≥95%) adherence using Poisson and ordinary least square models, respectively, and inverse probability of treatment weighting to control for confounding.

Results: Among the 2,683 patients included, 51% had poor, 19% suboptimal, and 30% optimal adherence. Younger age, non-capitated or dual Medicaid/Medicare insurance coverage, no prior ARV treatment, and asymptomatic HIV were associated with higher risk of poor adherence (Table 1). Patients with suboptimal adherence had longer hospital stays, more long-term care admissions, and higher medical costs compared to patients with optimal adherence (Figure 1).
Conclusions: Suboptimal adherence was associated with higher HRU and costs compared with optimal adherence. Poor adherence to ARVs was observed in over half of Medicaid patients. The risk of patients being poorly or suboptimally adherent should be a consideration when selecting an ARV regimen.

Risk factor	Odds ratio (95% CI)	*P*-value**
Age 18-29 (vs ≥50)	1.58 (1.19 ; 2.11)	0.002
Non capitated insurance coverage	1.40 (1.16 ; 1.69)	<0.001
Dual Medicaid and Medicare coverage	5.98 (4.39 ; 8.16)	<0.001
No prior ARV medication use at baseline	1.98 (1.62 ; 2.41)	<0.001
Asymptomatic HIV	1.37 (1.13 ; 1.68)	0.002

ARV = antiretroviral; CI = confidence interval; PDC = proportion of days covered.
*PDC at 6 months was defined as the sum of non-overlapping days of supply of any ARV during a fixed period of time post-index date (i.e., 180 days) divided by the length of the period (i.e., 180 days).
** Only factors with a p-value<0.05 were presented. Other predictors in the multivariable logistic regression model included: gender, race, state, urbanicity, year of index date, Quan-Charlson comorbidity index, specific baseline comorbidities (chronic pulmonary disease, diabetes, hypertension, psychoses, substance-related and addictive disorders, and any other mental comorbidity except substance-related and addictive disorders).

[Table 1. Risk factors of poor adherence to ARVs (PDC <80% at 6 months)]*



[Figure 1. Comparison of monthly HRU and costs during the observation period between patients with suboptimal (80%≤PDC<95%; N=652) vs. optimal adherence (PDC≥95%; N=661)]

WEPED1419

Changes in antiretroviral therapy (ART) and maximal viral suppression over time by age, sex, race/ethnicity, and HIV risk among HIV-infected patients in an integrated health system in the United States

M. Horberg[1,2], J. Blank[1,2], K. Rubenstein[2], P. Kadlecik[3], L. Hurley[4,5], M. Silverberg[4,5]
[1]Kaiser Permanente, HIV Initiative, Rockville, United States, [2]Kaiser Permanente, Mid-Atlantic Permanente Research Institute, Rockville, United States, [3]Mid-Atlantic Permanente Medical Group, Infectious Diseases, Washington, United States, [4]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [5]Kaiser Permanente, HIV Initiative, Oakland, United States
Presenting author email: michael.horberg@kp.org

Background: ART prescription and viral suppression vary by age, gender, race/ethnicity, and HIV risk, even in integrated health systems such as Kaiser Permanente Mid-Atlantic States (KPMAS), which has pharmacy financial assistance available and equal access to care. KPMAS implemented physician reports to address these disparities and program-wide emphasis (including physician conferences, patient outreach) on reducing these disparities. We sought to determine if we had reduced such disparities.
Methods: Retrospective cohort analysis of adult (≥18 years) HIV-infected patients receiving care in KPMAS during 2014-2016. The primary outcomes evaluated were ART use (≥2 fills of ART in year) and HIV RNA as maximally suppressed ("BLQ", defined as HIV RNA< 200/mL at last measure of year; if not performed then not BLQ). We computed percentages achieving BLQ by age group, sex, race/ethnicity, and HIV risk for each calendar year (see Table). Odds ratios (OR) were obtained from a logistic model using GEE, adjusting for the patient demographics in Table 1b.
Results: Higher percentages achieving BLQ were observed for age group 50-64, Whites, and men having sex with men (MSM) (see Table 1a). While Blacks had improving odds of BLQ each year, Blacks have persistently lower odds of BLQ or ART compared with Whites. Asians had the lowest odds BLQ compared with Whites. As for age, 30-49 and 50-64 had improving likelihood of ART each year but all ages had lower odds BLQ compared with 65+. Conversely, women had persistently lower odds of ART than men, but no significant difference in BLQ. There were no significance differences in ART or BLQ where risk group was known.

Table 1a	Raw Data: N of Subpopulations and % BLQ					
	2014		2015		2016	
	Number patients	% BLQ	Number patients	% BLQ	Number patients	% BLQ

IV Drug User	243	76.5%	280	72.9%	313	83.7%

Table 1b	Odds Ratio (95% CI) of BLQ and ART Compared with Reference Group 2014 and within Subpopulation Change over Time*			
	BLQ to Reference	BLQ Over Time	ART to Reference	ART Over Time
Age: 65+	Reference			
18 - 29	0.54 (0.44, 0.67)	1.05 (0.83, 1.32)	0.63 (0.40, 1.00)	1.27 (0.97, 1.65)
30 - 49	0.56 (0.41, 0.77)	1.02 (0.84, 1.24)	0.71 (0.48, 1.05)	1.34 (1.08, 1.67)
50 - 64	0.72 (0.54, 0.95)	1.01 (0.82, 1.23)	0.91 (0.62, 1.33)	1.30 (1.05, 1.62)
Sex: Male	Reference			
Female	0.99 (0.83, 1.19)	0.99 (0.88, 1.11)	0.76 (0.62, 0.92)	1.03 (0.92, 1.15)
Race/Ethnicity: White	Reference			
Asian	0.15 (0.08, 0.29)	1.21 (0.94, 1.57)	0.71 (0.35, 1.44)	0.80 (0.59, 1.10)
Black	0.41 (0.30, 0.56)	1.26 (1.06, 1.49)	0.57 (0.44, 0.73)	1.17 (0.99, 1.39)
Hispanic	0.92 (0.50, 1.69)	0.94 (0.67, 1.30)	0.70 (0.45, 1.09)	0.98 (0.71, 1.36)
Risk: MSM	Reference			
Heterosexual	0.87 (0.74, 1.02)	1.01 (0.89, 1.16)	1.02 (0.82, 1.27)	1.13 (0.99, 1.30)
IV Drug User	0.92 (0.75, 1.13)	1.20 (1.00, 1.45)	0.86 (0.66, 1.11)	1.17 (0.96, 1.42)

*--Main effects from models including only significant interaction terms ($p < 0.05$) are shown.

[Table 1a and 1b]

Conclusions: While we see improvement in ART and BLQ over time, particularly among Blacks, many groups still fall short compared with reference populations, and some other populations had declines over time. Novel efforts to improve ART prescription and viral suppression are needed.

WEPED1420

Implementation of point-of-care (POC) HIV viral load (VL) monitoring during antenatal care at a primary care clinic in Cape Town, South Africa

L. Dunning[1,2], L. Ndlovu[1,2], N.-Y. Hsiao[3], L. Myer[1,2]
[1]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [3]National Health Laboratory Services & University of Cape Town, Division of Medical Virology, Cape Town, South Africa
Presenting author email: ldunning@mgh.harvard.edu

Background: POC VL testing could increase access to virologic monitoring and help improve viral suppression on antiretroviral therapy (ART). However, limited data is available on the use of POC VL monitoring during pregnancy, implementation challenges in field settings and the acceptability of the device to patients.
Methods: We conducted an implementation science study using the Alere q POC device (input 25µL whole blood; results available in approximately 55 minutes) at a large public sector primary care facility. POC VL testing was conducted for pregnant women initiating ART or requiring routine VL monitoring. As part of the implementation, possible benefits of receiving a POC result were explained to patients; POC results were returned if patients chose to wait. Analysis examined the rate of errors and successful result-return, acceptability to patients and impact of POC VL monitoring on patients' HIV knowledge (determined using a standardized 8-item scale).
Results: Overall 356 tests were completed between January-November 2016. POC tests were completed as a baseline assessment of VL for 103 women initiating ART and in addition to laboratory-based testing for 253 women undergoing a routine VL. Error results were displayed for 5% of tests (n=18) and 3 machine breakdowns occurred meaning 43 eligible participants did not receive a POC test. POC results were returned to 78% of women; rates of result return did not vary by

age, VL result, time on ART, education, mode of transport, gravidity or time of diagnosis. HIV knowledge improved for 62% of women who received a baseline POC (mean score 5.4 vs 6.1, p=0.005) and was significantly higher at time of VL testing than those who did not receive a baseline POC test (mean score; 5.6 p=0.007).
Conclusions: POC VL monitoring appears feasible in a busy primary care, resource limited setting. Most women who received a POC test waited for their result, allowing healthcare providers to act immediately during a high-risk window for mother-to-child transmission of HIV. POC VL testing during pregnancy has potential to improve adherence but further research is required to facilitate the adoption of this technology in low-resource settings.

WEPED1421

Low level of virological success in decentralized HIV care sites in Cameroon

F. Taieb[1], A. Gonzales-Antalo[2,3], N. Lamarre[4], A. Aghokeng[4,5], A. Boupda[6], E. Delaporte[7], A.-C. Bissek[8], C. Kouanfack[9], Y. Madec[10]
[1]Institut Pasteur, Centre for Translational Science, Paris, France, [2]Insitut Pasteur, Emerginng Diseases Epidemiology Unit, Paris, France, [3]Universidad de Santiago de Compostela, Barcelona, Spain, [4]CREMER/IMPM/IRD, Virology Laboratory, Yaoundé, Cameroon, [5]Institut de Recherche pour le Développement, TransVIHMI, Montpellier, France, [6]Care and Health Program, Yaoundé, Cameroon, [7]Institut de Recherche pour le Développement, TransVIHMI Unit, Montpellier, France, [8]Ministry of Public Health, Operational Health Research Department, Yaoundé, Cameroon, [9]Central Hospital of Yaoundé, Infectious Disease Department, Yaoundé, Cameroon, [10]Institut Pasteur, Emerging Diseases Epidemiology Unit, Paris, France
Presenting author email: fabien.taieb@pasteur.fr

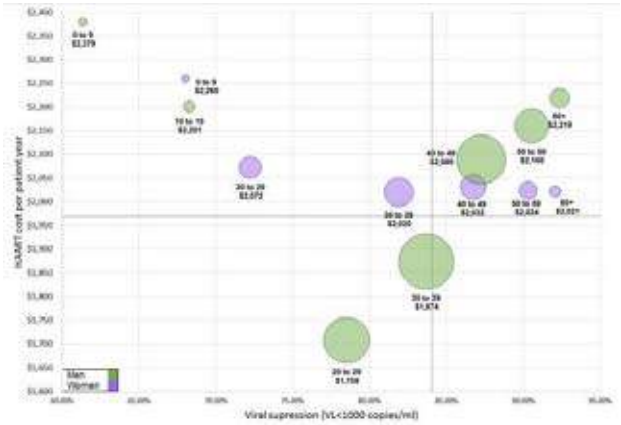
Background: In many resource-limited countries, access to viral load (VL) monitoring remains scarce due to the difficulty to access a laboratory able to perform VL measurements, and patients followed in decentralized area have even more limited access. The goal of this study was to evaluate the rate of virological success at 12, 24 and 36 months of ART in patients followed in decentralized area in Cameroon.
Methods: Cross-sectional evaluation of patients on first line ART followed in 12 decentralized HIV care sites in three regions of Cameroon (East, North-West and Centre), 12 (11-15), 24 (23-27), and 36 (35-39) months of ART initiation. All patients contributed to two dried blood spot cards transferred to the IRD-CREMER laboratory in Yaoundé (Cameroon) for VL measurement and HIV drug resistance genotyping in patients with VL >1000 cp/mL.
Results: From September 2015 to June 2016, 398, 339 and 204 patients were virologicaly evaluated at 12, 24 and 36 months of ART, respectively. Overall, 72.9% of them were women, this proportion did not differ by evaluation month (p=0.22). Median age at ART initiation was 40 years, and constant across evaluation month (p=0.40). Median CD4 level at ART initiation was 200 cells/mm3, and did not differ by evaluation month (p=0.26).
At the threshold of 1000 cp/mL, the proportion of patient sin virological success was 67.3%, 63.0% and 59.8% at 12, 24 and 36 months of ART, respectively. At all evaluation month, patients who missed no clinical visit planned in the national protocol had a significantly higher risk of virological success. Only at 12 months was another factor associated with virological success; shorter distance between home and hospital was significantly associated with higher chance of virological success. HIV drug resistance is undergoing.
Conclusions: In this cross-sectional evaluation, the proportion of patients in virological success was lower than the standards expected by the WHO. This low rate of virological success is worrisome. Strong efforts must be made so that patients adhere to clinical care. The result from HIV drug resistance genotyping will indicate whether the low level of virological success is due to lack of adherence to ART, or to ART failure.

WEPED1422

How much does it cost to achieve HIV viral suppression?

M. Valenzuela-Lara, E. León Juárez, E. Becerril Vargas, C. Magis-Rodriguez
Centro Nacional para la Prevención y el Control del VIH y el Sida, Dirección de Atención Integral, Mexico, Mexico
Presenting author email: marisol.censida@gmail.com

Background: 66% of PLWH on HAART in Mexico receives care through the Mexican Social Protection System in Health which includes ARV access. We wanted to estimate the cost-effectiveness of State HIV Programs.
Methods: Cross-sectional analysis of 78,624 PLWH treated in 32 Mexican states on January 1, 2017 and registered at the national database ‚SALVAR'. We estimated annual HAART cost per patient using ARV prices negotiated by the Mexican government and the recorded therapy. Effectiveness was defined as the percent of PLWH with a last viral load < 1000 copies/mL in the last year.
Results: The mean cost per patient-year across the 32 states was $1,973 ppy (min-max $1,774 - $2,208 ppy) and 83.8% viral suppression (min-max 74 - 91%). Significant differences of up to 17% were found in the percentage of viral suppression between State HIV Programs with similar costs. We found a significant $108 ppy difference (p<0.05) between men and women, and a positive correlation between the cost of treatment and age, as well as time in treatment (p<0.05). Lowest regimen costs were observed at 20 to 29 age group ($1,776) especially in men.



[Mean cost PPY & viral supression by age & sex]

The difference in the mean cost of the regimens without efavirenz vs. with efavirenz was $1,095 ppy higher. The cost ppy at Hospitals was significantly higher ($133; p<0.05; 95%CI 110.59-156-40) than in HIV clinics. Nevertheless, HIV Clinics viral suppression was 2.9% higher (p<0.05; 95%CI 2.21-3.62). Median time at HAART was 0.57 years higher at Hospitals than HIV Clinics (p<0.05), and 0.65 higher in women than men (p<0.05).
Conclusions: It is possible to achieve higher viral suppression rates at a lower cost, with potential savings of up to $ 2 millions. It´s important to take into consideration the time in treatment and ageing of the epidemic.

Presenting author email: andrew.x.murungi@viivhealthcare.com

Background: While treatment advances have dramatically improved the life-expectancy of people living with HIV (PLHIV), a number of important needs remain. We conducted an international survey of PLHIV to explore the impact of living with an HIV diagnosis on outlook and aspirations; rate the impact and sources of emotional support at diagnosis compared to today and assess the extent of disclosure.
Methods: Qualitative in-depth interviews were performed with PLHIV & partners to identify key hypotheses. A steering group developed the study questions which was fielded online from November 2016 to March 2017 in nine countries. A mixed sampling/recruitment approach was used to ensure a broad cross-section of PLHIV. Respondents were screened via telephone interview prior to accessing to the online survey instrument.
Results: As of January 2017, 819 PLHIV had been recruited. 20% were women, 32% age ≥ 50 years, 11% recently diagnosed, ≥ 80% reporting > 1 co-morbidity. 90% believe their quality of life will improve with advances in treatment though 26% tend not to plan too far ahead into the future because of their status. At time of diagnosis, 26% did not receive any emotional support/guidance from their health care provider (HCP) with 48% seeking support from a close friend. In the last 12 months, 75% continued to experience some level of stigmatisation with social (20%) & self-stigma (28%) very/quite often reported. 63% believe that improved education of the general public would help with this while 25% feel that better training of physicians, nurses and other HCPs would reduce stigma in the healthcare setting. 93% have disclosed their status to their primary care doctor with main drivers being the acknowledged need to keep them fully informed and avoiding drug-drug interactions.

Conclusions: In this large international survey, PLHIV believe that advances in treatment will improve their quality of life. Support from HCPs at time of diagnosis is not always provided. Widespread stigma is still experienced with education of public and HCPs seen as potential remedies.

WEPED1424

Explorative data analysis to assess the Decentralized Pharmacovigilance System's potential to monitor adverse drug reactions in South Africa's HIV treatment programme

M. Dheda[1,2], H. Kambafwile[1], M. Moorhouse[3], W. Plummer[1], H. Mukudu[4], F. Oosthuizen[2], Y. Pillay[5]
[1]Pharmacovigilance Centre for Public Health Programmes, National Department of Health, Pretoria, South Africa, [2]University of KwaZulu Natal, School of Health Science, Durban, South Africa, [3]University of Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [4]University of Witwatersrand, School of Public Health, Johannesburg, South Africa, [5]National Department of Health, Pretoria, South Africa
Presenting author email: mukesh.dheda@gmail.com

Background: A robust pharmacovigilance programme is indispensable in South Africa for its massive antiretroviral public health treatment programme, which is the largest globally. It plays a key role in the healthcare system through discovery, assessment, monitoring and prevention of adverse drug reactions, toxicities and interactions amongst drugs and their effects on those receiving treatment. This study undertakes an explorative analysis of Adverse Drug Reactions (ADR) data related to antiretroviral HIV treatment that was entered into the Decentralized Pharmacovigilance System between 01 May 2013 and 31 March 2016.
Methods: Data were retrospectively analysed from anonymised suspected adverse drug reaction reports submitted by healthcare professionals from the ART programme in South Africa. A descriptive quantitative analysis of relations between ADR, SOC, and antiretroviral drug by age and sex of person receiving ART was conducted. These included the most suspected ADR-causing medicines, System Organ Class (SOC) involved and drugs responsible for the adverse events in each SOC. These were further disaggregated by age and sex.
Results: Reports (5063) received from the ART programme were assessed, analysed and reviewed.
Of all analysed ADR cases (5063), Stavudine was the main antiretroviral responsible for ADR (30%), followed by Tenofovir (20%). Nevirapine accounted for 3% of all reported ADRs. Females (79%) reported a significantly higher percentage of ADRs to nevirapine than males (18%). ADRs from the various age groups correlate well with the percentage on treatment. The most common SOCs found in relation to reported ADRs were metabolic and nutrition disorder (19%) and nervous system disorders (10%). The programme found low numbers of ADRs with cardiac disorder (0.1%) and endocrine disorder (0.2%) SOCs.
Conclusions: This analysis was the first comprehensive exploration of this data set. The exploration of the data set shows the wealth of data collected and the potential that the decentralised pharmacovigilance programme has for the monitoring and evaluation of drug safety in South Africa´s treatment programme. It is therefore crucial to ensure that HCP enter data correctly, that quantitative and qualitative ADR data is analysed regularly and that those findings are systematically used to inform South Africa´s treatment programmes.

WEPED1425

Perceptions on co-morbidities and research participation in HIV-positive individuals

M. Hlatshwayo, D. Gerke, W. Powderly, R. Presti
Washington University School of Medicine, Infectious Diseases, St. Louis, United States
Presenting author email: mhlatshwayo@wustl.edu

Background: Treatment with ART has significantly reduced morbidity and mortality among persons living with HIV (PLWH). It is critical to educate this population on potential co-morbidities, and alert them to available research focused on disease management and cure. Although previous studies have explored perceptions regarding risk of acquiring HIV, little is known about what HIV-infected individuals understand about diseases that are more prevalent with HIV, or their willingness to participate in research.
Methods: We conducted a cross-sectional survey of 106 consecutive PLWH from the Washington University Infectious Diseases Clinic. Questions covered potential co-morbidities, and attitudes towards HIV-related research specifically exploring their perception of cure research, medication safety, tolerable side effects, and willingness to participate in research.
Results: Study participant were mostly Black (66%) and male (71%). The majority of participants had at least high school education (86%), and almost all participants reported currently taking ART. Depression was the most common comorbidity believed to be more prevalent among PLWH (72.3%). Malignancy was also recognized as being common, with half of participants correctly reporting high risk of lymphoma (49%) and anal cancer (46%), although 39% incorrectly report higher risk of colon cancer among PLWH. The majority (98%) of participants reported that HIV-related research has improved the lives of people who have HIV, with high expectations for finding a cure. Only 12% believed a cure would never be found, and 31% recognized that one patient has already been cured. High rates of interest in research were noted, with 49% being very interested in participating in cure research even without direct benefit. Two thirds of patients were willing to undergo side effects to potentially cure HIV, with 13% willing to risk severe side effects including death for a chance for cure. Cure research is a priority to many patients, although they are less likely to prioritize participation the longer they are infected with HIV, and if not Caucasian.
Conclusions: Perceptions of long term comorbidities associated with HIV infection are not completely accurate, indicating a need for continuing education in this aging population. Research is viewed favorably, and PLWH are more willing to participate than had been expected.

WEPED1426

At what stage of disease progression are HIV-infected patients initiated on antiretroviral therapy? A retrospective cross-sectional analysis of patients initiated on ART in Masvingo District, Zimbabwe

M. Deda[1], K. Webb[2], V. Chitiyo[2], T. Maphosa[1], P. Nesara[1], S. Page-Mtongwiza[1], B. Engelsmann[1]
[1]Organisation for Public Health Interventions and Development, Operational Research, Harare, Zimbabwe, [2]Organisation for Public Health Interventions and Development, Knowledge Management and Impact Analysis, Harare, Zimbabwe
Presenting author email: vchitiyo@ophid.co.zw

Background: The 2013 Zimbabwe National ART guidelines expanded ART eligibility from a CD4 count of 350 to ≤500 cells/µl. Limited evidence has documented stage of disease severity at which ART naïve persons are initiated following implementation of the guidelines. Our objective was to describe the demographic, clinical and immunologic characteristics of adult HIV positive people newly initiated on ART.
Methods: A retrospective cross-sectional assessment was conducted using data from 325 non-pregnant adults (≥15 years) initiated on ART from January to June 2016 at 7 high volume priority public health facilities in Masvingo District. Demographic, baseline CD4 count and WHO staging data at initiation were abstracted from the ART-registers. The Mann-Whitney U test was used to compare baseline CD4 cell counts between different age groups and sex. Logistic regression was used to identify patient and institutional factors associated with initiating ART with advanced disease (CD4 cell count< 200 cells/µl).
Results: Out of the 325 people initiated on ART (Jan-Jun 2016), 289 (6%:15-24, 82%:25-49 and 12% ≥50 years; Females:51%) initiated ART with a median CD4 cell count of 237 cells/µl (IQR:107-402 cells/µl). Younger adults (15-24 years) had a higher baseline CD4 cell count (median= 372 cells/µl, IQR:311-505 cells/µl) at initiation compared to older adults (25-49 years) (median=238 cells/µl, IQR:107-401 cells/µl, p=0.005), and the elderly (≥50 years) (median=161 cells/µl, IQR:87-357 cells/µl, p=0.003). There was no significant difference in CD4 cell count between males and females. One hundred and twenty (40.5%) people initiated ART with advanced HIV disease. Factors associated with higher odds of initiating with advanced disease were initiating ART at an urban health facility [adjusted odds ratio (AOR = 1.09; 95% CI:1.09-3.17) and older age ($AOR_{50+ vs15-24}$=7.87; 95% CI: 1.88-32.95).
Conclusions: Three years following the expansion of the ART eligibility criteria, the majority of adults initiate ART at low CD4 cell counts below the previous threshold. Elderly people and urban dwellers are at increased odds of starting ART with advanced disease. Our findings, particularly relevant as many low resource countries transition to Test and Treat, underscoring the importance of increasing demand for timely uptake of HIV testing and treatment services to optimise treatment outcomes.

HIV community viral load as an additional tool to monitor effectiveness of treatment and prevention in Eastern European programs

A. Chuykov[1], A. Zakowicz[2], A. Davies[2], Z. Shabarova[2], I. Shumilova[1], G. Tyapkin[3]
[1]AIDS Healthcare Foundation, Europe Bureau / Russia Branch, St Petersburg, Russian Federation, [2]AIDS Healthcare Foundation, Europe Bureau, Amsterdam, Netherlands, [3]AIDS Healthcare Foundation, Europe Bureau / Ukraine Branch, Kiev, Ukraine
Presenting author email: anna.zakowicz@aidshealth.org

Background: Community viral load (CVL) has been proposed as a useful measure to monitor HIV treatment effectiveness and quantify its influence on transmission rates. First reports on CVL were published in 2009; however, until now there have been no publications on CVL from Eastern Europe. This evaluation is the first of an ongoing monitoring process of CVL.
Methods: We analyzed electronic medical records of 22417 patients from 20 clinical sites in Russia, 23050 patients from 23 clinical sites in Ukraine and 226 patients from Linda Clinic in Estonia. All data have been taken from databases created and maintained by AHF. CVL was defined as the average mean of the most recent viral loads of all HIV-positive individuals who were under care in all AHF-supported clinical programs in Russia, Estonia and Ukraine for the 12-month period starting from December 1st 2015 until November 30th 2016. CVL has been calculated for each geographical location and country in general.
Results: Coverage of patients in care on ARV's in Russia, Ukraine and Estonia were 63%, 84% and 88% respectively. Within this coverage, 50% of patients in Russia were virally suppressed, 42% in Ukraine, and 40% in Estonia. 88% of patients in Russia, 81% of patients in Ukraine and 98% of patients in Estonia had at least one of viral load test performed in the above-mentioned period. Average CVL in Russia was 61 223 copies/ml, with a minimum of 7699 copies/ml in the clinical program in Chelyabinsk and maximum of 146722 copies/ml in Vsevolozhsk (Leningrad Oblast). Average CVL in Ukraine was 28793 copies/ml, with a minimum of 5127 in Kherson Regional AIDS Center and maximum of 66702 copies in Ternovka (Dnepropetrovsk region). Average CVL in Estonia is was 26501 copies/ml.
Conclusions: The results reflect current situation with HIV prevention and treatment in our programs in Russia, Estonia and Ukraine. These results will serve as a baseline for evaluation of effectiveness of HIV prevention and treatment interventions in communities in Eastern Europe. We will continue to measure CVL in 6 month intervals for further analysis and present the results.

WEPED1428

Self-reported antiretroviral use in rural South Africa: a validation study

J. Manne-Goehler[1], J. Rohr[2], L. Montana[2], F.X. Gómez-Olivé[3], P. Geldsetzer[4], K. Kahn[3], T. Bärnighausen[5]
[1]Harvard T H Chan School of Public Health, Global Health & Population, Boston, United States, [2]Harvard University, Cambridge, United States, [3]Medical Research Council/Wits Rural Public Health & Health Transitions Research Unit, Johannesburg, South Africa, [4]Harvard T H Chan School of Public Health, Boston, United States, [5]University of Heidelberg Institute of Public Health, Heidelberg, Germany
Presenting author email: jmanne@post.harvard.edu

Background: Accurate estimates of antiretroviral therapy (ART) coverage among HIV-positive individuals are critical for policy planning and program implementation. However, few studies have been able to validate self-reported ART use (SR-ART) with data on biological exposure to ART (BE-ART). We conduct a validation study of SR-ART use among aging HIV-positive adults in South Africa.
Methods: The Health and Aging in Africa: Longitudinal Studies of an INDEPTH community in South Africa (HAALSI) Study is a cohort of adults aged 40 and above in Agincourt, South Africa. The baseline survey was conducted in 2014-2015 and includes socio-demographic data, self-reported HIV status and ART use. All participants underwent HIV antibody and viral load testing. HIV-positive participants by antibody also underwent dried blood spot testing for emtricitabine (FTC) and lamivudine (3TC), two medications that have been included in all first- and second-line ART regimens nationally. We use this information to determine the sensitivity and specificity of self-reported ART use overall and stratified by age and sex. We also calculate and graph the positive predictive value (PPV) and negative predictive value (NPV) by the prevalence of ART use. Finally, we use multivariable regression to determine any associations between accurate SR-ART use and demographic characteristics.
Results: The HAALSI cohort includes 1,048 (23%) HIV-positive participants, among whom 662 (64%) were positive for at least one of the two ART medications included in the BE-ART testing. In the BE-ART group, 450 (68%) self-reported ever accessing an ART program. The sensitivity of SR-ART use was thus 68% (95% CI: 64-72%) and the specificity 87% (95% CI: 83-90%); the PPV was 90% (95% CI: 87-93) and NPV 61% (95% CI: 56-65). The associated Figure 1 shows PPV and NPV over the full range of prevalence of ART use. Accurate SR-ART use was not associated with age, gender, educational attainment or wealth in regression analyses.
Conclusions: Many people on ART will accurately self-report their ART use. Thus, SR-ART is a useful approximation of actual ART use in the absence of biological exposure data and can be used to assess ART uptake and inform program planning.

Refusal to provide healthcare to sub-Saharan African migrants living in the Paris region: a comparison according to their HIV and HBV status

N. Vignier[1], P. Chauvin[2], J. Pannetier[3], A. Ravalihasy[3], F. Lert[4], N. Lydié[5], O. Bouchaud[6], A. Desgrées du Loû[3], R. Dray Spira[2], The ANRS PARCOURS Study Group
[1]Pierre Louis Institute of Epidemiology and Public Health (UMRS 1136, Inserm - Sorbonne Universités UPMC), Department of Social Epidemiology, Bois le Roi, France, [2]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Department of Social Epidemiology, Paris, France, [3]IRD, CEPED, Paris, France, [4]INSERM, CESP, Villejuif, France, [5]Santé Publique France, Paris, France, [6]Université Paris 13, Bobigny, France
Presenting author email: vigniernicolas@yahoo.fr

Background: Refusal to provide care has recently emerged as a preoccupation in France. Different situation surveys have demonstrated that two categories of patients were frequently denied: those infected by the HIV and/or the poorest (whose insurance status force professionals to ask them flat care fees). We aim to compare the frequency of reported denial of care in sub-Saharan African migrants living in the Paris region, according to their HIV and HBV status.
Methods: The ANRS PARCOURS is a life-event survey conducted in 2012-2013 in health-care facilities in the Paris region, among three groups of sub-Saharan migrants recruited in primary care centres (N=763; reference group), in dedicated centres for HIV care (N=923) and in centres for chronic hepatitis B care (N=778). The participants were questioned about their experiences of refusal of health care since their arrival in France.
Results: In the reference group, 6% reported denied health care (3% by a general practitioner, 1% in a hospital and 3% in a pharmacy). This proportion was twice as high in migrants living with HIV (12%; 6% by a general practitioner, 3% in a hospital and 5% in a pharmacy) and in migrants living with chronic HBV (10%; 5% by a general practitioner, 3% in a hospital and 6% in a pharmacy, p< 0.001).
The main reason for denial of care was their health insurance status (either for the poor or for the undocumented migrants) (40%, 30% and 52% of refusal for reference, HIV and HBV group respectively), followed by the HIV status (in 29% of cases for the HIV group). Other reasons concerned other health insurance problems, lack of financial resources or problems with supporting documents.
Conclusions: Our results show that public specific health insurance plans for poor people and for undocumented migrants, as well as infection by HIV, may lead to refusals of care in sub-Saharan African migrants in France.

WEPED1430

Continuation of HIV care postpartum among Zimbabwean mothers following implementation of option A

M.-S. Kang Dufour[1], S.I. McCoy[2], R. Buzdugan[3], C. Watadzaushe[4], J. Dirawo[4], A. Mushavi[5], F. Cowan[4,6], N.S. Padian[2]
[1]University of California San Francisco, Division of Prevention Science, San Francisco, United States, [2]University of California, Berkeley, School of Public Health, Berkeley, United States, [3]University of California, Berkeley, Berkeley, United States, [4]Centre for Sexual Health, HIV & AIDS Research, Harare, Zimbabwe, [5]Ministry of Health and Child Welfare, Harare, Zimbabwe, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom
Presenting author email: smccoy@berkeley.edu

Background: With the implementation of Option B+, understanding predictors of sustained engagement in HIV care postpartum is critical. Continuation of HIV treatment during breastfeeding is key is of particular importance as 5 to 20% of infections are estimated to occur then. Support of male partners may also be key to continued engagement in care following birth.
Methods: In 2014 we conducted a community-based serosurvey of mother-infant pairs residing in the catchment areas of 157 health facilities randomly selected from 5 provinces in Zimbabwe. Eligible mothers were ≥16 years old and had infants born 9-18 months before the survey. We collected questionnaires, blood samples, and verbal autopsies. We estimated the proportion of mothers who were receiving HIV treatment following pregnancy and predictors of remaining on anti-retroviral medications (ARVs) through the postpartum period.

Results: We enrolled 9619 mother-infant pairs with maternal HIV test results, of whom 1176 (12.2%) were HIV-infected. Among HIV-infected mothers, 34.3% reported testing HIV-positive prior to their pregnancy and 32.2% had taken ARVs prior to pregnancy. Overall, 69% of HIV positive mothers reported ARV use during the pregnancy and 66.4% reported ARV use at 9-18 months postpartum. Among the subset of mothers who reported taking HIV medication prior to pregnancy, 99.2% reported taking ARVs postpartum. Among those who had taken medication prior to, or during pregnancy, 95.0% of those who were still breastfeeding reported current ARV use, compared to 86.3% among those who were no longer breastfeeding. In logistic regression, continuing ARV use postpartum was associated with older age (OR 1.05 95%CI1.0, 1.11 per additional year), being on treatment prior to pregnancy (OR13.2 95%CI 4.0, 43.4) and current breastfeeding (OR 2.8 95% CI 1.5, 5.2) whereas women who had a husband/partner who was HIV infected and not receiving treatment were less likely to remain on treatment (OR 0.2 95%CI 0.07, 0.6).
Conclusions: These results indicate that although uptake of ARV during pregnancy is not complete, the majority of women in Zimbabwe who reported taking ARVs prior to or during pregnancy continue ARVs during breastfeeding. These data provide further compelling evidence of the importance of involving male partners in PMTCT programs.

WEPED1431

Estimating the number of HIV patients currently on antiretroviral therapy and others HIV care indicators in Chad: results from a prospective nationwide survey

C. Breye[1], R. Kariffene[1], J. Mad-Toingue[2], H. Belomal[3], Y. Miangotar[4], M. Abbas[5], J. Ndawinz[6]
[1]FOSAP, N'Djamena, Chad, [2]HGRN, N'Djamena, Chad, [3]PNLS, N'Djamena, Chad, [4]Université de N'Djamena, N'Djamena, Chad, [5]CNLS, N'Djamena, Chad, [6]SOLTHIS, Paris, France
Presenting author email: bchiackre@aol.com

Background: Effective monitoring, evaluation and planning of HIV care activities requires reliable health data. It was identified recurring weaknesses in reported data system in HIV facilities in Chad. These weaknesses negatively impacts the quality of data and leads to less-effective decision-making. To overcome these barriers, this study was carried out to evaluate multiple indicators of HIV care activities.
Methods: A prospective study was conducted in 84 of the 90 HIV facilities functioning in Chad during March to July 2016. Repeated data of HIV patients on ART attending HIV facilities during this period was collected. These data included sociodemographic, clinical and biological informations notified in the patient form at different visits. Statistical methods were used to estimate retention on ART care, number of patients regularly on ART, median CD4 evolution, and frequency of patient visits.
Results: During the study period, individual data for 34,142 ART patients were collected. Among them, 70.5% were women. At ART initiation, overall median age was 35 years (IQR:29-43) and median CD4 count was 266 cells/mm^3 (IQR:169-383). Median CD4 count at ART initiation increased from 209 cells/mm^3 before 2007 to 306 cells/mm^3 after 2013 among women and from 218 to 255 cells/mm^3 in the same period among man. About 30.0% of ART patients delayed medical consultation. In the past 12 months before the study period, the proportion of ART patients with at least one measure of CD4 cell count was 34.0% and the proportion with at least one viral load test was 0.2%. Survival analysis indicated that by July 2016, retention at 12 months on ART was 67.8 and 34.7%, respectively among adults and children. The average number of patients receiving ART in Chad at 31 July 2016 was estimated to 38,872 (95% CI:38,486-39,159).
Conclusions: This study provides accurate core indicators that will help HIV national programme to assess progress accomplished to track the HIV epidemic and to identified new strategies to overcome barriers to retention in HIV care.

WEPED1432

Predictors of survival, loss to follow-up among HIV-infected children on cART at Livingstone Central Hospital: 2005-2015

J.N. Mutanga[1,2], S. Mutembo[2,3], D. Sialondwe[1], C. Kanene[4], J. Chiyonga[3], R. Fubisha[1], C. Whalen[2]
[1]Livingstone Central Hospital, Pediatrics and Child Health, Livingstone, Zambia, [2]University of Georgia, Epidemiology and Biostatistics, Athens, United States, [3]Ministry of Health Zambia, Clinical Care, Choma, Zambia, [4]CDC, Zambia, Prevention, Choma, Zambia
Presenting author email: jane.mutanga@fulbrightmail.org

Background: In 2015, 61% of Zambian children in need of combination Antiretroviral therapy (cART) accessed the treatment which is a big increase from 33% in 2013. Despite this expanded ART coverage, there is paucity of information on effectiveness of pediatric cART programs in reducing morbidity and mortality. We aim to evaluate treatment outcomes among children commenced on cART at a dedicated pediatric center of excellence clinic at Livingstone Central Hospital (LCH), Zambia.
Methods: Using a retrospective cohort study design, we abstracted routinely collected clinical data from medical records of children enrolled in HIV care between 2005 and 2016. Our main and secondary outcomes are death and lost follow up respectively. We carried out descriptive analysis of the baseline characteristics and plotted Kaplan Meier to estimate survival distributions. We performed Cox Regression to assess predictors of mortality and loss to follow-up.
Results: A total of 1,100 children aged below 15 years enrolled in HIV at LCH from 2005 to 2016. 49% of these children were female and 53% had lost both parents. At least 18% of these children enrolled in care before their first birthday. The median age at cART initiation was 3.6 years (IQR;1.3-8.6) and the median duration on cART was 3.9 years IQR (1.2-6.5). 67 (6%) of the children died while in care and 150(13.6%) were lost to follow-up. The children who died were younger at baseline with median age of 6 months (IQR; 2 months to 6 years). The survival probability at 1 year was 0.95, at 2 years; 0.94, at 5 years; 0.93 and 0.89 after 11 years of follow-up. The probability of loss to follow-up was 0.92 at 1 year of follow-up, 0.90 after 2 years, 0.82 after 5 years and 0.70 after 11 years.
Conclusions: Attrition due to mortality was low after 11 years of follow up. Probability of loss to follow up decreases over time. These findings demonstrate that pediatric care is feasible in low resource settings. There is need to strengthen care within the first year of treatment.

145 National HIV treatment cascades compared by region, HIV prevalence, conflict and GDP

J. Levi[1], A. Pozniak[2], K. Heath[3], A. Hill[2]
[1]Imperial College London, London, United Kingdom, [2]Chelsea and Westminster Hospital, London, United Kingdom, [3]Oxford University, Oxford, United Kingdom
Presenting author email: jacob.levi11@imperial.ac.uk

Background: In 2014, UNAIDS and partners set the 90-90-90 targets. Reaching these targets may be more difficult in lower prevalence countries with ongoing military conflict or resource constraints. We assessed how close countries and regions are to reaching these targets, and analysed outcome predictors.
Methods: Country-level HIV treatment cascade data from 2010-2015 were extracted from national reports, published papers and the www.AIDSinfoOnline database and analysed. Weighted least squares regression was used to assess predictors of cascade achievement (diagnosis, ART coverage and viral suppression) by: region, HIV prevalence, Gross Domestic Product (GDP/capita) and the 2016 Global Peace Index, which measures societal safety, militarization and conflict.
Results: Data were available for 145 national cascades. The percentage of PLHIV diagnosed ranged from 90% (Sweden) to 3% (Madagascar), while ART coverage ranged from 83% (Sweden) to 2% (Madagascar) and viral suppression ranged from 79% (Sweden) to 4% (Pakistan). Regions with the lowest ART coverage rates were South East Asia & Pacific (36%), Eastern Europe & Central Asia (17%) and Middle East & North Africa (13%). Within Africa, countries with higher HIV prevalence had higher rates of ART coverage (p=0.002) and viral suppression (p=0.002) but not diagnosis (p=0.317). Outside Africa, countries with higher HIV prevalence had higher diagnosis rates, ART coverage and viral suppression (all p< 0.001). Countries with higher GDP/capita had higher ART coverage (all p< 0.001). Furthermore, countries with lower levels of peace (Global Peace Index) had lower ART coverage (p< 0.001). 7/11 countries with the lowest ART coverage had the highest conflict levels: South Sudan, Afghanistan, Somalia, Yemen, Sudan, Pakistan and Russia.

Region	Sample Size [PLHIV]	% of PLHIV Diagnosed [Range]	% of PLHIV On ART [Range]	% of PLHIV Virally Suppressed [Range]
Oceania	30,695 [3 countries]	85% [55%-86%]	65% [26%-68%]	62% [62%-62%]
Western Europe	687,720 [11 countries]	80% [75%-90%]	67% [44%-83%]	60% [40%-79%]
South America	1,301,200 [11 countries]	71% [39%-89%]	50% [29%-61%]	40% [12%-50%]
United States of America	1,201,100 [1 country]	86%	37%	30%
South East Asia & Pacific	4,696,578 [16 countries]	54% [23%-85%]	36% [7%-74%]	29% [5%-70%]
Sub-Saharan Africa	25,532,002 [37 countries]	59% [3%-87%]	42% [30%-69%]	29% [5%-70%]
Central America & Caribbean	615,320 [13 countries]	67% [62%-77%]	45% [30%-69%]	23% [10%-40%]
Eastern Europe & Central Asia	1,758,146 [14 countries]	55% [31%-87%]	17% [14%-44%]	13% [11%-37%]
Middle East & North Africa	654,340 [14 countries]	26% [11%-74%]	13% [3%-37%]	6% [4%-30%]

[Regional Data]

Conclusions: Only 1 country has reached the UNAIDS 90-90-90 targets, with three years left. Regions lagging behind should target resources to their cascade breakpoints. Difficulty meeting these targets is associated with lower GDP/capita, lower HIV prevalence and higher conflict levels.

WEPED1434

HIV care continuum outcomes: does Ethiopia meet the UNAIDS 90-90-90 targets?

H. Gesesew[1,2], P. Ward[2], K. Hajito[1], L. Mwanri[2]
[1]Jimma University, Epidemiology, Jimma, Ethiopia, [2]Flinders University, Public Health, Adelide, Australia
Presenting author email: hailushepi@gmail.com

Background: Ethiopia has pledged to the UNAIDS 90-90-90 framework in 2015. However, the progress towards achieving this target has never been assessed. We assessed HIV care continuum outcomes as surrogate markers for the 90-90-90 targets.
Methods: A retrospective cohort study was conducted over 12 years period. Complex surrogate makers were used to assessing the HIV care continuum outcomes, an overall proxy surrogate for UNAIDS targets. For measuring the UNAIDS diagnosis target, prevalence rate of early HIV diagnosis was considered as a surrogate marker. For the treatment target, number of people on ART, number of people who discontinued from ART or transferred out, and number of people who had fair or poor adherence were used as surrogate markers. For the viral suppression target, number of CD4 counts and/or WHO clinical stages were used to assess immunological, clinical and treatment successes and further show the viral suppression. Descriptive statistics was undertaken and estimated survival time was calculated using Kaplan-Meier.
Results: 8172 patients were enrolled for HIV care between June 2003 and March 2015. For the diagnosis target, the overall prevalence of early HIV diagnosis among patients on ART was 34.5% (females contributed to 35.7%) showing that 34.5% patients knew their status timely. For the treatment target, 5299 (64.8%) received ART and females accounted for 54.6%. For the virological suppression target 65.8% of patients had treatment successes, displaying that an estimated 65.8% of patients achieved the target.
Conclusions: The 35-65-66 performances of 90-90-90 targets of Ethiopia seem very far from achieving the target. This underscores the need for rigorous innovative methods, community distribution of ART, runaway packs during conflict, and use of GenXpert for HIV viral load testing would significantly help to hit the target.

WEPED1435

Uniquely identifying HIV cases: a comparison of deterministic and probabilistic matching for HIV case-based surveillance in the absence of a national unique persons' identifier in Kenya

A. Waruru[1], A. Natukunda[2], J. Odhiambo[3], E. Zielinski-Gutierrez[4], W. Waruiru[2], T. Kellog[2], K. Masamaro[4], D. Kwaro[5], J. Kwach[4], P. Young[4]
[1]Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB (DGHT), Nairobi, Kenya, [2]Global Programs for Research and Training, University of California San-Francisco, Nairobi, Kenya, [3]National AIDS and STI Control Program (NASCOP), Nairobi, Kenya, [4]Centers for Disease Control and Prevention, Division of Global HIV and TB (DGHT), Nairobi, Kenya, [5]Kenya Medical Research Institute, Kisumu, Kenya
Presenting author email: awaruru@cdc.gov

Background: In Sub-Saharan Africa, HIV case-based surveillance (CBS) has not been widely implemented, yet it is recommended for 2nd generation HIV surveillance. CBS is important for monitoring HIV treatment cascade including the UNAIDS Fast-Track 90-90-90 targets through individual tracking of HIV cases to understand who is getting diagnosed, linked to HIV care, accessing treatment; virally suppressed, dead, or lost-to-follow-up. In the absence of a national unique persons' identifier (NUPI), record linking and de-duplication of cases in surveillance systems may be dependent on name-matching algorithms. We present a comparison of deterministic and probabilistic algorithms in uniquely identifying cases in a CBS pilot in Kenya.
Methods: We used HIV case-based surveillance pilot data from 124 facilities in two high HIV-burden counties (Siaya and Kisumu) in Western Kenya. For de-duplication, we investigated three scenarios to account for patients' movement within the treatment cascade: HIV testing services (HTS), HTS-to-care, and within care. We included Soundex of first name, surname, sex and year of birth to create a unique key and matching identifier. For deterministic matching, we included medical record number in HTS-to-care and master facility list code (MFL) in within care scenarios. For probabilistic matching, we used a variety of string edit distance calculation methods; Jaro, Jaro-Winkler, Levenshtein and Damerau-Levenshtein implemented in R stringdist package.
Results: We abstracted 12,157 cases from 124 facilities, of which 4073 (33.5%) were from HTS, 1091 (9.0%) HTS-care and 6993 (57.5%) within care. Using the deterministic process 11,722 unique cases were identified, yielding 435 (3.6%) duplicate records. Of these, 67 (1.6%) of HTS records, 164 (15.0%) of HTS-care and 204 (2.9%) within care. Jaro-Winkler probabilistic matching yielded 615 (5.1%) duplicate records; 268 (6.6%) within HTS, 151 (13.8%) within HTS-care and 196 (2.8%) within care. Jaro probabilistic matching yielded 600 (4.9%) duplicate records overall while Levenshtein and Damerau-Levenshtein yielded 519(4.3%) duplicate records each.
Conclusions: Jaro-Winkler probabilistic matching yielded highest the number of duplicate records. In absence of a universal NUPI, we suggest Jaro-Winkler probabilistic matching. Kenya needs a standard national deduplication and persons-matching algorithm to improve accuracy in monitoring the Fast-Track 90-90-90 targets.

WEPED1436

Epidemiology and early childhood outcomes of HIV-infected children in Zimbabwe: a secondary data set analysis, 2015

T.H. Nyamundaya[1,2], B.R. Miutede[3], A. Mahomva[3], E. Tachiwenyika[3], A. Mushavi[4], N. Gombe[1]

Presenting author email: tnyamundaya@gmail.com

Background: Delays in pediatric HIV diagnosis are associated with high morbidity and mortality. Highly centralized testing leading to long turnaround time (TAT) of results contributes to delays in HIV early infant diagnosis (EID). EGPAF hosts an EID electronic database (EDB) utilized by 1223 sites in Zimbabwe. The EDB tracks EID results and facilitates prompt issuing of positive results and fast tracked commencement on ART. Analysis of this national dataset has potential to provide insight into the national and local-level EID steps, which may inform critical interventions to enable ending pediatric AIDS in Zimbabwe.
Methods: In 2016, a retrospective secondary data set analysis was conducted by EGPAF. Excel was utilized to generate frequencies, medians, interquartile ranges and graphs. The dataset had a total of 2740 EID entries with unique identifiers. Records with critical information missing were not considered in the dataset analysis. Confidentiality was assured and maintained through coding of data to exclude personal variables, password protection and no patient identification information was analysed.
Results: The median age at dried blood spot (DBS) specimen collection was 14 weeks (Q_1=7;Q_3=43). Out of 63 districts, three major cities and one peri-urban district contributed 20% yield of DNA PCR positive results. Overall median TAT was 35 days (Q_1=21; Q_3=62), with the laboratory incurring the largest length of time in the TAT process, at 15 days (Q_1= 10; Q_3 =21). The median time from sample collection to ART initiation was 8.8 weeks (Q_1=5.1; Q_3=10.7). By August 2015, 50% were on ART, 4% lost to follow, 2% transferred out, 6% died whilst 38% of the entries had a pending outcome.
Conclusions: High median age at testing, long TAT and late ART initiation has potential to contribute to high early morbidity and mortality. As program implementers in Zimbabwe focused on the care and treatment of HIV-positive children, we need to further decentralize EID services and introduce point-of-care diagnostics to reduce TAT to better meet the needs of children infected with HIV. MOHCC should consider targeting high yield geographic areas such as major cities with pediatric HIV prevention services to avert new infections.

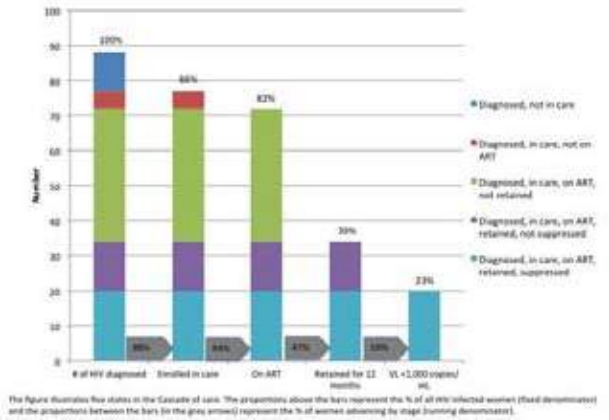
HIV treatment cascade among female entertainment and sex workers living with HIV in Cambodia: impact of amphetamine use and an HIV prevention program

M. Sokunny[1], L. Aynar[1], J. Evans[2], P. Maly[1], C. Sophal[3], Y. Neak[4], S. Ngak[1], E. Stein[2], A. Carrico[5], L. Maher[6], K. Page[7]
[1]FHI 360 Cambodia, Phnom Penh, Cambodia, [2]University of California, San Francisco, San Francisco, United States, [3]Ministry of Health, Department of Mental Health and Substance Abuse, Phnom Penh, Cambodia, [4]National Authority for Combating Drugs, Phnom Penh, Cambodia, [5]University of Miami, Miami, United States, [6]UNSW Australia, Kirby Institute for Infection and Immunity, Syndey, Australia, [7]University of New Mexico, Albuquerque, United States
Presenting author email: msokunny@fhi360.org

Background: A successful HIV continuum of care (COC) is key to effective clinical care and prevention. Few studies have examined this in female entertainment and sex workers (FESW). FESW in Cambodia have high risk of HIV associated with amphetamine-type stimulant (ATS) use. We examined COC outcomes among HIV-positive FESW participating in a comprehensive HIV prevention intervention that was integrated into the existing SMARTgirl HIV prevention platform in 10 provinces in Cambodia.
Methods: From 2013 to 2016, 1,198 FESW who reported multiple sex partners and/or transactional sex were recruited in 10 provinces in Cambodia; 88 women were identified with HIV at baseline. COC outcomes examined included: enrollment in care, antiretroviral therapy (ART) uptake, 12-month retention in care and viral suppression. Data on ATS use and other risk exposures were obtained from study surveys Logistic regression analyses examined correlates of 12-month retention in care.
Results: Median age was 32 years (interquartile range (IQR)) 28, 35). 50% of the women reported working in entertainment venues and 50% were freelance/brothel based; Overall, 88% were enrolled in care, 82% were on ART, 39% were retained in care, and 23% were virally suppressed at 12 months (Figure 1).



[HIV continuum of care in Cambodian FESW]

Women who screened positive for ATS substance use disorder had a 91% lower odds of 12-month retention in care (AOR 0.09; 95% CI 0.01, 0.97). Women who were engaged in SMARTgirl had 4-fold greater odds of 12-month retention in care (AOR=4.16, 95%CI: 1.27, 13.69)
Conclusions: The majority of women living with HIV were successfully linked to HIV care but retention and viral suppression were low. Tailored programs like SMARTgirl, targeting the broader population of HIV-positive FESW including those using ATS could optimize the clinical and population health benefits of HIV treatment.

The road to 90-90-90: the HIV cascade of care in Portugal

A. Diniz[1,2], R. Sarmento e Castro[3], T. Branco[4], J. Oliveira[5], R. Serrão[6], I. Aldir[7], HIV-SIVIDA Team Study Group
[1]Centro Hospitalar Lisboa Norte - HPV, Immunodeficiency Unit, Lisboa, Portugal, [2]Escola Nacional de Saúde Pública, Universidade Nova de Lisboa, Centro de Investigação em Saúde Pública (CISP), Lisboa, Portugal, [3]Centro Hospitalar do Porto, Infectious Diseases Department, Porto, Portugal, [4]Hospital Fernando da Fonseca, Internal Medicine Dpt, Amadora, Portugal, [5]Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Department, Coimbra, Portugal, [6]Centro Hospitalar de São João, Infectious Diseases Department, Porto, Portugal, [7]Directorate General of Health, National HIV/AIDS and TB Program, Lisboa, Portugal
Presenting author email: adinizfirst@gmail.com

Background: The 90-90-90 strategy is a key element to help end the AIDS epidemic. To reach this goal, each country must build, monitor and evaluate their own "HIV cascade of care" (HCC). Consistently with this strategy, this is the first HCC in Portugal, contributing to define the major issues and challenges to be addressed and overcome by 2020 in Portugal.
Methods: 1) Data reports to 2014, latest full epidemiological/clinical data available; 2) The number of people living with HIV (PLWH) and the number of PLWH diagnosed were estimated with ECDC HIV Modelling Tool (incidence method); 3) The remaining steps were analyzed according to the national hospital-based HIV information system (SIVIDA) that collects data from more than 90% of HIV-infected people followed in Portugal.
Results: According to ECDC HIV Modelling Tool, we estimate that, in 2014, the number of PLWH in Portugal was 45501 (44470-46508) and 41073 (40660-41504) were already diagnosed (**90.3%**). According to SIVIDA data, 33529 (81.6%) were retained in care and, from those in care, 26513 were on treatment (ART) (79.9%), meaning that a total of **64.6%** of diagnosed people were on ART. Of these, 22430 (**84.6%**) had undetectable viral load (UVL < 200copies/mL). In summary, at the end of 2014, 49.3% of PLWH had undetectable viral load.
Conclusions:
1. In Portugal (2014), the proportion of PLWH with undetectable viral load was similar or slightly lower than other european countries.
2. Portugal may have already reached the first „90-90-90" goal. However efforts regarding early diagnosis must be pursued.
3. Contrary to what was thought, linkage and retention in care and early ART are now the critical challenges to reach the „90-90-90" goals.
4. Strategies to improve the suboptimal proportion of people on ART with UVL need to be reinforced to overcome the last „90" goal.
5. The next HIV cascade of care must evaluate already the impact of the strategy of „treat all irrespective of CD4 cell count", adopted in 2015.

National 90-90-90 and HIV care continua for key populations

S. Gupta[1], R. Granich[2]
[1]International Association of Providers of AIDS Care, New Delhi, India, [2]International Association of Providers of AIDS Care, Washington, United States
Presenting author email: somyagupta17@gmail.com

Background: Men who have sex with men (MSM), people who inject drugs (PWID) and female sex workers (FSW) bear disproportionate burdens of HIV but often have the least access to HIV services. We review the published national HIV care continua for these key populations (KPs) to track progress towards the UNAIDS 90-90-90 target.
Methods: For 2010-2016, we searched the Internet, PubMed, surveillance reports, UNAIDS country reports, PEPFAR country operational plans, and conference abstracts for officially reported nationally-representative HIV care continua for KPs. We collected data on and methods to derive the estimated number of KPs (a) living with HIV, (b) diagnosed, (c) on ART, and (d) with viral suppression. The continua were graded high, medium or low quality based on the methods to derive the indicators.
Results: We found 24 care continua (12 for MSM, seven for PWID, and five for FSW) from 12 countries. HIV diagnosis, ART coverage and viral suppression varied between (a) 5-85%, 2-73% and 1-72%, respectively among MSM; (b) 54-97%, 14-78% and 8-66%, respectively among PWID; and (c) 27-63%, 8-16% and 2-14%, respectively among FSW. Among the KPs, progress toward 90-90-90 for FSWs was the lowest. HIV diagnosis, ART coverage, and viral suppression for MSM and PWID in European countries (Denmark, Netherlands, UK, and France) were comparatively higher and they are likely to achieve 90-90-90 for MSM and PWID well before 2020. The rates of HIV diagnosis were high (>85%) in Kazakhstan (PWID) and the United States (MSM and PWID), however, access to ART and viral suppression were relatively low (< 40% and < 35%, respectively). Continua from two countries (Denmark and Netherlands) used data from national cohorts and were ranked as using high quality methods to determine the continua.

Conclusions: Even though a few countries are close to achieving 90-90-90 for select KPs, data in the public domain are limited. Considerable additional efforts are likely needed to achieve this target for KPs in countries with high HIV burden and limited resources. Improved monitoring and evaluation with meaningful community engagement will be required to construct more reliable and standardized continua for KPs in order to promote accountability and data-driven programs.

Data accessibility as a barrier towards achieving the UNAIDS 90-90-90 goals in the HIV cascade of care among men who have sex with men (MSM) in Buenos Aires, Argentina

G. Kogan[1], N. Morando[1], R. Marone[2], L. Squiquera[2], N. Laufer[1,2], C. Ochoa[2], M.V. Iannantuono[2], M. Vila[3], H. Salomon[1], M.A. Pando[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Ciudad Autonoma de Buenos Aires, Argentina, [2]Nexo AC, Ciudad Autónoma de Buenos Aires, Argentina, [3]Unidad de VIH, Hepatitis, Tuberculosis e Infecciones de Transmisión Sexual, OPS/OMS, Ciudad Autónoma de Buenos Aires, Argentina
Presenting author email: hsalomon@fmed.uba.ar

Background: The HIV cascade of care has become an important tool for central assessment of treatment as prevention (TasP) strategy to stop the HIV epidemic. This study presents data of the HIV cascade among men who have sex with men (MSM) diagnosed with HIV in the main testing center for MSM in Buenos Aires, Argentina.
Methods: Recruitment was done by spontaneous demand of rapid HIV test (RHT), available for free in the testing center (Nexo NGO) from April-2014 to March-2015. HIV diagnosis was performed with finger-stick samples (Alere Determine HIV-1/2) after signing an informed consent. During the post-test interview, confirmatory/complementary studies (Ag/Ab ELISA, HIV viral load and CD4T cell count) were offered to RHT-reactive-individuals. A blood sample was withdrawn by venipuncture from those who accepted and delivery of results was planned at 10 days. All RHT-reactive individuals were contacted (via email and/or mobile phone) one year after HIV diagnosis in order to collect information about retention in care, HAART and viral suppression.
Results: 1496 MSM were tested at Nexo reaching an HIV prevalence of 12.5%. Among the RHT-reactive individuals, 83.4% (156/187) accepted to do confirmatory/complementary studies and 82.8% of them picked the results up, received counseling and were linked to care. A total of 62.0% had less than 500 CD4T cell/ml. At one year, 55.1% (103/187) could be contacted, 92.2% (95/103) were on HAART, 55.8% (53/95) remembered their last VL, and 83% (44/53) were virologically suppressed. The individuals that could not be contacted did not answer neither emails nor cell phone calls and messages.
Conclusions: Our data reveals that the first steps in the engagement in care were successful with more than 80% of the individuals linked to care through the confirmation of reactive RHT, the picking up of the results and the visits to the physician. Among those whose data were obtained, high frequency of retention in care, HAART and virologically suppression was observed. However, efforts should be concentrated on increasing strategies to collect data in countries, like Argentina, where follow up information is not centralized in national data bases due to the coexistence of different health care systems.

Presenting author email: msff-nairobi-medco-deputy@paris.msf.org

Background: Ongoing review of the quality of care and treatment programs is necessary to achieve the last two of the 90-90-90 targets. In a quality of care review, we sought to assess retention on HAART and 12-month viral suppression among patients enrolled for care in decentralized ART sites in Ndhiwa Sub-County, Kenya.
Methods: In December 2016, as part of routine program quality improvement, we conducted file reviews for 879 patients drawn from 26 facilities (1 hospital, 2 clinics, 20 dispensaries, 3 health centers) in a rural sub-county. Patients started on ART between June to November 2015 were included. Summary statistics were used to describe the cohort and chi-square test to assess association between various determinants and viral suppression at 12 months.
Results: Of 878 patients, 68.4%(602) were female, the median age at ART initiation was 28 years (IQR 22 - 36) and 10.4% (91/873) were aged 14 years or below. Viral load results were documented in the files of 42% (95% CI, 38.9% - 45.6%) and were less likely to be documented in the hospital (8/113, 7.1%) and health centers (29/124, 23.4%) compared to dispensaries (328/630, 56.1%), p<0.05. Viral suppression varied with age from 65%, 50% and 55.5% among those aged 0-4, 5-9 and 10-14 up to 89.7% and 91.6% among those aged 15-24 and 25+, respectively. There were no gender differences in viral suppression; males 86.2% vs females 87.9%, p=0.63. Viral suppression among individual facilities ranged between 60% and 100% with 9 of the 26 facilities having a 12-month viral suppression above 90%. Overall at 12 months, 81.9% (95% CI, 79.1% 84.4%) were alive and on ART; clinics 81.2% (95% CI, 48.2% - 97.7%), dispensaries 84.1% (95% CI, 81.0% - 87.0%), health centers 76.5% (95% CI, 67.8% - 83.8%) and the hospital 75.2% (95% CI, 66.2% - 82.9%).
Conclusions: Coverage of viral load was very low. To reliably assess progress towards achieving the 90-90-90 goals, there is need to strengthen relay, file documentation and utilization of viral load results. A focus on improving quality of care for children is necessary to achieve the 90% viral suppression target.

WEPED1442

What will it take to reduce HIV incidence in the United States: a mathematical modeling analysis

A. Perry[1], P. Kasaie[1], D. Dowdy[1], M. Shah[2]
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Baltimore, United States
Presenting author email: aperry17@jhu.edu

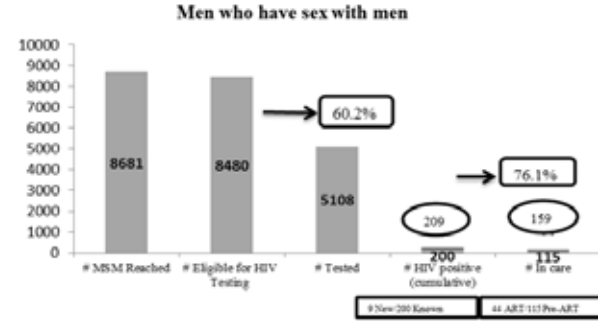
Background: UNAIDS has set ambitious "90-90-90" targets for population level HIV diagnosis, ART initiation and viral suppression to help end the AIDS epidemic. However, there is a paucity of data to inform program level care-continuum thresholds that are likely to translate to broader population-level epidemiologic goals.
Methods: We used a previously validated mathematical model of HIV transmission and care-engagement in the US to characterize care continuum parameters (including annual rates of screening, linkage to care after diagnosis and annual rates of retention in care) that would translate into achievement of population-level epidemiologic goals. We simulated the model multiple times - using different, randomly-selected care continuum parameters for each simulation - to ascertain the parameter values necessary to achieve target reductions HIV incidence. Primary outcomes were the projected HIV incidence and viral suppression among all people living with HIV [PLWH] after 10 years, compared to a base-case scenario of the current US continuum of care.
Results: Among 100,000 simulations that successfully achieved a 50% reduction in new HIV transmissions over 10 years, the median percentage virally suppressed among all PLWH was 80%. Retention in care was the primary driver of viral suppression, and thus, achievement of incidence targets. To achieve 80% population level viral suppression, the rate of annual disengagement from care (i.e. loss to follow-up), amongst those diagnosed and in care, could not exceed 8% per year, even at high rates of returning to care at later time-points. Among simulations that exceeded this annual rate of care disengagement, we found a median of 48% of PLWH achieving viral suppression, corresponding to an 18% reduction in incidence by 2025. By contrast, when 95% of individuals in care remained engaged each year, the median percent suppressed among PLWH was 84%, and the median percent reduction in incidence was 59%.
Conclusions: Our results suggest that long term retention in care is critical to achieve high levels of viral suppression and sustained reductions in HIV incidence. Health systems should aim to retain at least 95% of PLWH in care per - corresponding to at least 80% population viral suppression - to halve HIV incidence over the next decade.

WEPED1443

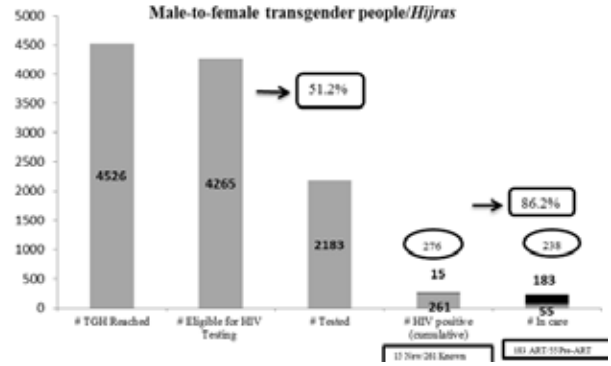
Monitoring and comparison of HIV cascade for MSM & TGH in Mumbai, India

S. Acharya[1], S. Katkar[1], P. Keskar[1], M.S. Setia[2], P. Todankar[3], A. Shrivasatav[3], V. Ranebennur[3], A. Das[3]
[1]Mumbai Districts AIDS Control Society, Mumbai, India, [2]Consultant Dermatologist and Epidemiologist, Mumbai, India, [3]FHI 360, New Delhi, India
Presenting author email: apdmdacs@gmail.com

Background: In India, men who have sex with men (MSM) and male-to-female transgender people/Hijras (TGH) are provided HIV prevention services by NGO-run targeted intervention (TI) programs, and are referred to Government facilities for testing and treatment. We assessed differences in the HIV cascade of services in a sample of MSM and TGH in Mumbai, India in order to design appropriate interventions.
Methods: We evaluated service data for cohorts from10 TIs, five focused on MSM and five on TGH. Specifically, we reviewed data from October 2015 through March 2016 on numbers tested for HIV, tested positive, and linked to Care, Support, and Treatment (CST) centers. We used chi-squared test to assess the difference in proportions, and estimated the odds ratio (OR) and their confidence intervals (CI).
Results: Sixty percent of MSM (Figure 1) and 51% of TGH (Figure 2) eligible for an HIV test during the six-month period had tested. About 76% of the MSM and 86% of the TGH who tested HIV positive were linked to CST. Thus, eligible MSM were significantly more likely to undergo HIV testing compared with TGH (OR: 1.44, 95% CI: 1.34, 1.56, p<0.001). TGH who tested HIV positive were significantly more likely to be linked to CST compared with MSM (OR: 1.97, 95% CI: 1.20, 3.24, p=0.004).



[Cascade of services for men who have sex with men]



[Cascade of services for male-to-female transgender]

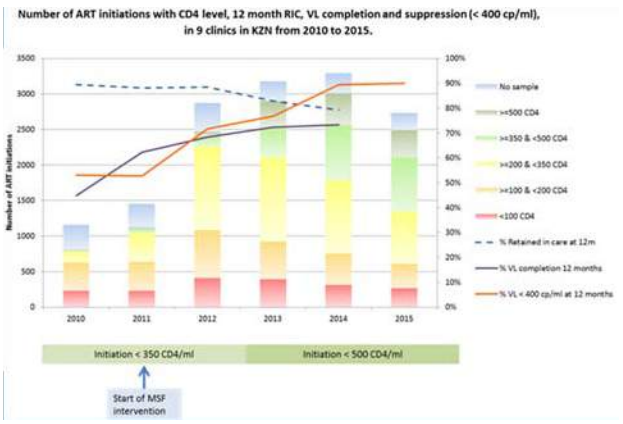
Conclusions: There is an urgent need to increase HIV testing for TGH, potentially by introduction of community-based testing facilities. Furthermore, linking HIV positive MSM to CST through peer navigation will be useful to achieve 90-90-90 in these groups.

WEPED1444

Scaling up and reaching the 3rd 90 with community testing and counselors support

B. Gergonne[1], A. Shroufi[2], V.V. Matutyana[1], L. Ohler[1], R. Uenishi[2], S.J. Steele[2], G. van Cutsem[3]
[1]Medecins Sans Frontieres, Eshowe, South Africa, [2]Medecins Sans Frontieres, Cape Town, South Africa, [3]SAMU-Médecins Sans Frontières, Cape Town, South Africa

Background: In Kwazulu-Natal (KZN), South Africa (SA), HIV prevalence is 25% in adults and up to 50% in women at 35 years. Since 2011 MSF, in collaboration with the department of health of KZN has implemented community interventions (rural population of 114000) aimed at reducing HIV incidence and reinforcing the HIV cascade of care. Community testing includes mobile and fixed-testing units, and door-to-door testing. Activities focusing on the 3rd 90 include initiation and adherence counseling, and clinical mentoring.
Methods: Twelve month retention in care (RIC), Viral Load (VL) completion (9 to 18 months after initiation) and suppression (VL < 400cp/ml) were calculated for all patients treated >= 6 months initiated between 2010 and 2015.
Results: The total number of active ART patients increased from 3601 to 12150. In 2010, 1157 patient were initiated, 54% of them with a CD4 <200. Only 53% of initiated were suppressed after one year. In 2012, community testing was introduced and initiations doubled. Retention in care decreased to 80% without decrease of the overall cohort. VL completion increased from 45% up to 73%. In 2014, 90% (1671/1869) of patients were suppressed after one year of treatment. Among those initiated <200 CD4/ml, the proportion suppressed increased to 83%. Among all active patients on ART >=6 months at the end of 2015, 85% (9390/10995) had a viral load done in time and among those, 90% (8498/9390) were suppressed. In the overall cohort, 5.75% patients (699/12150) were on 2nd line regimen.



[BG AIS 2017]

Conclusions: With "Test and Treat" introduced in SA in 2016, these results show that, with focused interventions on testing, adherence and support to the quality of care, it is possible to scale up initition and increase VL completion and suppression. Such strategies have supported achievement of the 3r 90, and will support the achievement of the first two 90's.

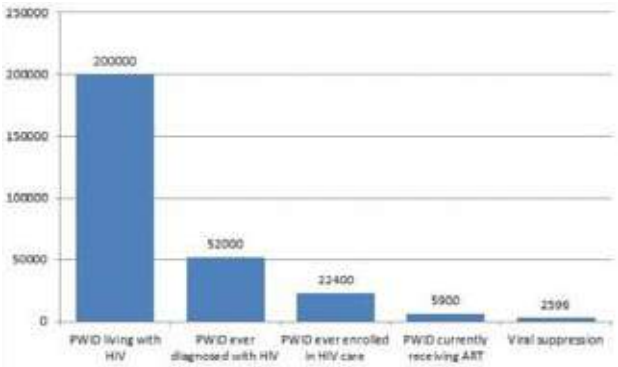
WEPED1445

Achieving 90-90-90 in the WHO Eastern Mediterranean region: key issues for people who inject drugs

G. Shaw[1], V. Macdonald[2], B. Mathers[2], A. Verster[2], J. Hermez[3]
[1]Gra, Cambridge, United Kingdom, [2]World Health Organisation, Geneva, Switzerland, [3]World Health Organisation - Regional Office for the Eastern Mediterranean, Cairo, Egypt
Presenting author email: hermezj@who.int

Background: There are 22 countries in the WHO Eastern Mediterranean (EM) Region which has the lowest coverage of ART worldwide. Use of contaminated injecting equipment by people who inject drugs (PWID) is the second most common route of transmission. PWID represent approximately one third of PLHIV in the region.
Methods: A systematic review of published and unpublished data, primarily from National AIDS Programme and other government reports, was conducted to estimate the population size of PWID in EM countries, number of PWID-LHIV who know their status, PWID-LHIV in care and on ART and PWID-LHIV achieving viral suppression.

Results: The number of PWID in the region is estimated to be 790,000 (range: 616,000-999,000; data from 8 countries) with 200,000 living with HIV. An estimated 52,000 PWID-LHIV have been diagnosed with HIV; 22,400 have ever been enrolled in HIV care; 5,900 were currently receiving ART. The proportion of those currently receiving ART who were virally suppressed was only available from 1 country; this proportion was used to estimate a regional figure for number virally suppressed of 2,596 (see Figure 1).



[Figure 1. HIV treatment cascade for PWID in WHO Mediterranean Region.]

Conclusions: While data is limited, results indicate that most PWID-LHIV in the region are unaware of their HIV status. For those diagnosed, there is poor linkage to ART services and treatment initiation is often delayed or denied. Retention in care and subsequent viral suppression are problematic. Achieving the 90-90-90 targets for PWID in EM countries requires higher coverage of simplified testing algorithms and focus on lay-provider and self-testing approaches integrated with peer-led assisted referral to navigate HIV treatment services. Attention should be paid to differentiated ART delivery approaches, service integration and better inclusion of NGOs and peer-led interventions. Stigma, knowledge and attitude of health care providers, local authorities and public security must be addressed.

WEPED1446

Trends and determinants of viral suppression among persons on HIV care in Italy

A. Mammone[1], A. Tavelli[2], A. Costantini[3], P. Caramello[4], A. Di Biagio[5], G. Madeddu[6], C. Mussini[7], A. D'Arminio Monforte[8], E. Girardi[1], Icona Foundation Study Group
[1]National Institute for Infectious Diseases 'L. Spallanzani', IRCCS, Department of Epidemiology, Rome, Italy, [2]Icona Foundation, Milan, Italy, [3]Univeristà Politecnica delle Marche, Ancona, Italy, [4]Ospedale Amedeo di Savoia, Torino, Italy, [5]IRCCS AOU San Martino-IST, Genoa University, Genoa, Italy, [6]University of Sassari, Sassari, Italy, [7]Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy, [8]Clinic of Infectious Diseases, S. Paolo Hospital, University of Milan, Milan, Italy
Presenting author email: antonella.darminio@unimi.it

Background: The HIV Continuum of Care is a useful framework to monitor access to care for people living with HIV and the potential contribution of cART to control HIV epidemic. Few studies however analyzed progress over time toward the UNAIDS 90-90-90 target of the CoC, especially the last about viral suppression.
Methods: We analyzed data of adult patients receiving clinical care in 2011-2015 in 42 Italian centers included in the ICoNA cohort. For each year of the study we computed the proportion of patients prescribed cART and of those with viral suppression (VS) in the last available viral load for that year (HIV-RNA< 200 copies/mL). Logistic regression models were set up for each year to identify clinical or demographic characteristics associated with cART-prescription or VS.
Results: The number of persons included in the analysis increased from 4,915 to 7,548 (2011-2015). Overall cART-prescription increased from 75.0 to 86.9% (p<0.001), in particular for patients with CD4>500/mmc (from 57.9 to 77.7%) and for foreign-born persons (from 67.1 to 83.2%). Recent HIV diagnosis, younger age, being foreign-born, higher CD4-cells count and lower HIV-RNA were associated with a lower probability of being on cART. The strength of the association with these three latter factors decreased during the study period (Table). Overall, VS increased from 68.5 to 84.3% (p<0.001) and, among those on cART, increased from 89.3 to 94.9%. Determinants of not obtaining VS were recent cART initiation (< 1 year), being foreign-born or IDU patients, higher HIV-RNA before cART.

	cART Prescription Adjusted OR (95% C.I.)		VL suppression among pts on cART Adjusted OR (95% C.I.)

In the analysis of cART prescription, baseline CD4 cells count and plasma HIV-RNA were included in the model.
In the analysis of VS, CD4 cells count and plasma HIV-RNA at cART initiation were included in the model

[Table. Factors associated with cART prescription and viral suppression among persons on care for HIV in Italy 2011-2015 - Multivariable logistic regression analysis]

Conclusions: The proportion of persons with VS has significantly increased among adults on care for HIV in Italy. Expanding indications for and access to cART and increased effectiveness of treatment may have contributed to this trend. Further interventions may be needed to improve access to treatment and its outcomes among some subpopulations, such as foreign-born and IDU patients.

WEPED1447

Assessment of pediatric HIV testing and linkage to HIV care and treatment in Lesotho, 2014

T.G. Harris, A. Schaaf, K. Hartsough, P. Tau, T. Gadisa
ICAP at Columbia University, New York, United States
Presenting author email: th2604@columbia.edu

Background: In 2015, 13,000 children were living with HIV in Lesotho, which has the second highest global HIV prevalence. Lesotho's HIV program has made substantial progress; however, challenges to achieve universal treatment access persist. As such, challenges across the pediatric HIV care continuum-testing uptake, timely linkage to care, and immediate ART initiation-need to be identified and addressed.
Methods: A Presidents Emergency Funding for AIDS Relief (PEPFAR)-funded evaluation was conducted from May-June 2016. Routine data was abstracted from HIV testing and counseling (HTC), pre-ART, and ART registers and HIV care cards for children age 0-14 years receiving services in 2014 in 62 facilities in five high HIV burden districts prioritized for the Lesotho Accelerating Children on Treatment (ACT) initiative. Data was limited to services provided within the testing facility, as no system for tracking inter-facility transfers exists. Descriptive and univariate analyses were conducted to identify factors associated with testing and testing positive. Statistical analyses accounted for clustering by health facility, using generalized linear mixed models.
Results: HTC registers recorded 24,443 children tested in 2014-3% positive, 97% negative, and < 1% indeterminate. Most tested were aged 10-14 years (37%). More boys were tested than girls (56% vs. 44%) and among those tested, females were more likely to test HIV-positive (2.9% vs. 2.4%, p=0.028). Positivity differed by age-< 1 year: 2.8%, 1-4 years: 2.9%, 5-9 years: 3.1%, 10-14 years: 2.1% (p=0.047). Including non-HTC register data, 674 children tested positive and 436 (65%) were enrolled in care at the same facility. Of the 436 in care, 333 (76%) initiated ART; 53% (167/317) initiated within one month. Children initiated on ART were more likely to be active in care than those not initiated (68% vs. 11%, p<0.0001).
Conclusions: Poor retention observed among children not started on ART suggests that successful implementation of immediate ART initiation should be prioritized to increase retention. More boys were tested likely due to the voluntary medical

male circumcision program that includes boys aged 10-14 years. Opportunities for testing more females aged 10-14 should be identified to support HIV prevention among adolescent girls and young women by providing a forum for prevention messaging/counseling.

WEPED1448

Reaching the first 90 among key population in India: whether this will be reached?

P. Kumar, B. Sangal, M. Zainab, N. Dhingra
National AIDS Control Organization, Strategic Information Management Unit, New Delhi, India
Presenting author email: drpradeep2014@gmail.com

Background: UNAIDS launched the ambitious "90-90-90" targets in 2014 to help end the AIDS epidemic as a public health threat by 2030. First target i.e. by 2020, 90% of people living with HIV will know their HIV status, fundamental to achieve the other two 90's, is often considered as the most challenging to achieve. This paper aims to report status of first 90 among key population in India from a large scale national Integrated Biological and Behavioral Surveillance (IBBS).
Methods: Data from first National IBBS, a probability based survey, implemented during 2014-15 was analyzed. IBBS enquired about HIV testing amongst key populations.. IBBS recruited 27,007 female sex workers (FSW) out of 670,000, 23,081 men who have sex with mem (MSM) out 247000 and 19,902 people who inject drugs (PWID) out of 132000 across 187 study domains spread across India. Unlinked anonymous testing with informed consent testing strategy was used.
Results: Among FSWs, 79.5% [95% Confidence Interval (CI) 78.2%-80.7%] reported to ever tested for HIV while 78.9% [95% CI 77.6%-80.1%] reported to undergone HIV testing in 12 months preceding the survey; 85.8% of HIV positive FSWs [95% CI 79.0%-90.6%] reported to be tested for HIV at least once. Among MSM, 74.5% [95% CI 72.9%-76.0%] reported to ever tested for HIV while 73.6% [95% CI 72.0%-75.1%] reported to undergone HIV testing in 12 months preceding the survey; 85.5% of HIV positive MSM [95% CI 79.9%-89.8%] reported to be ever tested for HIV. Among PWIDs, 62.2% [95% CI 60.5%-64.0%] reported to ever tested for HIV while 57.2% [95% CI 55.4%-59.0%] reported to undergone HIV testing in 12 months preceding the survey; 58.4% of HIV positive PWID [95% CI 53.8%-62.9%] were tested for HIV at least once.
Conclusions: National AIDS Control Programme (NACP) promotes routing HIV counselling and treatment (HCT) among key population through peer educator led interventions and offers free HCT at widely distributed Integrated Counseling and Testing Facilities. Clearly, NACP strategies had delivered and target that at least 90% of people living with HIV tested at least once is within striking distance among FSWs and MSM; however, coverage for HCT among PWID needs to be strengthened.

Expanding HIV cluster observed in Indigenous population in Australia

D. Russell[1], J. Newman[2], J. Ward[3]
[1]Cairns Sexual Health Service, Sexual Health, Cairns, Australia, [2]Gilead, Medical Affairs, Melbourne, Australia, [3]South Australian Health and Medical Research Institute (SAHMRI), Adeladie, Australia
Presenting author email: darrenrussell@optusnet.com.au

Background: We report on an expanding cluster of new HIV cases amongst the Indigenous population in Cairns, Australia. Over the last 20 years, Indigenous Australians experienced similar rates of HIV diagnosis to the non-Indigenous population despite higher rates of other STIs, an increasing proportion of cases of HIV acquired through injecting drug use, and a higher proportion of cases diagnosed among women and heterosexual people. We report on a four-fold increase in the rate of new cases of HIV in this Indigenous population.
Methods: We collected data on all new HIV diagnoses at the Cairns Sexual Health Service from 2014-2016. Cases were reported according to Indigenous status, and further examined to identify any concomitant diseases and cultural/socioeconomic factors that might contribute to this expanding cluster of new HIV cases.
Results: Since 2014 there has been a significant increase in the rate of diagnosis of HIV among the Indigenous population in Cairns, accounting for almost 50% of all new HIV diagnoses. Pre-2014, there were approximately 15 new diagnoses of HIV annually in Cairns, with 1-2 cases occurring in the Indigenous population (range: 6.5%-13%). In 2016, we observed an expanding cluster of new cases of HIV in the Indigenous population with 14 Indigenous diagnoses out of a total of 30 new cases of HIV (47%). Currently, 43 Indigenous patients are engaged with our service; 37 are on treatment (86%), but 8 (22%) remain detectable. In addition, 64% (9 of 14) of Indigenous individuals diagnosed with HIV in 2016 presented with syphilis or chlamydia. There were almost no new local cases of HIV among the non-Indigenous population during this time. We attribute this to high rates of testing among the non-Indigenous population, treatment as prevention (TasP), and recent uptake of Pre-exposure prophylaxis (PrEP).
Conclusions: We observed a 4-fold increase in the rate of new HIV diagnoses in the local Indigenous population over a 2-year period, coinciding with a local outbreak of syphilis. Cultural issues cannot be underestimated in this local epidemic. Early detection and culturally sensitive education will diminish the risk of HIV being further transmitted to outlying communities, with potentially devastating consequences for Indigenous Australians.

Using fingerprinting to de-duplicate program data for MSM and transgender women in Guatemala

J.M. Ikeda[1], O. Racancoj[1], A. Citalan[1], S. Ortega[2], N. Hearst[3], W. McFarland[4]
[1]Association for Investigation, Development and Integral Education, Quetzaltenango, Guatemala, [2]HIVOS Guatemala, Guatemala, Guatemala, [3]University of California, Family and Community Medicine and Epidemiology, San Francisco, United States, [4]University of California, Epidemiology, San Francisco, United States
Presenting author email: janet.m.ikeda@asociacionidei.org

Background: Country-level 90-90-90 monitoring requires quality data that tracks individuals across multiple observations and sites. For this purpose, the Guatemalan Ministry of Health created a unique identity code (CUI) based on the participant's sex, birthdate, nationality, birth municipality, birth department, and initials for use by HIV prevention and treatment service providers. We designed a computerized fingerprint recording and monitoring software to better identify and track individuals receiving HIV testing. We compared the effectiveness of the CUI to biometric fingerprint data for correctly de-duplicating MSM and transgender women receiving these HIV services.
Methods: We tested the fingerprint tool in MSM and transgender women who participated in a community-based prevention program package (behavior change, condom distribution, STI diagnosis and treatment, HIV testing and linkage to care) in 19 of the 21 departments of Guatemala. Following informed consent, trained educators from 6 CBOs entered the information to create the CUI as well as recording a middle finger right-hand fingerprint of the participant. The software captures the fingerprint image, extracts unique minute data, encrypts the data, and identifies matching fingerprints, thus serving as a gold standard to identify nonmatching CUI for the same individual.
Results: During August of 2016, we registered 3,017 individual fingerprints of MSM and transgender women participants in 91 municipalities. 86 participants (2.7%) refused to provide their fingerprint, so only the CUI was entered. The fingerprint software identified 114 instances of multiple observations for the same person that were entered with different (inconsistent) CUIs. These nonmatching CUIs occured due to inconsistent or changed data for: 39 (34%) birth dates, 26 (22%) birth municipality, 31 (26%) birth department, 21 (18%) initials. The unique fingerprint identified an additional 333 repeat obsevations on the same person that were also correctly identified as duplicates by the CUI.
Conclusions: Fingerprint monitoring was accepted by service providers and 97% of service recipients. It was far more accurate than a "unique" idntification code in identifying multiple observations of the same individual. This technique has great potential for improving accuracy of tracking data to monitor the HIV treatment cascade for key populations in resource limited settings with high stigma.

WEPED1451

Extended PMTCT cascade and implications for PMTCT program coverage in the era of lifelong ART for pregnant and breastfeeding women living with HIV: Rwanda national impact study 2011-2012

L. Tsague[1], P. Mugwaneza[2], A. Lyambabaje[3], A. Umubyeyi[3], J. Humuza[3], F. Mwanyumba[4], C. Lombard[5], D. Jackson[5,6,7]
[1]UNICEF, Regional Office West and Central Africa, Dakar, Senegal, [2]Rwanda Biomedical Center/Institute of HIV, Disease Prevention and Control (RBC/IHDPC), Kigali, Rwanda, [3]School of Public Health, National University of Rwanda (SPH-NUR), Kigali, Rwanda, [4]UNICEF, Kigali, Rwanda, [5]Biostatistics Unit, South African Medical Research Council (SAMRC), Cape Town, South Africa, [6]University of the Western Cape (UWC), Cape Town, South Africa, [7]UNICEF HQ, New York, United States

Background: Lifelong ART for all pregnant and breastfeeding women living with HIV (Option B+) to prevent MTCT (PMTCT) is broadening the traditional PMTCT cascade in resource limited settings. We assessed coverage and determinants across a traditional PMTCT cascade and an extended (pre-pregnancy, pregnancy and postpartum) PMTCT cascade.

Methods: We abstracted data from a national Option B/B+ PMTCT impact study conducted in Rwanda (July 2011 - June 2012). We included all infants aged 6-10 weeks and their mothers. We constructed for the traditional PMTCT cascade a standard package (SP) (maternal ART + infant ARV), and three incremental packages (a, b and c): package a= SP + early attendance to first ANC; package b= package a + early retention on ART up to 6-10 weeks; and package c= package b + planned index pregnancy. We estimated coverage of each PMTCT package and assessed its determinants (health system and maternal) using logistic regression models in STATA.
Results: The analysis included 1,521 mother-infant pairs. Coverage for the SP, packages a, b and c was 88%, 61%, 56% and 29% respectively. Mothers who attended first ANC visit during the first/second trimester were twice as likely to receive SP during pregnancy and delivery compared to mothers attending first ANC after second trimester (adjusted Odd Ratio - aOR = 2.0; 95% CI 1.3-3.0). Mothers who were married and those who were cohabiting were respectively 2.9 times (aOR = 2.9; 95% CI 1.4-6.3) and 3 times (aOR = 3.1; 95% CI 1.5-6.3) more likely to complete package c compared to single mothers. In addition, mothers who had four to six household assets were twice as likely
(aOR = 2.1; 95% CI 1.2-3.5) to complete package c compared to mothers who had no household assets. By contrast, mothers who had no source of income were 70% less likely to complete package c compared to mothers who were employed (aOR = 0.4; 95% CI 0.2-0.9).
Conclusions: Rwanda PMTCT program should address the specific needs of single mothers and those from poorer households. Interventions aiming to increase access to income for women and mothers could significantly improve coverage across the extended PMTCT cascade.

WEPED1452

Progress towards 90-90-90 along the paediatric HIV care continua in South-East Asia

S. Gupta[1], S. Wangdi[1], S. Sultana[2], A. Sinha[3], F. Wijayanti[4], M. Thu Aung Hsan[5], S. Lakhe[6], M. Sharma[7], B. Rewari[1]
[1]WHO SEARO, New Delhi, India, [2]WHO Country Office, Dhaka, Bangladesh, [3]NACO, New Delhi, India, [4]WHO Country Office, Jakarta, Indonesia, [5]WHO Country Office, Yangon, Myanmar, [6]WHO Country Office, Kathmandu, Nepal, [7]WHO Country Office, Bangkok, Thailand
Presenting author email: rewarib@who.int

Background: The WHO South-East Asia region has an estimated 180,000 children (0-14 years) living with HIV. But in a setting where the epidemic is concentrated among key populations, paediatric HIV is largely overlooked. We construct HIV care continua for children living with HIV and assess progress towards the 90-90-90 target for them in the region and its 10 Member States.
Methods: We searched the Internet, PubMed, UNAIDS global AIDS response progress reports, PEPFAR country/regional operational plans, and conference abstracts/presentations for data on HIV care interventions for children. We also contacted the WHO country offices and Ministry of Health. We collected data on the following indicators to construct national HIV care continua for children:
(a) estimated children living with HIV,
(b) diagnosed,
(c) on antiretroviral therapy (ART),
(d) tested for viral load (VL), and
(e) with viral suppression.
Results: For 2015, of the 10 countries, we obtained data on at least one indicator from seven (~100% of the regional paediatric HIV burden). Proportion of children living with diagnosed HIV (first 90) was unavailable since countries do not use unique identifiers and it is challenging to estimate this number from data on cumulative HIV cases ever diagnosed. ART coverage among children living with HIV for the region was 38%, ranging between 22%-95% across countries. The regional ART coverage is less than the global average of 49% [42%-55%]. Also, the region is far from achieving the second 90 target, which translates into 81% of children living with HIV on ART by 2020. Availability of VL is limited in majority of the countries - only 44% [3%-86%] of children on ART received VL testing in the four countries reporting data on this indicator. Viral suppression among children on ART (third 90) was high at 86% [67%-89%].
Conclusions: Limited data from the region show that getting to 90-90-90 by 2020 in paediatric HIV requires intensified efforts to expand HIV services for children, especially early infant diagnosis and immediate ART irrespective of CD4/VL count or WHO clinical stage. Additionally, monitoring and evaluation systems need to be strengthened so that progress towards 90-90-90 for children can be evaluated for data-driven decision-making.

WEPED1453

Diversity of ART treatment site decisions by HIV-positive Thai MSM challenges HIV cascade monitoring

M. Avery[1], E. Stephan[1], T. Sattayapanich[1], A. Arunmanakul[1], T. Nakpor[2], P. Chanlearn[3], R. Reankhomfu[4], S. Janyam[5], D. Linjongrat[6], P. Krisintu[1]
[1]FHI 360, USAID LINKAGES Project, Bangkok, Thailand, [2]Sisters Foundation, Pattaya, Thailand, [3]MPlus Foundation, Chiang Mai, Thailand, [4]Caremat, Chiang Mai, Thailand, [5]Service Workers in Group (SWING), Bangkok, Thailand, [6]Rainbow Sky Association of Thailand, Bangkok, Thailand
Presenting author email: pkrisintu@fhi360.org

Background: Although timely treatment initiation and adherence lead to better health outcomes for individuals living with HIV and reduced likelihood of ongoing HIV transmission, only 1/3 of known HIV-positive men who have sex with men (MSM) in Thailand are receiving antiretroviral therapy (ART). We introduced Unique Identifier Codes (UICs) and real-time, mobile data collection (eCascade) to follow a cohort of MSM clients across the HIV cascade, track linkage to care and treatment, and increase ART uptake.
Methods: eCascade is implemented by a collection of community-based organizations and private clinics across 4 sites in Thailand. Clients are registered via outreach contact or clinic walk-in, provided with HIV testing, and referred to ART services at participating clinics. Data on treatment initiation are recorded in eCascade and tracked over time, and community-based care, support and treatment officers follow-up regularly with HIV-positive clients.
Results: Between October 2015 and September 2016, 340 clients registered in eCascade were tested HIV positive, but only 40% were successfully tracked to an ART providers (n=137). 60% (n=203) of all newly diagnosed HIV-positive clients in eCascade were considered lost to follow-up (LTFU). However, follow-up revealed that 43% (n=88) of those "LTFU" patients were receiving ART from providers not affiliated with the service utilization network connected to the real-time monitoring system, eCascade. An additional 36% of LTFU clients had still not initiated ART; reasons included structural and policy barriers, the need to wait for additional test results, and being "unready" for treatment. 42 clients (21%) could not be contacted to ascertain their treatment status.
Conclusions: Real-time HIV cascade monitoring provides valuable insights into programmatic performance, but the diverse ARV treatment site decisions of clients can contribute to misleading conclusions. In this case, the "true" rate of successful linkage to care, support and treatment services was 66%, or twice the national rate. To provide a clearer picture of cascade functioning, monitoring systems must account for numerous service delivery points, including those external to the project's network. However, gaps in data collection cannot account for all "leaks" in a cascade. Significant work also remains to reduce structural barriers and increase patient willingness to access ART.

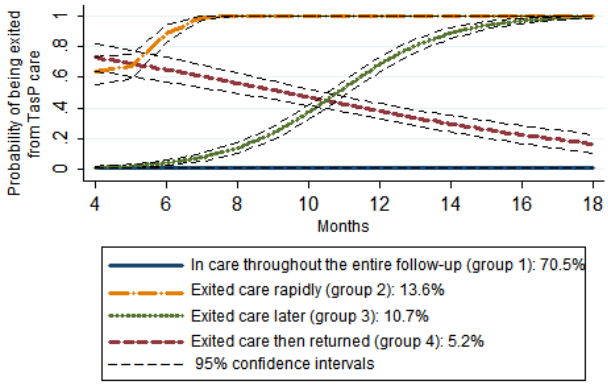
WEPED1454

Care trajectories among people living with HIV and followed within a universal test and treat programme in rural South Africa (ANRS 12249 TasP trial)

A. Gosset[1,2], C. Protopopescu[1,2], N. Okesola[3], B. Spire[1,2], J. Larmarange[3,4], J. Orne-Gliemann[5,6], N. McGrath[3,7,8], D. Pillay[3,9], F. Dabis[5,6], C. Iwuji[3,8], S. Boyer[1]
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]Africa Centre for Population Health, University of KwaZulu-Natal, Durban, South Africa, [4]Ceped UMR 196 (Paris Descartes IRD), SageSud ERL Inserm 1244, IRD, Paris, France, [5]Univ. Bordeaux, INSERM, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [6]INSERM, ISPED, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [7]Faculty of Medicine and Faculty of Human, Social and Mathematical Sciences, University of Southampton, Southampton, United Kingdom, [8]University College London, Research Department of Infection and Population Health, London, United Kingdom, [9]University College London, Division of Infection and Immunity, London, United Kingdom
Presenting author email: bruno.spire@inserm.fr

Background: Retention in care is essential to optimize antiretroviral treatment (ART) impact on viral suppression and ensure the success of the universal test and treat (UTT) strategy. We aimed to identify care trajectories and associated factors among ART-eligible patients within the UTT cluster-randomized TasP trial.
Methods: Following home-based HIV testing, HIV-positive individuals were referred to TasP clinics and offered immediate ART (intervention arm) or according to national guidelines (control arm). This analysis included all patients ART-eligible at their first clinic visit ≥18 months before the trial end. Monthly clinical follow-up was offered in TasP clinics. A patient was considered exiting care if ≥3 months late for the last appointment, transferred-out or dead.

Care trajectories, assessed over 18 months of follow-up, and their associated factors were identified using a group-based trajectory model (Nagin, 2005, Harvard University Press).
Results: Among the 787 ART-eligible patients who attended TasP clinics, four trajectory groups were identified: 70.5% remained in care throughout the entire follow-up period (group 1), 13.6% exited care rapidly (median 4 [IQR 4-6] months after first visit) (group 2), 10.6% exited care later (11 [9-13] months) (group 3) and 5.2% exited care then returned after 4 [3-9] months (group 4) (Figure 1). The risk of exiting care (groups 2&3) was higher in newly diagnosed patients and those ≤29 years. The "returning group" members (group 4) were more likely male, with CD4 >350 cells/mm^3 at first visit, living in high HIV prevalence clusters (>34%) with the lower nurse-patient ratio, and less likely to have initiated ART.
Conclusions: Although most patients remained in care over the 18-month period, a significant proportion exited care at different follow-up times. Particular attention should be paid to men, young and newly diagnosed patients, and those with CD4>350 in order to improve retention in care and maximize the effect of UTT strategies.



[Figure 1. Care trajectories in TasP clinics over 18 months of clinical follow-up among ART-eligible patients at the first visit (ANRS 12249 TasP trial, n=787)]

WEPED1455

A case for age and gender disaggregation in Malawi

J.R. Chinkonde
UNICEF Malawi Country Office, HIV & AIDS Section, Lilongwe, Malawi
Presenting author email: jacquernkhoma@yahoo.co.uk

Background: Malawi's routine monthly reporting from site-level does not enable reporting of age- and sex-disaggregated data. Subsequently, variations in service provision across different age groups are not well understood. A health facility assessment analysed routine health service statistics to estimate coverage of HIV and reproductive health services among patients aged 10 to 24 years.
Methods: Stratified random sampling was used to select 61 urban and rural facilities, representing 22% of health facilities in 8 high HIV burden districts. Age- and sex-disaggregated data for April-September 2016 were collected from clinic registers and included ANC rates, known HIV status, treatment, STI rates and contraceptive use. Counts and frequencies were used to analyze the data with MS Excel and SPSS.
Results: 21,946 pregnant women registered for ANC during July- September 2016, and a 100% had their HIV status ascertained. Of the 2020 clients who tested positive, 7.2 % were aged 10-19 years, 23.7% were 20-24 years, and 69.1% were 25 years and above. ART coverage within ANC increased with age, ranging from 40% among 10-19 year olds, 49% for 20-24 year olds and 58% in those 25 years and above. HTC coverage was lowest among 10-14 year old non-pregnant females at 22%, yet this subgroup had the highest positivity rate at 6% compared to both genders in the 15-19 year, and 20-24 year age bracket who had the average HIV prevalence of 3.4%. Although ART initiation was lowest among 10-14 year olds (56%), they had better ART retention at 3 and 6 months (91% and 85%) than 15-19 year olds (84% and 80%). Of note, retention was lowest among females aged 15-19 years. STI infection is again disproportionately higher among females aged 15-19 years at 74% than in males of the same age at 26%.
Conclusions: Adolescents are exposed to significant risk of contracting HIV, but are less likely to know their HIV status or access treatment. The magnitude of the problem is masked by the absence of age- disaggregated data. Data disaggregation by sex and age will provide a better understanding of where to intensify HIV service delivery to achieve the 90-90-90 goals.

Sexual orientation, HIV retention and mortality among people living with HIV in rural Mozambique

C. Audet[1], L. González Calvo[2], M.H. Aliyu[3], M. Blevins[3], M.F.S. Alvim[4], S. Van Rompaey[4]
[1]Vanderbilt University, Health Policy, Nashville, United States, [2]Friends in Global Health, Quelimane, Mozambique, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Friends in Global Health, Maputo, Mozambique
Presenting author email: carolyn.m.audet@vanderbilt.edu

Background: HIV-related outcomes among persons of same-sex orientation are poorly documented in sub-Saharan Africa. We investigate program performance along the HIV continuum of care among persons of minority sexual orientation in rural Mozambique.
Methods: This is a large retrospective cohort study of HIV-infected adults with bisexual, homosexual, and heterosexual preferences (n=49,058) receiving care in a comprehensive HIV program in Zambézia Province, Mozambique. We compared linkage to care, time to initiation of antiretroviral therapy (ART) and CD4+ cell count at enrollment using chi-squared and Wilcoxon rank sum tests. Pre- and post-ART loss-to-follow-up (LTFU), as well as patient mortality, was compared using Cox regression analysis and the Gray test.
Results: From 2014 to 2016, 49,058 HIV-infected patients reported their sexual preference (heterosexual [n=47,780, 97.4%], homosexual [n=1013, 2.1%], bisexual [n=256, 0.5%]) through routine data collection at treatment initiation. Among pre-ART patients, sexual orientation was significantly associated with higher LTFU at one year using Cox regression (p=0.02). Homosexual pre-ART patients (but not bisexual patients) had a significantly higher hazard of LTFU (Hazard Ratio: 1.27 [1.06, 1.51]) vs. heterosexual pre-ART patients. Among ART patients, sexual orientation was not associated with LTFU in the first year of treatment (p=0.20). At one year, homosexual (4.5% [95% confidence interval: 6.7%, 2.3%]) and bisexual (7.2% [13.1%, 0.9%]) patients had a higher rate of mortality vs. heterosexual patients (3.1% [3.4%, 2.8%]), but this difference was not statistically significant (p=0.11).
Conclusions: We found sexual orientation to be an important factor predicting LTFU among pre-ART patients but not among those enrolled on ART. Of concern is the trend toward higher mortality rates among our bisexual and homosexual populations, compared to individuals with heterosexual preferences. Our analysis was limited by the incomplete documentation of sexual preference in the clinical records coupled with reluctance to disclosure sexual preference due to social stigma. This likely creates an invisible population of bisexual and homosexual people living with HIV. HIV programs in Mozambique need to actively engage sexual minority patients and health agents to prioritize addressing underlying social mechanisms and norms that limit their uptake and retention in HIV services.

WEPED1457

Dynamic modelling of the HIV care cascade in the United States: where are people leaving the cascade and where should we intervene?

F. Fadero, M.-C. Boily, K.M. Mitchell
Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom
Presenting author email: kate.mitchell@imperial.ac.uk

Background: Only 30% of people living with HIV/AIDS (PLWHA) in the US are virally suppressed. The US HIV care cascade shows that large numbers of PLWHA are not retained in care, but it assumes unidirectional progression and fails to capture cascade dis/re-engagement. We used a dynamic model of the US care cascade to identify weak points where most PLWHA disengage from the cascade, and evaluate the effects of targeted interventions.
Methods: We developed a deterministic compartmental model of the HIV care cascade which allowed PLWHA to enter and leave care, start and stop antiretroviral therapy (ART), and achieve and lose viral suppression. We modelled movement of PLHIV through the US HIV care cascade from 1995 until 2015. The model was parameterised using published estimates of transition rates between different care cascade stages and calibrated to data from 1995-2012 on the number of people at each cascade stage. We used the calibrated model to identify where most people are lost, and to assess the impact upon viral suppression of strengthening different parts of the cascade.
Results: The calibrated dynamic cascade model suggested that failure to retain PLWHA in care after linkage significantly contributes to the low numbers achieving viral suppression, consistent with the static cascade. The dynamic model additionally suggested that a substantial proportion of people not in care have previously achieved viral suppression. Improvement of patient retention rates gave the largest improvement in viral suppression: 50% greater retention rates would have improved the proportion of PLWHA with suppressed viral load by 11 percentage points in 2012 (from 31% to 42%); increasing rates of testing, linkage rates, or re-

engagement by 50% only increased suppression in 2012 by 2-3 percentage points. Simultaneous 50% improvements in linkage, retention and re-engagement rates were additive, giving an 18-percentage point increase in the proportion virally suppressed in 2012 (from 31% to 49%).
Conclusions: Although the dynamic model of the US HIV care cascade gives additional information about how PLHA transition through care, the overall conclusion agrees with that from the static cascade: that improving retention in care is crucial to optimise the US HIV care cascade.

Global status report of HIV care continua and the 90-90-90 target

R. Granich[1], S. Gupta[2], I. Hall[3], J. Aberle-Grasse[3], S. Hader[3], J. Mermin[3]
[1]IAPAC, Washington, United States, [2]IAPAC, Delhi, India, [3]CDC, Atlanta, United States
Presenting author email: rgranich@iapac.org

Background: The 2014 UNAIDS 90-90-90 target specifies that by 2020, 90% of individuals living with HIV will know their HIV status, 90% of people with diagnosed HIV infection will receive antiretroviral treatment (ART), and 90% of those taking ART will be virally suppressed. Consistent methods and routine reporting in the public domain are necessary for tracking progress towards the 90-90-90 target.
Methods: For 2010-2016, we searched PubMed, UNAIDS country progress reports, World Health Organization (WHO)/UNAIDS reports, national surveillance and program reports, United States President's Emergency Plan for AIDS Relief (PEPFAR) Country Operational Plans, and conference presentations and/or abstracts for the latest available national HIV care continuum in the public domain. Continua included the number and proportion of people living with HIV (PLHIV) diagnosed, on ART and virally suppressed of the estimated number of PLHIV. We ranked the described methods for indicators to derive high, medium and low quality continuum.
Results: For 2010-2016, we identified 55 national care continua with viral suppression estimates representing 21.8 million (59%) of the 2015 global estimate of PLHIV. Of the 55, six (2% of 2015 global HIV burden) were high quality, using standard surveillance methods to derive an overall denominator and program data from national cohorts for estimating steps in the continuum. Only nine countries in sub-Saharan Africa had care continua with viral suppression estimates. Of the 55 countries, the average proportion of PLHIV from all countries on ART was 48%, and Virally suppressed was 40%. Seven countries (Sweden, Cambodia, United Kingdom, Switzerland, Denmark, Rwanda and Namibia) were within 12% and 10% of achieving the 90-90-90 target for on ART and Viral suppression, respectively.
Conclusions: Relatively few national continua of care are available in the public domain and there is wide variation in methods for determining progress towards the 90-90-90 target. A standardized monitoring and evaluation approach could improve the use of scarce resources to achieve 90-90-90 through improved transparency, accountability and efficiency.

12 months virological outcomes among HIV-1-infected patients initiated on first-line combination antiretroviral therapy in the Zambian national ART program

L.B. Mulenga[1,2], A. Mweemba[3], L. Chirwa[2], C. Moyo[4], H. Phiri[4], D. Phiri[4], S. Suwilanji[1,2], J. Todd[5], D. Heimburger[6], H. Duber[7], C. Kankasa[1,2]
[1]University of Zambia School of Medicine, Adult Infectious Disease Centre/Internal Medicine, Lusaka, Zambia, [2]University Teaching Hospital, Division of Infectious Diseases, Lusaka, Zambia, [3]University of Zambia School of Medicine, Internal Medicine, Lusaka, Zambia, [4]Ministry of Health, Ndeke House, Lusaka, Zambia, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Vanderbilt University, Vanderbilt Institute of Global Health, Nashville, United States, [7]University of Washington, Institute for Health Metrics and Evaluation, Seattle, United States
Presenting author email: lbmulenga@yahoo.com

Background: There is scarce data on Viral load (VL) suppression and HIV drug resistance (HIVDR) especially in the sub-Saharan region; a region mostly affected by HIV and where there has been unprecedented roll out of HIV combination antiretroviral therapy (cART) . Achieving a high level of viral suppression among individuals on cART is important for achieving the third 90-90-90 goal - 90% of people on ART virally suppressed by 2020. Such a goal is important as it reduces HIV transmission and has individual health benefits. We thus assessed the VL suppression and HIVDR among HIV-1 infected individuals at 12 months of first line cART in the Zambian national ART program.
Methods: We conducted a cross sectional survey among HIV-1 infected individuals at 12 months (± 3 months) of first line cART. Sampling of clinics was performed using systematic sampling to generate probability proportional to proxy size samples. 20 clinics were selected based on the random starting-point, sampling interval and cumulative population size giving a sample size of 460. Eligible patients had their blood specimens collected for VL and CD4 count testing. Specimens with VL ≥ 1,000 copies/mL were genotyped to determine HIVDR status. Proportions for each outcome at linearized standard error 95% confidence interval and summary estimates were determined.
Results: Of the 476 patients enrolled, 98% were on TDF/3TC/EFV and 2% on TDF/3TC/NVP. At 12 months of cART 90.27% were virologically suppressed (VL <1000 copies/mL) and the median CD4 was 375 cells/mm^3 (IQR: 236-563) whereas the BMI was 22.7 kg/m^2 (IQR:19.1-25.6). Current BMI > 18.5 kg/m^2 and CD4 > 100 cells/mL were significantly associated with virologic suppression (OR 1.8, CI:1.12-3.02, P=0.017 and OR 2.2, CI:1.19-4.11, P=0.012 respectively).
Among individuals with VL>1000copies/mL, 83.3% had either NRTI and/or NNRTI associated mutations whereas 6.7% had no mutations at all and none had PI associated mutations.
Conclusions: Patients on 12 months of first line cART had achieved more than 90% of the recommended virologic suppression target. Not all patients with virologic failure had HIVDR mutations. In the absence of routine viral load monitoring, low BMI and low CD4 would aid in targeting viral load testing.

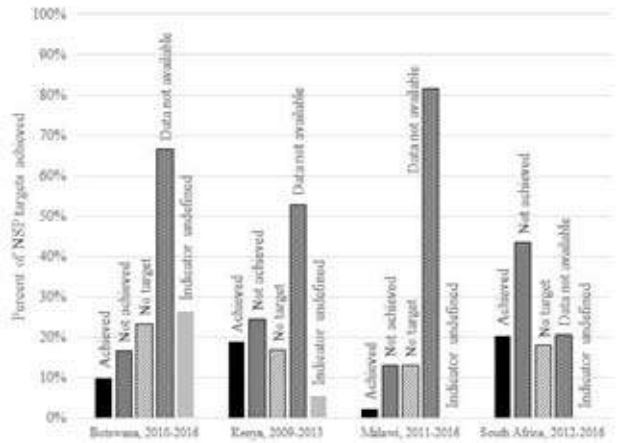
Quality assessment of national strategic plan targets

A. Sharp, R. O'Hagan, B. Honermann, S. Blumenthal, G. Millett
amfAR, Washington, United States
Presenting author email: alana.sharp@amfar.org

Background: National Strategic Plans (NSPs) for HIV have become foundational documents that frame national responses to HIV. Both Global Fund (GF) and PEPFAR require coordination with NSPs as part of their processes. Despite this role of NSPs in planning, no rigorous assessment of NSP targets and performance exists. We performed a quantitative analysis of the quality of NSP indicators and targets, and an assessment of achievement of historical NSP targets.
Methods: We extracted all identifiable targets and indicators from publicly available NSPs from 32 countries with generalized HIV epidemics and GF support eligibility for HIV in 2017. Targets and indicators were evaluated for specificity, measurability, and achievability. Additionally, progress toward achieving targets was evaluated using historical NSPs from four countries with available NSP progress reports.
Results: On average, 21% of country's NSP indicators were disaggregated by sex, age, or population group. The average percent of indicators that included numeric targets or baselines was 69% and 46%, respectively; 38% identified data sources for either measure. Targets were a 165% increase (or decrease) relative to baselines (IQR = 75.4% - 208.3%). Achievement of historical NSP targets ranged from 2% of targets in Malawi to 21% in South Africa. Assessment of achievement was limited by lack of numeric targets, available data, and well-defined indicators.

	Mean	Minimum	Maximum
Number of indicators	84.5	8.0	232.0
Have numeric target	69.0	0.0	100.0
Have numeric baseline	45.7	0.0	91.5
Percent change baseline to target (for non-missing)	167.8	15.5	646.6
Indicators identify data source for baseline and/or target	38.3	0.0	100.0
Target or baseline has a disaggregate (age, sex, high-risk population)	21.2	0.0	76.6

[Table 1. % Indicators/targets with each criterion]



[Figure 1. Progress toward NSP targets.]

Conclusions: Country NSPs are limited by a lack of specific, measurable, and achievable targets. The low achievement of targets in historical NSPs corroborates that targets are often poorly defined, aspirational, and not linked to available data sources. The use of NSPs for country planning, grant applications, and monitoring and evaluation is limited by low quality target setting.

Health provider perspective on the pediatric HIV referral system in Lesotho

K. Hartsough, A. Schaaf, T. Gadisa, P. Tau, T.G. Harris
ICAP at Columbia University, New York, United States
Presenting author email: kch2104@columbia.edu

Background: Lesotho has the second highest adult HIV prevalence in the world, and 13,000 children living with HIV in 2015. While progress has been made towards universal access to HIV treatment, multiple barriers persist. As part of Lesotho's Accelerating Children's HIV/AIDS Treatment Initiative, we interviewed health care providers to obtain their perspective on the existing referral system for children living with HIV and HIV-exposed infants (HEI).
Methods: Interviews were conducted from May-June 2016 with health facility level providers involved in pediatric HIV-related referrals to identify gaps in the system. Guidelines, standard operating procedures, and monitoring and evaluation tools were reviewed. Descriptive analyses were conducted.
Results: We interviewed 101 individuals from 27 health facilities. Among health facility staff, 96% used the HIV testing and counseling (HTC) register to document pediatric HTC, while the Under-5 (74%), tuberculosis (59%), and pediatric inpatient (30%) registers were also used. Patient escort was the primary mechanism used for within facility referrals (72%). Decisions on where to make inter-facility referrals is primarily made through provider knowledge (70%) while few (5%) used a referral directory. Most providers made inter-facility referrals using the standard patient referral form (88%) and writing referral information on the patient's personal medical record book (64%). Twenty-eight percent of providers indicated there was a system to confirm referral completion, with the most common method a phone call to the receiving facility (62%); 45% indicated no referral follow-up is done. Fifty-four percent of health facilities used a referral protocol. Multiple tools were used to document prevention of mother-to-child transmission (PMTCT) services and to track HEI.
Conclusions: A variety of mechanisms were used for within and inter-facility pediatric referrals, which can lead to poor linkage and retention. Consistent use of client escort to ensure within facility linkage, establishment of a standardized referral directory, and a system to conduct and document referral completion are needed to strengthen the referral system. Until a national unique patient identifier is implemented, a unique number within facilities to enable longitudinal tracking of women living with HIV and HEI across different service points is needed.

WEPED1462

Stock-outs of antiretroviral and tuberculosis medicines in South Africa: a national cross-sectional survey

B. Hwang[1], T. Gils[2], G. Van Cutsem[2], A. Shrouffi[2], S.-J. Steele[2], J. Hill[2], S. Tafeni[3], L. Jankelowitz,[4], A. Grimsrud[5]
[1]Medecins Sans Frontieres, North Vancouver, Canada, [2]Medecins Sans Frontieres, Cape Town, South Africa, [3]Stop Stock Outs Project, Johannesburg, South Africa, [4]Southern Africa HIV Clinicians Society, Johannesburg, South Africa, [5]International Aids Society, Cape Town, South Africa
Presenting author email: bellah@gmail.com

Background: Stock-outs of antiretroviral medicines (ARVs) and tuberculosis (TB) medicines in treatment facilities limit the capacity of national programs to treat growing numbers of patients successfully and prevent the development and spread of antimicrobial resistance.
The aim of this analysis was to determine the magnitude of stock-outs of ARVs and TB medicines in public health facilities in South Africa.
Methods: This was a cross-sectional study using structured telephonic interviews with healthcare workers in all public health facilities providing ARVs and TB services in South Africa between October and December 2015. Data included the existence of stock-outs of ARVs and TB medicines on the day of the call and in a three-month period preceding the contact. When stock-outs were reported, questions were asked about the medicines out-of-stock, the duration of the stock-out and solutions the facility proposed to patients presenting during the stock-out.
Results: Out of 3547 facilities identified, 2804 (79%) could be reached, of which 2463 (88%) participated and 2370 (96%) were analysed. Nationwide, 36% (864/2370) and 20% (285/2370) of facilities reported at least one ARV and/or TB medicine stock-out during the three month period prior to contact and the day of contact, respectively. Out of 1467 stock-outs reported in three months, 74% were adult ARVs, 20% paediatric ARVs and 7% TB-related medicines. 70% (532/763) of resolved stock-outs had lasted over one month. In 25% (366/1449) of stock-out cases patients did not receive treatment or an incomplete ART regimen. Stock-outs occurrence, duration and mitigation mechanisms varied widely between provinces. While 24% (348/1476) of facility stock-outs resulted from a nationwide stock-out of adult lopinavir/ritonavir, 76% (1128/1476) of cases happened while the medicines were available in country. The national stock-out resulted from inability of the single supplier to meet demand. Legislative reform should ensure market access for multiple suppliers of lifesaving medicines. In-country, province-specific supply chains should be evaluated and improved. Independent alert mechanisms could reduce stock-out duration and impact.
Conclusions: Stock-outs of ARVs and TB medicines in South Africa affect patient and threaten national ambitions to end the epidemics. Patient-centred action is needed from multiple stake-holders to stop stock-outs.

WEPED1463

HIV treatment cascade assessment of a community-based test and start model for key populations in Lagos, Nigeria: where are the gaps?

J. Njab[1], S. Adebajo[1], W. Tun[2], E. Shoyemi[3], P. Osakwe[3], C. Eke[3], D. Offie[3], G. Eluwa[1], D. Iriaye[1], Y. Adamu[4]
[1]Population Council, Abuja, Nigeria, [2]Population Council, Washington, United States, [3]Population Council, Lagos, Nigeria, [4]US Military HIV Research, Department of Defense Walter Reed Program-Nigeria, Abuja, Nigeria
Presenting author email: jnjab@popcouncil.org

Background: Targeted community-based test and start (TAS) models have shown potential to improve clinical outcomes for key populations because they provide unrestricted access to comprehensive HIV services. We assessed the performance of a TAS model for key populations (KP) in Lagos along the UNAIDS 90/90/90 cascade.
Methods: Men who have sex with men (MSM), female sex workers (FSW), and persons who inject drugs (PWID), >14 years of age were recruited through peer-referral for HIV testing services (HTS) at a community-based KP-friendly clinic in Lagos between June 2015 and September 2016. The clinic provides comprehensive HIV services, including HIV treatment. Those who test positive are enrolled and provided with TAS services. Using routine service data, we determined the performance along the 90/90/90 cascade.
Results: In total, 8,812 KPs comprising MSM (51.6%), FSW (32.7%) and PWID (15.7%) were tested during this period. About one-half (46.4%) were young KP (15 - 25 years). The majority (76.1%) were male, single (86.1%), almost all (99%) had at least primary school level education, and about one-quarter (25.1%) were employed. Among MSM, 506 (11.1%) tested positive, 276 (54.5%) were initiated on ART, of whom 155 conducted viral load testing and 88 (56.7%) had achieved viral suppression (< 1000 copies per milliliter). Among FSW, 88 (3.1%) tested positive, only 28 (31.8%) were initiated on ART, of whom 15 conducted viral load testing and 9 (60%) achieved viral suppression. Among PWID, of 15 (1.1%) who tested positive, only 2 (13%) were initiated on ART and none had conducted viral load testing.
Conclusions: The current community-based model shows excellent capacity to achieve the first 90 goal among target KP communities. However, linkage to care and treatment, adherence, and retention remain significant challenges in achieving the second and third nineties at the community level.

WEPED1464

Are health systems addressing comorbidities in people living with HIV? An assessment of key European HIV guidelines and monitoring mechanisms

J.V. Lazarus[1,2], K. Safreed-Harmon[2], M. Hoekstra[2], N. Azzopardi-Muscat[3], U. Davidovich[4], M. Kall[5], T. Noori[6], J. Anderson[7], on behalf of the Health Outcomes Beyond Viral Suppression Study Group
[1]CHIP, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [2]Barcelona Institute of Global Health (ISGlobal), University of Barcelona, Barcelona, Spain, [3]University of Malta, Faculty of Health Science, Department of Health Services Management, Msida, Malta, [4]Amsterdam Public Health Service and the Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Public Health England, London, United Kingdom, [6]European Centre for Disease Prevention and Control, Stockholm, Sweden, [7]Homerton University Hospital NHS Foundation Trust, London, United Kingdom
Presenting author email: janderson@nhs.net

Background: Widespread access to antiretroviral therapy has brought about major reductions in HIV-related morbidity and mortality in much of the WHO European Region, but non-AIDS related comorbidities now impose a large burden of disease on people living with HIV (PLHIV). It is unclear whether health systems have sufficient information about comorbidity prevention and treatment in PLHIV, or whether they are effectively monitoring service delivery issues related to comorbidities.
Methods: We selected nine non-AIDS-related comorbidities that are prevalent among PLHIV in Europe, based on recent literature. Two researchers independently used a three-point grading system to assess the extent to which each is addressed in the WHO European clinical protocols for HIV (2012), European AIDS Clinical Society (EACS) guidelines (2016) and the 2016 Dublin Declaration Questionnaire developed by the European Centre for Disease Prevention and Control (ECDC). Discrepancies in grades were reviewed by two other researchers and resolved through consultation.
Results: The WHO protocols deal only with liver diseases and to some extent depression. EACS guidelines address physical comorbidities in a concise yet comprehensive manner, but do not address prevention of neurocognitive and mental health issues. The Dublin questionnaire does not ask for information on specific comorbidities other than tuberculosis. It does ask if there are "effective systems in place to ensure that" PLHIV are linked to care and services in very broadly defined areas, such as "mental health" and "chronic disease" (Table 1).

Type of comorbidity	Addressed in WHO/Europe HIV clinical protocols	Addressed in European AIDS Clinical Society guidelines	Access to services monitored via Dublin questionnaire	Comorbidity burden monitored via Dublin questionnaire
Non-AIDS malignancies	C	B[1]	C	C
Cardiovascular disease	C	A	C	C
Renal disease	C	A	C	C
Hepatitis B virus	A	A	A	C
Hepatitis C virus	A	A	A	C
Liver diseases other than chronic viral hepatitis	A	B	C	C
Neurocognitive disorders	C	B[2]	C	C
Depression	B	B[2]	B	C
Drug dependence	C	B[2]	B	B

[1] Vaccination and screening only. [2] Treatment only (i.e., not prevention). [3] Burden of HIV disease monitored in people who inject drugs.

A = addressed sufficiently
B = addressed but not sufficiently
C = not addressed

[Table 1. Analysis of how comorbidities are addressed in the WHO/Europe clinical protocols for HIV, European AIDS Clinical Society guidelines and the 2016 Dublin Declaration Questionnaire]

Conclusions: When revising WHO/Europe and EACS HIV clinical guidelines, greater attention to non-AIDS-related comorbidities will help to inform healthcare officials and providers about the full range of PLHIV health needs. Likewise, ECDC might consider consulting countries on the need to monitor the burden of specific comorbidities and to expand the list of specific types of care and services to which access is being monitored.

WEPED1465

Using effective and flexible M&E systems for timely and accurate data in HIV/AIDS programming: bridging data quality gaps

D. Damba
Baylor College of Medicine Children's Foundation, Strategic Planning and Monitoring & Evaluation, Kampala, Uganda
Presenting author email: ddamba@baylor-uganda.org

Background: In the era of "last mile" HIV programming to meet the UNAIDS 90-90-90 targets, strategies to increase HIV service coverage have been widely advocated for and implemented. However less attention has been given to strengthening M&E systems for tracking and decision making. This abstract presents evidence based M&E best practices for improved data quality and challenges.
Methods: Baylor Uganda is implementing three HIV/AIDS/TB projects in 266 health facilities in Uganda. M&E related interventions implemented include; onsite training, mentorship, support supervision, M&E financing, provision of data tools, computerization, leadership training and human resource support. In 2014, we implemented additional interventions: monthly onsite data review meetings, district coordination meetings and data quality improvement projects. In this study 54 sites had their M&E systems assessed before (2014) and after additional interventions (2016). We reviewed reports, registers and compared reported data versus actual count. Open-ended interviews were held with supervisors. Indicators selected to assess accuracy were: HIV positive individuals identified, started ART and 12 month ART retention. Odds ratios were estimated using SAS 9.2.
Results: Results showed a great improvement in data quality and data use for decision making as a result of the interventions. Reporting rates increased from 83% to 100% and timely reporting from 70% to 95%. The odds of facilities reporting accurately after the additional interventions were higher than before by 4.1 times (OR=4.1 95%CI, 2.97-7.15), report completeness was higher by 2.3 times (OR=2.3, 95%CI=1.71-6.19) and consistency was two-fold better (OR=2.12, 95%CI=1.32-3.74). The average time of generating reports improved from 7-10 days to 1-3 days. Ten out of 15 supervisors indicated that they used data to make a decision. The proportion of sites that had action plans tracked and updated increased from 25% to 60%. All facilities had a dedicated person for data management, However sustainability and Irregular supply of data tools were their main challenges.
Conclusions: Scale-able and effective M&E best practices resulted in improved data quality and data-use for decision making. Program implementer need to plan for prioritized implementation and innovate strategies for sustainability.

Presenting author email: genevieve.martin@ndm.ox.ac.uk

Background: CD32 has been identified as a marker of a substantially enriched HIV reservoir. Here we explore the relationship of CD32 expression on CD4 T cells with other correlates of reservoir size including time to viral rebound after treatment interruption.
Methods: CD32 expression was measured by flow cytometry on PBMCs (n=39) and tonsillar tissue (n=1) from individuals who initiated ART during primary HIV infection (PHI), and uninfected controls (n=10). Co-expression with immune checkpoint receptors (ICRs), lineage, memory and T follicular helper (Tfh) markers was measured. HIV DNA was quantified in bulk and sorted CD32+ and CD32- populations.
Results: One-year post-ART initiation, the frequency of CD32+ CD4 T cells was 1.5% (range 0.2-6.4), and did not differ from controls. CD32+ CD4 T cells were found predominantly within differentiated memory subsets (transitional, effector memory, and T_{EMRA}) compared with CD32- CD4 T cells (all p< 0.001) for HIV+ (n=20) and controls. CD32+ CD4 T cells were highly enriched for HIV DNA compared with CD32- cells (average 103-fold, n=6, p=0.03), although CD32 percentage did not correlate with reservoir size (n=29). In a subset of individuals (n=19) who interrupted ART after 48 weeks, CD32+ CD4% did not predict viral load rebound, although all three individuals with persistently undetectable viraemia had CD32+ CD4% below the median.
CD32+ CD4 T cells from blood had higher expression of PD-1, Tim-3 and TIGIT (all p< 0.0001) and a higher density of CD2 (p=0.001) than CD32- cells in HIV+ participants (n=20) and controls. Tonsil CD32+ CD4 T cells (n=1) showed a similar pattern of memory distribution and ICR expression as the periphery. Although tonsillar CD32+ CD4 T cells had higher individual expression of Bcl-6, ICOS and CXCR5 than CD32- cells, the co-expression pattern was not consistent with a Tfh phenotype.
Conclusions: We confirm the role of CD32 as a marker of the HIV reservoir, and show that this may occur early during PHI on more differentiated CD4 T cells and is highly co-expressed with ICRs. That expression is similar between HIV+ and HIV- individuals suggests that preferential infection or survival of CD32+ cells, rather than CD32 up-regulation, is responsible for the observed enrichment.

Background: Integrase strand transfer inhibitors (INSTIs) are recommended as first-line antiretroviral therapy in combination with 2 nucleoside reverse transcriptase inhibitors. Bictegravir (B), a novel, potent INSTI with a high in vitro barrier to resistance and low potential for drug interactions, has been coformulated with emtricitabine (F) and tenofovir alafenamide (TAF) as a fixed-dose combination (B/F/TAF). We report results from a blinded phase 3 study comparing B/F/TAF to coformulated abacavir, dolutegravir, and lamivudine (ABC/DTG/3TC).
Methods: HIV-infected, treatment-naïve, HLA-B*5701-negative, HBV-uninfected adults with estimated glomerular filtration rate (eGFR) ≥50 mL/min were randomized 1:1 to receive blinded treatment with fixed-dose combination B/F/TAF (50/200/25 mg) or ABC/DTG/3TC (600/50/300 mg) with matching placebos once daily. The primary endpoint was proportion of participants with HIV-1 RNA (VL) < 50 c/mL at W48 (FDA snapshot). Noninferiority was assessed through 95.002% confidence intervals (CI) (12% margin). Secondary endpoints were safety (adverse events [AEs] and laboratory abnormalities) and pre-defined analyses of changes from baseline in bone mineral density (BMD) and measures of renal function, including eGFR and proteinuria.
Results: 629 participants were randomized and treated (314 B/F/TAF, 315 ABC/DTG/3TC): 10% women, 36% Black, 16% VL >100,000 c/mL, 11% CD4 < 200 cells/mL. Median baseline characteristics: age 32 yrs, CD4 count 444 cells/μL, and VL 4.47 log10 c/mL. At W48, B/F/TAF was noninferior to ABC/DTG/3TC, with 92.4% on B/F/TAF and 93.0% on ABC/DTG/3TC achieving HIV-1 RNA < 50 c/mL (difference -0.6%; 95.002%CI -4.8% to 3.6%, p=0.78). No resistance mutations emerged in either group. Comparing B/F/TAF to ABC/DTG/3TC throughout, the most common AEs were diarrhea (13%, 13%), headache (11%, 14%), and nausea (10%, 23%). Few participants (0 vs 4 [1%]) had any AEs leading to premature study drug discontinuation. At W48, mean % changes from baseline in BMD were -0.83% vs. -0.60% (p=0.39) [lumbar spine] and -0.78% vs. -1.02% (p=0.23) [total hip]. No differences between treatments were noted in changes from baseline for eGFR and proteinuria at W48.
Conclusions: At W48, B/F/TAF achieved virologic suppression in 92.4% of treatment-naïve adults and was noninferior to ABC/DTG/3TC, with no emergent resistance. B/F/TAF was safe and well tolerated with less nausea than ABC/DTG/3TC. Bone and renal safety profiles were similar between groups.

Dual therapy with darunavir/ritonavir plus lamivudine for HIV-1 treatment initiation: week 24 results of the randomized ANDES study

O. Sued[1], M.I. Figueroa[1], A. Gun[2], W. Belloso[3], D. Cecchini[4], G. Lopardo[5], D. Pryluka[6], M.J. Rolon[1], V. Fink[1], S. Perez Lloret[7], P. Cahn[1]
[1]Fundacion Huesped, Clinical Research, Buenos Aires, Argentina, [2]Fundacion Huesped, Laboratory research, Buenos Aires, Argentina, [3]Hospital Italiano, Clinical Research, Buenos Aires, Argentina, [4]Hospital Cosme Argerich, Infectious Diseases Unit, Buenos Aires, Argentina, [5]Centro de Estudios Infectologicos SA (CTD Stamboulian), Buenos Aires, Argentina, [6]Consultorio Infectológico Dr. Pryluka, Buenos Aires, Argentina, [7]Institute of Cardiology Research , University of Buenos Aires, National Research Council (CONICET-ININCA), Buenos Aires, Argentina
Presenting author email: omar.sued@huesped.org.ar

Background: Following the results of the GARDEL trial, dual therapy (DT) has been explored in different studies. Generic fixed dose combinations (FDC) of Darunavir/ritonavir (DRV/rtv) 800/100 mg and Tenofovir/Lamivudine(TDF/3TC)

are available in Argentina. This study compares DRV/rtv plus 3TC to standard-of care triple therapy (TT) based on these same drugs plus Tenofovir (TDF).
Methods: ANDES is a randomized, open-label, phase IV study, designed to assess the antiviral efficacy, safety and tolerability of DT with DRV/rtv (800/100 mg) FDC, plus 3TC (300 mg), compared to TT with DRV/RTV (800/100 mg) plus TDF/3TC (300/300mg) FDC in treatment-naïve HIV-1 infected patients. Primary endpoint: proportion of patients with viral load (pVL) <50 copies/mL at week 48. Preplanned analyses at week 24, measured by the proportion of patients with pVL <400 copies/mL (ITT-exposed analysis, FDA snapshot algorithm) are reported. ClinicalTrials.gov Identifier:NCT02770508.
Results: Out of 182 patients screened, 145 were randomized to receive: DT (n:75) or TT (n:70). Screening failure rate 20%. At baseline: 91% were male; median age 30 years; CDC stage A: 92%; 24% had pVL >100,000 copies/mL. At week 24, 94.7% (n:71) of patients receiving DT and 97.1% (n:68) receiving TT were responders (pVL < 400 copies/mL), difference -2.5 % (95% CI:-7.9-2.9) Patients with baseline pVL >100,000 copies/mL (n:35) showed 100% response in both arms. One patient had virological failure at W24 due to non-compliance (control arm). Mean CD4+ increases were similar in both arms (DT=206 cells/mm3; TT=204 cells/mm3).Sixty-seven grade 2-3 possible/probable related adverse events (AEs) were reported in 51 patients (36%), most frequent were gastrointestinal (22%) and rash (14%). AEs incidence was similar in both arms; one patient was discontinued due to a drug-related grade 3 adverse event (rash).
Conclusions: A generic combination of DRV/RTV in fixed-dose plus 3TC showed non-inferiority to a generic triple drug regimen of DRV/RTV plus TDF/3TC at 24 weeks. These results, if confirmed at week 48, may provide further evidence about the potential efficacy of dual therapy based on 3TC and a drug with a high genetic barrier.

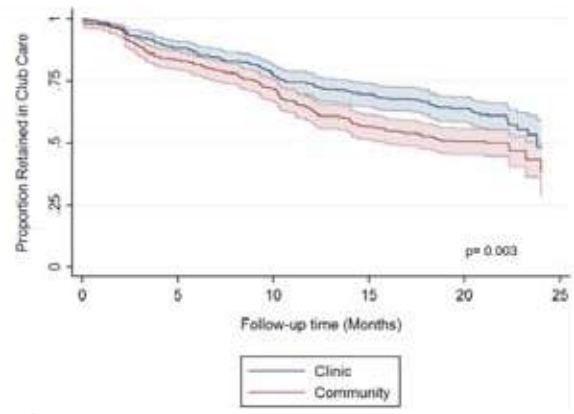
Retention in community versus clinic-based adherence clubs for stable ART patients in South Africa: 24 month final outcomes from a randomized controlled trial

C. Hanrahan[1], S. Schwartz[1], V. Keyser[2], M. Mudavanhu[2], N. West[1], L. Mutunga[2], J. Steingo[2], J. Bassett[2], A. Van Rie[3]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Witkoppen Health and Welfare Centre, Johannesburg, South Africa, [3]University of Antwerp, Antwerp, Belgium
Presenting author email: chanrah1@jhu.edu

Background: Adherence clubs, where groups of 25-30 patients stable on antiretroviral therapy (ART) meet for counselling and medication pick-up, is an innovative model to retain patients in care and facilitate task-shifting. Adherence clubs can be organized at a clinic or community venue. We performed a randomized controlled trial to compare club retention between community and clinic-based adherence clubs.
Methods: Stable patients with undetectable viral load at Witkoppen Clinic in Johannesburg, South Africa, were randomized to a clinic- or community-based adherence club. Clubs were held every other month. All club participants received annual viral load monitoring and medical exam at the clinic. Patients were referred back to standard clinic-based care if they missed a club visit without ART pickup within 5 days, had two consecutive late ART pickups, developed a comorbidity requiring closer monitoring, or had viral rebound. We assessed the proportion referred back to routine care by 24 months following randomization.



[Figure]

Results: From February 2014-May 2015, we randomized 775 adults into 12 pairs of clubs—376 (49%) clinic-based, and 399 (51%) community-based. Characteristics were similar by arm: 65% female, 89% on fixed-dose combination ART, and median CD4 count of 506 cells/mm^3. The proportion referred back to standard clinic-based care was greater among community-based (47%, n=191) compared to clinic-based clubs (37%, n=140, p=0.003) (Figure).
Adjusted for age, gender, employment and baseline CD4 count, community-based club participants had an increased risk of loss from club (aHR 1.43, 95% CI:1.15-1.79, p=0.001). Main reasons for return to clinic-based care were missing ART pickup (59%, n=198) or pregnancy (11%, n=36), and were similar by arm. Among those referred to standard care, 63% and 80% made a visit within 60 and 90 days respectively of their last club visit.
Conclusions: By two years, drop-out from adherence club participation was high (43%) and higher among community-based compared to clinic-based clubs.

HIV self-testing among female sex workers in Zambia: a randomized controlled trial

M. Chanda[1], K. Ortblad[2], M. Mwale[1], S. Chongo[1], C. Kanchele[1], N. Kamungoma[1], A. Fullem[3], C. Dunn[3], L. Barresi[2], G. Harling[2], T. Bärnighausen[2,4,5], C. Oldenburg[6]
[1]John Snow, Inc, Lusaka, Zambia, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]John Snow, Inc, Boston, United States, [4]University of Heidelberg, Heidelberg, Germany, [5]Africa Health Research Institute, Somkhele, South Africa, [6]University of California, San Francisco, F.I. Proctor Foundation, San Francisco, United States
Presenting author email: catherine.oldenburg@ucsf.edu

Background: HIV self-tests (HIVST) may help increase HIV testing coverage to meet the 90-90-90 target in female sex worker (FSW) populations. We report the results of a randomized controlled trial of HIVST among FSW in Zambia.
Methods: Trained peer educators in Kapiri, Chirundu, and Livingstone, Zambia each recruited 6 FSW participants. Peer educator-FSW groups were randomized to: 1) direct distribution of an oral HIVST from the peer educator, 2) distribution of a coupon for an oral HIVST available from a health clinic/pharmacy, or 3) referral to standard HIV testing. HIVST-arm participants received one HIVST at baseline and another three months later. Participants completed baseline, month-1, and month-4 questionnaires.
Results: 965 participants were enrolled between September-October 2016; 20% had never tested for HIV. 98.3% of direct distribution arm participants reported using their HIVST at month-1, compared to 86.3% in the coupon arm (P=0.001); this difference had disappeared by month-4. There was no significant difference in reported past-month testing for HIV at month-1 or month-4, although rates were highest for the direct arm at both timepoints. At month-1, 94.9%, 84.4% and 88.5% of direct-, coupon- and standard-arm participants reported testing in the past month (P=0.10 direct vs. standard, P=0.29 coupon vs. standard). At month-4, past-month testing coverage was 84.1%, 79.8% and 75.1% (P=0.11 direct vs. standard, P=0.42 coupon vs. standard).
Of 144 participants reporting a positive HIV test at month-1, 51.0% and 52.8% in direct- and coupon-arm participants reported linking to care, compared to 74.6% in the standard arm (P=0.07 direct, P=0.12 coupon). At month-4, of 235 participants reporting a positive test, 71.6%, 76.6% and 85.7% of direct-, coupon-, and standard-arm participants reported linking (P=0.13 direct, P=0.17 coupon). Three cases of HIVST-related intimate-partner violence (IPV) were reported, despite 60% of participants reporting IPV in the previous year.
Conclusions: HIVST provision via peer educators to Zambian FSW led to high test uptake and rapid linkage to care, including amongst those who had never previously tested, without a significant increase in IPV. HIVST should be considered as part of an intervention package to maximize HIV protection for FSW populations.

MOAX0106LB

Performance and usability of INSTI, a blood-based rapid HIV self test for qualitative detection of HIV antibodies in intended use populations in Kenya

M. Mwau, L. Achieng, P. Bwana
Kenya Medical Research Institute, Nairobi, Kenya
Presenting author email: mmwau@kemri.org

Background: HIV self testing is rapidly gaining acceptance as an effective method to reach undiagnosed individuals in sub-Saharan Africa, however there is very little documented data on performance of blood-based self tests in diverse intended-use populations. The self testing concept was approved in Kenya in 2015, but no products were available.
Methods: The Kenya Medical Research Institute (KEMRI) completed a study of the blood-based 60-second INSTI HIV Self Test to measure its performance, usability and readability in 688 consenting adults with broad demographic diversity, from Matayos, Bumutiru, Khunyangu, Aterait and Asinge villages in Busia County, Western Kenya. All subjects participated in the performance study, comparing INSTI results to 4th generation EIA results from venous blood collected from each subject. Portions of the study subjects also participated in qualitative usability and readability studies to assess label comprehension, ease of use and result interpretation.
The study was conducted between 22nd March and 11th April 2017, under ethics approval by the KEMRI Ethical Review Committee.
Results: Compared to the bioelisa HIV-1+2 Ag/Ab (Biokit S.A., Barcelona, Spain) EIA test, the specificity of the INSTI HIV Self test was 99.26% and sensitivity was 98.51%. Negative predictive value was 98.89% and positive predictive value was 99.00% for the study population. From the 350 subjects in the usability study, 98.00% found the test instructions easy to follow; 99.71% successfully added the blood droplet into INSTI bottle 1; 97.71% indicated willingness to use the test again; and 98.29% would recommend the kit to a partner. For the 91 subjects in the readability study, 100% correctly interpreted the positive, negative and invalid results, while 65.93% were unsure how to interpret the weak positive result.
Conclusions: INSTI is unique for its use of a "hanging" fingerstick blood drop, without the need for a collection device. This first field study of such a fingerstick blood-based self test provides strong evidence that the INSTI HIV Self Test is accurate, acceptable and easy to use by self testers with diverse backgrounds in sub-Saharan Africa. Modifications to the kit instructions to include a visual of a weak positive result would provide a more consistent interpretation.

Background: Cryptococcal meningitis (CM) accounts for 10-20% of HIV-related deaths and >100,000 deaths/year. Amphotericin (AmB) plus flucytosine for 2 weeks is considered the gold standard but is unavailable in resource-limited settings where fluconazole treatment predominates.
Methods: Based on phase II studies, we tested, against 2 weeks AmB-based treatment, 2 new strategies, which could be sustainable in Africa, and more effective than fluconazole: optimized oral therapy of high dose fluconazole plus flucytosine, and short (1 week) induction with AmB-based treatment. In the AmB arms we compared fluconazole and flucytosine as adjunctive treatments.
Between 2013 and 2016, 721 participants from 9 centres in Malawi, Zambia, Cameroon, and Tanzania with first-episode CM were randomized to:
Oral (238): fluconazole (1200mg/day) plus flucytosine (100mg/kg/day) for 2 weeks.
1-week (240): AmB (1mg/kg/d), plus fluconazole (1200mg/day), or flucytosine (100mg/kg/day) (ratio 1:1), for 7 days. Days 8-14, fluconazole 1200mg/day.
2-weeks (243): AmB (1mg/kg/d) plus fluconazole (1200mg/day), or flucytosine (100mg/kg/day) (ratio 1:1), for 14 days.
After 2 weeks, all received standard fluconazole consolidation. ART was started, or restarted, at 4 weeks, and patients followed-up to 10 weeks.
Results: Only 4 participants were lost-to-follow-up. Mortality at 2 and 10 weeks for oral, 1-week, and 2-weeks was 18%, 22%, 21%, and 35%, 36%, 40%, respectively. The upper 1-sided 95%CI limits for the difference in mortality comparing oral and 1-week against 2 weeks AmB-based treatment (primary endpoint) were 3.0% and 6.8%, below the pre-specified 10% non-inferiority margin. Hazard ratios (95%CI) were 0.82 (0.54-1.25) and 1.01 (0.68-1.51) at 2, and 0.83 (0.61-1.13) and 0.89 (0.66-1.21) at 10 weeks, for oral and 1-week vs 2-weeks, respectively. As adjunctive treatment with AmB, flucytosine was superior to fluconazole [HR(95%CI): 1.62(1.19-2.20) p=0.002]. One week AmB plus flucytosine had the lowest 10-week mortality (24%), significantly lower than all other AmB arms [HR(95%CI): 0.56(0.35-0.91) comparing 1-week with 2-weeks AmB plus flucytosine]. Side effects were more frequent with 2 weeks AmB than with 1 week AmB, or oral therapy.
Conclusions: One week AmB plus flucytosine and the oral combination provide safe, effective and sustainable induction therapy in resource-limited settings. Flucytosine should be made widely available for treatment of cryptococcosis.

Dolutegravir / tenofovir / emtricitabine (DTG/TDF/FTC) started in pregnancy is as safe as efavirenz / tenofovir / emtricitabine (EFV/TDF/FTC) in nationwide birth outcomes surveillance in Botswana

R. Zash[1,2,3], D. Jacobson[4], G. Mayondi[3], M. Diseko[3], J. Makhema[3], M. Mmalane[3], T. Gaolathe[3], C. Petlo[5], L. Holmes[6], M. Essex[2,3], S. Lockman[2,3,7], R. Shapiro[2,3]
[1]Beth Israel Deaconess Medical Center, Division of Infectious Diseases, Boston, United States, [2]Harvard TH Chan School of Public Health, Boston, United States, [3]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [4]Harvard TH Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [5]Ministry of Health, Gaborone, Botswana, [6]Massachusetts General Hospital for Children, Boston, United States, [7]Brigham and Women's Hospital, Boston, United States
Presenting author email: rzash@bidmc.harvard.edu

Background: Global rollout of DTG-based antiretroviral therapy (ART) has been hampered by lack of safety data in pregnancy.
Methods: We captured birth outcomes data at 8 government hospitals throughout Botswana (~45% of all deliveries) starting August 2014. In 2016, Botswana changed first-line ART from EFV/TDF/FTC to DTG/TDF/FTC, including for pregnant women. This analysis included women initiating either EFV/TDF/FTC (delivered August 2014 to August 2016) or DTG/TDF/FTC (delivered November 2016 to April 2017) during singleton pregnancy. Outcomes included combined endpoints of any adverse outcome (stillbirth, preterm birth [< 37 weeks], small for gestational age (SGA)[< 10th% weight-for-gestational age], or neonatal death [< 28 days]) and severe adverse outcomes (stillbirth, neonatal death, very preterm birth [< 32 weeks] and very SGA [< 3rd% weight-for-gestational age]). We fit log-binomial regression models, controlling for maternal age, gravidity and education, to estimate adjusted risk ratios (aRRs). Congenital abnormalities were detected by maternity nurse surface exam.
Results: Maternal characteristics were similar for women starting DTG/TDF/FTC (N=845) or EFV/TDF/FTC (N=4593), including age, education, occupation, parity, alcohol/tobacco use, history of adverse birth outcome, delivery site, gestational age at presentation for antenatal care, and CD4 cell count. ART was initiated at median [IQR] 19 [15, 25] weeks gestation for DTG/TDF/FTC and 21 [16, 27] for EFV/TDF/FTC. There were no significant differences in stillbirth, neonatal death, preterm or very preterm birth, SGA or very SGA by regimen (Table 1). Comparisons of any adverse birth outcome (aRR 1.0, 95%CI 0.9,1.1) and severe outcomes (aRR 1.0, 95%CI 0.8,1.2) were similar by regimen. Among 512 first-trimester ART initiations (116 DTG/TDF/FTC, 396 EFV/TDF/FTC), one major congenital abnormality was identified (skeletal dysplasia in an EFV-exposed infant).
Conclusions: Adverse birth outcomes were similar for DTG-based ART and EFV-based ART when started during pregnancy. Further studies are needed to determine the safety of DTG exposure from conception.

	Tenofovir/ emtricitabine/ DOLUTEGRAVIR (DTG/TDF/FTC) N=845	Tenofovir/ emtricitabine/ EFAVIRENZ (EFV/TDF/FTC) N=4593	Adjusted Relative Risk (95% CI) DTG/TDF/FTC vs. EFV/TDF/FTC
Any Adverse Outcome	291 (34.4%)	1606 (35.0%)	1.0 (0.9,1.1)
Severe Adverse Outcome	92 (10.9%)	519 (11.3%)	1.0 (0.8,1.2)

Weekly oral MK-8591 protects male rhesus macaques against repeated low dose intrarectal challenge with SHIVC109P3

M. Markowitz[1], A. Gettie[1], L. St. Bernard[1], H. Mohri[1], C.D. Andrews[1], A. Horowitz[1], J. Blanchard[2], B. Grasperge[2], L. Sun[3], K.L. Filigrove[3], D.J. Hazuda[3], J.A. Grobler[3]
[1]Aaron Diamond AIDS Research Center, Rockefeller University, New York, United States, [2]Tulane National Primate Research Center, Covington, United States, [3]Merck Sharp and Dhome, Kenilworth, United States
Presenting author email: mmarkowitz@adarc.org

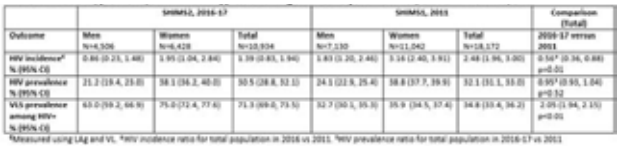
Background: MK-8591 (4'-Ethynyl-2-Fluoro-2'-Deoxyadenosine; EFdA) is a potent and long-acting nucleoside RT translocation inhibitor (NRTTI) in clinical development for the treatment of HIV-1 infection. Single 10 mg doses of MK-8591 resulted in suppression of viremia in HIV-1 infected patients for at least 10 days as have weekly doses of 3.9 mg/kg or greater in SIV-infected rhesus macaques (RM).
Methods: Two groups of 8 male RM were given 5 mL/kg of 10% Tween80 with (treated) or without (placebo) 3.9 mg/kg MK-8591 by oral gavage on day 0, day 7 and weekly thereafter for a maximum of 14 doses or until SHIV infection was confirmed. All animals were challenged intrarectally (IR) with 1 ml of 50 $TCID_{50}$ of SHIVC109P3, a viral stock derived from the third passage in RM of the molecular clone SHIVC109F.PB4, which contains an HIV Env initially derived from a newly HIV-infected Zambian. Challenges occurred on day 6 and weekly thereafter for a maximum of 12 challenges or until infection was confirmed. Prior to weekly challenge, blood was drawn to determine infection status and drug levels. Infection was confirmed by real-time RT PCR amplification of viral gag sequences in plasma on 2 consecutive samples. Proviral DNA was measured by PCR and virus-specific antibody responses were assessed. Intracellular levels of MK-8591-triphosphate (TP) were measured by LC/MS/MS.
Results: All placebo animals became infected after 1-4 challenges (median 1, mean 2). All treated animals remained uninfected after 12 challenges and were followed through week 24 without evidence of infection as determined by the absence of plasma viremia, proviral DNA and seroconversion. MK-8591-treated macaques had a 41.5-fold lower risk of infection (95% C.I 7.3, 237.9) compared with placebo macaques (p<0.0001, log-rank test). Mean trough concentrations of the active MK-8591-TP at the time of challenge were 4.07 mM (range: 2.26-5.17) and compare favorably with the level achieved by a weekly oral dose of 10mg in HIV-1-infected humans.
Conclusions: MK-8591 is a potent NRTTI that completely protected against repeated low-dose IR challenge in this SHIVC109P3/RM model with intracellular active drug concentrations readily achieved in humans. These results support the potential use of MK-8591 for HIV prophylaxis.

MOAX0204LB

Substantial progress in confronting the HIV epidemic in Swaziland: first evidence of national impact

R. Nkambule[1], H. Nuwagaba-Biribonwoha[2], Z. Mnisi[1], T.T. Ao[3], C. Ginindza[4], Y.T. Duong[5], H. Patel[6], S. Saito[5], N.M. Philip[5], K. Brown[6], C. Draghi[7], A.C. Voetsch[6], K. Mabuza[8], A. Zwane[4], R. Sahabo[2], V. Okello[1], T. Dobbs[6], B. Parekh[6], C. Ryan[3], J. Justman[5]
[1]Ministry of Health - Swaziland, Mbabane, Swaziland, [2]ICAP at the Columbia University, Mailman School of Public Health, Mbabane, Swaziland, [3]U.S. Centers for Disease Control and Prevention/ U.S. President's Emergency Fund for AIDS Relief (PEPFAR), Mbabane, Swaziland, [4]Central Statistics Office, Mbabane, Swaziland, [5]ICAP at the Columbia University, Mailman School of Public Health, New York, United States, [6]U.S. Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/AIDS, Atlanta, United States, [7]Association of Schools and Programs of Public Health, Washington, United States, [8]National Emergency Response Council on HIV/AIDS (NERCHA), Mbabane, Swaziland
Presenting author email: jj2158@columbia.edu

Background: Swaziland has the highest national HIV incidence and prevalence in the world. In response, the Swazi government extensively scaled-up national HIV prevention and treatment services. The 2016-17 Population HIV Impact Assessment (PHIA) Swaziland HIV Incidence Measurement Survey (SHIMS2) provides the first measure of the impact of national HIV programs scale-up on the epidemic's trajectory since the previous SHIMS1 survey conducted in 2011.
Methods: A nationally representative sample of individual ≥15 years (y) underwent household-based, rapid HIV testing from August 2016-March 2017. All HIV-positive samples were tested for HIV RNA and limiting antigen (LAg) Avidity. WHO criteria for HIV incidence estimates were used (LAg < =1.5 ODn and HIV RNA >1000 copies/ml). Viral load (VL) suppression (VLS) was defined as < 1000 copies/ml. Weighted measures of national HIV incidence, HIV prevalence, and population VL (among all HIV+, regardless of HIV knowledge or ART use) were compared with SHIMS1 results among adults 18-49 year.



[Table. HIV incidence, prevalence, and viral load suppression among adults 18-49 years in SHIMS2, 2016-17 and SHIMS1, 2011]

Results: A total of 10,934 participants ≥15y were tested, 3,003 tested HIV+, with HIV prevalence [95% Confidence Interval] of 27.0% [25.7, 28.3], and HIV incidence of 1.36% [0.92, 1.81]. Among adults 18-49y incidence was 1.39% [0.83, 1.94], a 44% decrease from the 2011 incidence estimate of 2.48% [1.96, 3.00]. Adult HIV incidence was higher among women 1.95% [1.04, 2.84] than men 0.86% [0.23, 1.48], with 38% and 53% decreases in women and men, respectively, from 2011. VLS among all HIV+ participants was 73.1% [71.3, 75.0]. Among HIV+ adults 18-49y, VLS was 71.3% [69.0, 73.5], a two-fold increase from the 2011 VLS of 34.8% [33.4, 36.2].
Conclusions: Since 2011, VLS prevalence in Swaziland has doubled and national HIV incidence has decreased by nearly half. These remarkable findings in a high prevalence setting provide the first direct measure of the national impact of expanded HIV prevention and treatment programs. Sustaining these achievements will be paramount to Swaziland's success in curbing its severe HIV epidemic.

Background: Long-acting (LA) injectable nanosuspensions of cabotegravir (CAB) and rilpivirine (RPV) are being developed. At the LATTE-2 W32 primary endpoint, response rates were statistically comparable between injectable every 4 weeks (Q4W), injectable every 8 weeks (Q8W) LA arms and daily oral CAB 30 mg + ABC/3TC (PO) dosing.
Methods: Phase 2b, multicenter, parallel group, open-label study in ART-naïve HIV infected adults. Patients with plasma HIV-1 RNA <50 c/mL during the 20-week Induction Period on once daily oral CAB + ABC/3TC were randomized 2:2:1 to IM CAB LA + RPV LA Q4W, Q8W or PO in the Maintenance Period (MP). Evaluations included; antiviral activity < 50 c/mL (FDA snapshot analysis), protocol defined virologic failure (PDVF), and safety at the pre-specified W96 secondary endpoint in MP (ITT-Maintenance Exposed (ME)).

Week 96 Snapshot Study Outcomes (ITT-ME) **	CAB LA + RPV LA Q8W[δ] (n=115)	CAB LA + RPV LA Q4W[δ] (n=115)	Oral CAB 30 mg + ABC/3TC (n=56)
%HIV-1 RNA <50 c/mL at W96: Diff in Proportions (95%CI)	94% (10.0: -0.6, 20.5)	87% (3.0: -8.4, 14.4)	84%

Intent to Treat- Maintenance Exposed (ITT-ME)
BL = baseline (last value prior to first Induction Period dose at Week -20)
IQR = Interquartile range
**W96 represents 116 weeks on study (20 Week Induction Period with oral CAB 30 mg + ABC/3TC followed by 96 Weeks of Randomized Maintenance Period Therapy)
δQ8W: CAB LA 600 mg + RPV LA 900 mg IM every 8 Weeks; Q4W: CAB LA 400 mg + RPV LA 600 mg IM every 4 Weeks
* Includes one subject with withdrawn consent due to intolerance to injections
* Q8W: ISR/chills/body pain (n=1); Q4W: Hepatitis C (HCV) (n=1), rash (n=1), depressive reaction (n=1), psychotic state (n=1), Churg Strauss vasculitis (n=1), epilepsy (death) (n=1), mesenteric vein thrombosis (n=1), QT prolongation/Sinus Tachycardia (n=1), met liver stopping criteria (n=1); PO: Acute HCV (n=1), Drug Induced Liver Injury (DILI) (n=1)
‡ Based on observed values at Week 96 (Q8W: n=109; Q4W: n=100; Oral: n=47)

[Table]

Results: 309 patients were enrolled (ITT-Exposed): 91% male, 20% non-white, and 19%>100,000 c/mL HIV-1 RNA. 286 patients were randomized into the MP. At W96, 94% (Q8W), 87% (Q4W) and 84% (PO) remained suppressed (ITT-ME). Three ME patients had PDVF through W96; two Q8W (one at W4 and one at W48 with NNRTI/INI mutations) and one PO at W8. SAEs occurred in 10% (Q8W), 10% (Q4W) and 13% (PO) patients, none were drug related. Excluding injection site reactions (ISRs), 2% (Q8W) 4% (Q4W) and 2% (PO) reported drug-related AEs ≥ grade 3. Only two patients had ISRs leading to discontinuation through W96. Majority of ISRs were mild/moderate pain and discomfort with < 1% of ISRs classified severe. Emergent lab abnormalities ≥ Grade 3 occurred in 19% (Q8W), 29% (Q4W) and 21% (PO).
Conclusions: LA injectable 2-drug therapy given either Q8W or Q4W IM demonstrated high rates of virologic response and was well tolerated through 96 weeks. Difference in virologic success between Q8W and Q4W is primarily due to non-virologic reasons. Phase 3 studies are evaluating Q4W dosing.

Treatment of chronic hepatitis C genotype 1, 2 and 4 in patients with or without HIV and living in Central or West Africa: the TAC ANRS 12311 trial

K. Lacombe[1], R. Moh[2], C. Chazallon[3], J. Lecarrou[3], B. Sylla[4], M. Lemoine[5], C. Kouanfack[6], L. Ciaffi[6], F. Fadiga[2], N. Rouveau[7], J. Gozlan[8], M. Seydi[9], V. Cissé[8], C. Danel[2], P.M. Girard[1], A. Attia[10], and the TAC ANRS 12311 study group
[1]Inserm UMR-S1136, Université Paris VI - APHP, Paris, France, [2]MEREVA, PACCI, Abidjan, Cote D'Ivoire, [3]ISPED, Bordeaux, France, [4]IMEA, Paris, France, [5]Imperial College, London, United Kingdom, [6]Hôpital Central, Site ANRS, Yaoundé, Cameroon, [7]ANRS, Paris, France, [8]Service de Virologie, Hôpital St Antoine, APHP, Paris, France, [9]Service de Maladies Infectieuses - CRCF, Hôpital Fann, Dakar, Senegal, [10]10Service d'Hépatologie, CHU Yopougon, Abidjan, Cote D'Ivoire

Background: With the advent of highly effective direct antiviral agents against chronic hepatitis C (CHC) and the recent World Health Organization commitment, HCV elimination has become realistic. However, in sub-Saharan Africa (SSA) the HCV epidemic remains a neglected issue and access to care and treatment is almost inexistent. The TAC ANRS 12311 trial is an international multicenter open label trial aimed to assess the feasibility, efficacy and safety of q combination of interferon-free DAA in HCV-infected patients in the SSA setting.
Methods: Adult patients with treatment-naïve CHC were recruited in Senegal, Côte d'Ivoire and Cameroon. Patients without decompensated cirrhosis received a 12 week-combination of sofosbuvir plus weight-based ribavirin (SOF+RBV) if infected with genotype (GT) 2 or sofosbuvir/ ledipasvir (SOF+LDV) if infected with GT1 or 4. This trial included 120 participants (40 per GT). We present here the outcomes in the first 110 participants (GT-1, n=33; GT-2, n=40; GT-4, n=37).
Results: Among the participants (male 55%, median age 58 years [IQR 48-63], median plasma HCV-RNA 6.0 logIU/mL [IQR 5.5 -6.5]), 32 were HIV-coinfected (median CD4: 624/mm3, IQR 442-844), all with plasma HIV-RNA< 200 copies/ MI. Eleven patients were cirrhotic (APRI score>2). All but one patient completed the 12-week treatment course, and the remaining one discontinued treatment for personal reason (travel abroad). No patient died or was lost to follow-up. No severe adverse event occurred. Four patients had a haemoglobin decrease between 85 and 100 g/L, and two had a consequent reduction of RBV dosage. HCV-RNA was measured at week 24 (documenting SVR12) and 98/110 (89%) had undetectable viral load (threshold of detectability 12 or 25 IU/mL): 29 (88%) in GT-1, 36 (90%) in GT-2, and 33 (89%) in GT-4. Three out of 12 failing patients were cirrhotic at baseline. Viral strains of failing patients are currently been sequenced.
Conclusions: In this interim analysis, HCV treatment appeared to be feasible, safe and effective in sub-Saharan Africa including in HIV co-infected patients. With the growing access to HCV drugs at generic price worldwide, it is time to prompt scaling up of HCV care and management in Africa.

TUAA01 The Wrestling Match: Virus Versus Immune Cells

TUAA0106LB

Efficacy of epithelial stem cell-based AIDS vaccine to induce mucosal immune responses offering protection against SIV challenge in macaques

M.-C.E. Gauduin[1], R. White[1], J. Garcia[1], P. Kozlowski[2], P. Blancou[3], P. Frost[4]
[1]*Texas Biomedical Research Institute, Virology and Immunology, San Antonio, United States,* [2]*Louisiana State University Health Sciences Center, New Orleans, United States,* [3]*University of Nice-Sophia Antipolis, Valbonne, France,* [4]*Southwest National Research Center, San Antonio, United States*
Presenting author email: mcgauduin@txbiomed.org

Background: A key obstacle limiting the development of an effective AIDS vaccine is the inability to deliver antigen for a sufficient period of time resulting in weak and transient protection. HIV transmission occurs predominantly across mucosal surfaces; therefore an ideal vaccine strategy would be to target HIV at mucosal entry sites to prevent infection.
Methods: We developed a SIV single cycle vaccine under the control of the involucrin promoter (pINV-SIVsc), which was tested for its ability to drive SIV expression in terminally differentiated epithelial cells, induce mucosal immune response, and offer better protection against SIV challenge. A total of 20 naïve young Rhesus macaques were selected (10/20 expressed MHC class I Mamu-A*01 allele). The pINV-SIVsc vaccine was administrated intravaginal (n=12) at week 0. Animals were monitored overtime for specific immune responses in blood and various tissues (n=4). Eight animals were challenged at week 12 (n=4) or at week 24 (n=4) using repeated pathogenic SIVmac239 and monitored for specific immune responses in blood and various tissues. Eight additional animals were infected with repeated SIVmac239, and served as unvaccinated Controls. Complementary approaches were used to characterize SIV-specific immune responses in blood, vaginal secretions, LN, and vaginal biopsies collected at various times.
Results: This vaccine induced strong mucosal IgA and IgG responses and specific T cells expressing a4ß7 homing to the mucosa. Repeated challenges revealed significant delay and lower viremia with 3-4 logs reduction at peak, 4-5 logs-reduction at set-point, and undetectable viremia by week 10-14 post-SIV in vaccinated females compared to Controls. Following challenge, we demonstrated a positive correlation between the generation of mucosal and systemic T cell responses and control of viremia, an Inverse association between viremia and post-infection vaginal IgA/IgG responses.
Conclusions: We have obtained evidence, within the limitation of the small animals´ number studied, that macaques vaccinated with pINV-SIVsc can generate strong mucosal SIV-specific T cell responses and local antibody responses (IgA/IgG). We demonstrated the efficacy of an epithelial stem cell-based SIV vaccine to serve as antigen delivery system suggesting an important role in protection against mucosal Infection.

Background: Doravirine (DOR) is a novel non-nucleoside reverse transcriptase inhibitor (NNRTI) with once-daily (QD) dosing. In the phase 3 DRIVE-FORWARD study in HIV-1 treatment-naïve adults receiving 2 NRTIs, DOR 100mg QD was non-inferior to darunavir+ritonavir on efficacy, and demonstrated a more favorable lipid profile.
Methods: DRIVE- AHEAD compared doravirine with efavirenz (EFV) in an ongoing phase 3, multicenter, double-blind, non-inferiority trial. Eligible participants were antiretroviral treatment-naïve adults with HIV-1 infection and pre-treatment HIV-1 RNA ≥1,000 c/mL. Participants were randomized (1:1) to a once-daily fixed-dose regimen of DOR 100mg, lamivudine 300mg and tenofovir disoproxil fumarate 300mg (DOR/3TC/TDF) or EFV 600mg, emtricitabine 200mg and TDF 300mg (EFV/FTC/TDF) for up to 96 weeks. Randomization was stratified by screening HIV-1 RNA (≤/>100,000 c/mL) and hepatitis B/C co-infection (yes/no). Primary efficacy endpoint was % of participants with HIV-1 RNA < 50 c/mL at week 48 (FDA Snapshot approach). Predefined non-inferiority margin was 10%. Primary safety endpoint was % of participants with prespecified neuropsychiatric adverse events (dizziness, sleep disorders/disturbances, altered sensorium).
Results: Of 734 participants randomized, 728 received study drug (364 in each treatment group) and were included in the analyses (mean age 33 years, 85% male, 48% white). At week 48, HIV-1 RNA < 50 c/mL was achieved by 84.3% (307/364) of DOR/3TC/TDF recipients and 80.8% (294/364) of EFV/FTC/TDF recipients (difference 3.5%, 95%CI [-2.0, 9.0]). The incidence of dizziness, sleep disorders/disturbances, and altered sensorium (table) was lower in DOR/3TC/TDF recipients than in EFV/FTC/TDF recipients (p< 0.001, p< 0.001, and p=0.033, respectively). Fasting LDL-C and non-HDL-C (table) were reduced by DOR/3TC/TDF and increased by EFV/FTC/TDF (both p< 0.0001).
Conclusions: In HIV-1 treatment-naïve adults, the efficacy of DOR/3TC/TDF at week 48 was non-inferior to EFV/FTC/TDF and similar regardless of baseline HIV-1 RNA. DOR/3TC/TDF was generally safe and well tolerated, with significantly fewer neuropsychiatric events than EFV/FTC/TDF and a favorable lipid profile.

Week 48 Efficacy & Safety Outcomes

HIV-1 RNA <50 copies/mL	DOR/3TC/TDF n/N	DOR/3TC/TDF %	EFV/FTC/TDF n/N	EFV/FTC/TDF %	Difference % (95% CI)
Overall†	307/364	84.3	294/364	80.8	3.5 (-2.0, 9.0)

Superior efficacy of dolutegravir (DTG) plus 2 nucleoside reverse transcriptase inhibitors (NRTIs) compared with lopinavir/ritonavir (LPV/RTV) plus 2 NRTIs in second-line treatment: interim data from the DAWNING study

M. Aboud[1], R. Kaplan[2], J. Lombaard[3], F. Zhang[4], J. Hidalgo[5], E. Mamedova[6], M. Losso[7], P. Chetchotisakd[8], J. Sievers[1], D. Brown[9], J. Hopking[10], M. Underwood[11], M.C. Nascimento[1], M. Gartland[11], K. Smith[11]
[1]ViiV Healthcare, Brentford, United Kingdom, [2]Desmond Tutu HIV Foundation, Cape Town, South Africa, [3]Josha Research, Bloemfontein, South Africa, [4]Beijing Ditan Hospital, Beijing, China, [5]VÍA LIBRE, Lima, Peru, [6]Kiev AIDS Centre, Kiev, Ukraine, [7]Hospital J M Ramos Mejía, Buenos Aires, Argentina, [8]Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand, [9]ViiV Healthcare, Abbotsford, Australia, [10]GlaxoSmithKline, Stockley Park, United Kingdom, [11]ViiV Healthcare, Research Triangle Park, United States

Background: DAWNING is a non-inferiority study conducted to compare a protease inhibitor-sparing regimen of DTG+2NRTIs with a current WHO-recommended regimen of LPV/RTV+2NRTIs in HIV-1 infected subjects failing first-line therapy of a non-nucleoside reverse transcriptase inhibitor (NNRTI) + 2 NRTIs (ClinicalTrials.gov: NCT02227238). An Independent Data Monitoring Committee (IDMC) performed periodic reviews of data to protect the ethical and safety interests of subjects.
Methods: Adult subjects failing first-line therapy, with HIV-1 RNA ≥400 copies(c)/mL, were randomised (1:1, stratified by Baseline plasma HIV-1 RNA and number of fully active background NRTIs) to 52 weeks of open-label treatment with DTG or LPV/RTV combined with an investigator-selected dual NRTI background, including at least one fully active NRTI. An IDMC review was performed, which included data from 98% (612/627 randomised) of subjects through 24 weeks on therapy.
Results: At Week 24, 78% of subjects on DTG versus 69% on LPV/RTV achieved HIV-1 RNA < 50 c/mL (adjusted difference 9.6%, 95% CI: 2.7% to 16.4%, p=0.006 for superiority). The difference was primarily driven by lower rates of Snapshot virologic non-response in the DTG group. The safety profile of DTG+2NRTIs was favourable compared to LPV/RTV+2NRTIs with more drug-related adverse events (AEs) reported in the LPV/RTV group, mainly due to higher rates of gastrointestinal disorders.
Following review of Week 24 data and large subsets of data from Weeks 36 and 48, the IDMC recommended discontinuation of the LPV/RTV arm due to persistent differences in rates of Snapshot virologic non-response and protocol-defined virologic failure (PDVF) favouring the DTG arm.

Week 24 outcomes	DTG (N=307)	LPV/RTV (N=305)
Snapshot virologic success	240 (78%)	210 (69%)
Snapshot virologic non-response	36 (12%)	64 (21%)
Data in window not <50 c/mL	33 (11%)	59 (19%)
Discontinued for other reason while not <50 c/mL or change in ART	3(1%)	5 (2%)
Snapshot no virologic data	31 (10%)	31 (10%)
Discontinued due to AE or death	5 (2%)	14 (5%)
Discontinued for other reason or missing data during window but on study	26 (8%)	17 (6%)
PDVF	5/312 (2%)	12/312 (4%)
Drug-related AEs	45/314 (14%)	107/310 (35%)

[Week 24 outcomes]

Conclusions: The IDMC recommended discontinuation of the LPV/RTV arm due to superior efficacy of DTG+2NRTIs and the potential to harm subjects on LPV/RTV based on available data. Final Week 24 results of this study will be presented. DAWNING provides important information to help guide second-line treatment decisions in resource-limited settings.

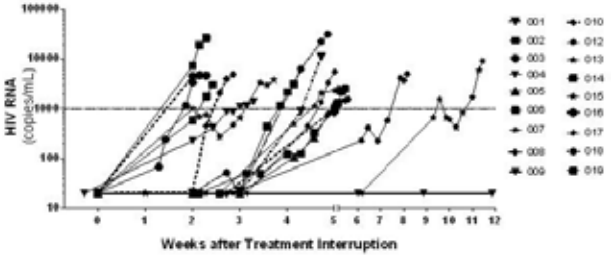
Presenting author email: tcrowell@hivresearch.org

Background: We present interim, blinded data exploring kinetics of viral load (VL) rebound in a randomized, placebo-controlled trial of VRC01 following analytic treatment interruption (ATI) in adults who initiated antiretroviral therapy (ART) during acute HIV infection (AHI). Study arms will be unblinded in June 2017.
Methods: Virologically-suppressed adults who initiated ART during AHI underwent ATI and randomization (3:1) to receive VRC01 40mg/kg or placebo intravenously every three weeks for up to 24 weeks. If virologically-suppressed at 24 weeks, observation continued off all therapies. Participants were monitored every 3-7 days for VL rebound and resumed ART for confirmed VL >1000 copies/ml or CD4 < 350 cells/mm^3.
Results: Twenty-three Thai males were enrolled. Four received no study product and one experienced grade II generalized urticaria during the first infusion, terminating study participation without ATI. These analyses include 18 participants who initiated ART during Fiebig I (n=1), II (n=10), or III (n=7); underwent randomization and ATI; and met a study endpoint (Table and Figure). As of May 9, 2017, one participant remained off ART with an undetectable VL for 32 weeks. All other participants experienced VL rebound, restarted ART, and re-achieved virologic suppression. Ten participants had detectable VL via single copy assay (range 0.44-2.1 copies/mL) at median 10 (range 7-29) days prior to rebound >20 copies/mL. There were no serious adverse events.

Baseline Participant Characteristics (n=18)	Median	Range
Age (years)	28	21-50
Duration of ART (years)	3.0	2.3-6.6
CD4 Count (cells/mm^3)	716	402-1,032
Key Results (n=17; excluding one participant without VL rebound)		
Time to Rebound Viral Load >20 copies/mL (days from ATI)	21	9-65
First Detectable Viral Load (copies/mL)	447	21-7,395
Highest Viral Load (copies/mL)	3,845	1,401-31,807
Time to Viral Load <20 copies/mL (days from ART resumption)	21	6-34

[Participant Characteristics and Key Results]



[Clinical Viral Load Assessments]

Conclusions: Participants who initiated ART during AHI and received VRC01 or placebo during ATI mostly experienced rapid VL rebound. Early ART alone or with VRC01 during ATI appears insufficient to delay time to VL rebound in most individuals.

Presenting author email: rlandovitz@mednet.ucla.edu

Background: Cabotegravir (CAB) is a novel strand-transfer integrase inhibitor, available as a long-acting injectable nanosuspension, under development for HIV treatment and prevention.
Methods: HPTN 077 is a Phase 2a, randomized double-blind placebo-controlled study of CAB at two doses. Participants were low-risk HIV-uninfected individuals at eight sites globally, randomized (3:1) to daily oral CAB 30mg (or placebo [PBO]) for four weeks(W), followed by CAB (or PBO) 800mg IM at W5, 17, and 29 (Cohort 1[C1]) or 600 mg IM at W5, 9, 17, 25, and 33 (Cohort 2[C2]).
Results: 110 participants enrolled in C1, 89 in C2. Median age 31y (IQR: 24,40), BMI 27 (IQR: 23,32), 66% female, 41% Black, 27% White, 24% Latino, 8% mixed/other. Overall, 94% completed the oral phase, 89% received at least one injection, and 75% completed all injections, which did not differ by arm, cohort or sex (**Table**). Over 41W, injection site pain and injection site reactions (ISR) were more common in CAB vs. PBO. No other differences were found in safety or tolerability. ISR led to injection discontinuation in 2/134 (1.5%).

	Overall (n=199)		Cohort 1 (n=110)		Cohort 2 (n=89)	
	CAB	PBO	CAB	PBO	CAB	PBO

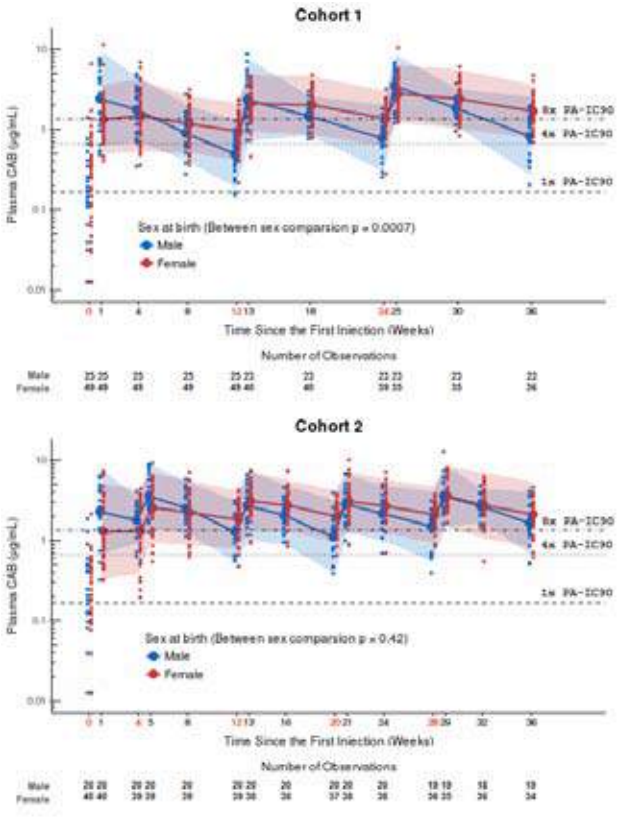
Female	80 (90%)	10 (36%)	44 (90%)	4 (27%)	36 (90%)	6 (46%)

[Table. Outcomes of Study PPTs by Cohort/Sex]

One seizure (participant with previous seizures) and one seroconversion (48W post last injection) occurred in CAB participants; CAB levels at the time of events were 278 ng/mL and < 25 ng/mL (LLQ), respectively. C2 dosing consistently achieved plasma trough targets; C1 dosing did not (Figure).



[Figure. Geometric Mean Conc and 90% Pred Interval]

Conclusions: CAB was well tolerated among low-risk HIV-uninfected men and women. Pharmacokinetics support the development of CAB for HIV prevention using 600mg IM every 8 weeks with a 4-week loading dose for all sexes.

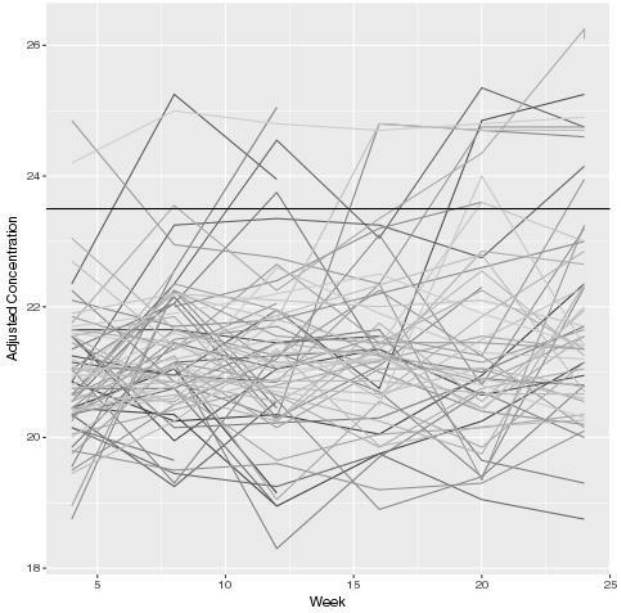
Presenting author email: kbunge@mail.magee.edu

Background: Young women ages 15-25 years are disproportionately affected by the HIV epidemic. Two phase 3 trials of a 25 mg dapivirine vaginal ring demonstrated HIV-1 risk reduction in adult women over 21, but not in those ages 18-21. Lack of protection was correlated with low adherence.
Methods: A Phase 2a randomized, double-blind, placebo-controlled trial of the dapivirine ring was conducted in sexually active females, ages 15-17. Participants were randomized 3:1 to a dapivirine or placebo ring to be inserted monthly for 6 months. Safety endpoints included grade 2 product-related adverse events (AE) and grade 3 and higher AEs. Adherence to ring use was assessed through self-report, plasma dapivirine concentrations and residual levels in used rings. A plasma dapivirine concentration >95 pg/mL was used to define short- term adherence

(hours); a dapivirine residual level < 23.5 mg was used to define long term adherence (monthly). Acceptability was assessed through computer assisted self-interviews.
Results: Ninety six participants were enrolled across six US sites. The mean age was 16.3 years; 59% were black and 34% white. Adherence to study visits was 97%. There were no differences in safety outcomes between treatment arms. By self-report 42% (95% CI 32, 52) of participants reported that they never removed the ring except to replace it monthly. In the dapivirine group, drug levels indicated adherence in 87% of plasma samples and 95% of rings. Participants noted no discomfort due to the ring at 87% of visits and "liking" the ring at 93% of visits. The most frequently cited concern (28%) involved their primary sex partner feeling the ring during sex.



[Spaghetti Plot of Residual Dapivirine Concentration]

Conclusions: The dapivirine vaginal ring, a promising microbicide approach, is safe and acceptable in this population. By self-report and objective measures, adherence was high. Discussing potential partner concerns with participants prior to ring use may positively influence adherence.

Pluspills: an open label, safety and feasibility study of oral pre-exposure prophylaxis (PrEP) in 15-19 year old adolescents in two sites in South Africa

K. Gill[1], J. Dietrich[2], G. Gray[2], T. Pidwell[1], F. Kayamba[1], T. Bennie[1], L. Myer[3], L. Johnson[3], H. Spiegel[4], C. Slack[5], V. Elharrar[4], A. Strode[5], J. Rooney[6], L.-G. Bekker[1,3,7]
[1]Desmond Tutu HIV Foundation, Cape Town, South Africa, [2]Perinatal HIV Research Unit, Johannesburg, South Africa, [3]University of Cape Town, Cape Town, South Africa, [4]NIH, Baltimore, United States, [5]University of Kwazulu Natal, Pietermaritzburg, South Africa, [6]Gilead Sciences, California, United States, [7]Desmond Tutu HIV Centre, Cape Town, South Africa
Presenting author email: katherine.gill@hiv-research.org.za

Background: South African adolescents are at risk for HIV acquisition. PrEP is licensed and being offered to key populations, but not yet to adolescents. This open-label 12-month PrEP study examined uptake, safety and adherence to PrEP and assessed sexual risk behaviour among adolescents in Soweto and Cape Town, South Africa
Methods: Sexually active, healthy, HIV negative, adolescents (15-19 years) participated in a study of Tenofovir/Emtricitabine PrEP. Participants were asked to take daily PrEP for at least 3 months, were seen monthly, after which they could opt-out of PrEP if preferred. At subsequent 3-monthly follow-up visits, participants could decide to stay on or off PrEP per preference. Laboratory and clinical safety monitoring occurred at each visit, including HIV and pregnancy testing. Plasma and dried blood spots (DBS) were serially collected for tenofovir (TFV) and tenofovir diphosphate (TFV-DP) levels at every PrEP refill visit. Plasma TFV levels were offered at each visit as part of adherence counselling.
Results: 244 individuals were screened and 148 were enrolled (median age 18,67%F). 3(1%) had undiagnosed HIV infection and 9 (6%) were pregnant at screening. STI diagnosis at baseline was high (40%) and remained high throughout. 26 (18%) participants opted out of PrEP at 12 weeks. Thereafter PrEP opt-out (and opt-in) at months 6 and 9 included 41% and 43% (5% and 7%) of the cohort respectively. PrEP was safe and reasonably well tolerated. Plasma TFV levels were detectable in 57% of participants at week 12, 38% at week 24 and 38% at study end. One HIV seroconversion occurred on study (0.76/100 person-years) in a 19 year old woman who had stopped PrEP 24 weeks prior to diagnosis
Conclusions: Pluspills enrolled a cohort of self-selected adolescents at high risk of HIV acquisition and offered an opportunity to engage on ethical norms for adolescent research. PrEP was safe and tolerable in those who persisted. However PrEP usage decreased and adherence diminished over time, when visits became less frequent. STI diagnoses remained constant and HIV incidence was low. SA adolescents need access to PrEP with tailored adherence support and potentially augmented visit schedules.

TUAC04 Prevention: It's Not Just about PrEP

Increasing knowledge of HIV status among men: a cluster-randomised trial of community-based distribution of oral HIV self-test kits nested in four HPTN 071 communities in Zambia

H. Ayles[1,2], S. Floyd[3], C. Mulubwa[2], B. Hensen[1], A. Schaap[2,3], M. Phiri[2], B. Chiti[2], K. Shanaube[2], M. Simwinga[2], V. Bond[2,4], S. Fidler[5], R. Hayes[3], A. Mwinga[2], on behalf of the HPTN 071 study team
[1]London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [5]Imperial College London, HIV Clinical Trials Unit, London, United Kingdom
Presenting author email: helen@zambart.org.zm

Background: HPTN071 (PopART) is a community-randomised trial evaluating the impact of a combination HIV-prevention intervention on HIV incidence. Overall, this intervention has reached the first UNAIDS 90, yet men and younger adults still have lower knowledge of HIV status. We nested a cluster-randomised trial of oral HIV self-testing (HIVST) in addition to rapid finger-prick HIV testing (HIVFP) offered door to door by lay counsellors (CHiPs) within HPTN071 to evaluate the impact on knowledge of HIV status.
Methods: Four of the Zambian HPTN071 intervention communities were randomised by CHiP zones, with an average of 471 households per zone. In HIVST zones (n=33/N=66), individuals aged ≥16 years who did not self-report being HIV-positive, were offered a choice of HIVST or HIVFP. Secondary distribution of HIVST was offered for absent partners. A population-average logistic regression model was used to estimate the effect of the HIVST intervention on knowledge of HIV status (definition: self-report HIV-positive or accepted HIV testing services), using total population enumerated as the denominator, adjusting for community, sex and age, and accounting for clustering by zone.

Characteristic	Enumerated in non-HIVST Zones	Knows HIV-status in non-HIVST Zones	Percent (%)	Enumerated in HIVST Zones	Knows HIV-status in HIVST Zones	Percent (%)	Odds Ratio	95% Confidence Interval	p-value
Total	13,383	8,203	61.3	12,852	8,139	63.3	1.25	1.01-1.56	0.04
Sex: Male	6,311	3,171	50.2	6,200	3,412	55.0	1.30	1.07-1.60	0.01
Sex: Female	7,072	5,031	71.1	6,652	4,727	71.1	1.03	0.85-1.25	0.74
Age (yrs): 16-29	6,841	4,541	66.4	6,565	4,508	68.7	1.24	1.01-1.53	0.04
Age (yrs): 30 and above	6,542	3,662	56.0	6,287	3,631	57.8	1.20	0.97-1.48	0.10
Community 1	3,670	1,971	53.7	3,585	1,933	53.9	1.01	0.79-1.29	0.93
Community 2	1,567	715	45.6	1,650	992	60.1	1.99	1.39-2.85	<0.001
Community 3	4,150	2,477	59.7	4,604	2,784	60.5	1.17	0.88-1.55	0.29
Community 4	3,996	3,040	76.1	3,013	2,430	80.7	1.45	0.68-3.10	0.34

[Knowledge of HIV status in non-HIVST & HIVST zones]

Results: Between February 1st and April 30th 2017, 63.3% (8,139/12,852) of adults enumerated in the HIVST arm knew their HIV status compared to 61.3% (8,203/13,383) in the non-HIVST arm, adjusted OR 1.25 (95% CI 1.01-1.56, p=0.04). Women had high knowledge of HIV status (71.1% in both HIVST and non-HIVST, adjOR 1.03, 95%CI 0.85-1.25, p=0.74). Among men, knowledge of HIV status was 55.0% in HIVST compared to 50.2% in non-HIVST (adjOR 1.30, 95%CI 1.07-1.60, p=0.01), with strong evidence that the effect of the HIVST intervention was different for men and women (p=0.004; Table).
Conclusions: Introducing HIVST for 3 months in communities already exposed to door-to-door HIV-testing services for 3 years, increased the proportion of the population who knew their HIV status. This effect was seen most markedly in men.

TUAC05 The Key to Key Populations

HIV treatment prevents HIV transmission in male serodiscordant couples in Australia, Thailand and Brazil

B. Bavinton[1], B. Grinsztejn[2], N. Phanuphak[3], F. Jin[1], I. Zablotska[1], G. Prestage[1], A. Kelleher[1], A. Pinto[1], D. Cooper[1], A. Grulich[1], The Opposites Attract Study Group
[1]University of New South Wales, Kirby Institute, Sydney, Australia, [2]Instituto de Pesquisa Clínica Evandro Chagas, Rio de Janeiro, Brazil, [3]Thai Red Cross, AIDS Research Centre, Bangkok, Thailand
Presenting author email: agrulich@kirby.unsw.edu.au

Background: Prospective data on the association of HIV transmission and undetectable viral load (UVL) in homosexual male HIV-serodiscordant couples (HM-SDC) are extremely limited. We report the final results from the Opposites Attract cohort study of HM-SDC in Australia, Bangkok and Rio de Janeiro.
Methods: HM-SDC were recruited through clinics. Information on sexual behaviours was collected at each visit from the HIV-negative partner (HNP). HNPs were tested at baseline and follow-up for HIV antibodies/sexually transmitted infections (STIs), and positive partners (HPPs) for HIV viral load/STIs. Phylogenetic analysis of pol and env genes was performed to identify linked HIV transmissions within couples based on genetic distance and monophyletic grouping. Incidence was calculated per couple-year of follow-up (CYFU), and stratified by pre-exposure prophylaxis (PrEP) use and by whether different forms of condomless anal intercourse (CLAI) were reported. UVL was defined as < 200 copies/mL. One-sided upper 95% confidence limits (UCL) were calculated.
Results: By end 2016, 358 HM-SDC were enrolled: 157, 105 and 96 from Australia, Thailand and Brazil respectively. There were 591 CYFU in 343 couples with at least one follow-up visit of whom 57.4% reported anal sex with outside partners during any point in follow-up. At baseline, 79.9% of HPPs were on anti-retroviral therapy (ART) and 77.9% had UVL; STI prevalence was 14.3%/11.7% in HPPs/HNPs respectively. There were 318 CYFU in periods where CLAI was reported with a total of 16,889 acts of CLAI. There were 3 new HIV infections but no linked transmissions. The overall UCL of the transmission rate when CLAI was reported was 1.16/100 CYFU, and it was 1.56/100 CYFU when there was UVL.

	Linked transmissions (n)	Couple-years of follow up (CYFU)	CLAI acts (n)	Incidence per 100 CYFU (95% CI)
Overall	0	591.2	16,889	0 (0-0.62)
Any CLAI	0	318.0	16,889	0 (0-1.16)
Any CLAI, no daily PrEP	0	241.3	12,928	0 (0-1.53)
Insertive CLAI	0	210.0	8,389	0 (0-1.76)
Receptive CLAI	0	132.1	4,569	0 (0-2.79)
UVL (VL <200)	0	236.2	12,638	0 (0-1.56)
VL >200	0	5.17	290	0 (0-71.4)
STI diagnosed	0	23.2	1,007	0 (0-15.9)
First 6 months ART	0	10.0	341	0 (0-36.9)

[HIV incidence by category of CLAI]

Conclusions: There were no linked HIV transmissions in almost 600 CYFU involving close to 17,000 acts of CLAI in HM-SDC. Our results provide strong support for the hypothesis that undetectable viral load prevents HIV transmission in homosexual men.

TUAD01 Treat All: How to Make It Happen and Can We Afford It?

TUAD0106LB

Index partner testing and targeted case finding in northern Haiti

V.A. Francois
JHPIEGO, HIV TB, Cap Haitian, Haiti
Presenting author email: valerie.francois@jhpiego.org

Background: In Haiti, national guidelines recommend HIV testing for partners of people living with HIV (PLHIV), but uptake and documentation have been low. While some healthcare providers recommend partner testing, it is not prioritized and delivery is inconsistent. HIV-positive women may be reluctant to notify their partners for fear of abuse or abandonment, and additional strategies are needed to increase case finding, particularly among men.
Methods: Jhpiego-Haiti, through the USAID-funded Maternal and Child Survival Program, and in collaboration with the National AIDS Control Program (PNLS), attempted to strengthen index partner testing by introducing training and documentation at 20 health facilities in northern Haiti. The 2-day training, conducted in October 2016, addressed targeted case finding, and strategies for supporting index clients living with HIV to refer their partners for testing. Counselling and communication skills were reinforced, and data collection and reporting tools were presented. Providers offered counselling on partner testing to all newly diagnosed HIV-positive clients, and submitted monthly reports on key indicators for partner testing.
Results: From October 2016 - March 2017, a total of 593 index clients tested HIV-positive in 20 health facilities in northern Haiti, 63% of whom were women. 519 index clients (88%) accepted counselling for partner testing, and 112 (22%) of those agreed to refer their partners. Only 61 partners attended the clinic for HIV testing, 30 (49%) of whom were HIV-positive, and 31 of whom were in discordant couples. The primary reason partners were not referred is because index clients were afraid to disclose their status for fear of their partner's reaction and stigmatization.
Conclusions: Training providers, equipping them with monitoring tools, and supporting them to counsel newly diagnosed PLHIV on partner testing can lead to the identification of HIV-positive partners and discordant couples. Further efforts to strengthen this targeted testing approach, including ongoing counselling and support for index patients to disclose, are needed to achieve the UNAIDS 90-90-90 targets in Haiti.

Willingness and ability of OST clients to pay for some OST services in Odesa region in the light of the Ukraine crisis

L. Khomych[1], O. Postnov[2], N. Avaliani[3], O. Iaremenko[3], M. Duda[3]
[1]Deloitte Consulting Overseas Projects, LLC, USAID Project HIV Reform in Action, Kyiv, Ukraine, [2]Ukrainian Research Antiplague Institute named after Mechnikov, Odesa, Ukraine, [3]Deloitte Consulting Overseas Projects, LLC, USAID Project HIV Reform in Action, Kyiv, Ukraine
Presenting author email: lkhomych@hss-share.net.ua

Background: Odesa region is one of the highest burden of HIV in Ukraine. HIV epidemic is mainly concentrated among key populations (PWIDs, CSWs and their partners, MSMs). The international donors' support of OST programs for PWIDs are currently in the process of financing reduction. The economic crisis in Ukraine complicated the nationwide state financing of OST programs in Ukraine. The implementation of the alternative financing models such as co-payment is optimal way to secure critical for PWIDs services. The aim of the study is to assess the willingness and ability of current OST clients to pay for some OST services.
Methods: Cross-sectional study was conducted in Odesa city in 2016 among current OST clients in Odesa city. Random sampling strategy was used for respondent recruitment. Structured questionnaire was used for data collection. The study protocol received an approval of IRB at Ukrainian Institute on Public Health Policy. Bivariate analysis was used to estimate correlates of clients' willingness to pay for some OST services.
Results: A total of 161 clients of OST programs (125 (77.6%) males and 36 (22.4%) females) were interviewed. The average age of the respondents was 41.98 years (SD=8.0). 66.5% of interviewed OST clients in Odesa city had a secondary education and 14.9% had a higher education. Half of the respondents (49.7%) had a single

marital status. 74% of respondents uptake OST program for more than 12 months. Overall 89% of respondents (n=143) demonstrate willingness to pay for some OST services in Odesa. The willingness to co-pay for some OST services is higher among clients listed "possibility to uptake additional medical care at OST site" as personal benefit of OST participation. The willingness is also correlated with income per family member (p=0.009), self-assessment of financial well-being (p=0.008) and perceived social support (p=0.014).
Conclusions: Clients of OST program in Odesa region demonstrated willingness and ability to pay for some OST services despite on economic crisis in the country. Their willingness depends on socio-economic status of PWID and his/her family. These important correlates of willingness and ability to pay should be considered for design and implementing OST co-payment service delivery model in Odesa region.

Background: DNA methylation is an epigenetic mechanism of HIV-1 latency. The methylation profile of the latent viral 5'LTR is heterogeneous in latency model cell lines and in patient cells in which it increases progressively during cART. Moreover, we previously reported that the DNA methylation inhibitor decitabine (5-aza-2'deoxycytidine) induces different levels of HIV-1 reactivation in latently-infected T cell lines and ex vivo patient cell cultures. However, the mechanism of DNA methylation-mediated HIV-1 silencing remains unclear.
Methods: Sodium bisulfite sequencing, EMSAs, ChIP-qPCR assays, RNA interference, GFP fluorescence FACS, p24 ELISA experiments and purification of primary cells from HIV+ patient blood.
Results: To explore this mechanism, we took advantage of two latently-infected J-Lat cell lines (the 8.4 and 15.4 clones) representing distinct integration sites and showed that these two cell lines exhibited similar levels of 5'LTR CpG methylation in basal conditions but different DNA demethylation extents in response to decitabine. Demethylation at CpG dinucleotides following decitabine-induced reactivation of HIV-1 production occurred at specific and reproducible CpG positions that differed depending on the two J-Lat cell lines studied. Interestingly, a site comprising one of this hotspot for decitabine-induced demethylation was shown to bind UHRF1 (Ubiquitin-like PHD and ring finger domain-containing protein 1), only in one of the J-Lat cell line, whereas DNMTs were recruited to both J-Lat cell lines. Treatment with decitabine caused a decreased in vivo UHRF-1 recruitment to the 5'LTR. UHRF1 knockdown using RNA interference or pharmacological approaches showed increased levels of HIV-1 transcription and production that were accompanied by an increased recruitment of RNA polymerase II to the 5'LTR. We are currently studying UHRF1 functional role in latently-infected primary cells from aviremic cART-treated HIV+ patients.
Conclusions: We have identified UHRF1 as a factor recruited to the HIV-1 5'LTR in a methylation- and integration-dependent manner during latency and which plays a functional role in DNA methylation-mediated repression of HIV-1 gene expression. UHRF1 is known to regulate and maintain heterochromatic equilibrium via its combined action on both DNA methylation and histone modifications. This factor has not previously been identified as a regulator of HIV latency and might thus constitute a new therapeutic target for HIV cure strategies.

Zoledronic acid is superior to TDF-switching for increasing bone mineral density in HIV-infected adults with osteopenia: a randomised trial

J. Hoy[1,2], R. Richardson[3], P.R. Ebeling[1], J. Rojas[4], N. Pocock[5], S. Kerr[3], E. Martinez[4], A. Carr[6], Zoledronate or Switch Tenofovir (ZeST) Study Group
[1]Monash University, Melbourne, Australia, [2]The Alfred Hospital, Melbourne, Australia, [3]St Vincent's Hospital, Centre for Applied Medical Research, Sydney, Australia, [4]Hospital Clínic, University of Barcelona, Infectious Diseases Unit, Barcelona, Spain, [5]St Vincent's Hospital, Sydney, Nuclear Medicine, Sydney, Australia, [6]St Vincent's Hospital, Sydney, HIV, Immunology and Infectious Diseases Unit, Sydney, Australia
Presenting author email: andrew.carr@svha.org.au

Background: Tenofovir disoproxil fumarate (TDF) reduces bone mineral density (BMD) and probably increases fracture risk in HIV-infected adults. Proven strategies for improving BMD in HIV-infected adults on TDF are TDF switching or bisphosphonate therapy; which strategy is superior is unknown.
Methods: We randomised virologically-suppressed, HIV-infected adults on TDF with low BMD (T score < -1.0 at hip or spine by dual-energy x-ray absorptiometry [DXA]) to either switch TDF or to continue TDF and receive intravenous zoledronic acid (ZOL) 5mg every 12 months. Calcium (all patients) and vitamin D (if serum 25OH vitamin D was < 50 nmol/L) were supplemented. The primary study outcome was change in lumbar (L1-L4) spine BMD at 24 months by intention-to-treat analysis. Secondary outcomes included femoral neck and total hip BMD, fractures, safety, and virological failure (confirmed viral load ≥400 cp/mL).
Results: We randomised 87 patients (44 to TDF switch and 43 to ZOL): mean age 50 years (SD 11), 96% men, mean TDF duration 5.9 years (SD 3.1), 22% on a boosted PI, mean spine and hip T scores -1.6 and -1.3, respectively. TDF switches were mostly to abacavir (62%) or raltegravir (19%). Adherence to each strategy was high: four switch patients (10%) recommenced TDF at a median of 9 months; 98% of ZOL doses were administered. Mean spine BMD changes at 24 months were 7.4% (SD 4.3%) with ZOL vs. 2.9% (4.5%) with TDF-switching (mean difference 4.4%, 95%CI 2.6-6.3; p< 0.001). Mean left femoral neck BMD changes were 4.1% (3.8%) and 2.1% (4.6%), respectively (mean difference 2.0%, 95%CI 0.2-3.8; p=0.03). Mean left total hip BMD changes were 4.6% (2.6%) and 2.6% (4.0%), respectively (mean difference 1.9%, 95%CI 0.5-3.4; p=0.009). There was 1 fracture in the ZOL group (1 patient) and 7 separate fracture events in the TDF switch group (4 patients). Serious adverse events occurred in 9 (19%) ZOL patients and 6 (14%) TDF-switch patients; none was related to study drugs or procedures. Virological failure occurred in 1 TDF-switch patient and no ZOL patient.
Conclusions: ZOL is more effective than TDF switching at increasing BMD in osteopenic adults on TDF, and may result in fewer fractures.

Pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in the Netherlands: motives to choose for, switch to, or stop with daily or event-driven PrEP

H. Zimmermann[1], S. Eekman[1], R. Achterbergh[1,2], M. Prins[1,3], M. Schim van der Loeff[1], H. de Vries[2,3], E. Hoornenborg[1,2], U. Davidovich[1,3], HIV Transmission Elimination Amsterdam (H-Team)
[1]Public Health Service Amsterdam, Infectious Diseases - Research & Prevention, Amsterdam, Netherlands, [2]Public Health Service Amsterdam, Infectious Diseases - STI Outpatient Clinic, Amsterdam, Netherlands, [3]Academic Medical Center of Amsterdam, Amsterdam, Netherlands
Presenting author email: hzimmermann@ggd.amsterdam.nl

Background: Proper implementation of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) requires a clear understanding of the reasons why MSM choose one PrEP-dosing regimen over another in real-life settings. Therefore, we aimed to gain insight into the motives for choosing or switching between daily and event-driven PrEP or (temporarily) stopping PrEP use.
Methods: We used data from the Amsterdam PrEP (AmPrEP) demonstration study (June 2015-February 2017), where both daily and event-driven PrEP (dPrEP and edPrEP, respectively) are offered. MSM's motives to choose a regimen were measured at baseline among 376 participants of whom 273 chose dPrEP and 103 chose edPrEP. Motives to switch or stop were recorded at every 3-monthly follow-

up visit. Standardized closed- and open-end items were used. Open answers were coded and analyzed following qualitative research methods.
Results: Among the reasons to use dPrEP were the convenience of daily routine (n=133), perceived higher dPrEP efficacy (n=34), and fear of side-effects relating to edPrEP re-initiation (n=5). Perceived toxicity and burden of daily medication were reasons to choose edPrEP (n=38). Infection risk was also considered: dPrEP was preferred for unplanned and/or frequent sexual risk behavior (n=79), while edPrEP was chosen when risk was more predictable (n=57). Some chose for, or switched to, edPrEP to inhibit sexual risk behavior (n=4), while others chose for, or switched to, dPrEP to gain more sexual freedom (n=17). Other reasons to switch to edPrEP included experiencing side-effects (n=14), having less sex than anticipated (n=20), experimenting with another regimen (n=2) and receiving negative reactions from the environment (n=1). Doubts about edPrEP's safety (n=2), inability to plan sex (n=13) and desire for more structure (n=9) were motivators to switch to dPrEP. Motives to temporarily stop dPrEP (n=99) were situational (e.g. medical issues or vacations). Changed life circumstances (n=2) and reduced sexual risk (n=6) were motives to completely stop with PrEP use (n=12).
Conclusions: A great variety of personal and contextual factors determine the choices for PrEP regimens, related switches and stops. In order to successfully support future PrEP users, a tailored approach, addressing choices for PrEP regimens as a continuum of flexible and changeable choices, is essential.

The cost-effectiveness of integrating maternal ART into maternal & child health (MCH) services during the postpartum period in South Africa

C. Dugdale[1,2,3], T. Phillips[4,5], L. Myer[4,5], E.P. Hyle[1,2,6], K. Brittain[4,5], K.A. Freedberg[1,2,6], L. Cunnama[7], R. Walensky[1,2,6], A. Zerbe[8], E.J. Abrams[8,9], A. Ciaranello[1,2], the MCH-ART Trial Team
[1]Medical Practice Evaluation Center, Massachusetts General Hospital, Boston, United States, [2]Division of Infectious Diseases, Department of Medicine, Massachusetts General Hospital, Boston, United States, [3]Division of Infectious Diseases, Department of Medicine, Brigham & Women's Hospital, Boston, United States, [4]Division of Epidemiology and Biostatistics, School of Public Health & Family Medicine, University of Cape Town, Cape Town, South Africa, [5]Centre for Infectious Diseases Epidemiology & Research, School of Public Health & Family Medicine, University of Cape Town, Cape Town, South Africa, [6]Division of General Internal Medicine, Massachusetts General Hospital, Boston, United States, [7]Health Economics Unit, School of Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, [8]ICAP at Columbia, Mailman School of Public Health, Columbia University, New York, United States, [9]College of Physicians & Surgeons, Columbia University, New York, United States

Background: Despite improved PMTCT services in South Africa, poor retention in care and low maternal ART adherence after delivery increase risk of postnatal MTCT and adverse maternal outcomes. We projected the clinical and economic impact of the MCH-ART trial, which evaluated integrated, co-located maternal and pediatric care throughout breastfeeding in Cape Town.
Methods: Using the CEPAC model, we simulated HIV-infected women initiating ART during pregnancy and their infants (mean maternal age: 28.6y, median CD4: 354 cells/μL). We compared two strategies: routine care (referral to local clinics after delivery for separate adult ART and well-baby care) and integrated maternal/pediatric care in the MCH service through weaning (median: 8m, then referral to local clinics). Trial-derived inputs included: primary trial outcomes of 12-month maternal retention (routine: 71%, integrated: 81%) and virologic suppression (routine: 56%, integrated: 77%); breastfeeding duration (routine: 6m, integrated: 8m); and infant HIV testing uptake at 6-10w (routine: 78%, integrated 82%). We assumed an intervention cost of $200/mother-infant pair and equal monthly LTFU and ART failure rates in both strategies after 12 months. Model outcomes included MTCT rates, maternal and pediatric life expectancy (LE), and lifetime HIV-related per-person costs (2014 US$). We calculated incremental cost-effectiveness ratios (ICERs) from discounted (3%/year) maternal + pediatric LE and costs, defining "cost-effective" as an ICER < $6,500/life-year saved (South Africa 2014 per-capita GDP).
Results: Compared to routine care, integrated care was projected to decrease maternal 1-year mortality (1.7% vs. 1.5%), increase maternal LE (27.0y vs. 28.6y, undiscounted), and result in an ICER of $940/LYS. Modeled pediatric outcomes were similar between arms. The intervention remained cost-effective with lower intervention efficacy (50%: Table), higher intervention costs (up to $4,650), and longer breastfeeding duration (12m).
Conclusions: Integrated maternal-pediatric care, co-located in MCH services through the end of breastfeeding, is a cost-effective strategy to optimize postpartum maternal and infant outcomes in South Africa.

Cost-effectiveness of routine viral load monitoring in low and middle income countries: a systematic review

R.V. Barnabas[1], P. Revill[2], N. Tan[1], A. Phillips[3]
[1]University of Washington, Seattle, United States, [2]University of York, York, United Kingdom, [3]University College London, London, United Kingdom
Presenting author email: rbarnaba@uw.edu

Background: Routine viral load (VL) monitoring for HIV-1 management of persons on ART has been recommended by the WHO to identify treatment failure. However, VL testing represents a substantial cost in resource constrained health care systems. The central challenge is whether and how VL monitoring may be delivered such that it maximizes health gains across the population for the costs incurred. We hypothesized that key efficiency assumptions about program design and cost drive the cost-effectiveness of programs with viral load monitoring.
Methods: We conducted a systematic review of studies on the cost-effectiveness of viral load monitoring in low and middle income countries (LMIC). We followed the Cochrane Collaboration guidelines and the PRISMA reporting guidelines.
Results: We identified 18 studies that evaluated the cost-effectiveness of viral load monitoring in HIV treatment programs. Overall, we identified three key factors that make it more likely for viral load monitoring to be cost-effective: 1) Use of lower cost, robust approaches to viral load monitoring; 2) Ensuring the pathway to health attainment is established and that viral load results are acted upon; 3) Viral load result is used to simplify HIV care in patients with viral suppression (i.e. differentiated care, with fewer clinic visits and longer prescriptions); viral load monitoring in differentiated care programs provides evidence that reduced clinical engagement, where appropriate, is not impacting health outcomes.
Conclusions: The cost-effectiveness of viral load monitoring critically depends on the context. To achieve this goal of being cost effective, viral load monitoring will need to facilitate scale up of differentiated care approaches to HIV treatment - introducing viral load monitoring without differentiated care is unlikely to be cost-effective in most settings and results in lost opportunity for health gains through an alternative use of limited resources. As countries scale up differentiated care programs, data on clinical outcomes and cost are essential to evaluate the on-going cost-effectiveness of viral load monitoring as utilized in practice.

Breast milk dapivirine pharmacokinetics and estimated infant exposure during dapivirine intravaginal ring use among lactating women

L. Noguchi[1,2], R. Beigi[3], J. Biggio[4], M. Marzinke[1], C. Kelly[5], R. Scheckter[6], K. Bunge[3], J. Piper[7], S. Hillier[3], A. Nel[8], C. Hendrix[1]
[1]Johns Hopkins University, Baltimore, United States, [2]MCSP, Washington, United States, [3]Magee-Womens Hospital/University of Pittsburgh, Pittsburgh, United States, [4]Ochsner Health System, New Orleans, United States, [5]SCHARP, Seattle, United States, [6]FHI 360, Durham, United States, [7]DAIDS/NIAID/US NIH, Rockville, United States, [8]International Partnership for Microbicides, Silver Spring, United States
Presenting author email: lnoguch1@jhu.edu

Background: The 25 mg dapivirine (DPV) vaginal ring (VR) can reduce women's risk of acquiring HIV infection. Most studies of HIV prevention products exclude lactating women, despite global recommendations for breastfeeding and continued risk for HIV acquisition during lactation. MTN-029/IPM 039 was a Phase I, open-label study of pharmacokinetics; safety and tolerability, and adherence associated with DPV VR use.
Methods: Between January 2016 and March 2017, 16 healthy, HIV-uninfected women aged 18 or older were enrolled in Pittsburgh and Birmingham, USA. Eligible women had weaned infants from breastfeeding before enrollment, but were able to pump breast milk. Participants were instructed to wear the VR continuously for 14 days. Milk and blood plasma samples were collected (pre-insertion, Hour 3, Hour 6, Hour 24, Day 7, Day 14 after ring placement, and two days after ring removal) and analyzed for DPV using validated ultra-performance liquid chromatography-tandem mass spectrometry assays, with lower limits of quantification of 10 pg/mL and 20 pg/mL for milk and plasma, respectively. We estimated infant DPV intake assuming 150 mL/kg/day milk ingestion. Adverse events (AEs) were collected at all participant contacts.
Results: All participants had detectable DPV in milk and plasma. Median DPV concentrations in milk and plasma rose gradually to relatively steady concentrations on Day 7 and Day 14, followed by falling concentrations after ring removal to approximately 40% of Day 14 concentrations by Day 16. Median (interquartile range) peak concentration for milk and plasma were 676 pg/mL (443, 924.5) and 327 pg/mL (274.5, 378), respectively. Time-adjusted median milk/plasma ratio was 1.70 (1.38, 1.86). Estimated daily infant exposure was 68.0 ng/kg/day (53.0, 85.1). Estimated terminal concentration half-life after ring removal was 39.0 hours (27.1, 53.4) and 35.2 hours (29.8, 46.4) for milk and plasma, respectively. Six of 16 (38%) participants experienced eight total AEs, most of which were mild.
Conclusions: In this first study of DPV exposure during lactation, DPV VR use was associated with low levels of detectable DPV in milk and plasma, very low estimated levels of infant exposure, and a favorable safety profile. Future DPV VR studies should evaluate longer periods of use among breastfeeding mother-infant pairs.

[1]University of the Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [2]Stellenbosch University, Family Clinical Research Unit, Department of Paediatrics and Child Health, Stellenbosch, South Africa, [3]Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States, [4]University of the Witwatersrand, Centre for HIV and STIs, National Institute for Communicable Diseases and Faculty of Health Sciences, Johannesburg, South Africa, [5]Anova Health Institute, Johannesburg, South Africa, [6]Univerity of Cape Town, School of Public Health & Family Medicine, Cape Town, South Africa, [7]University College London, Medical Research Council, Clinical Trials Unit, London, United Kingdom
Presenting author email: violari@mweb.co.za

Background: In the 6-year CHER trial (2005-2011), HIV-infected infants were randomized to deferred antiretroviral therapy (ART) or early limited ART for 40 (ART-40W) or 96 (ART-96W) weeks; ART reinitiation was based on CD4 and clinical criteria. We describe a child, randomized to ART-40W in 2008, who on long term follow-up, maintains an undetectable viral load after 8.5 years off-ART.
Methods: Studies conducted to describe immunological and viral characteristics included: ultrasensitive qualitative nested and quantitative semi-nested PCR assay to assess HIV DNA reservoir; co-culture of CD4 cells with MOLT-4/CCR5 and CD8-depleted phytohaemagglutinin-activated lymphocytes to detect replication-competent virus.
Results: HIV diagnosis was confirmed by HIV-DNA PCR+ at age 32 days, and on days 39 and 60, VL was >750,000 and 151,000 copies/ml respectively. ART started at age 8.7 weeks and was interrupted at 40 weeks post randomisation. On ART, VL declined to < 50copies/ml at week 24 and was < 20 copies/ml post-interruption .During later follow-up 6-monthly VLwere also < 20copies/ml. At age 9.5 years, the child was clinically asymptomatic with CD4 802 cells/µl. Qualitative DNA PCR was negative. HIV-antibody by ELISA was negative but was weakly reactive to Gag p40 and p24 on Western blot; a weak Gag-specific CD4 T-cell response was detected by whole blood intracellular cytokine assay. Proviral DNA was positive by ultrasensitive nested (int) PCR and HIV DNA reservoir size was estimated at 2.2 copies/10^6 PBMCs by semi-nested quantitative (RT) assay. DNA sequencing of Gag confirmed subtype-C virus. No replication-competent virus was detected in culture supernatants by day 22 using p24 ELISA and ultrasensitive nested RT-PCR. All HLA loci were heterozygoous (A*30:02:01/66:01; B*08:01:01/44:03:01; C*04:01:01/07:01:01; DRB1*12:01:01/13:02:01; DPB1*01:01:01/18:01; B1*05:01:01/06:09:01). The KIRAA1 genotype included both full-length and truncated KIR2DS4. Immunophenotyping showed few CCR5-expressing CD4 T-cells (6.6%), low CCR5 density, low immune activation (HLA-DR, TIGIT), high PD-1expression and high % naive CD8 T-cells.
Conclusions: To our knowledge, this is the first case of sustained virological control from a randomized trial of ART interruption following early treatment of infants. Further investigation may expand our understanding of how the immune system controls HIV replication and inform future research strategies for ART interruption after early ART.

Presenting author email: psax@bwh.harvard.edu

Background: In a phase 2 study, bictegravir (BIC, B), a novel, potent integrase strand transfer inhibitor (INSTI) with a high barrier to resistance, was directly compared with dolutegravir (DTG), each given with the recommended N(t)RTI combination of emtricitabine and tenofovir alafenamide (F/TAF) in treatment-naïve, HIV-infected adults. Both treatments demonstrated high efficacy and were well tolerated through Week (W) 48. We now report results from a phase 3 study of this comparison of BIC and DTG, each with F/TAF, utilizing a single-pill coformulation of B/F/TAF.
Methods: Treatment-naïve, HIV-infected adults with estimated glomerular filtration rate (eGFR)
≥30 mL/min were randomized 1:1 to receive blinded treatment with fixed dose combination B/F/TAF (50/200/25 mg) or DTG (50 mg) + F/TAF (200/25 mg) with matching placebos once daily through W48. Chronic hepatitis B and/or C infection was allowed. The primary endpoint was the proportion of participants with HIV-1 RNA < 50 copies/mL (c/mL) at W48 (FDA snapshot). Noninferiority was assessed through 95.002% confidence intervals (CI) using a margin of 12%. Secondary endpoints were safety measures (adverse events [AEs] and laboratory results).
Results: 645 participants were randomized and treated (320 B/F/TAF, 325 DTG + F/TAF): 12% women, 31% Black, 19% viral load (VL) >100,000 c/mL, 12% CD4 < 200 cells/μL, median age 34 yrs, CD4 count 440 cells/μL, and VL 4.44 log10 c/mL. At W48, B/F/TAF was noninferior to DTG + F/TAF, with 89.4% on B/F/TAF and 92.9% on DTG + F/TAF achieving HIV-1 RNA < 50 c/mL (difference -3.5%; 95.002%CI -7.9% to 1.0%, p=0.12). At W48, proportion of participants with HIV-1 RNA ≥50 c/mL was < 1% in each arm. No study subject in either treatment arm developed resistance to any of the study drugs. The most common AEs were headache (13% B/F/TAF, 12% DTG + F/TAF) and diarrhea (12% for both). Few participants (5 [2%], 1 [< 1%]) had AEs leading to premature study discontinuation. Lipid changes were not significantly different between study arms. No renal discontinuations and no cases of proximal renal tubulopathy were reported.
Conclusions: After 48 weeks, B/F/TAF achieved virologic suppression in 89.4% of treatment- naïve adults and was noninferior to DTG + F/TAF. B/F/TAF was safe and well tolerated.

Single doses as low as 0.5 mg of the novel NRTTI MK-8591 suppress HIV for at least seven days

R.P. Matthews[1], D. Schürmann[2], D.J. Rudd[1], V. Levine[1], S. Fox-Bosetti[1], S. Zhang[1], M. Robberechts[1], A. Huser[2], D.J. Hazuda[1], M. Iwamoto[1], J.A. Grobler[1]
[1]Merck & Co., Inc., Kenilworth, United States, [2]Charité Universitätsmedizin Berlin, Research Hospital, Berlin, Germany
Presenting author email: randolph.matthews@merck.com

Background: MK-8591 is a nucleoside reverse transcriptase translocation inhibitor (NRTTI) in early clinical development for the treatment of HIV-1 infection. MK-8591-triphosphate (MK-8591-TP), the active phosphorylated anabolite of MK-8591, exhibits a half-life of ~150-160 hrs in human PBMCs. Here we describe antiviral efficacy and tolerability of single doses of 0.5 mg to 30 mg MK-8591 over 7 to 10 days in HIV-1 infected subjects in an ongoing Phase 1b monotherapy proof-of-concept efficacy study.
Methods: In an open-label study in HIV-1-infected subjects naïve to antiretroviral treatment (ART), subjects are being administered a single dose of MK-8591 across a range of doses. Blood samples are being collected for viral load (VL), MK-8591 PK, and MK-8591-TP PK at prespecified time points up to 7 to 10 days post-dose. Following completion of Day 7 or Day 10 procedures, subjects are being offered standard of care ART. Safety, PK, and VL data from the doses of 0.5 mg, 1 mg, 2 mg, 10 mg, and 30 mg (N=6/panel) are available.
Results: Single doses of MK-8591 across the entire tested range were associated with a rapid and robust reduction in VL. At 168 hours postdose, a mean (95% CI) placebo-corrected VL reduction of 1.18 log10 (0.95, 1.46) was observed for 0.5 mg. For the 30 mg dose, mean VL continued to decline through Day 10 with a mean placebo-corrected reduction of 1.57 log10 (1.34, 1.85), with no evidence of recrudescence at any dose. In samples with sufficient VL for testing (14/24), no common mutant strains, including M184V/I, were detected. All doses were generally well tolerated, with a limited number of mild/moderate adverse experiences reported. MK-8591 plasma and MK-8591-TP PBMC PK were similar to previously observed data in healthy subjects.
Conclusions: MK-8591 suppressed HIV replication for at least seven days when administered as a single dose as low as 0.5 mg. The antiviral potency, human pharmacokinetics (PK), and physical properties of MK-8591 have the potential to open new paradigms for extended duration HIV treatment and prophylaxis approaches.

TUPDB0203LB

Pharmacokinetics, pharmacodynamics and pharmacogenomics of efavirenz 400mg once-daily during pregnancy and postpartum

M. Lamorde[1], X. Wang[2], M. Neary[3], E. Bisdomini[4], S. Nakalema[1], P. Byakika[1], J. Mukonzo[1], W. Khan[4], A. Owen[3], M. McClure[2], M. Boffito[2,4]

Presenting author email: marta.boffito@nhs.net

Background: Antiretroviral dose reductions may compensate for the finite global manufacturing capacity and allow access programmes to reach larger numbers of HIV-infected patients. The ENCORE-1 study showed that efavirenz 400mg (EFV400) is non-inferior to the standard adult dose. WHO clinical guidelines now recommend EFV400 as an alternative first-line agent, however with a disclaimer that no data on EFV400 during the third trimester of pregnancy (TT) exist. This study investigated the pharmacokinetics (PK), efficacy and CYP2B6 pharmacogenetics of EFV400 in women living with HIV (WLWH) during TT and post-partum (PP) with a view to removing the disclaimer and allowing wider EFV400 use in first-line.
Methods: Open-label, multicentre study (UK and Uganda) in WLWH receiving tenofovir disoproxil fumarate (TDF), emtricitabine (FTC) and EFV 600mg with an undetectable viral load (VL), who switched to TDF/FTC/EFV400 was performed. Weekly therapeutic drug monitoring (TDM), steady-state PK profiles during TT and PP, safety, virologic efficacy and polymorphisms in CYP2B6 (516C>T; 938T>C) were evaluated.
Results: 22 WLWH of African origin were enrolled, baseline median (range) age and CD4 were 30 (18-41) years and 548 (190-882) cells/mm^3, respectively. All had VL< 50 copies/mL at baseline, which was maintained throughout the study (only 2 blips were observed but confirmed < 50, when repeated). None of the children were HIV-infected. No WLWH were excluded from the study because of low EFV400 TDM results (< 800 ng/mL in >3 consecutive visits). Geometric mean (GM) ratios (TT/PP; 90% confidence intervals) of EFV400 Cmax, AUC, and C_{24h} were 0.86 (0.68-1.09), 0.74 (0.59-0.94), 0.62 (0.47-0.83). GM C_{24h} was 1256 ng/mL (coefficient of variation 79%). 20/22 WLWH were carriers of the CYP2B6 516G allele and only 2 were slow metabolisers. EFV400 was well tolerated during pregnancy with no grade 3 or 4 laboratory abnormalities.
Conclusions: Cmax, AUC, and C_{24h} in TT were 14%, 26% and 38% lower compared to PP but within ranges of those measured for EFV600 during TT by Schalkwijk et al. (2016) and those measured in ARV-naïve patients on EFV400 in ENCORE-1 (Dickinson et al. 2015). All subjects maintained a VL< 50, suggesting that EFV400 can be used in pregnant WLWH.

Universal sputum testing vs. symptom-based testing for tuberculosis (TB) in HIV-infected pregnant women: a cluster-randomized implementation trial in South Africa

N. Martinson[1], K. Motihaoleng[1], E. Variava[2], G. Barnes[3], P. Abraham[1], L. Lebina[1], S. Cohn[3], L. Moulton[4], N. Salazar-Austin[3], R. Chaisson[3]
[1]Perinatal HIV Research Unit, University of the Witwatersrand, Soweto, South Africa, [2]Klerksdorp Tshepong Hospital Complex, Internal Medicine, Klerksdorp, South Africa, [3]Johns Hopkins University, Center for TB Research, Baltimore, United States, [4]Bloomberg School of Public Health, Johns Hopkins University, International Health, Baltimore, United States
Presenting author email: martinson@phru.co.za

Background: TB in HIV-infected pregnant women is a leading cause of maternal and infant morbidity and mortality. Currently-recommended symptom-based screening of HIV-infected pregnant women may be insensitive.
Methods: We conducted a cluster-randomized trial to compare universal sputum TB testing of HIV-infected pregnant women against standard symptom-based testing. Sixteen public-sector antenatal clinics in two health districts were assigned to either strategy by constrained randomization. HIV-infected pregnant women without currently diagnosed TB were eligible. In universal testing clinics (UC), all HIV-positive pregnant women were asked to produce a sputum sample. In symptom clinics (SC), only those with WHO criteria for TB testing (cough, fever, night sweats, or weight loss) were asked to produce sputum. Sputa were tested by Xpert MTB/RIF and midway through the study liquid MGIT culture was added. Women and infants were followed through 2 months postpartum. Cluster-adjusted results are shown.
Results: From 5/2015 through 3/2017, 937 and 1095 HIV-infected pregnant women were enrolled in the UCs and SCs, respectively. Median age was 30 years, median gestational age 24 months, 11% had prior TB, 90% were on ART, with no significant differences by arm. At baseline 17% of UC women and 22% of SC women had ≥1 TB symptom (p=0.40).
In UCs and SCs, respectively, 35 and 4 women were diagnosed with TB during pregnancy (UC prevalence = 3.7%, SC 0.37%, adjusted p=0.01). Two months post-partum, infant mortality in UCs was 0.9% vs. 2.1% in SCs (adjusted p= 0.06). Miscarriages and stillbirths were similar in both arms and two women died in the SCs .
MGIT culture identified more TB than Xpert: 25/487 samples (5%) were MGIT+ vs 19/1400 (1.4%) Xpert+ (p< 0.05). 440 samples were tested with both assays, 4 were Xpert+/MGIT+, 412 negative for both, 3 Xpert+/MGIT-, and 21 Xpert-/MGIT+.
Conclusions: Universal TB screening of all HIV-infected pregnant women increased case detection 10-fold and was associated with reduced early infant mortality. MGIT identified more TB than Xpert in women whose pregnancy may mask TB symptoms. Our data support sputum testing all HIV-infected pregnant women for TB in high burden areas such as South Africa. Cost-effectiveness studies of universal testing are needed.

Sub-study 202094 of SWORD 1 & SWORD 2: switch from TDF containing regimen to DTG+RPV improves bone mineral density and bone turnover markers over 48 weeks

G. McComsey[1], J. Gonzalez-Garcia[2], S. Lupo[3], J. De Wet[4], D. Parks[5], L. Kahl[6], B. Wynne[7], M. Gartland[8], K. Angelis[9], M. Cupo[10], K. Vandermeulen[11], M. Aboud[6]
[1]Case Western Reserve University, UH Clinical Research Center, Cleveland, United States, [2]Hospital Universitario la Paz. IdiPAZ, Madrid, Spain, [3]CAICI Instituto Centralizado, de Asistencia e Investigación Clínica Integral, Santa Fe, Argentina, [4]Spectrum Health, Vancouver, Canada, [5]Southampton Clinical Research Group, St. Louis, United States, [6]ViiV Healthcare, Brentford, United Kingdom, [7]ViiV Healthcare, Collegeville, United States, [8]ViiV Healthcare, Research Triangle Park, United States, [9]GlaxoSmithKline, Uxbridge, United Kingdom, [10]GlaxoSmithKline, Collegeville, United States, [11]Janssen, Beerse, Belgium

Background: Loss of bone mineral density (BMD) has been attributed to traditional risk factors for osteoporosis, HIV infection and antiretroviral therapy (ART), in particular tenofovir (TDF). 202094, a sub-study of the international, multicenter SWORD 1 & 2 studies, evaluated change in BMD (by DEXA) following switch from a triple ART regimen containing TDF to the 2-drug regimen (2DR) dolutegravir (DTG) + rilpivirine (RPV). Week 48 SWORD data demonstrated maintenance of suppression with DTG+RPV and noninferiority to continuing current ART (CAR).
Methods: Subjects were HIV-infected adults, with HIV-1 RNA< 50c/mL and who received ART containing TDF both for ≥ 6 months prior to randomization to DTG+RPV or CAR on Day 1 through Week 48 in SWORD-1/2. Hip and lumbar spine BMD were measured by DEXA scans which were centrally read. The primary endpoint was the percentage change in total hip BMD. Secondary endpoints included change in lumbar spine BMD and bone turnover markers. The ANCOVA BMD analysis of the intent-to-treat population adjusted for baseline parameters (see Table 1).
Results: The results at Week 48 are shown in Table 1. DTG + RPV patients had an increase from Baseline to Week 48 in hip (1.34%) and spine BMD (1.46%) which differed statistically significantly (p=0.014, p=0.039, respectively) from CAR patients. (Table 1). Consistent with this, DTG + RPV patients had a decrease from Baseline to Week 48 in bone specific alkaline phosphatase, procollagen type 1-N-propeptide, osteocalcin and Type I Collagen C-Telopeptide bone turnover markers which differed statistically significantly from the CAR group (p range from < 0.001 to 0.029 across markers).

Treatment Assignment in Parent SWORD Study	DTG + RPV	CAR	p value
Evaluable subjects at Baseline and Week 48(a)	46	35	
Primary Endpoint: Total Hip(b) BMD			
Mean adjusted % change from Baseline to Week 48 (95% CI)(c)	1.34 (0.68, 2.01)	0.05 (-0.71, 0.82)	
Difference in adjusted % change from Baseline to Week 48 between treatment groups (95% CI) and p value(c)	1.29 (0.27, 2.31)		p = 0.014
Secondary Endpoint: Lumbar Spine(d)BMD			
Mean adjusted % change from Baseline to Week 48 (95% CI)(c)	1.46 (0.65, 2.28)	0.15 (-0.79, 1.09)	
Difference in adjusted % change from Baseline to Week 48 between treatment groups (95% CI) and p value(c)	1.32 (0.07, 2.57)		p = 0.039
a. Subjects having evaluable BMD data at both Baseline and Week 48 had their DEXA scans performed within the predefined time period for the study visit b. Total hip includes the femoral neck, trochanter and intertrochanter areas c. BMD is expressed as areal density. Estimates and associated p-values are from an ANCOVA model adjusted for Baseline BMD value, age at study entry, and Baseline BMI d. Lumbar spine includes the first lumbar vertebra (L1) to the fourth lumbar vertebra (L4)			

[202094 Week 48 Results: ITT-Exposed Population]

Conclusions: Switch to the 2 drug-regimen of DTG+RPV is associated with significant improvement in bone mineral density and markers of bone health compared to continuation of a TDF-based 3 drug regimen, and provides a robust option for preserving bone health while continuing suppressive HIV treatment.

Presenting author email: toyiniyun@gmail.com

Background: The context of HIV prevention and treatment for children in South Africa has significantly improved and there is a recent shift toward birth early infant diagnosis and early infant antiretroviral therapy (ART). We describe the characteristic and outcomes of children initiating ART in the context of changing paediatric HIV testing and treatment guidelines in South Africa.
Methods: A retrospective cohort analysis was conducted using data from the IeDEA-SA collaboration. HIV-infected children initiating combination ART at < 3 months old, from 2006-2016 were included. We described changes in characteristics of children starting ART and mortality, loss to follow-up (LTFU) and transfer out by 12 months on ART.

Results: Among 1380 infants, the median age at ART initiation was 62 days (interquartile range (IQR) 37-79); median time on ART was 13.6 months (IQR 4.0-34.5). The median age at ART start decreased from 67 days (IQR 53-81) in 2006-2009 to 48 days (IQR 9-74) in 2013+ (p<0.001). There was a decline in median log viral load at ART initiation from 5.9 (IQR 5.4- 6.4) in 2006-2009 to 5.4 (IQR 3.9-6.3) in 2013+ (p<0.001). The median absolute CD4 count (cells/μL) increased progressively from 888 (IQR 380-1703) in 2006-2009 to 1526 (IQR 659-2231) in 2013+ (p<0.001). Among infants with data on WHO disease staging (n=865), 84% (n=299) started ART with WHO disease stage 3/4 in 2006-2009 compared to 39% (n=279) in 2013+ (p<0.001). After 1 year on ART, 11% (median age 68 days (IQR 55-75)) and 4% (median age 60 days (IQR 25-83)) of children died in 2006-2009 and 2013+ respectively (p<0.001). LTFU increased from 7% in 2006-2009 to 21% in 2013+ (p=0.002) and transfer out declined from 20% in 2006-2009 to 12% in 2013+ (p<0.001).
Conclusions: Children are starting ART earlier, with less progressive disease and associated declines in mortality; however mortality and LTFU in infants starting ART remains unacceptably high. In view of the scale up of birth PCR testing in South Africa, a significant proportion of children still start ART with advanced disease, highlighting the need for a focused approach to early infant HIV testing and follow-up on ART.

TUPDC01 TRANScending Barriers for Prevention

Presenting author email: gbeatriz@ini.fiocruz.br

Background: PrEP Brasil is a demonstration study to assess feasibility of daily oral tenofovir-disoproxil-fumarate plus emtricitabine (TDF/FTC) provided at no cost to high-risk men who have sex with men (MSM) and transgender women (TGW) within the Brazilian public health system. We report week 48 PrEP retention, adherence to daily pill use, trends in sexual behavior and incidence of HIV and sexually transmitted infections.
Methods: PrEP Brasil was initiated on April/2014; participants were followed for 48 weeks. Adherence was evaluated based on tenofovir diphosphate (TFV-DP) concentrations in dried blood spot samples. Logistic regression models were used to quantify the association of socio-demographic, behavioral and clinical variables with high levels of adherence (≥4 doses/week).
Results: 450 participants initiated PrEP, of which 376 (83%) were retained through 48 weeks. At week 48, 73.7% (277/376) had protective levels consistent with ≥4 doses/week. Higher odds of achieving protective levels was observed among participants from São Paulo (adjusted odds ratio [aOR] 2.01, 95% confidence interval [95%CI] 1.16-3.47), as well as among those who reported sex with HIV-positive partners (aOR 1.77, 95%CI 1.03-3.04), and those who had protective levels of TFV-DP at week 4 (aOR 3.26, 95%CI 1.87-5.68). The prevalence of rectal chlamydia and rectal gonorrhea ranged from 8.0% and 4.9% at enrollment to 7.7% and 3.7% at week 48, respectively (p=0.88 and p=0.42). Syphilis incidence was 9.0/100PY (95%CI 6.5-12.5). The mean number of sexual partners slightly decreased from 11.0 to 8.6 (p=0.20) whereas the proportion of participants engaging in condomless receptive anal sex slightly increased from 44.7% to 47.8% (p=0.37). Two individuals seroconverted during follow-up (HIV incidence 0.51 [95%CI 0.13-2.06] infections/100PY); both had undetectable TFV-DP levels at seroconversion.
Conclusions: Our results show high levels of retention and adherence to PrEP corroborating PrEP's feasibility in a real-life setting of a middle-income country. Moreover, sexual behavior and STI incidence remained stable over time, suggesting a lack of risk compensation in this population.

Are associations between HIV and HPV transmission due to behavioural confounding factors or biological effects?

C. van Schalkwyk[1,2], J. Moodley[3], A. Welte[2], L. Johnson[1]
[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [2]University of Stellenbosch, DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis, Stellenbosch, South Africa, [3]University of Cape Town, Cape Town, South Africa
Presenting author email: carivs@sun.ac.za

Background: Epidemiological studies suggest 2 to 5 fold unadjusted increased risk of newly detecting HPV infection for HIV-infected individuals and of HIV acquisition following HPV detection. Meta-analyses of the latter association, using estimates adjusted for behavioural risk factors, estimate ~2 fold increased risk. We conducted a mathematical modelling study to assess whether confounding behavioural factors and network effects are sufficient to explain associations between HIV and HPV infection status, without biological interactions.
Methods: MicroCOSM, a dynamic individual-based network model, was used to simulate epidemics of HIV and 13 oncogenic HPV types. Heterogeneity in sexual risk behaviour was represented by distinguishing relationship types and allowing for variation between individuals in their rate of partner acquisition and propensity for concurrent partnerships. No biological effects were assumed to modify transmission parameters of HIV in the presence of HPV infection and vice versa. Bayesian methods were used to calibrate the model to South African HIV and type-specific HPV prevalence data. Medians of the posterior distributions of the model parameters were used to simulate cohorts with bi-annual HIV and HPV testing from 2010 to 2015. Cox proportional hazards models were used to estimate hazard ratios for each of 100 simulated cohorts and mean hazard ratios were calculated.
Results: The 2010 mean HIV prevalence and oncogenic HPV prevalence among adults aged 15-49 in the 100 cohorts are 20.1% (95% CI 18.7-21.4%) and 38.9% (95% CI 36.5-41.2%), respectively. The modelled mean unadjusted hazard ratio of HIV acquisition following detection of an oncogenic HPV type is 3.2 (95% CI 2.6-3.8). The mean unadjusted hazard ratio for the effect of HIV on newly detected HPV is 3.7 (95% CI 3.4-4.1). Model findings are similar for different years of study enrolment and frequency of testing.
Conclusions: Model results are comparable to unadjusted results from observational studies, even when no biological effects are included. This suggests that observed associations between HPV and HIV transmission could be attributed to confounding by behavioural factors and network-level effects, implying that primary prevention of HPV (for example by vaccination) may not play a significant role in HIV prevention.

WEPDD01 Getting to the First 90

Accelerating progress towards the first 90 among men: a trial of the peer-based distribution of HIV self-test kits in Bulisa, Uganda

M. Nanfuka[1], A. Choko[2,3], J. Birungi[1], G. Taasi[4], P. Kisembo[1], A. Juliet[1], S. Helleringer[5]
[1]The AIDS Support Organisation, Kampala, Uganda, [2]Malawi- Liverpool Wellcome Trust Clinical Research Program, Blantrye, Malawi, [3]London School of Hygiene and Tropical Medicine, Department of Infectious Diseases Epidemiology, London, United Kingdom, [4]Ministry of Health, Kampala, Uganda, [5]Bloomberg School of Public Health, John Hopkins University, Baltimore, United States
Presenting author email: nanfukam@tasouganda.org

Background: Too few men living with HIV are aware of their status, particularly in fishing communities around the great lakes of Africa. HIV self-testing (HIVST) addresses barriers preventing men from testing. But current approaches to distributing HIVST kits (e.g., through health facilities) only reach a subset of the men requiring HIV testing. We conducted a pilot trial of the distribution of HIVST kits through peer networks of fishermen.

Methods: We recruited seed participants among male patients of a TASO-supported facility. We introduced them to HIVST, and asked if they would distribute HIVST kits to peers who have not recently been tested for HIV. If so, we provided a package containing up to 5 HIVST kits (OraQuick), instructions and scripts addressing questions their peers may ask about HIVST. Recruited peers were referred to the study using a coupon with a unique number, and were asked to return the HIVST kit (used or unused). We conducted audio computer assisted self-interviews with seeds and recruits to measure a) the occurrence of adverse events (e.g., coercion) and b) the uptake of HIVST kits. The accuracy of HIVST was measured against a confirmatory HIV test conducted by a health worker.
Results: A total of 19 seeds offered an HIVST kit to 115 men, and 95 (82.6%) accepted the offer. Among those, 29 had never been tested (25.8%), and 42 (44.2%) had tested more than a year ago. According to confirmatory testing, HIV prevalence was 4.3% among recruits (4/94). Compared to this standard, the sensitivity of HIVST was 100%. Three men living with HIV learned of their infection through HIVST (yield = 1 new diagnosis per 6.3 seeds). The specificity of HIVST was 93.3% (88/94). The 6 false positives were due to a faint grey line appearing on the test location of the OraQuick kit. No recruit reported coercion, but one seed experienced hostility from family members of a recruit.
Conclusions: A novel network-based distribution model of HIVST had high uptake and yield among men in this pilot study. It could constitute a crucial tool in reaching the 90-90-90 targets in under-served fishing communities in Uganda and elsewhere.

MOLBPEA01

Majority of HIV virions exclusively express either functional or nonfunctional forms of Env

A. Arakelyan[1], W. Fitzgerald[1], D. King[2], P. Rogers[2], H. Cheeseman[2], J.-C. Grivel[3], R. Shattock[2], L. Margolis[4]
[1]NIH,NICHD, Bethesda, United States, [2]Imperial College, London, United Kingdom, [3]Sidra Medical and Research Center, Doha, Qatar, [4]NIH,NICHD, Bethesa, United States
Presenting author email: anush.arakelyan@nih.gov

Background: HIV is one of the most variable viruses because of its high mutation rate and the conformational plasticity of env. The rapid evolution of this virus, in particular of its envelope (Env), within an infected individual allows it to evade host cellular and humoral immune responses. The correct conformation of Env is critical for the HIV infection.
In this study, we investigate the conformation of Envs on individual virions using our new technology "flow virometry" and a panel of antibodies that discriminate between various gp120 conformations.
Methods: To analyze native HIV virions individually we used magnetic nanoparticles (MNPs) coupled with anti-HIV antibodies to capture HIV virions, followed by staining of resultant complexes with different combinations of fluorescent "detection" antibodies recognizing different conformations of Envs. The resultant complexes were separated in a strong magnetic field using magnetic columns, and analyzed with a flow cytometer. To investigate how Envs of different conformations may affect viral infection we depleted HIV preparation of viruses carrying trimeric Envs recognized by PG16 antibodies or of virions carrying Env stumps recognized by 4B3 antibodies. We then infected tonsillar tissue blocks ex vivo with these depleted preparations or mock depleted preparation and monitored infection for 12 days by measuring p24 released in culture medium.
Results: We found that the majority of virions did not carry defective and trimeric spikes simultaneously. Accordingly, the depletion of the virions that carry defective Envs only mildly decreased the infection of human lymphoid tissue. 4B3-MNPs depleted viral preparation infected human lymphoid tissues ~40% less (60.8±15.5%, n=6) than the control preparation. In contrast, viral preparations depleted with PG16-MNPs or VRC01-MNPs were significantly less infectious (p=0.01 and p=0.03, respectively). These preparations infected human lymphoid tissue to the level of 28.6 ±8.8% (n=6) and 19.5%±2.7 (n=5) of control, respectively.
Conclusions: The observed lack of mosaicism for the majority of infectious virions suggests that this all-or-nothing viral strategy likely aids immune evasion by subverting the focus of humoral responses to generate multiple non-neutralizing antibodies at no cost to infectious virions.

Presenting author email: nikaiafjsmith@gmail.com

Background: Plasmacytoid dendritic cells (pDC) are the first line of host defence against viruses and bacteria and link innate to adaptive immunity. These immune cells are activated after recognition of pathogen nucleic acids by sensors such as Toll-like receptors (TLR). TLR activation triggers production of type I interferon and proinflammatory cytokines. RNA viruses, such as human immunodeficiency virus type 1 (HIV-1) induce high secretion of type I interferon. However, prolonged pDC activation and consequently massive type I interferon production may have adverse effects in the chronic phase of AIDS. Therefore, modulating pDC function and understanding the mechanisms underlying this pDC regulation is of great clinical interest. It was shown that Histamine strongly inhibits cytokine production by Influenza A-activated pDC and inhibits type I interferon production by activated pDC from psoriasis patients.
Methods: Human pDC were purified from healthy donors and cultivated in presence of HIV overnight. IFN-a production by pDC was quantified by ELISA and relative mRNA levels of different interferons, ISG and pro-inflammatory cytokines

were measured by RT-qPCR. We tested natural (histamine, spermine, serotonine) and synthetic (clobenproppit) amines on pDC activated by HIV. siRNA was performed successfully for the first time on primary human pDC to evaluate the implication of the proteins of interest (Smith et al., 2016). 29S8 mice were infected by inhalation with influenza in presence or not of the amines and IFN levels in bronchoalveolar fluids were measured.
Results: Here we show that natural and synthetic monoamines and polyamines inhibit type I interferon production, membrane TRAIL expression and interferon-stimulating genes (ISG) by HIV-stimulated pDC and PBMCs in vitro. Furthermore, IFN production was fully inhibited in a mouse model of influenza infection. Surprisingly, histamine receptors are not required for pDC inhibition. We show that the positive ammonium moiety is essential for the inhibitory activity and we identify CXCR4 as the unexpected common link between amine effect and pDC inhibition.
Conclusions: Our study establishes a functional link between natural amines and the innate immune system and identifies CXCR4 as a potential 'on-off' switch of pDC activity and therefore as a promising therapeutic target in HIV chronic phases (Smith et al., 2017).

MOLBPEA03

Higher levels of NK cell phenotypic diversity and transcriptional activation prior to HIV-1 infection are associated with increased set point viral load

M.C. Costanzo[1,2], D. Kim[1,2], M. Creegan[1,2], K.G. Lal[1,2], L.A. Eller[1,2], H. Kibuuka[3], L. Maganga[4], S. Nitayapan[5], F. Sawe[1,6], D.L. Bolton[1,2], N.L. Michael[1], M.L. Robb[1,2], M.A. Eller[1,2]

Presenting author email: mcostanzo@hivresearch.org

Background: Natural killer (NK) cells are innate lymphocytes expressing a diverse set of activating/inhibitory receptors that drive their effector activity. Transcriptional signatures differentiate NK cell functions, however, the significance of this functional diversity remains unknown. NK cells are critical for antiviral responses and are generally considered to participate in the control of HIV-1, yet the mechanism remains unclear. A better understanding of NK cell diversity during acute HIV-1 infection (AHI) may be important in the development of treatment and vaccine strategies to eradicate HIV-1.
Methods: NK cell immunophenotyping was evaluated in 24 participants from the RV217 early capture HIV-1 acute infection cohort. PBMC, collected prior to infection and 7-8 time-points over the first 60 days of infection, were thawed and stained to characterize activation, differentiation, homing, and activating/inhibitory receptor expression of NK cells using flow cytometry. In addition, longitudinal NK cell transcriptional signatures were defined in 12 of these donors using Fluidigm BioMark multiplex qPCR.
Results: Throughout AHI, coincident with viral expansion, NK cell counts increased from a median 228 cells/μl (49-589) to 317 cells/μl (100-864)($p< 0.01$). Nevertheless, the kinetics and magnitude of NK cell expansion showed marked variability indicating substantial donor diversity in response to AHI. Analysis of 10 surface receptors revealed broad phenotypic diversity, and there were clear signatures of NK cell activation and trafficking. Moreover, we identified unique transcriptomic fingerprints, related to NK cell effector activity including direct cell recognition, response to cytokines, and antibody dependent cellular cytotoxicity. None of these aspects of NK cell biology were associated with viral control. Interestingly, an index of receptor diversity, prior to infection, trended to a correlation to set point viral load ($r=0.37$, $n=23$, $p=0.1031$). Furthermore, at baseline, expression of 54 genes associated with NK cell effector activity strongly correlated to set-point viral load ($r>0.578$, $n=12$, $p< 0.048$).
Conclusions: Together, this data shows novel phenotypic and transcriptomic signatures associated with NK cells involved in the early responses of HIV-1 infection. Importantly, while NK cell activity can contribute to control of HIV-1 viremia, we observe distinct signatures prior to infection that may be associated with higher set point viral load and worse clinical outcome.

MOLBPEA04

Expanded clones in SIV-infected macaques on antiretroviral therapy recapitulate key features of expanded clones in HIV infection: implications for evaluation of "HIV Cure" interventions

J. Lifson[1], X. Wu[2], G. Del Prete[1], A. Ferris[3], A. Swanstrom[1], D. Wells[3], S. Guo[3], S. Hughes[3]
[1]Leidos Biomedical Research, Inc./Frederick National Laboratory for Cancer Research, AIDS and Cancer Virus Program, Frederick, United States, [2]Leidos Biomedical Research, Inc., Frederick Naitonal Laboratory for Cancer Research, Cancer Research Technology Program, Frederick, United States, [3]National Cancer Institute, Frederick, HIV Dynamics and Replication Program, Frederick, United States
Presenting author email: lifsonj@mail.nih.gov

Background: Residual sources of HIV that persist despite seemingly effective combination antiretroviral therapy (cART) and can give rise to recrudescent infection when cART is stopped ("viral reservoir") include expanded clones of CD4+ T cells, characterized by identical proviral integration sites. These cells can be broadly distributed anatomically, and may contain replication competent proviruses that can contribute significantly to the total viral reservoir.
Methods: To assess whether SIV infected rhesus macaques (RM) receiving cART recapitulate the biology of expanded clones in HIV infected humans, and thus might serve as a useful animal model in this important research area, we analyzed SIV integration sites in RM and human CD4+ T cells infected in vitro, and compared them to HIV integration sites in in vitro infected human CD4+ T cells. We also extensively analyzed integration sites in blood and tissue samples (lymph node, spleen) from four SIV-infected RM started on cART 4 weeks post-infection, and treated for one year.
Results: SIV integration sites in RM and human CD4+ T cells infected in vitro with SIV showed the same overall patterns observed for HIV integrations in human CD4+ T cells (preference for integration into the bodies of highly expressed genes in gene-rich regions), with extensive overlap in the top 500 genes identified as integration hot spots for both viruses. For in vivo specimens, of 997 integration sites documented, 31% represented expanded clones and 7 of the 10 most frequently identified clones were found in at least two different tissues, similar to findings for HIV-infected humans.
Conclusions: These results indicate that SIV integration in RM cells recapitulates essential features of HIV integration in human cells, in vitro and in vivo, including the formation of expanded clones with identical integration sites, and should provide a useful animal model for studies of this critical viral reservoir component. Key questions for future studies include demonstration of the replication competence of at least some of the expanded SIV proviral clones, the role of antigen specific proliferation in their establishment and maintenance and initial evaluations of the impact of appropriate "HIV cure" strategies on this compartment.

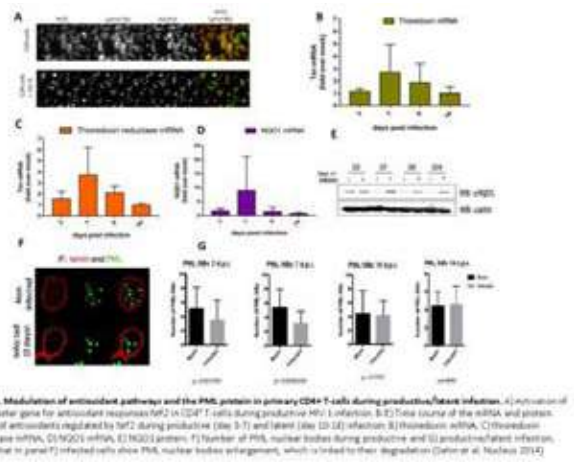
Oxidative stress-related PML nuclear body degradation: a novel pharmacologically druggable mechanism behind the establishment of latency during acute infection

B. Lucic[1,2], I.L. Shytaj[1,2], C. Ahlmann-Eltze[1], S. Bicciato[3], A. Savarino[4], M. Lusic[1,2]
[1]Heidelberg University, Infectious Diseases Integrative Virology, Heidelberg, Germany, [2]German Center for Infection Research (DZIF), Heidelberg, Germany, [3]University of Modena and Reggio Emilia, Department of Life Sciences, Modena, Italy, [4]Italian Institute of Health, Rome, Italy
Presenting author email: luca.shytaj@gmail.com

Background: Unravelling the mechanisms establishing HIV-1 latency may provide new therapeutic tools. Latent HIV-1 resides proximally to nuclear bodies, and their main component, the PML protein, is susceptible to the anticancer drug arsenic trioxide, resulting in latency reversal [Lusic et al. 2013]. We here investigated, in primary $CD4^+$ T-cells, the redox modulation of PML degradation/reformation during transition from acute/productive to latent HIV-1 infection, and its potential therapeutic implications.
Methods: Primary $CD4^+$T-cells were used to model the productive/latent infection transition. Cells were activated with α-CD3-CD28, ex-vivo infected with wild-type NL4-3 HIV-1 and kept in culture for 14 days to revert to a resting state. Viral production was measured by qPCR and FACS. Integrated HIV-1 DNA was measured by ALU-gag PCR. Transcriptomic profiles were obtained by microarray and the results validated by qPCR and western blot. Single cell (co)localization of PML and HIV-1 DNA were assessed by 3Dimmuno-DNA FISH. Data were analyzed with the Graphpad, Volocity and "R" software.
Results: Acute/productive infection (days 3-7 post-infection) was characterized by increased oxidative stress (decreased reduced/oxidized glutathione ratio) and concomitant upregulation of the master gene for antioxidant responses (Nrf2) and its

downstream targets. Particularly, expression of thioredoxin, thioredoxin reductase, and NQO1 peaked 7 days post-infection. Generation of oxidative stress was accompanied by PML degradation and decreased nuclear bodies number (P<0.001).



[NRF2 pathway-PML dynamics during HIV-1 infection]

These effects were reverted during the transition to latent infection (days 9-14 post-infection). Conversely, establishment of latency was prevented both by drug-induced PML degradation and by glutathione depletion using BSO, which selectively induced dose/time dependent death of productively HIV-1 infected cells.
Conclusions: Productive HIV-1 infection activates Nrf-2/antioxidant pathways and leads to PML degradation. These effects are reversed upon latency establishment and can be pharmacologically exploited using pro-oxidant drugs to selectively kill infected cells, thus providing a new tool to hamper latency establishment during acute infection.

MOLBPEA06

Estimating the contribution of proliferation to HIV-infected lymphocyte persistence

J.M. Gerold, A.L. Hill
Harvard University, Program for Evolutionary Dynamics, Cambridge, United States
Presenting author email: jgerold@fas.harvard.edu

Background: Despite suppressive antiretroviral therapy (ART), HIV persists in infected individuals as provirus integrated into the genomes of resting memory CD4+ T cells. The relative importance of intrinsic longevity versus homeostatic proliferation of provirus-containing cells in maintaining this stability remains unknown. To understand how lymphocyte proliferation contributes to reservoir stability, we developed a statistical method to infer dynamical parameters of the HIV-infected lymphocyte population and applied this method to integration site data.
Methods: Recent investigations of HIV integration sites provide a window into the dynamics of resting memory CD4+ T cells. Because HIV integrates randomly into the human genome, the frequency of multiple integrations at the same site is extremely low, implicating clonal proliferation in these observations. Here, we developed a method to use the observed distribution of proviral integration clone sizes to infer the dynamics of cells tagged by these integrations. Using a branching process model and a Bayesian statistical framework, we inferred proliferation and death rates of these cells.
Results: Integration site data from 5 individuals obtained from the Retrovirus Integration Database yielded median a posteriori estimates of proliferation rates in the range of 1.5-5.3 divisions per year, significantly larger than the net rate of latent reservoir decay (~0.2/year). The integration site data were consistent with a model of homogenous dynamics with occasional bursts of proliferation, possibly due to antigenic stimulation of a small subset of T cell lineages. Finally, we connected the statistical uncertainty in our method to sample size and timing in order to guide future studies.
Conclusions: Our results provide a quantitative estimate of resting memory T cell proliferation in individuals with HIV. Because the efficacy of strategies designed to bias the turnover of latently infected cells towards extinction depends critically on this population's intrinsic dynamics, this work is a first step towards evaluating these strategies. Given our model, a reduction in proliferation of latently infected cells could substantially decrease the half-life of the reservoir. In an individual with a latently infected cell proliferation rate of 5 divisions per year, a 90% reduction in proliferation would decrease the half-life of latently infected cells to 1.8 months.

Presenting author email: rthomas@hivresearch.org

Background: IgG antibodies to HIV-1 Envelope (Env) amino acid positions 120-204 (reference sequence HXB2) were identified as a predictor of decreased risk of infection in the RV144 vaccine trial (Haynes et al. NEJM 2012). Env (120-204)-specific IgG antibody levels were a correlate of protection only in the presence of a specific HLA class II allele: DPB1*13 (Prentice et al. STM 2015). Two recent HIV-1 vaccine trials in Thailand, RV305 and RV306, employed the same vaccine regimen as RV144 with additional boosts. This presented a unique opportunity to further examine effect of HLA genotype on vaccine induced IgG responses to HIV- 1 Env.
Methods: HLA-DPB1 was genotyped in 137 and 316 vaccinated individuals from the RV305 and RV306 studies, respectively. IgG binding was detected to scaffolded subtype B and CRF01-AE Env antigen, consisting of the variable loops 1 and 2 flanked by partial regions of the first and second conserved domains. Association of HLA-DPB1*13 with Env (120-204)-specific IgG responses at the timepoint coinciding with peak immunogenicity in RV144 were computed using linear regression adjusted for gender.
Results: In RV306 higher levels of Env (120-204) IgG antibody directly correlated with the presence of HLA-DPB1*13 (P=0.03, q=0.07). The association was stronger when considering only Env-specific IgG responses directed to Env antigen from the CRF01-AE subtype dominant in Thailand (P=0.01, q=0.04). In RV305 association of HLA-DPB1*13 with higher levels of Env (120-204) IgG showed a similar strength association which trended to significance in this smaller sample size (P=0.06, q=0.19).
Conclusions: Presence of a specific HLA class II allele associated with the only protective immune correlate identified to date in a HIV-1 vaccine trial. We were able to replicate this finding in independent donors from two subsequent HIV-1 vaccine trials. HLA-DPB1*13 is known to be expressed at high levels on the cell surface and could modulate CD4+ T cell stimulation of antibody production by B cells in an HLA class II restricted manner. Transcriptome analysis is being performed to identify specific differences in vaccine-induced responses elicited by individuals with HLA-DPB1*13. Understanding this mechanism of protection of the vaccine will enable improved HIV vaccine design.

Cervicovaginal bacteria and HIV acquisition in young South African women

C. Gosmann[1], M. Anahtar[1], S. Handley[2], M. Farcasanu[1], G. Abu-Ali[3], B. Bowman[1], Y. Chen[4], T. Ndung'u[5], M. Ghembremichael[1], D. Wesemann[4], C. Mitchell[6], K. Dong[5], C. Huttenhower[3], B. Walker[1], H. Virgin[2], D. Kwon[1]
[1]The Ragon Institute of MGH, MIT and Harvard, Infectious Diseases, Cambridge, United States, [2]Washington University School of Medicine, St. Louis, Pathology and Immunology, St. Louis, United States, [3]Harvard School of Public Health, Biostatistics, Boston, United States, [4]Brigham and Women's Hospital, Rheumatology, Immunology and Allergy, Boston, United States, [5]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [6]Massachusetts General Hospital, Obstetrics and Gynecology, Boston, United States
Presenting author email: dkwon@mgh.harvard.edu

Background: Increased inflammation in the female genital tract (FGT) is associated with an elevated risk of HIV infection. The role of cervicovaginal bacteria in HIV susceptibility has not been fully elucidated.
Methods: We characterized the gut and cervicovaginal microbiome of HIV-uninfected South African women aged 18-23 years using 16S rRNA gene and DNA/RNA virome sequencing. We performed flow cytometry and Luminex/ELISA to measure numbers of activacted CD4+ T cells and cytokine concentrations in the FGT of these women, as well as in the FGT of mice intravaginally inoculated with low- and high-risk bacteria and in a 3D in vitro model of the FGT. We also used single-cell sequencing to assess the effect of bacteria in vivo.
Results: Women with Lactobacillus-deficient anaerobic cervicovaginal bacterial communities, which constitute the majority of healthy black South African women, had 4-fold higher risk for acquiring HIV than those with Lactobacillus crispatus-

dominant communities. This finding was independent of STIs and HIV risk behaviors. Unlike bacteria, highly prevalent alphapapillomaviruses, Anelloviridae and bacteriophages did not form distinct communities and were neither associated with bacterial communities nor with HIV acquisition. Women with low Lactobacillus abundance, high-diversity bacterial communities had up to 17-fold higher numbers of cervical HIV target cells, providing a biological mechanism for the observed increase in HIV infection. We further identified specific bacterial taxa associated with HIV infection, showing that L. crispatus, but not L. iners, was linked to lower HIV incidence, while genera including Prevotella and Sneathia were associated with elevated inflammation and HIV acquisition. We additionally identified relationships between vaginal and rectal colonization of high-risk bacteria. Finally, germ-free mice intravaginally inoculated with high-risk bacteria had increased numbers of activated mucosal CD4+ T cells.
Conclusions: Our results indicate that cervicovaginal bacteria modulate HIV infection risk and that the predominant microbial communities of South African women place them at increased risk for acquiring HIV. High-risk bacteria engender inflammation through innate sensing by epithelial and mucosal antigen presenting cells in the FGT. These findings and the identification of specific targets within the genital bacterial microbiome may inform future prevention strategies to reduce HIV acquisition in women living in sub-Saharan Africa.

MOLBPEA09

Medroxyprogesterone acetate, unlike norethisterone, increases R5 HIV-1 replication in ecto- and endocervical explant tissue and PBMCs, at physiologically relevant concentrations, by a glucocorticoid receptor-dependent mechanism

R. Ray[1], M. Maritz[1], C. Avenant[1], J. Hapgood[2,3]
[1]University of Cape Town, Cape Town, South Africa, [2]University of Cape Twon, Cape Town, South Africa, [3]Institute for Infectious Disease and Molecular Medicine, Cape Town, South Africa
Presenting author email: janet.hapgood@uct.ac.za

Background: The synthetic progestins, depo-medroxyprogesterone acetate (DMPA) and norethisterone enanthate (NET-EN), are widely used in developing countries as injectable contraceptives, where HIV-1 prevalence is high. Recent epidemiological data show that MPA, unlike NET, increases HIV-1 acquisition in women (HR 1.4), although data for NET-EN are limited. We have previously shown that MPA has relatively potent glucocorticoid (GC)-like activity, unlike NET. We hypothesized that MPA and NET would differentially affect HIV-1 replication due to their differential GC-like actions in HIV-1 target cells, at physiologically relevant concentrations.
Methods: Infection assays were performed in the absence and presence of progestins using HIV-1BAL-RENILLA IMCs in both peripheral blood mononuclear cells (PBMCs) and cervical tissue explants from HIV-1-negative women not on contraception. The GR antagonist RU486 was used to investigate the involvement of the GR in modulating ligand-specific effects.
Results: We show for the first time that MPA, unlike NET, significantly increases HIV-1 replication in human endo- and ectocervical explant tissue at 10 nM (3.8 ng/mL) concentrations detected in the serum of DMPA users. Dose response analysis shows similar effects in PBMCs, with an EC50 of about 15 nM. The results support a mechanism whereby MPA, acting via the glucocorticoid receptor, directly increases HIV-1 replication in HIV-1 target cells and tissue, unlike NET.
Conclusions: The results suggest that the effects on HIV-1 of MPA in injectable contraceptive users are likely to be due, at least in part, to its GC-like actions and unrelated to hypoestrogenism. Collectively, the data suggest that NET, unlike MPA, would be a safer choice of injectable progestin contraceptive in young women in high risk areas for HIV-1 infection.

MOLBPEA10

HIV-1 up-regulates endogenous Galectin-3 to facilitate virological synapse formation and CD4+ T cell-to-cell transmission

R.-Y. Yuan[1], C.-S. Yeh[1], H.-Y. Chen[2], Y.-M. Chen[3], F.-T. Liu[2], S.-F. Wang[1,4]
[1]Kaohsiung Medical University, Department of Laboratory Science and Biotechnology, Kaohsiung, Taiwan, Province of China, [2]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Province of China, [3]Center for Infectious Disease and Cancer Research, Kaohsiung Medical University, Kaohsiung, Taiwan, Province of China, [4]Kaohsiung Medical University, Center for Infectious Disease and Cancer Research, Kaohsiung, Taiwan, Province of China
Presenting author email: wasf1234@kmu.edu.tw

Background: Galectin-3 (Gal-3), a β-galactoside-binding lectin, promotes HIV-1 budding via associations with Alix and Gag. Gal-3 localized in membrane lipid rafts regulates dendritic cell migration. Researchers have shown that HIV-1 spreads between T cells by forming supramolecular structures called virological synapses (VSs), which crucially depend on lipid rafts for integrity and cell-to-cell HIV-1 transmission. We hypothesized that Gal-3 may also play a role in cell-to-cell HIV-1 transmission.
Methods: Immunofluorescent assay and memebrane flotation assays were used to evaluate the colocalization Gal-3 with Gag, Alix and GM1 and virological synapse (VS) formation in Gal-3 expression or knockdown CD4+ T cells. Cell-to-cell transmission assay and FACS were used for valuation of regulating effect of Gal-3 on HIV-1 transmission via VS. Mass spectrometry was conducted to analyze the lipid raft components alteration by Gal-3.
Results: Immunofluorescence staining and immunoblotting data indicate that HIV-1 infection induces Gal-3 up-regulation in CD4+ T cells; translocates with Alix, Gag, and GM-1 to cell-to-cell interfaces, and facilitates VS formation. Time-lapse confocal images show the co-transfer of Gal-3 with Gag between HIV-1 effector and target cells. Membrane flotation data indicate that Gal-3 expression regulated the coordination of Alix, Gag, and flotillin-1 into plasma membranes fractions. Functional cell-to-cell transmission data suggested a significant correlation between HIV-1 transmission efficacy and Gal-3 levels in CD4+ T cells. Other results indicate that Gal-3 expressed in effector cells plays a more important role in facilitating HIV-1 cell-to-cell transmission, than the protein present in target cells. Mass spectrometry and cholesterol quantification data indicate higher levels of sphingomyelin, phosphatidylcholinesphosphatidylcholine, and cholesterol in the membrane lipid rafts of Gal-3-positive CD4+ T cells compared to CD4+ T cells subjected to Gal-3 knockdown. In short, we found evidence that endogenous Gal-3 up-regulates lipid raft components of CD4+ T cells and facilitates intercellular HIV-1 transmission
Conclusions: This study indicates that endogenous Gal-3 is up-regulated by HIV-1 and further facilitates HIV-1 cell-to-cell transmission. We suggest that endogenous Gal-3 is a potential target for HIV-1 intervention.

Colorectal distribution of lymphocytes and cell-free HIV surrogate in autologous seminal plasma following simulated anal intercourse

E.D. Weld[1], K. Ogasawara[2], E.J. Fuchs[3], C.W. Hendrix[4]
[1]The Johns Hopkins University School of Medicine, Medicine (Clinical Pharmacology & Infectious Diseases), Baltimore, United States, [2]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [3]Johns Hopkins University, Medicine (Clinical Pharmacology), Baltimore, United States, [4]Johns Hopkins University, Medicine (Clinical Pharmacology & Infectious Diseases), Baltimore, United States
Presenting author email: ethelweld@gmail.com

Background: Unprotected anal intercourse remains the greatest HIV sexual transmission risk for men who have sex with men (MSM). Rational design of topical rectal antiretroviral microbicides depends critically on understanding the spatiotemporal distribution of HIV infectious elements throughout the colorectal space. The objective of this study was to explore the luminal distribution and clearance of cell-associated (lymphocytes) and cell-free (seminal plasma) HIV surrogate within the distal colon following simulated receptive anal intercourse.
Methods: Six healthy, HIV-uninfected men were recruited and gave semen samples in sterile containers. Samples were centrifuged and the supernatant (seminal plasma) collected and frozen. Peripheral blood lymphocytes were harvested from subjects via apheresis and labeled with ^{111}Indium (In)-oxide on the dosing day. ^{111}In-labeled autologous lymphocytes and ^{99}Technetium (Tc)-sulfur colloid (HIV surrogate) were reconstituted with 3 mL of autologous seminal plasma. Reconstituted seminal plasma was inserted into the rectum using a phallic device with artificial urethra; the device was manipulated to simulate the physical stresses of coitus. Distribution of radiolabels in time and space was assessed with SPECT/CT at 3 timepoints.

Analysis of radiolabel distribution was performed using a flexible principal curve algorithm in R. Pharmacokinetic distance parameters were defined as follows: Dmin (most distal signal, closest to the anorectal junction); DCmax (point of greatest luminal concentration); Dave(average distance, similar to mean residence time); & Dmax (most proximal signal, furthest from the anorectal junction).
Results: Quantitative colonic luminal distance parameters are summarized in the Table for the 1 hour SPECT/CT scans. Differences between cell-free and cell-associated HIV surrogates were not statistically significant; neither were differences among 1, 4, and 8 hour images.

	Cell-Associated (Lymphocytes; In)		Cell-Free (Sulfur colloid; Tc)	
PK Distance Parameter at 1 hour	N	Median (IQR) (cm)	Median (IQR) (cm)	p-value (t-test)
Dmin	6	0.95 (-0.08, 3.45)	1.73 (-0.08, 2.92)	0.75
Dave	6	6.13 (5.15, 8.44)	7.12 (5.23, 7.23)	0.77
DCmax	6	6.15 (5.22, 8.51)	7.08 (5.45, 7.57)	0.73
Dmax	6	14.59 (13.63, 15.78)	16.46 (13.73, 16.92)	0.76

[Distribution of HIV Through Colorectum]

Conclusions: Cell-free and lymphocyte-associated HIV distribution throughout the rectosigmoid can be quantified spatiotemporally. Both autologous lymphocytes and HIV surrogate particles in seminal plasma distribute to a maximal distance of approximately 15 cm from the anorectal junction, with a maximal concentration approximately 6 cm from the anorectal junction. This provides a target anatomic distribution for topical rectal microbicide product development.

Development and *in silico* evaluation of a novel formulation of oral long-acting antiretroviral therapy

A.L. Hill[1], M. Craig[1], A.R. Kirtane[2], O. Abouzid[2], C.D. Bruno[1], S.S. Mo[1], M.A. Nowak[1], R. Langer[2], G. Traverso[2]
[1]Harvard University, Program for Evolutionary Dynamics, Cambridge, United States, [2]Massachusetts Institute of Technology, Department of Chemical Engineering, Cambridge, United States
Presenting author email: alhill@fas.harvard.edu

Background: Global access and adherence to antiretroviral therapy (ART) is limited by high pill burdens. Investigational long-acting formulations exist, but administration requires injection or implantation. Here we sought to develop an oral system for long-acting ART, and create a mathematical-modeling framework to guide the development of extended-release formulations.
Methods: A polymer matrix capsule loaded with ART was engineered, and evaluated in large swine. Device stability and drug release kinetics were measured longitudinally. To predict in vivo therapeutic outcomes with this formulation, we developed a multi-scale model of ART within individual patients. The pharmacokinetic component predicts drug disposition throughout the body (e.g. plasma, lymph; population mean/variance) by simulating absorption, distribution, metabolism, and excretion using physiochemical principles. The pharmacodynamic component relates instantaneous drug levels to suppression of viral replication using ex vivo efficacy measurements. The viral dynamics component tracks active and latent infection, with drug-level-dependent infectivity rates. Drug-sensitive and resistant viral strains interact by mutation and selection, and are defined by existing laboratory or clinical identification of resistance pathways. To model PrEP, we also developed and calibrated a mechanistic model of HIV transmission.
Results: Our device continually released drug (DTG, RPV, CAB) for 7+ days post-dosing in pigs and maintained plasma concentrations well above the daily trough levels of immediate-release formulations. Based on these findings, we used our model to evaluate the therapeutic potential of weekly oral long-acting ART. We predict that long-acting DTG and RPV for maintenance monotherapy is similarly effective as daily formulations, for a range of adherence levels, and substantially more effective if individuals who missed scheduled doses can restart any day of the week. The fraction of treatment failures accompanied by resistance increases with long-acting RPV but not DTG. For PrEP, our model reproduces the dose-dependent efficacy of TFV-based regimens, and predicts that DTG could be highly-effective as PrEP, with over 95% relative-risk-reduction in transmission with perfect adherence and over 50% up to 10 days after the last dose.
Conclusions: This work presents the first pre-clinical development of an orally-delivered long-acting ART formulation, and provides a modeling framework for risk-benefits analysis of these dose regimens and prioritize them for clinical evaluation.

Ledgins hamper the establishment of a reactivation competent HIV reservoir

L. Vranckx[1], G. Vansant[1], A. Bruggemans[1,2], R. Gijsbers[1], F. Christ[1], Z. Debyser[1]
[1]KU Leuven, Centre for Molecular Virology and Gene Therapy, Leuven, Belgium, [2]UZ Leuven, Internal Medicine, Leuven, Belgium
Presenting author email: anne.bruggemans@kuleuven.be

Background: Since HIV integrates into the host genome, it can persist for life in a latent reservoir. HIV integrase uses LEDGF/p75, a host co-factor, to target integration towards transcription units. LEDGINs were developed to block this interaction, but they also allosterically inhibit integrase and lead to aberrant progeny virus. Since a sterilizing cure remains elusive and integration sites may influence viral latency, we investigated if LEDGINs could alter integration site distribution and thus affect the latent reservoir.
Methods: Integration sites were amplified by linker-mediated PCR and sequenced using 454/Roche pyrosequencing. To test reactivation potential, we infected with various cell lines (SupT1, MT4 and Jurkat cells) and primary activated CD4+ T cells, with a double-reporter virus (OGH, Chavez et al., 2015). LEDGINs were either added during infection with or production of the virus. We reactivated cells with TNFα and measured viral reactivation by flow-cytometry to detect reporter gene expression. Finally, we infected primary activated CD4+ T-cells with wild type NL4.3 virus and treated them with LEDGIN or raltegravir. Cells were reactivated with PMA and PHA and virus production was measured by p24 ELISA.
Results: In cell lines, LEDGIN treatment during infection strongly reduced infectivity. Residual proviruses were shifted out of transcription units in a dose-dependent manner. LEDGIN treatment during both infection and virus production increased the latent fraction of the residual reservoir and made the reservoir less prone to reactivation.
In activated CD4+ T-cells, both LEDGIN and raltegravir hindered HIV infection, but only LEDGIN treatment made the residual reservoir refractory to reactivation.
Conclusions: LEDGINs strongly inhibit viral integration and replication and retarget residual integration sites out of transcription units. The resulting reservoir is significantly smaller, more latent and refractory to reactivation. LEDGINs will thus be useful to study latency in vitro. In vivo, LEDGINs may help silence the latent reservoir when administered as part of PrEP or early during acute infection. This could contribute to longer treatment intervals or HIV remission, although this remains to be tested. Further investigation is also need to determine if LEDGINs could also influence the reservoir in chronic infection.

Background: Broadly neutralizing antibodies (bNAbs) against HIV are defined by their breadths of reactivity against globally diverse HIV isolates. These bnAbs hold potential as curative therapeutics if they can bind to reactivated latent reservoirs, targeting these for elimination by natural killer and phagocytes. We evaluated the binding of bnAbs to reservoir virus that had been reactivated from participant CD4+ T-cells. Intra- and inter- participant breadths of reactivity were assessed with a panel of bnAbs by testing binding to multiple reservoir viruses each from 6 individuals.
Methods: Quantitative viral outgrowth assays (QVOAs) were performed with CD4+ T-cells from participants on long-term ART. A panel of bnAbs were conjugated with fluorophores, and tested for surface binding to cells from p24+ QVOA wells.
Results: We observed substantial heterogeneity in the binding of different bnAbs to cells infected with reactivated reservoir virus. The V3-Glycan antibody 10-1074 and the V1/V2 antibody PG9 exhibited potent and highly-specific binding to HIV-infected (Gag+) cells from 4/6 participants. PG9 additionally bound to a subset of viral isolates from the 2 remaining participants, while 10-1074 showed mixed binding to viruses from one and a lack of binding to viruses from the other. PGT-121 (V3-Glycan) exhibited particularly strong binding to HIV-infected cells for all 35 viral isolates (6 participants), but also appreciable binding to bystander cells (Gag-). The CD4 binding site bnAb 3BNC117 and the MPER bnAb 2F5 each exhibited specific binding to infected cells in 2/6 individuals. The remaining antibodies exhibited either little binding or limited specificity for Gag+ cells for each of the viruses tested in this in vitro assay (2G12, VRC01, VRC07, N6, 10E8, 4E10, PGDM1400, CAP256.VRC26.25).
Conclusions: BnAbs exhibit distinctive binding profiles for HIV-infected primary CD4+ T-cells, which may not fully parallel neutralization potency. Encouragingly, the bnAbs which bound well to HIV-infected cells exhibited substantial coverage

of reactivated reservoir virus with PGT121, PG9, and 10-1074 binding to 35/35, 31/35, and 27/35 isolates, respectively. Our results add further support to the idea that bnAbs may contribute to 'kick and kill' strategies, and provide guidance on the selection of bnAbs based on magnitude, specificity, and breadth of binding.

MOLBPEA15

Rapid CTL recognition of HIV-1 latently infected cells depends on the levels of inducible viral reactivation and CTL activation status

A. Ruiz[1], O. Blanch-Lombarte[1], E. Jimenez-Moyano[1], R. Peña[1], M. Genescà[2], P. Goulder[3], B. Clotet[1], J. Garcia Prado[1]
[1]*AIDS Research Institute IrsiCaixa, Germans Trias i Pujol Hospital, Badalona, Spain,* [2]*Germans Trias i Pujol Research Institute (IGTP), Germans Trias i Pujol Hospital, Badalona, Spain,* [3]*University of Oxford, Department of Pediatrics, Oxford, United Kingdom*
Presenting author email: aruiz@irsicaixa.es

Background: HIV-1 "shock and kill" cure strategies depend on the induction of viral transcription in HIV-1 latently infected cells by latency-reversing agents (LRAs), and the clearance of reactivated cells by cytotoxic T-lymphocytes (CTL). However, the therapeutic window of opportunity between HIV-1 latency reversal and CTL recognition is unknown. Here, we aimed to investigate the kinetics of CTL recognition and killing of HIV-1 reactivated cells by LRAs.
Methods: We developed an HIV-1 "Resting-Like model" (RELI) to measure HIV-1 inducible reactivation and CTL killing in the presence of LRAs. We assessed the kinetics of CTL recognition and killing at 3, 6 and 20 hours after coculturing LRAs-treated cells with HLA-matched CTLs. We measured CD107a, MIP1β and IFNg secretion as a surrogate marker of CTL activation and reduction of intracellular p24 in cocultures as readout of killing. We monitored the impact of continuous antigenic exposure in CTL exhaustion by PD1/LAG3/TIM3/CD39 expression and we evaluated changes in the killing of LRAs reactivated cells by CTL.
Results: We detected HIV-1 reactivation in RELI cells after LRAs treatment with SAHA (4-fold; p<0.005) and Panobinostat (2-fold; p<0.05). LRAs-driven reactivation increased CTL clearance of HIV-1 infected cells (p<0.05). In terms of kinetics, we observed killing of reactivated cells by CTLs from 3 hours in SAHA and SAHA/Bryostatin conditions (p<0.05). By contrast, Panabinostat reactivated cells exhibited slower kinetics of CTL killing which magnitude increased with the addition of Bryostatin. The kinetics of CTL activation showed an augment in CD107a and MIP1β expression and a reduction of IFNg production from 3 hours post-coculture. In addition, Bryostatin-treated cells induced higher levels of CTL cytokine expression in the absence of virus reactivation. Upon continuous antigen exposure, up-regulation of LAG3/TIM3/CD39 by CTLs was associated with reduced killing of reactivated cells (p<0.05).
Conclusions: LRAs induce viral proteins expression and increase CTL recognition and killing of HIV-1 reactivated cells. Rapid killing of HIV-1 reactivated cells by CTLs depends on the LRAs potency and the CTL pre-activation status, which can be modulated by Bryostatin. Our results have direct implications for the optimization of "shock and kill" therapeutic strategies.

Presenting author email: gwantwa@umn.edu

Background: CD8 T cells are crucial for controlling both human and simian immunodeficiency virus (HIV/SIV) infections. Low levels of virus-specific CD8 T cells within B cell follicles permit ongoing replication of HIV and SIV. The B cell homing molecule, CXCR5, is required for homing to B cell follicles. We hypothesize that engineering virus-specific CD8 T cells to express CXCR5 will enable them to home to B cell follicles and suppress viral replication. To begin to test this hypothesis we developed a novel ex vivo B cell migration assay.
Methods: We first determined the optimal time that lymph node tissue slabs could be incubated and maintain follicular morphology. Next we evaluated whether CD8 T cells engineered to express CXCR5, accumulated within B cell follicles. We transduced CD8 T cells from SIV infected rhesus macaques, with a control vector or a CXCR5 transducing vector, labeled with a live cell dye CTV, layered these cells onto 300um thick fresh tissue slabs and incubated for six hours. Sections were then fixed and stained via IHC with anti-CD20 to stain B cell follicles. Sections were imaged using a confocal microscope and CTV labeled cells were quantified inside and outside of B cell follicle.
Results: We determined that follicular morphology was maintained after 4 and 6 hours of incubation, but was lost after overnight incubation.
Preliminary migration results showed a fivefold increase in the follicular to extra follicular ratio (F: EF) of CTV labeled cells in the CXCR5 transducing vector samples compared to control samples.
Conclusions: We successfully created an ex vivo B cell migration assay. Preliminary results using this assay suggest that CXCR5 transduction induces T cell migration into B cell follicles.

MOLBPEA17

Detection and activation of naive B cells expressing the germline precursors of protective antibodies

M. Pancera
Fred Hutchinson Cancer Research Center, Seattle, United States
Presenting author email: mpancera@fredhutch.org

Background: Various strategies are being pursued to identify and characterize the precursors of bNAbs, as a way to guide HIV immunogen-design approaches. In many cases, the precursors of bNAbs do not bind Env, which limits the design of appropriate immunogens. b12 is a CD4 binding site antibody that neutralize ~40 % of circulating HIV-1 strains. However, none of the 80 recombinant Envs that we screened bound germline b12 (glb12).
Methods: To overcome this obstacle, we developed anti-idiotypic antibodies against the predicted glb12 and obtained crystal structures of two anti-idiotypic antibodies, ib2 and ib3 in complex with glb12.
Results: The structures revealed that the two antibodies contact germline b12 in different manners. Interestingly, ib2 interacts with glb12 heavy chain only, similarly to gp120 interactions with b12. ib2 CDRH3 inserts between glb12 CDRH3 and CDRH1 in an identical manner as the CD4 binding loop of gp120 CD4 interacts with b12. ib3 contacts glb12 with a different angle, facing the glb12 combining site. We then used the ib2 anti-idiotypic antibodies to isolate very efficiently germline b12-like antibodies from HIV-1 negative patients, something that is not feasible using recombinant Env.
Conclusions: In conclusion, anti-idiotypic antibodies against predicted glb12 can be used to isolate glb12-like antibodies and the knowledge of their interactions with glb12 should guide further immunogen design.

The impact of mass incarceration of African American men on HIV acquisition among African American women: an agent-based modelling study

J. Adams[1], M. Lurie[1], M. King[1], K. Brady[2], M. Khan[3], S. Galea[4], S. Friedman[5], B. Marshall[1]
[1]*Brown University, Department of Epidemiology, Providence, United States,* [2]*AIDS Activities Coordinating Office, Philadelphia Department of Public Health, Philadelphia, United States,* [3]*New York University, Division of Comparative Effectiveness and Decision Science, Department of Population Health, New York City, United States,* [4]*Boston University School of Public Health, Boston, United States,* [5]*National Development and Research Institutes, New York City, United States*
Presenting author email: joella_adams@brown.edu

Background: The United States has the highest incarceration rate in the world, with significant racial disparities. Incarceration can increase HIV risk behaviors and may be a driver of HIV acquisition for women. Our objective was to estimate the impact of mass incarceration of African American men on HIV acquisition among African American women.
Methods: An agent-based model simulated HIV transmission in a dynamic sexual-contact network representing all heterosexual African American men and women living in Philadelphia from 2005-2015. The model was calibrated using epidemiologic surveillance data. Informed by current literature, incarceration and partner incarceration increased the number of sexual partners and decreased HIV care engagement for men post-release. To quantify the impact of incarceration, we compared a status quo scenario (i.e., calibrated model with current incarceration rates) to one in which there was no incarceration. Since there is a pronounced racial disparity in incarceration rates, we also compared the status quo model to one in which the incarceration rate for African American men was equal to that for white

men in Philadelphia. Our outcome was the average number of HIV transmissions among African American women during the study period.
Results: On average, the status quo scenario resulted in 1,775 (95% Simulation Interval [SI]: 1,480-2,140) new HIV infections among women over ten years. The scenario with no incarceration decreased HIV transmissions to 1,638 (95% SI: 1,380-1,990), resulting in 137 averted infections, while the scenario without racial disparities in incarceration resulted in 1,709 (95% SI: 1,410-2,030) HIV transmissions, and 66 averted infections. A sensitivity analysis increasing the duration of male post-release high-risk sexual behavior from six to twelve months intensified the impact of incarceration: 169 infections were averted in the no incarceration scenario, and 77 infections averted in the no disparities scenario.
Conclusions: The mass incarceration of African American men increases HIV acquisition among African American women. Our findings emphasize the importance of ending mass incarceration and the impact of substantial racial disparities in incarceration rates. Future research should evaluate points of intervention that may lessen the impact of incarceration, such as improving HIV care engagement post-release.

Estimated hepatitis C prevalence and key population sizes in San Francisco: a foundation for elimination

S. Facente[1,2], H.F. Raymond[2,3], K. Burk[3], E.L. Murphy[4], A. Mirzazadeh[2], M.D. Morris[2], A.A. Smith[3], M.A. Sanchez[3], J.L. Evans[2], A. Nishimura[3], E. Grebe[5], End Hep C SF
[1]Facente Consulting, San Francisco, United States, [2]University of California San Francisco, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States, [4]Blood Systems Research Institute, San Francisco, United States, [5]Stellenbosch University, South African Centre for Epidemiological Modelling and Analysis, Stellenbosch, South Africa
Presenting author email: eduardgrebe@sun.ac.za

Background: Initiated in 2016, End Hep C SF is a comprehensive initiative to eliminate hepatitis C (HCV) infection in San Francisco. The introduction of direct-acting antivirals (DAAs) to treat and cure HCV provides an opportunity for elimination. To properly measure progress, a baseline estimate of HCV prevalence, and of the number of people in various subpopulations infected with HCV, is required to target and measure the impact of interventions.
Methods: Our estimates are based on triangulation of data found in case registries, medical records, cohort studies, and published literature from 2010 through 2017. We stratified the population by sex, age and/or HCV risk group, and estimated the population size and HCV prevalence in each group. When multiple sources of data were available, we calculated a weighted average using inverse variance weighting. Credible ranges (CRs) were derived from 95% confidence intervals of population size and prevalence estimates.
Results: We estimate that 23,311 residents of San Francisco are HCV seropositive (Credible Range: 11,281-43,997), representing an overall seroprevalence of 2.7% (CR: 1.3%-5.1%). Of these, 17,517 are estimated to be viremic (CR: 7,114-38,968), but this estimate includes treated (and cured) cases. People who inject drugs (PWID) represent 69.9% of viremic HCV infections. Of those MSM with HCV viremia, 1,656 (CR: 823-2,748), or 73% (CR: 73-75%) are estimated to be co-infected with HCV and HIV. Results are summarized in the table.

Subpopulation	# HCV seropositive (CR)	HCV seroprevalence (CR)	% of citywide HCV seropositives (CR)	% of citywide HCV viremics (CR)
PWID	15,988 (8,852-23,592)	65.3% (63.1-67.5)	68.6%	69.9%
MSM	3,057 (1,634-4,535)	4.4% (2.4-6.4)	13.1%	12.9%
HIV+ MSM	***2,269 (1,634-3,455)***	***15.7% (8.8%-22.7%)***	***9.7%***	***7.1%***
Transgender Women (low SES)	211 (132-299)	22.1% (14.9-29.5)	0.9%	0.9%
Baby Boomers	8,917 (4,256-16,221)	4.4% (2.2-7.5)	38.3%	37.8%
Men	16,872 (8,503-29,261)	3.8% (2.0-6.5)	72.4%	71.7%
Women	6,228 (2,645-14,447)	1.5% (0.6-3.4)	26.7%	27.3%
Total	***23,311 (11,281-43,997)***	***2.7% (1.3-5.1)***	***100.0%***	***100.0%***

[Summary of Estimated HCV Burden by Subpopulation]

Conclusions: Our estimate provides a useful baseline against which the impact of End Hep C SF can be measured. We estimate approximately 9,000 more HCV seropositive cases than are included in the San Francisco HCV case registry.

The impact of HIV self-testing on recent testing, status knowledge, and linkage to care among female sex workers in Kampala, Uganda: a randomized controlled trial

K. Ortblad[1], D. Kibuuka Musoke[2], T. Ngabirano[3], A. Nakitende[2], J. Magoola[3], P. Kayiira[3], G. Taasi[4], L. Barresi[5], C. Oldenburg[6], T. Barnighausen[7]
[1]Harvard T.H. Chan School of Public Health, Global Health and Populatoin, Boston, United States, [2]International Research Consortium, Kampala, Uganda, [3]Uganda Health Marketing Group, Kampala, Uganda, [4]Uganda Ministry of Health, Kampala, Uganda, [5]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [6]Francis I. Proctor Foundation, University of California San Francisco, San Francisco, United States, [7]Heidelberg University, Heidelberg, Germany
Presenting author email: katrina.ortblad@mail.harvard.edu

Background: HIV self-testing (HIVST) is a promising new testing strategy for female sex workers (FSW) because it has the potential to reduce testing barriers for this population, i.e. provider stigma and discrimination. We explored the impact of HIVST via different delivery platforms on recent testing, status knowledge, and linkage to care among FSW in Kampala, Uganda.
Methods: FSW peer educators each recruited and enrolled 8 eligible participants. Peer educator-participant groups were randomized to one of three study arms:
(1) distribution of a HIVST,
(2) distribution of a HIVST coupon (exchangeable at specified clinics), or;
(3) referral to standard testing services, all by the peer educator.
Participants in the intervention arms received two HIVSTs or coupons, one after enrollment and one three months later. Participants completed baseline, one-month, and four-month assessments. HIV status knowledge was assessed at four months with a perceived conditional cash transfer; participants received ~1 USD if their reported HIV status matched the results of a rapid test.
Results: 960 participants were enrolled from October to November 2017; median age was 28 years (IQR: 24-32). Relative to the standard arm, recent HIV testing was more common in the HIVST arm at one-month (95.2% HIVST vs. 71.5% standard, P=< 0.001) and both intervention arms at four-months (45.9% standard; 59.5% HIVST, P=0.04; 62.3% coupon, P=0.008). There were no significant differences in correct HIV status knowledge across study arms at four-months (88.0% standard; 88.1% HIVST, P=0.96; 86.9% coupon, P=0.73). Among those testing positive, there was no difference in linkage to care between HIVST and standard arms. Linkage was lower in the coupon arm compared to the standard arm at both follow-up assessments (one-month: 24.1% coupon vs. 64.1% standard, P=0.001; four-months: 49.2% coupon vs. 75.0% standard, P=0.02).
Conclusions: HIVST is acceptable among FSW in Kampala, Uganda. Compared to standard testing, HIVST increased rates of recent testing, but did not change correct HIV status knowledge and resulted in decreased linkage to care among HIV-positive participants who received HIVST coupons. In order for HIVST to reduce gaps in the HIV treatment cascade, additional efforts are need to ensure individuals correctly interpret the HIVST results and link to care.

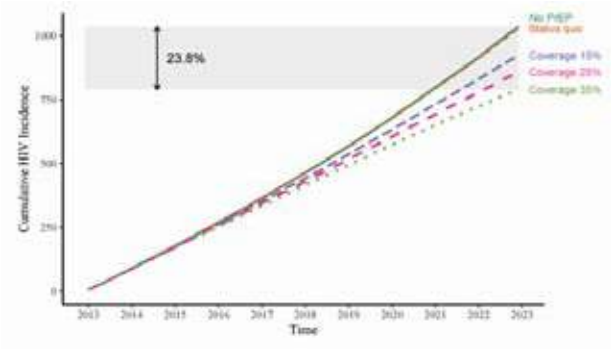
The impact of a real-world pre-exposure prophylaxis program on HIV transmission among men who have sex with men: an agent-based modelling study

J.R. Gantenberg[1], B.D.L. Marshall[1], M. King[1], O. Galárraga[2], M. Prosperi[3], A. Tributino[4], M. Montgomery[4], P.A. Chan[4,5]
[1]Brown University, Department of Epidemiology, Providence, United States, [2]Brown University, Department of Health Services, Policy, and Practice, Providence, United States, [3]University of Florida, Department of Epidemiology, Gainesville, United States, [4]The Miriam Hospital, Division of Infectious Diseases, Providence, United States, [5]Brown University, Division of Infectious Diseases, Providence, United States
Presenting author email: jason_gantenberg@brown.edu

Background: In the United States, men who have sex with men (MSM) continue to be disproportionately impacted by HIV. Pre-exposure prophylaxis (PrEP) has emerged as an important preventive intervention, but the impact of PrEP implementation on population-level HIV incidence remains unknown.
Methods: We used an agent-based model to evaluate the impact of a real-world clinical PrEP program which provides the majority of PrEP care in the state of Rhode Island. We simulated HIV transmission among all MSM (N = 23,815) in the state between 2013 and 2023. In a status quo scenario, PrEP was scaled up until 2023 based on the initiation rate and partner number distribution observed within the current PrEP program. Several hypothetical scenarios were modelled to determine the scale-up required to substantially reduce HIV incidence. We compared incidence across scenarios and calculated the person-years on PrEP per averted infection (PYPAI). Estimates are presented as medians with 95% simulation intervals (SI).

Results: A total of 203 prescriptions were provided to MSM between February 2013 and October 2016. Assuming linear scale-up, 1.3% of the at-risk MSM population is projected to be on PrEP after 10 years. In the absence of PrEP, 1037 (95% SI: 917.9, 1163.0) new infections would occur by 2023 (Figure). Under the status quo, approximately 7.2 infections would be averted (95% SI: -121.8, 127.3), amounting to 191 PYPAI (95% SI: 10.9, 1381.8). With 35% of MSM taking PrEP by 2023, 247.2 (95% SI: 149.2, 337.3) transmissions would be avoided, nearly a 24% decrease, resulting in 162 PYPAI (95% SI: 119.1, 269.2).



[Cumulative HIV incidence over 10 years]

Conclusions: Among MSM in this setting, current PrEP implementation programs are having a modest impact on HIV incidence. To achieve a 25% reduction in new infections, dramatic and sustained scale-up of PrEP is required.

MOLBPEC29

A field safety and acceptability study of PrePex male circumcision device when removing the foreskin shortly after device placement

D. Linyama
Ministry of Health, Choma, Zambia
Presenting author email: dmlinyama@yahoo.co.uk

Background: This study was designed to validate the safety and efficacy of an adjusted PrePex procedure of removing the foreskin shortly after device application on day 0 (FRP). An initial assessment in Rwanda showed this procedure is feasible without injected anesthesia 30 to 60 minutes after device placement.
We validated that the updated procedure maintains the device non-surgical advantages while resolving some of the procedure limitations, such as anaerobic environment that may be prone for anaerobic bacteria growth, odour and foreskin hygiene.
Methods: Between March 2017 to May 2017, study procedures were performed in 2 mobile offices close to health care facilities in Lusaka and Livingstone, Zambia. 500 eligible male subjects scheduled for circumcision ages 13 to 49 were enrolled, the average age was 22.7 years (SD6.7).
The study was conducted in 2 phases:
Phase 1 (Establishing FRP protocol), 119 subjects.
Phase 2 (Validating the procedure), 381 subjects.
Results: For all 500 subjects, there was no need for injected anaesthesia for the FRP, 96.4% reported no pain at all, the average reported pain for the remaining 4.6% was 2.66 (VAS of 0 to 10 was used to evaluate subject reported pain).
The average waiting time from placement to FRP was 36 minutes.
During the 1st phase, while the FRP protocol was not yet established, there were 5 bleeding events (AE rate of 5%), 4 requiring device removal and sutures. At the 2nd phase, with an established FRP protocol, there were 2 bleeding events only, 1 requiring device removal and sutures (AE rate of 0.5%).The difference between the AE rates of both groups was statistically significant (p< 0.003).
Conclusions: This study demonstrates that removing the foreskin after device placement is safe and easy to perform while eliminating some of the device limitations, most importantly per WHO guideline it puts the device at the same tetanus risk level as surgical circumcision reducing the requirements for 2 tetanus toxoid contacting vaccine prior to PrePex.
This study will significantly contribute to the continuation of PrePex implementation in VMMC programs halted in 2016 following WHO tetanus guidelines.

MOLBPEC30

The impacts of a demand-side VMMC incentives program on the male circumcision rate in 2 districts in Malawi: a synthetic control approach

J. Suzi[1], J. Friedman[2], A. Longosz[2], R. Rodriguez-Garcia[2], J. Mkandawire[3], A. Chilungo[3], B. Matatiyo[4], J. Njobvuyalema[4], A. Mwansambo[4], H. Chimbali[5], E. Chamanga[5], S. [1]Malawi National AIDS Commission, Social and Behaviour Change Communication, Lilongwe, Malawi, [2]The World Bank, Washington DC, United States, [3]Invest in Knowledge, Zomba, Malawi, [4]Malawi National AIDS Commission, Malawi National AIDS Commission, Lilongwe, Malawi, [5]Malawi Ministry of Health, HIV Department, Lilongwe, Malawi, [6]Malawi Ministry of Education Science and Technology, Lilongwe, Malawi
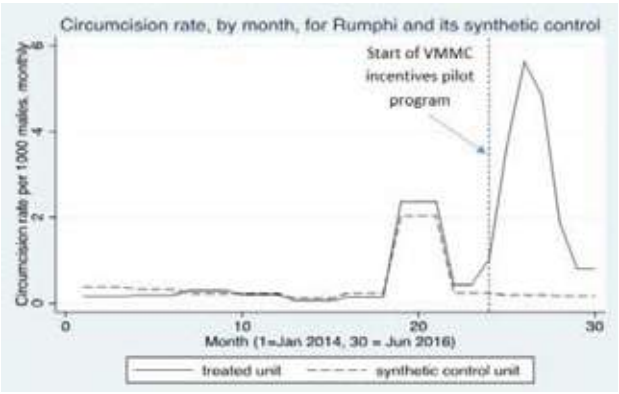
Presenting author email: suzij@aidsmalawi.org.mw

Background: Voluntary Medical Male Circumcision (VMMC) is an effective HIV prevention intervention. The Malawian government responded to the need to increase VMMC, but progress has been slow and innovative solutions were needed to increase VMMC uptake. In this light, the Malawi National AIDS Commission undertook a study of using incentives to create VMMC demand in Mchinji and Rumphi districts. This pilot program, implemented from Oct 2015 to April 2016, extended in-kind incentives to primary and secondary schools, as well as school-based mother groups, with the value determined by the number of young men voluntarily undergoing VMMC at their District Hospital.
Participating organizations also offered vouchers to potential circumcision clients and their caretakers - and a second set to hand out to their friends and caregivers - that covered the cost of transport for them and their caregiver for the procedures and two follow-up visits.
Methods: Synthetic control methods are used to estimate the causal effect of the program on the circumcision rate of males 14-34 years old. Information on VMMC rates for the two years before study onset, as well as district-level socio-demographic and health information, inform the synthetic counterfactual for each of the study districts. Permutation tests establish the robustness of impact estimates.
Results: The program led to a substantial increase in circumcisions: an additional 16.05 male circumcisions per 1,000 adult males in Rumphi (see Figure 1), and an additional 9.15 in Mchinji. Overall, an individual who received a voucher was 7 times more likely to be circumcised than someone who had not received one. Complementary qualitative findings suggest that mothers' groups were more effective in motivating young men due to personal attention, and that caregivers play an important supportive function in the circumcision decision.



[Figure 1 - Rumphi results]

Conclusions: Despite implementation challenges, VMMC incentives are highly effective in increasing the circumcision rate from low baseline levels.

Presenting author email: shk9078@nyp.org

Background: Tenofovir (TDF)-containing PrEP is effective for HIV prevention, but its effect on health-related quality of life (QOL) is unknown. Using data from HPTN 069/ACTG 5305, a randomized trial of potential PrEP regimens comparing maraviroc (MVC) alone, or together with TDF or emtricitabine (FTC), to TDF/FTC (control), we evaluated the impact of these regimens on QOL in at-risk HIV-uninfected U.S. women and men.
Methods: QOL was measured at baseline (before starting medications) and every 8 weeks until week 48 using the EQ-5D, a validated instrument. Responses were converted to health utilities, on a scale from 0.0 to 1.0, using published valuation weights. Mean utilities were compared between groups at each time point using nonparametric statistical testing. Multivariable linear regression was used to adjust for potential confounders.
Results: We analyzed data from 186 women (median age 35 years, 65% black, 17% Hispanic) and 405 men (median age 30 years, 28% black, 22% Hispanic), including 9 transgender participants analyzed based on phenotypic sex. Mean baseline QOL was 0.91 for women and 0.95 for men. There were minimal changes in mean QOL for any regimen from baseline over time (Figure). Mean QOL did not differ significantly by regimen at any time point, both unadjusted and after adjustment for age, race/ethnicity, alcohol use, opiate use, other substance use, or adherence. There were no significant differences between participants who continued the regimen (n=396) compared to participants who discontinued (n=107).
Conclusions: QOL in at-risk individuals starting candidate HIV PrEP regimens in a clinical trial is similar to the general population and maintained over time. This finding did not vary among regimens or when adjusted for demographics, adherence, and substance use. Our findings are the first to show that starting a candidate PrEP regimen in at-risk HIV-uninfected U.S women and men was not associated with significant changes in QOL.

HPTN 076: safety and pharmacokinetics of rilpivirine LA through week 76 in HIV-uninfected women

N.D. Sista[1], S. Li[2], M. Marzinke[3], N. Mgodi[4], J. Justman[5], S. Swaminathan[6], A. Adeyeye[7], E. Piwowar-Manning[8], S. Pathak[2], J. Farrior[1], L.-G. Bekker[9], and the HPTN Study Team
[1]FHI 360, Science Facilitation, Durham, United States, [2]Fred Hutchinson Cancer Research Center, SCHARP, Seattle, United States, [3]Johns Hopkins University, Pharmacology, Baltimore, United States, [4]UZ-UCSF Collaborative Research Programme, Harare, Zimbabwe, [5]Columbia University, Division of Infectious Diseases, College of Physicians and Surgeons, New York, United States, [6]Rutgers, The State University of New Jersey, Division of Infectious Diseases, New Jersey Medical School, Newark, United States, [7]NIAID, National Institues of Health, Diivision of AIDS, Rockville, United States, [8]Johns Hopkins University, Pathology, Baltimore, United States, [9]University of Cape Town, Institute of Infectious Diseases and Molecular Medicine, Desmond Tutu HIV Centre, Cape Town, South Africa
Presenting author email: nsista@fhi360.org

Background: Long-acting injectable agents may be an alternative to daily oral tablets for pre-exposure prophylaxis (PrEP). HPTN 076 evaluated safety and pharmacokinetics of the long-acting injectable form of rilpivirine (RPV LA) for 76 weeks.
Methods: HPTN 076 was a phase 2, double-blind, 2:1 randomized trial comparing the safety of 1200mg RPV LA (LA) to placebo (P) in low risk, sexually active HIV-uninfected women in the United States (US), South Africa and Zimbabwe. After four weeks of daily oral product, participants received the injectable product every eight weeks. Each dose consisted of two gluteal, intramuscular (IM) injections, the last dose was at Week 44 and participants were followed until Week 76. All samples collected on the same day as injection administration were obtained prior to dosing.
Results: Of 136 enrolled women, 122 (80 LA, 42 P) received ≥ one dose; 98 (64 LA, 34 P) received all six. From Week 4 to 76, there were 16 product discontinuations (10 LA, 6 P); 6 (8%) LA and 2 (5%) P were due to AEs. There were no significant differences between two arms in AEs, including liver abnormalities, and one seroconversion occurred in the P arm. Three LA and no P arm participants developed Gr ≥3 injection site reactions.
The median plasma RPV trough concentration (C_{Trough}) at Week 52, was 92 ng/mL, 94% > PA-IC_{90} (12.5ng/mL); at Week 76, plasma RPV concentration (C_{W76}) was 44.2 ng/mL, 92% > PA-IC_{90}. Among participants receiving all six injections, the median plasma C_{W76} was 47.7 ng/mL, 100%> PA-IC90. In five women who received only the first injection at Week 4, C_{W76} < PA-IC90, but only one was below detectable level (1.0 ng/mL). Week 36/44 C_{Trough} in cervico-vaginal fluid (N=80) and vaginal tissue (N=16) had medians of 90 and 60 ng/g respectively, moderately correlating with contemporaneous plasma concentrations (Spearman correlation ρ=0.53, 0.32, p=<0.0001, 0.23).
Conclusions: RPV LA, 1200 mg IM every eight weeks was well tolerated and safe through 76 weeks in African and US women. RPV plasma concentration at Week 76 was above the PA-IC90 in 92% and detectable in 99% of participants.

Presenting author email: eweld@jhmi.edu

Background: Unprotected receptive anal intercourse (uRAI) carries a high risk of acquiring HIV. Large trials demonstrate efficacy of oral tenofovir (TFV)-based pre-exposure prophylaxis (PrEP), though poor adherence reduces efficacy and systemic drug exposure has associated toxicities. Pericoital douching is commonly practiced with uRAI. Therefore, a behaviorally-congruent pericoital medicated enema could provide uRAI PrEP for those who struggle with oral PrEP or prefer topical methods.
Methods: Six healthy, HIV-uninfected men received a single 125 mL rectal enema containing 220mg TFV. Plasma, PBMCs, rectal fluid, and colon tissue were sampled for TFV and activated TFV-DP concentration. Four participants re-

ceived a ^{99}Tc-DTPA labelled enema to assess colonic distribution using SPECT/CT imaging. Colon biopsies assessed ex vivo explant susceptibility to HIV infection. Acceptability was assessed via questionnaire.
Results: No related Grade 2 or higher adverse events were observed. All participants said they would be likely or very likely to use the enema, especially applying it before uRAI, if it protected against HIV. Drug concentrations (median [range]) are presented in the Table.

Post-Dose	Plasma TFV	Tissue TFV	Tissue TFV-DP	Tissue Cell TFV-DP
Hours	*ng/mL*	*ng/mg*	*fmol/mg*	*fmol/10^6 cells*
1	1.9 (0.4, 9.1)	94 (39, 150)	907 (135, 1680)	1100 (793, 1407)
3	4.3 (1.0, 21.7)	16 (13, 992)	562 (BLQ, 1855)	4081 (16, 24782)
24	0.8 (BLQ, 1.9)	10 (1, 95)	82 (BLQ, 200)	1799 (823, 2670)
72	BLQ (BLQ,BLQ)	2 (1, 3)	111 (BLQ, 221)	103 (BLQ, 206)

[DREAM 01 Pharmacokinetic Summary]

From 1-24 hours post-dose, median colon cellular TFV-DP concentrations exceeded target concentrations by 1.1-1.7 $\log_{10}$. (Target: TFV-DP 83 fmol/10^6 colon tissue cells, estimated as the TFV-DP level associated with iPrEx IC_{90} dose frequency of 4 doses/week). Observed concentrations were consistent with steady-state daily dosing of 1% TFV rectal gel. SPECT/CT indicated radiolabel distribution from rectosigmoid to splenic flexure in all subjects. Compared to pre-drug baseline, biopsies collected from 1-24 hours after dosing reduced viral replication in ex vivo colon tissue explants by median (quartiles) 0.77 $\log_{10}$ (0.20, 0.81) ($p< 0.01$).
Conclusions: Tenofovir enema is a novel, behaviorally-congruent delivery method for uRAI PrEP. A single dose was safe, well-tolerated, acceptable, and reduced HIV replication in ex vivo explants. Colon cell TFV-DP exceeded by >10-fold the steady-state colon mucosal cell concentrations associated with >90% efficacy (based on modeling iPrEx and smaller pharmacokinetic studies), yet with minimal systemic TFV exposure.

MOLBPEC34

Pooled efficacy analysis of two phase III trials of dapivirine vaginal ring (DVR) for the reduction of HIV-1 infection risk in HIV uninfected women in sub-Saharan Africa

Z. Rosenberg[1], A. Nel[1], N. van Niekerk[1], B. Van Baelen[2], J. Van Roey[3], T. Palanee-Phillips[4], E. Brown[5], L. Soto-Torres[6], S. Hillier[7], J. Baeten[8], IPM 027/Ring Study and MTN-020/ASPIRE Study Teams
[1]International Partnership for Microbicides, Silver Spring, United States, [2]Janssen Research and Development, Beerse, Belgium, [3]Janssen Global Public Health, Beerse, Belgium, [4]Wits Reproductive Health and HIV Institute (WRHI), Johannesburg, South Africa, [5]Fred Hutchinson Cancer Research Center, Seattle, United States, [6]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [7]University of Pittsburgh School of Medicine, Pittsburgh, United States, [8]University of Washington, Seattle, United States
Presenting author email: zrosenberg@ipmglobal.org

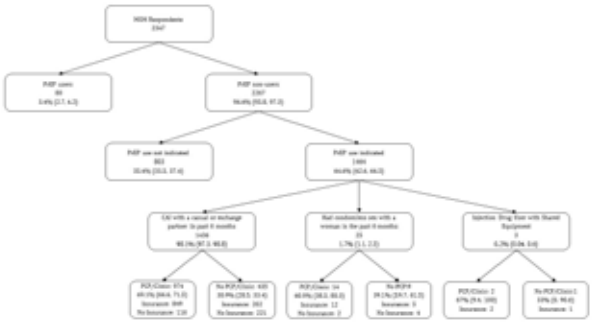
Background: Efficacy of the DVR in reducing the risk of HIV-1 infection via vaginal intercourse in HIV-1 uninfected women has been demonstrated in two independent, well-controlled Phase III trials, IPM 027 and MTN-020, conducted in four countries in sub-Saharan Africa. DVR is meant to be used in combination with safer sex practices. The pooled efficacy results of these two trials are presented.
Methods: In the pooled efficacy analysis, HIV-1 infection as measured by HIV-1 seroconversion was the primary endpoint. The efficacy analysis was repeated using the time of first detection of HIV-1 RNA as the endpoint. Adherence to DVR use was defined as ≤23.5 mg of residual dapivirine levels in used rings and dapivirine plasma concentrations of ≥95 pg/mL, measures that indicate at least some DVR use during the prior month.
Results: The rate of HIV-1 seroconversion per 100 person-years was 3.7 (95% CI, 3.1 to 4.3) and 5.0 (95% CI, 4.2 to 5.8) in the dapivirine and placebo ring groups, respectively, resulting in a statistically significant reduction in the risk of HIV-1 infection by 27.4% (95% CI, 8.6 to 42.3%; p=0.0063) relative to placebo. This risk reduction was statistically significantly higher (p=0.026) in participants older than 21 years (39.8%, 95% CI, 20.2 to 54.6%) than in participants 21 years or younger (-4.8%, 95% CI, -57.3 to 30.2). Using time of first detection of HIV-1 RNA, use of the DVR showed a statistically significant reduction in the risk of HIV-1 infection of 29.9% (95% CI, 11.8 to 44.3; p=0.023) relative to placebo. For periods in which participants were defined as adherent to at least some DVR use, HIV-1 infection risk reduction improved to 45.3% (95% CI, 27.4 to 58.8%; p<0.0001).
Conclusions: The pooled results of two independent well-controlled Phase III trials of DVR, which achieved similar and statistically significant results, resulted in an overall HIV-1 risk reduction of 27.4%. Higher HIV-1 risk reduction was observed with increased adherence to product use. The maximum level of HIV-1 infection risk reduction from vaginal exposure with consistent ring use cannot be determined based on the available data.

MOLBPEC35

Potential healthcare insurance and provider barriers to PrEP utilization among YMSM

R. Merchant[1], S. Marks[2], M. Clark[3], T. Liu[4], J. Rosenberger[5], J. Bauermeister[6], K. Mayer[7]
[1]Alpert Medical School of Brown University, Emergency Medicine, Providence, United States, [2]Rhode Island Hospital, Emergency Medicine, Providence, United States, [3]University of Massachusetts, Worcester, United States, [4]Brown University, Biostatistics, Providence, United States, [5]Pennsylvania State University, University Park, United States, [6]University of Pennsylvania, Philadelphia, United States, [7]Fenway Health, Boston, United States
Presenting author email: rmerchant@lifespan.org

Background: Given the relative low utility of pre-exposure prophylaxis (PrEP) compared to its need, we examined potential healthcare insurance and provider barriers to its utilization among black, Hispanic, and white young adult MSM (YMSM).
Methods: Social media was used to recruit 18-24-year-old black, Hispanic, and white HIV negative YMSM for an online survey on sexual behavior, healthcare access and previous use of PrEP. We identified PrEP-eligible YMSM based on US Centers for Disease Control and Prevention guidelines (condomless anal intercourse (CAI) with men, condomless sex also with women, and injection-drug use with equipment sharing). Multinomial logistic regression was used to identify potential barriers to PrEP usage based on having healthcare insurance and a primary care provider (PCP)/clinic for healthcare.
Results: Of the 2,347 YMSM surveyed, 3.4% had previously used PrEP. Of the non-PrEP users, 65% were PrEP eligible, and of these 59% had both healthcare insurance and a PCP/clinic.



[PrEP Eligibility and Healthcare Access]

In the multinomial regression analysis, age, race/ethnicity, years of formal education, and US geographic region of residence were associated with greater healthcare insurance and PCP/clinic barriers to accessing PrEP among YMSM who were PrEP eligible.

Reference group is full access to care-have both PCP/clinic and healthcare insurance (n=863)

	No PCP/Clinic & No Healthcare Insurance (n=226) OR (95% CI)	No PCP/Clinic, but have Healthcare Insurance (n=208) OR (95% CI)	Have PCP/Clinic, but No Healthcare Insurance (n=118) OR (95% CI)
Age	1.19 (1.08, 1.23)	1.07 (0.98, 1.18)	1.18 (1.05, 1.33)
Race			
White	1	1	1
Black	1.53 (0.96, 2.42)	1.10 (0.72, 1.69)	2.40 (1.38, 4.17)
Hispanic	3.47 (2.43, 4.95)	1.29 (0.91, 1.82)	2.81 (1.74, 4.53)
Education			
Less than high school	2.69 (1.19, 6.08)	1.06 (0.45, 2.49)	6.20 (2.45, 15.68)
High school/GED	4.03 (2.35, 6.91)	1.37 (0.80, 2.36)	2.29 (1.01, 5.18)
Less than bachelor degree	1.34 (0.86, 2.08)	0.75 (0.51, 1.11)	1.91 (1.04, 3.49)
Bachelor degree or higher	1	1	1
Region			
Northeast	1	1	1
Midwest	1.56 (0.91, 2.68)	1.49 (0.89, 2.50)	2.10 (0.93, 4.74)
South	2.08 (1.29, 3.35)	1.52 (0.94, 2.44)	3.16 (1.51, 6.58)
West	1.34 (0.76, 2.37)	2.13 (1.26, 3.60)	3.30 (1.49, 7.31)

[Factors impacting healthcare insurance and provide]

Conclusions: PrEP uptake was low in this population of YMSM, although the potential for expansion is high. Scale up efforts must address potential healthcare insurance and provider barriers related to age, race/ethnicity, geography and education levels.

MOLBPEC36

HVTN 100: the effects of a 12-month booster on immune responses in healthy HIV-uninfected adults vaccinated with ALVAC-HIV (vCP2438) and bivalent subtype C gp120/MF59® in South Africa

Presenting author email: linda-gail.bekker@hiv-research.org.za

Background: HVTN 100 evaluated an HIV clade C pox-protein vaccine regimen. A 12-month booster was included in the regimen to extend and, ideally, enhance vaccine-induced immune responses. We present effects of this booster on peak post-boost and memory vaccine-induced immune responses.
Methods: We conducted a phase 1-2 randomized, double-blind, placebo-controlled trial administering clade C ALVAC-HIV (vCP2438) (months 0, 1) and the latter plus Bivalent Subtype C gp120/MF59® (months 3, 6, 12). Cellular and humoral immune responses were evaluated at peak (month 6.5 and 12.5) and at durability (month 12 and 18) time-points. IgG binding antibody responses (magnitude and breadth) were measured by HIV-1 binding antibody multiplex assay (BAMA). Intracellular cytokine staining (ICS) measured HIV-specific T-cells expressing interferon-gamma and/or interleukin-2.
Results: Of 252 participants (210 vaccine/42 placebo), 231 samples were available at month 6.5. For all other time-points, samples from a subset of 70 vaccine-recipients and 5 placebo-recipients were evaluated. Antibody responses following the 12-month booster were higher in magnitude and more durable than those following the month 6 vaccination; ICS responses were similar. However, significant waning of binding antibody responses, especially to V1V2 antigens, was seen at month 12 and 18 durability time-points. Evaluating paired samples, month 18 response rates were significantly higher than month 12 for most gp120 (10/13), most gp140 (7/9), and 5/18 V1V2 antigens (p's <0.04). Month 18 magnitudes were significantly higher than month 12 (p<0.04) for all gp120 and gp140 antigens, and for 13/18 V1V2 antigens (p's <0.04) with geometric mean fold-difference 4.32; magnitude/breadth scores were significantly higher as well (p's<0.001). Response rates for Env-specific CD4+ T cells expressing interferon-gamma and/or interleukin-2 declined from 62.1% at month 6.5 (95% CI 50.1%-72.9%) to 35.9% at month 12 (95% CI 25.3%-48.2%; p=0.0003), but increased after the booster to 69.7% at month 12.5 (95% CI 57.8%-79.4%; p<0.0001), and measured 56.9% at month 18 (95% CI 44.8%-68.2%; p=0.275).
Conclusions: A 12-month booster extends binding antibody responses to 18 months after initial vaccination and prolongs robust CD4+ T-cell responses.

Online HIV self-testing: a tool to expand first HIV testing for young high-risk MSM in Brazil

R.B. De Boni[1], V.G. Veloso[1], N. Fernandes[1], F. Lessa[1], R. Girade[2], M. Cruz[3], J. Oliveira[4], N. Lentine[5], R. Miranda[5], T. Bingham[6], A. Barbosa[5], B. Grinsztejn[1]
[1]FIOCRUZ, STD/AIDS Laboratory - INI Evandro Chagas, RIO DE JANEIRO, Brazil, [2]Ministry of Health's National Department of STD, AIDS and Viral Hepatitis, Brasilia, Brazil, [3]FIOCRUZ, Escola Nacional de Saúde Pública, Rio De Janeiro, Brazil, [4]Secretaria Municipal de Saúde, Curitiba, Brazil, [5]CDC/Brazil, Brasilia, Brazil, [6]CDC/CGH/DGHT, Atlanta, United States
Presenting author email: raqueldeboni@gmail.com

Background: UNAIDS indicates that less than 50% of men who have sex with men (MSM) have been tested for HIV in Brazil. E-testing is an online, anonymous and free-of-charge HIV self-testing (HIVST) strategy designed to expand HIV testing among MSM in Curitiba, Brazil.
We describe the socio-demographic and behavior profile of E-testing MSM users, as well as the prevalence of and factors associated with first-time testing among HIVST users in this population.
Methods: We developed an online platform for HIVST request/delivery for MSM in 2014. Data were collected between February 2015 and February 2017. The CDC HIV Incidence Risk for MSM scale was used to stratify risk behavior. Logistic regression was performed to assess factors associated HIVST usage as first HIV test.
Results: Over 23,000 unique visitors accessed the online platform and 6040 questionnaires were completed and fulfilled inclusion criteria for HIVST request. Most individuals (72%; n=4356) self-identified as MSM, median age was 25 years, 73% had at least enrolled into college and 31% were first-time testers. The majority of first-time testers (59.4%) were classified as high risk, although 51.5% perceived themselves as having a low chance of acquiring HIV infection in the following year (Table).

	Total, n=4356(%)	Previously tested, n=3002(%)	Never tested, n=1354(%)	P-value*
Age -median(IQR)	25 (21 -29)	26 (22-30)	22 (21-29)	<0.001
Self-reported as white	3324 (76.3)	2332 (77.7)	992 (73.2)	0.004
College education (Complete/incomplete)	2566 (58.9)	1779 (59.3)	787 (58.1)	<0.001
Post-graduation	607 (13.9)	503 (16.8)	104 (7.7)	
Reported a STI diagnosis (prior 6 months)	380 (8.8)	304 (10.1)	76 (5.7)	<0.001
High risk score (prior 6 months)α	2591 (59.5)	1787 (59.5)	804 (59.4)	0.476
Perceives low chance of HIV infection in the next year	2321 (53.3)	1624 (54.1)	697 (51.5)	<0.001
Answered questionnaire between Feb'15-Feb16	2341 (53.7)	1571 (52.3)	770 (56.9)	0.005

The most frequent categories are presented, except for schooling. *Chi-square or rank sum test. αScore ≥ 10 in the CDC HIV Incidence Risk for MSM scale

[Socio-demographic and risk behavior profile of MSM]

Factors associated with being a first-time tester included: being 18-28 vs. ≥41 years (adjusted Odds ratio- aOR- 2.2; CI95% 1.3-3.5), having completed high school or less vs. post-graduation (aOR 2.5; CI95% 1.9-3.2) and college vs. post-graduation (aOR 1.7; CI95% 1.3-2.2), and not having a STD diagnosis in the prior 6 months (aOR1.9; CI95%1.4-2.5). CDC incidence risk score was not statistically associated with first time testing.
Conclusions: The E-testing strategy proved to be an acceptable and feasible approach to expand HIV test coverage among MSM in Curitiba, Brazil. E-testing is now being introduced in other Brazilian cities to reach young MSM who have not previously accessed HIV testing.

Presenting author email: andreas.ronit@regionh.dk

Background: Several authorities currently recommend lung cancer screening in current or former smokers from the general population. Such recommendations may not be applicable in people living with HIV (PLWHIV).
Methods: We performed low dose chest CT scans (LDCT) and assessed prevalence of histologically proven lung cancers and positive CT images (i.e. pulmonary non-calcified nodules). These outcomes were accessed in the entire cohort and in the high risk group (>50 years and >30 pack-years).
Results: In total, 901 PLWHIV underwent a LDCT. Lung cancer was diagnosed in two individuals, both in the high risk group, constituting 1.8% (95%CI 0.5-6.2) of the high risk subgroup. A positive CT image was identified in 3.1% (2.2-4.5) of the primary cohort and in 9.7% (5.5-16.6) of the high-risk subset. A positron emission tomography was carried out in 10/28 of those with a positive image, 14/28 individuals had one follow-up CT scan, 8/28 individuals had two follow-up CT scans, and 1/28 had three follow-up CT scans. Invasive diagnostic procedures were performed in eight patients. Three localized pneumothoraxes occurred of which none required intervention.

After controlling for age and cumulative smoking, a current CD4 count< 500 cells/μL and CD4 nadir count< 200 cells/μL were each associated with an increased odds of a positive image (OR 2.32 [1.01-5.13, P=0.04] and OR 2.63 [1.13-6.66, P=0.03], respectively).

[Table 1. Characteristics of study population]

CD4/CD4 nadir	CT findings	Invasive diagnostic procedures	Lung cancer/differential
Non calcified nodule(s)			
553/72	Multifocal nodules	TFFNB and VATS	No
1110/360	Multifocal nodules	Bronchoscopy/TBBx	No
172/2	Nodules (8 and 9 mm)	Bronchoscopy/TBBx	Vulvar and anal cancer#
580/140	Nodules (6 and 7mm)	Bronchoscopy/TBBx	NSCLC, adenocarcinoma (IIIa)
845/368	Nodule (15 mm)	Bronchoscopy/TBBx and VATS	No
Non-nodular lesions			
590/140	Mediastinal mass	UGNBx/VATS	Thymoma B2
570/550	Atelectasis, consolidation	Bronchoscopy/TBBx	No
1100/186	Endobronchial mass	Bronchoscopy/TBBx and VATS	NSCLC, adenocarcinoma (IIa)

[Table 2. All invasive procedures]

Conclusions: Lung cancer prevalence and prevalence of positive CTs in PLWHIV at high risk for lung cancer was comparable to screening rounds in the general population. LDCT screening seems to be feasible although data from interventional trials are lacking.

TULBPEB19

People living with HIV and HIV-negative individuals with similar lifestyles show greater age advancement compared to healthy blood donors

D. De Francesco[1], S. Oehlke[2], A. Bürkle[2], F.W. Wit[3], C. Franceschi[4], N.A. Kootstra[5], C. Libert[6], T. Grune[7], D. Weber[7], E.H.J.M. Jansen[8], P. Reiss[3], C.A. Sabin[1], for the Co-morBidity in Relation to Aids (COBRA) Collaboration
*[1]UCL, Department of Infection & Population Health, London, United Kingdom, [2]University of Konstanz, Department of Biology, Konstanz, Germany, [3]Academic Medical Center, University of Amsterdam, Department of Global Health & Division of Infectious Disease, Amsterdam, Netherlands, [4]Alma Mater Studiorum Università di Bologna, Department of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy, [5]Academic Medical Center, University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands, [6]Vlaams Instituut voor Biotechnologie, Inflammation Research Center, Gent, Belgium, [7]German Institute of Human Nutrition, Department of Molecular Toxicology, Nuthetal, Germany, [8]National Institute of Public Health and the Environment, Center for Health Protection, Bilthoven, Netherlands

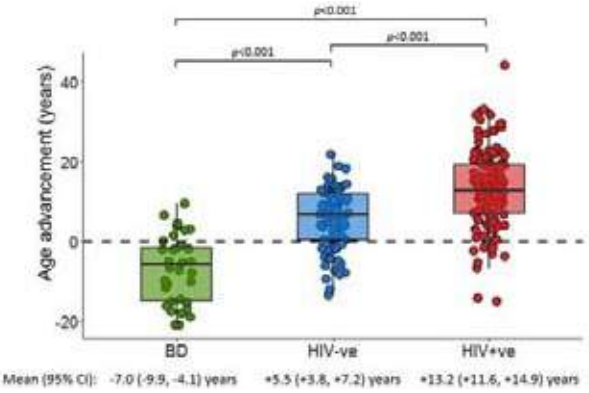
Background: It is suggested that HIV, even when treated, may be associated with premature aging. We investigated relationships between established ageing biomarkers and HIV infection, and explored factors associated with age advancement among participants in the COBRA Collaboration (www.fp7-cobra.eu).

Methods: Biological age was derived in 134 ART-treated and virally-suppressed HIV+ve (median 56 years, 93% male, 88% white) and 79 demographically-lifestyle-comparable HIV-ve (median 57 years, 92% male, 97% white) study participants, and 35 age-matched blood donors (BD, median 59 years, 51% male) using 10 ageing biomarkers (www.markage.eu). Associations between 'age advancement' (biological minus chronological age) and HIV-status/parameters, lifestyle, cytomegalovirus (CMV), hepatitis B (HBV) and hepatitis C (HCV) infections were investigated using linear regression.

Results: Age advancement was significantly greater in the HIV+ve persons than in both other groups, but also in HIV-ve participants compared to BD (Figure).



[Age advancement in BD, HIV-ve and HIV+ve people]

No significant associations were found between age advancement and lifestyle, but anti-CMV IgG titer, chronic HBV and CD8+ T-cell count were each associated with increased age advancement, independently of HIV/group (Table).
Among HIV+ve persons, age advancement was increased by 3.5 (95% confidence interval 0.1-6.8) years among those with nadir CD4+< 200 cells/μL (p=0.04) and by 0.1 (0.06-0.2) years for each additional month of exposure to saquinavir (p<0.001).

Conclusions: Both treated HIV+ve and lifestyle-comparable HIV-ve individuals show signs of age advancement compared to BD, to which persistent CMV and HBV co-infection, and CD8+ T-cell activation may have contributed. Age advancement remained greatest in HIV+ve people and was related to prior immunodeficiency and cumulative saquinavir exposure.

Variable	Regression coefficient (95% CI)	p-value	Regression coefficient (95% CI) Adjusted for HIV-status/Group	p-value
HIV-status/Group				
HIV-ve vs HIV+ve	-7.8 (-10.2, -5.3)	<0.001		
BD vs HIV+ve	-20.2 (-23.5, -16.9)	<0.001		
Total anti-CMV IgG titer [per 1 log(AU)]	3.5 (2.2, 4.8)	<0.001	2.1 (0.7, 3.4)	0.002
HBV vs no HBV infection	14.5 (6.1, 22.8)	<0.001	9.1 (2.4, 15.8)	0.008
CD8+ T-cell count [per 100 cells/μL]	0.9 (0.5, 1.3)	<0.001	0.4 (0.1, 0.9)	0.020

Background: In the ONCEMRK study, RAL 1200mg (2x600mg reformulated tablets) once daily had non-inferior efficacy and similar safety and tolerability to RAL 400mg BID at Week 48. Here we report final (Week 96) results from this study.

Methods: ONCEMRK is a phase 3, multicenter, double-blind, randomized, controlled trial to evaluate if reformulated RAL 1200mg QD is non-inferior to RAL 400mg BID. Treatment-naïve HIV-1-infected adults were assigned (2:1) to reformulated RAL 2x600mg QD or RAL 400mg BID, both with TDF/FTC, for 96 weeks. Randomization was stratified by screening HIV-1 RNA and chronic hepatitis B/C status. The primary efficacy endpoint was the proportion of participants with HIV-1 RNA < 40 copies/mL at Week 48 (Non-Completer=Failure); the non-inferiority margin was 10 percentage points.

Baseline Characteristics	RAL 1200 mg QD (N=531)	RAL 400 mg BID (N=266)	Total (N=797)
Mean (SD) HIV-1 RNA, log_{10} c/mL	4.6 (0.7)	4.6 (0.7)	4.6 (0.7)
HIV-1 RNA >100,000 c/mL	28.1 %	28.9 %	28.4 %
Mean (SD) CD4+ T-cells/mm^3	407.6 (213.7)	428.9 (217.3)	414.7 (215.0)
Efficacy & Safety Outcomes, Week 96	**RAL 1200 mg QD**	**RAL 400 mg BID**	**QD–BID (95% CI)**
HIV-1 RNA <40 c/mL, All participants (NC=F)	81.5 %	80.1 %	1.4 (-4.4, 7.3)
Baseline HIV-1 RNA >100,000 c/mL (OF)	84.7 %	82.9 %	1.8 (-8.2, 13.6)
Baseline ≤200 CD4+ T-cells/mm^3 (OF)	79.0 %	80.0 %	-1.0 (-17.2, 18.6)
HIV-1 RNA <200 c/mL, All participants (NC=F)	85.3 %	82.7 %	2.6 (-2.9, 8.1)
Integrase resistance	0.8 %	0.8 %	n/a
Mean Change (95% CI), CD4+ T-cells/mm^3 (OF)	261.6 (242.9, 280.3)	262.2 (236.4, 288.0)	-0.6 (-32.8, 31.6)
One or more clinical adverse events	90.2 %	93.2 %	-3.0 (-6.8, 1.3)
Drug-related clinical adverse events	26.0 %	26.7 %	-0.7 (-7.4, 5.6)
Serious clinical adverse events	9.2 %	15.8 %	-6.6 (-11.9, -1.8)
Discontinued due to any adverse event	1.3 %	2.3 %	-0.9 (-3.6, 0.9)

Data are % of participants, unless otherwise specified.
NC=F: Non-Completer=Failure, as defined by FDA snapshot approach (all missing data treated as failures).
OF: Observed Failure approach.

[ONCEMRK Week 96 Results]

Results: Of 802 participants randomized, 797 received study therapy and were included in the analyses. The study population was 84.6% male, 59.3% white, mean (SD) age 35.9 (10.5) years. 694 participants (86.5%) completed 96 weeks of treatment (87.6% QD; 84.4% BID) with low rates of discontinuation due to lack of efficacy (1.1% for both groups) and adverse events (1.3% QD; 2.3% BID). At Week 96, RAL 1200mg QD was non-inferior to RAL 400mg BID (HIV-1 RNA < 40 copies/mL in 81.5% and 80.1%, respectively, Δ(QD-BID)=1.4%, 95% CI [-4.4, 7.3]). Resistance to raltegravir was infrequent, occurring in 4/531 (0.8%) and 2/266 (0.8%) in the QD and BID groups, respectively. Increases in CD4+ T-cell counts from baseline were comparable for the two treatment regimens. Both treatment regimens were generally well-tolerated with low rates of discontinuation due to adverse events (table).
Conclusions: In HIV-1-infected treatment-naïve adults receiving TDF/FTC, RAL 1200mg QD demonstrated non-inferior efficacy compared to RAL 400mg BID that was durable to Week 96. RAL 1200mg QD was well tolerated with a safety profile similar to RAL 400mg BID through Week 96.

Presenting author email: b-taiwo@northwestern.edu

Background: DTG+3TC has attractive attributes for initial HIV-1 treatment, but limited data exist particularly in individuals with high pre-treatment plasma viral load (VL).
Methods: A5353 is a phase II, single-arm, pilot study of once-daily DTG (50mg) + 3TC (300 mg) in treatment-naïve HIV-1-infected participants with VL ≥1000 and < 500,000 copies/mL (cpm). Active hepatitis B or integrase, reverse transcriptase or major protease resistance mutations were exclusions. Primary outcome of virologic efficacy (VL < 50 cpm by FDA snapshot algorithm) was estimated using a two-sided exact 95% confidence interval (CI). Secondary as-treated analysis focused on participants who remained on DTG+3TC. Comparisons between entry VL (≤100,000 versus >100,000 cpm) used Fisher's exact tests. Virologic failure (VF) was defined as confirmed VL >400 cpm at week 16 or 20, or confirmed VL >200 cpm at/after week 24. DTG plasma levels and resistance testing were performed at VF.
Results: Of 120 participants who initiated study treatment, 37 (31%) had VL > 100,000 cpm. Majority were male (87%); median age 30 (IQR: 24, 41) years; 40% Black, 28% White, 27% Hispanic. Median entry VL and CD4 count were 4.61 (3.94, 5.05) log_{10} cpm and 387 (288,596) cells/mm^3. Virologic efficacy at week 24 was 108/120 (90%, CI [83%, 95%]) with no significant difference between the low and high VL strata: 90% [82%, 96%] and 89% [75%, 97%], respectively (p>0.99). In the as-treated population, 108/112 (96% [91%, 99%]) had VL < 50 cpm, with no difference between the VL strata (99% [93%, 100%] vs. 92% [78%, 98%], p=0.10). Median CD4 change from entry to week 24 was +167 (86, 275) cells/mm^3. The three participants (2 in low, 1 in high VL strata) with VF had plasma DTG levels below the limit-of-quantification around the time of VF. There were no integrase mutations; M184V was detected in one participant at VF off study treatment. Two participants experienced Grade 3 possibly/probably treatment-related adverse events, however no Grade 4 adverse events or discontinuations occurred.
Conclusions: In this pilot study of treatment-naïve HIV-1-infected participants with VL < 500,000 cpm, once-daily DTG+3TC was effective and well tolerated. Randomized trials of this regimen versus standard-of-care are warranted.

Saint-Pierre, Brussels, Belgium, [5]Hospital Universitari de Bellvitge, Barcelona, Spain, [6]Hôpital de la Croix Rousse, Lyon, France, [7]Hôpital Gui de Chauliac, Montpellier, France, [8]ABIVAX, Paris, France
Presenting author email: rparedes@irsicaixa.es

Background: ABX464, the first drug candidate from Abivax's proprietary antiviral platform, inhibits HIV replication through a novel mechanism (i.e. the modulation of RNA splicing) which may have a sustained antiviral effect as shown in preclinical testing. In an earlier Phase IIa study, the results of which were presented at CROI 2016, ABX464 showed dose-dependent viral load reductions in treatment-naïve HIV-subjects and a good safety and tolerability profile.
Methods: Multi-center, randomized, double-blind, placebo-controlled Phase IIa trial in Spain, Belgium and France. Subjects with VL< 50 copies/mL under boosted darunavir monotherapy for at least 8 weeks prior to enrolment were randomized (3:1) to add ABX464 QD or placebo to boosted darunavir monotherapy during 28 days. At the end of such 28 days, all treatments were interrupted. Viral load was regularly measured and ART was reinstalled when viral load was > 1000 copies/ml. Safety was the primary endpoint of the trial. Blood samples (D0 and D28) were taken to assess the potential effect of ABX464 on the HIV reservoir (Total HIV DNA in PBMC's). A significant reduction HIV reservoir (i.e. Responders) was defined as subjects who had a minimum reduction of 50 copies and a greater than 25% decrease in total HIV DNA copies.
Results: 30 subjects (29 males, 1 female) were included. They had been infected with HIV-1 for 10.2 years and on ART for 5.6 years. ABX464 was well tolerated. There were no serious adverse events reported in the treatment group. Mean time to viral load rebound was 14 days (placebo) and 13 days (ABX464). Amongst subjects with validated viral DNA results (4 placebo and 15 ABX464-treated subjects), an important reduction in viral DNA was observed in 8/15 (53%) ABX464 treated subjects (mean change of -38%, ranging from -27% to -67% and a mean decrease of 185 copies [-434; -82] / Mio PBMC's. No responders were observed in the placebo group.
Conclusions: This is the first time we see a signal with any therapeutic candidate that it may be possible to reduce HIV reservoirs in patients. Further clinical trials with longer treatment duration are needed to further understand the mechanisms and implications of these findings.

Background: The primary aim of the Icistem Project is to guide clinicians involved in allogeneic HSCT procedures in HIV infected individuals. The scientific aim is to understand the causes for the only successful intervention to cure HIV to date. This requires the identification of immunological mechanisms and predictors of the restriction or eradication of the HIV reservoir as well as the innate and adaptive responses before and after HSCT.
Methods: The study includes 28 HIV positive patients with hematological malignancies. 22 of these patients received an allogenic transplant (8 x CCR5Δ32 donor). PBMC samples were collected longitudinally before and after HSCT and were analyzed via multicolor flow cytometry. The first panel focuses on the possible reservoir CD4 T cell populations such as central, transitional and effector memory cells, Tregs and their cytotoxic CD8+ counterpart. On these populations we measure the expression of HIV coreceptors (CCR5, CXCR4), the activation (CD38, HLA-DR and Ki-67) as well as the level of exhaustion (PD-1) and capacity to migrate to the gut (α4β7 integrin). In a second panel we focussed on unconventional T cell populations (γδT cells, MAIT cells, NKT cells) and NK cells that share the capacity for a quick immune response whithout prior clonal expansion.
Results: Seven patients passed the 12 months follow-up after HSCT and 10 patients have died after transplantation. Preliminary analysis shows systematic reduction of HIV-1 reservoirs to very low levels post SCT. Three patients show no detectable virus in blood independent of CCR5 expression. Overall we found a significant reduction in the frequency of naïve CD4 and CD8 T cells after HSCT, an inverted CD4/ CD8 ratio, a loss of MAIT cells as well as an inverted ratio of Vδ2/Vδ1 cells in comparison to healthy controls. Preliminary results show a high immune activation of NK cells in one of the patients without detectable viral load. Further correlation to clinical data and the HIV reservoir size is ongoing, which will help to characterize "beneficial" anti viral immune responses.
Conclusions: The immune composition and activation of the graft might contribute to the clearance of the viral reservoir independent of the CCR5 status of the donor.

Presenting author email: craig.cohen@ucsf.edu

Background: Concomitant use of efavirenz-containing antiretroviral therapy (ART) among HIV-infected women using contraceptive implants leads to an increased risk of pregnancy. Since the contraceptive hormone concentration decreases gradually after implant insertion, we conducted a retrospective cohort study to investigate whether implant failures (i.e. pregnancies), especially among efavirenz users, was associated with the duration of implant use.
Methods: We analyzed electronic medical record data from the East Africa International Epidemiology Databases to Evaluate AIDS. HIV-positive women 15 to 45 years of age using implants while enrolled in HIV care between January 2011 and December 2015 were included. Pregnancies identified in the records were confirmed, along with implant insertion dates, by phone interviews with the women. We used pooled logistic regression generalized estimating equation models to generate odds ratios (ORs) for implant failure associated with ART, implant type, and time from implant insertion, categorized into 6-month intervals.
Results: We conducted 788 phone interviews among implant users and identified 51 (6.5%) women who became pregnant while using an implant, of which 36 (71%) women were concomitantly using efavirenz-containing ART. Of these 51 women, 39 (76%), 11 (22%), and one (2%) became pregnant while using levonorgestrel, etonogestrel, or unknown type of implant, respectively. The median time to implant failure was similar for levonorgestrel (24.9 months; IQR 13.0, 37.2) and etonogestrel (21.1 months; IQR 4.2, 26.6) users. Compared to the first 6 months of implant use, the ORs for pregnancy did not differ significantly for each subsequent 6-month interval for either levonorgestrel or etonogestrel implants (Table 1; p>0.05 for each comparison). The OR for pregnancy was not statistically different among levonorgestrel vs. etonogestrel users (1.61; 95% CI 0.83, 3.14). Efavirenz- vs. nevirapine-containing ART was associated with a significantly increased OR for pregnancy (6.27; 95%CI 2.92, 13.49). Models including interaction terms with ART revealed no significant effects.
Conclusions: Contraceptive implant failures among HIV-infected women, including those using efavirenz, do not appear to be associated with the duration of implant use. Replacing implants prior to the approved length of use is unlikely to prevent implant failures among women using efavirenz, and alternative strategies to improve contraceptive effectiveness need to be explored.

Presenting author email: victoria.watson@lstmed.ac.uk

Background: HIV self-testing (HIVST) is being evaluated globally as an innovative approach to reach the 40% of people living with HIV who don´t know their status. No external quality assurance (EQA) systems have been established to support HIVST implementation. We evaluated the visual stability of late re-reading of used OraQuick® kits exposed to different environmental conditions to determine whether re-reading of returned kits may offer an accurate quality assurance approach.
Methods: A panel of 444 OraQuick® kits was established using a plasma matrix comprising HIV high-reactive (n= 148), weak-reactive (n=148) and HIV non-reactive (n=148) results. Kits were read at 20 minutes by three independent readers blinded to the initial results and each other. Subsequently, kits were incubated under four different conditions: temperature low/ humidity low, temperature low/ humidity high, temperature high/ humidity low, temperature high/ humidity high. Baseline condition was defined as temperature of 30°C, humidity 20%. Kits were re-read daily for a week, weekly for a month, and monthly for six months. Consensus between two or more readers was taken as the true result. Test result transition hazards between states were estimated using a multi-stage Markov model.
Results: Over six months, 43 of the 144 non-reactive kits (29.24%) changed to a weak-reactive result across all conditions. The earliest changes were seen on Day 4 (n=9 kits). There was dynamic movement between non-reactive and weak-reactive states over time, but no kits with initially reactive results changed over time. Compared to the baseline conditions there were no statistically significant differences in the hazard of transition between storage conditions for any group.
Conclusions: We found a high incidence of OraQuick® results changing from 'true non-reactive' to 'false reactive' results over 6-months, making late re-reading an inaccurate option for EQA monitoring. Studies using returned used HIVST kits for 'late' visual re-reading for monitoring test results may overestimate true HIV positivity rates. Programmes scaling up HIVST need to ensure clear messaging regarding the correct read times to avoid misinterpretation of results by self-testers who fail to dispose of kits after having conducted the test.

Background: The Republic of South Africa (RSA) has the largest ART cohort in the world with over 3.3 million clients. Unfortunately the country faces substantial ARV stock-outs at point of service, with 20% of public health facilities reporting at least one ARV out of stock the day of the national survey. This economic analysis aims at estimating the economic impact of ARV stock-outs on patients.
Methods: We use a modelling approach utilizing already-existing data, combining the stock-out national survey database with data from literature review of ART services in South Africa. Prevalence and duration of ARV stock-outs are combined with unit costs and patients' characteristics. Analyses are run by category of ARVs at provincial level using 2015 data.
Results: In 2015, 709 stock-outs of ARV were reported nationwide, resulting in 33,189 ART clients leaving their facility with no medicines, a shortened supply or an incomplete regimen. Our findings further suggest that 80,440 ART clients would have been affected if facilities had not managed to (informally) borrow ARVs from each other's and change patient regimen.
A patient affected by an ARV stock-out therefore bore the financial burden of an extra visit, estimated to an average ZAR 68 (USD 5.6). This cost can be considered as a catastrophic expenditure for at least 50% of ART clients (median income of ZAR 972), and as an impoverishing expenditure for at least 40% of ART clients (already facing financial distress for monthly ART services).
Conclusions: Extra cost resulting from stock outs of ARVs significantly increase financial distress on thousands of ART clients in South Africa, further impoverishing the poorest and jeopardizing their access to care. The 90/90/90 objective results in a dramatic increase in the number of ART clients, and therefore in the number of patients potentially affected. In addition, the RSA spent ZAR 8.9 Billion (USD 850.3 Million) in 2013/14 on HIV treatment activities. Addressing stock-outs and ensuring ARV availability at point of service should therefore be a priority.

TULBPED40

Reaching the first 90 in Philippines: community-based screening: a strategy to increase HIV coverage and testing

L. Rigil[1,2], A. Kechi[3], M. Imran[3]
[1]Save the Children-Philippines, Manila, Philippines, [2]Save the Children-USA, Global Health, Washington, United States, [3]Save the Children-USA, Global Health-HIV&TB Unit, Washington, United States
Presenting author email: mimran@savechildren.org

Background: Globally, the number of new HIV cases has declined by 33 percent in 2013. However, the Philippines bucks this downward trend. Despite the significant increase in the number of new cases, program coverage and testing remains low particularly for the MSM and TG population who are the key drivers of HIV epidemic in Philippines. To address this gap and fast-track the country's progress towards first 90, Save the Children through its Global Fund program piloted the Community-based screening (CBS) approach in 3 geographical regions. CBS is a testing option that is envisioned to help increase testing uptake with the support of community based organizations. It is not meant to replace diagnostic testing options in the country, rather increases the screening and testing options to clients.
Methods: Quantitative analysis of the HIV testing data for MSM and TG in the 3 priority areas: NCR, Cebu City and Davao City for the pilot phase i.e. 3 months was done.
Results: A total of 70 motivators were engaged. A total of 777 MSM and TG were Reached and 774 (99.6%) were motivated to be screened in the 3 areas. Average positivity rate was at 5% among those who were screened. The highest rate was noted in NCR and Cebu which are 2 of the highest prevalence areas in the country (Table 1).

Indicators	NCR	Cebu	Davao	Total
Total Reached	438	140	199	777
Total Screened	436	140	198	774
Total Screened Reactive	24	9	8	41
Rate of Reactive Screened Clients	6%	6%	4%	5%

[Indicator dis-aggregation per site]

Conclusions: The rise in HIV cases in the Philippines is alarming. One of the bottleneck is the low testing of high risk population due to fear of the testing clinics and lack of manpower for testing. The scale-up of CBS strategy in the next GF funding cycle will be a major intervention to reach the first 90 based on the following: First, In the 3 months of implementation, it yielded a 5% positivity rate compared to the 1-2% positivity rate of the ongoing outreach activities. Second, 99% of the clients who were reached were motivated to be tested compared to the average 70% testing rate of the outreach activities. Third, based on feedback from clients, they are more likely to submit to screening due to rapport established with the motivators.

TULBPED41

Predictors of linkage to and retention in HIV care following release from Connecticut, USA jails and prisons

K.B. Loeliger[1,2], F.L. Altice[1,2,3], M.M. Desai[4], M.M. Ciarleglio[5], C. Gallagher[6], J.P. Meyer[2]
[1]Yale School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, United States, [2]Yale School of Medicine, AIDS Program, New Haven, United States, [3]University of Malaya, Center for Excellence in Research in AIDS (CERiA), Kuala Lumpur, Malaysia, [4]Yale School of Public Health, Department of Chronic Disease Epidemiology, New Haven, United States, [5]Yale School of Public Health, Department of Biostatistics, New Haven, United States, [6]Connecticut Department of Correction, Quality Improvement Health and Addiction Services Program, Wethersfield, United States
Presenting author email: kelsey.loeliger@yale.edu

Background: One in six people living with HIV (PLH) in the USA transition through prisons/jails annually. During incarceration, people may engage in HIV care, but transition to the community remains challenging. Linkage to care (LTC) post-release and retention in care (RIC) are necessary to optimizing HIV outcomes, but have been incompletely assessed in prior observational studies.
Methods: We created a retrospective cohort of all PLH released from a Connecticut jail or prison (2007-14) by linking Department of Correction demographic, pharmacy, and custody databases with Department of Public Health HIV surveillance monitoring and case management data. We assessed time to LTC, defined as time from release to first community HIV-1 RNA test, and viral suppression status at time of linkage. We used generalized estimating equations to identify correlates of LTC within 14 or 30 days after release. We also described RIC over three years following initial release, comparing recidivists to non-recidivists.
Results: Among 3302 incarceration periods from 1350 unique PLH, 21% and 34% had LTC within 14 and 30 days, respectively, of which >25% had detectable viremia at time of linkage. Independent correlates of LTC at 14 days included incarceration periods >30 days (adjusted odds ratio [AOR]=1.6; p< 0.001), higher medical comorbidity (AOR=1.8; p< 0.001), antiretrovirals prescribed before release (AOR=1.5; p=0.001), transitional case management (AOR=1.5; p< 0.001), re-incarceration (AOR=0.7; p=0.002) and conditional release (AOR=0.6; p< 0.001). The 30-day model additionally included psychiatric comorbidity (AOR=1.3; p=0.016) and release on bond (AOR=0.7; p=0.033). RIC after release declined over one year (67%), two years (51%) and three years (42%). Recidivists were more likely than non-recidivists to have RIC but, among those retained, were less likely to be virally suppressed (Figure 1).
Conclusions: For incarcerated PLH, both LTC and RIC are suboptimal after release. Targeted interventions and integrated programming aligning health and justice goals may improve post-release HIV treatment outcomes.

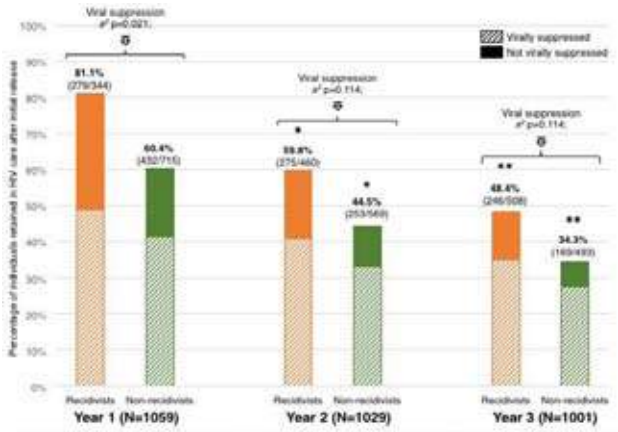

Figure 1. Longitudinal sustained retention in HIV care at one, two, and three years post-release, based on frequency of HIV-1 RNA viral testing, stratified by whether individuals were reincarcerated at some point during the follow-up period.

* statistically significant decline (McNemar's test p<0.0001) compared with initial one-year rates. ** statistically significant decline (McNemar's test p<0.0001) compared with sustained two-year rates. ❖ statistically significant difference (χ^2 p<0.0001) in retention rates between recidivists and non-recidivists across all time points. Among those retained, non-recidivists had significantly higher viral suppression rates compared to recidivists at the end of year 1 (p=0.021) and year 3 (p=0.048).

[Figure 1]

TULBPED42

PrEP in Zimbabwe: an integrated approach

E. Gwavava, O. Chinake
Population Services International Zimbabwe, Social Franchising, Harare, Zimbabwe
Presenting author email: emily.gwavava@online.liverpool.ac.uk

Background: Zimbabwe has one of the highest burdens of HIV with a prevalence rate of 16.7% in adults aged 15-49 years. PSI/Z offers comprehensive HIV/SRH integrated services through a social franchise network called New Start. Services on offer include HTS, including self-testing, HIV care & treatment services, family planning, cervical cancer screening, TB screening and treatment, and IPT. PrEP was introduced at New Start in August 2016 for use as an additional HIV prevention strategy by all at substantial risk of HIV.
Methods: Programme data from August 2016 to April 2017 was analysed for trends. PrEP is offered through 6 New Start centres across Zimbabwe. Data was collected using PrEP programme M&E tools - registers, client visit tracker.
Results: 1,255 clients were enrolled on PrEP between August 2016 and April 2017. The age/sex disaggregations are outlined in the table.

Age (Years)	10-14	15-19	20-24	25-49	50+	Total
Male	0	1	30	77	6	114
Female	1	132	380	621	7	1141
Total	1	133	410	698	13	1255

[Number of Clients Enrolled on PrEP by Age and Sex]

Client categories include female sex workers (58%), MSM (2%), HIV-negative partner in serodiscordant relationships (15%). 8% of clients includes those answering "Yes" to transactional sex. The remaining clients have risk profiles that put them at substantial risk of HIV. 34 clients stopped PrEP for reasons including side effects (7), pressure to stop from family (2), relocation to areas with no PrEP services (7), challenges with adherence (2), and no longer at risk - partner tested HIV-negative, abstinence, no longer in relationship with an HIV-positive partner, regular condom use.
Since inception, programme data shows poor retention of clients on PrEP as shown in the cohort analysis table.

[PrEP Cohort Analysis]

Conclusions: Despite being at substantial risk of HIV, clients on oral PrEP are not returning for resupply as expected. More needs to be done in terms of information dissemination of the benefits of PrEP to the public.

TULBPED44

Costs of HIV viral load testing using POC and central laboratories: assessing an efficient viral load testing network in Kenya

C. Cintron[1], V. Mudhune[2], C. Avila[1], J. Batuka[3], F. Angira[2], T. Minior[4]
[1]Abt Associates, Bethesda, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]USAID Kenya and East Africa, Health, Population and Nutrition Office, Nairobi, Kenya, [4]USAID, Office of HIV/AIDS, Washington, United States
Presenting author email: christopher_cintron@abtassoc.com

Background: Kenya´s HIV care guidelines stipulate universal coverage of routine viral load (VL) monitoring for people receiving ART. Reaching UNAIDS 90-90-90 targets will incur significant costs given the 826,000 adults receiving ART and additional scale-up required to reach 1.5 million people living with HIV.
Methods: We applied Activity-Based-Costing methods for VL testing on point-of-care (POC) and central laboratory (CL) platforms. Costing included a probability sample of 21 health facilities in Siaya County and their affiliated central lab at Kenya Medical Research Institute (KEMRI) in Kisumu. Unit costs were calculated for the Alere™ q and Cepheid GeneXpert IV POC platforms, and the Abbott m2000 RealTime, Roche Cobas AmpliPrep, and Cobas TaqMan CL platforms. Cost inputs included equipment, human resources, reagents, supplies, training, transportation, quality assurance, and recurrent costs.
Results: Average VL unit costs were US$29.74 using POC platforms, compared to US$24.63 at central labs. Reagent procurement accounted for the largest proportion of unit costs; 74% for VL-POC L and68% for VL-CL. Human resource costs were low due to little hands-on time needed for workflows at high testing volumes. Deploying a dedicated POC technician to ensure VL testing on-site increases the unit cost to US$31.93. Low demand constrains performance and increases unit cost; estimating the cost of deploying VL-POC to the 21 facilities in Siaya County showed average unit cost of US$47; seven high-demand facilities could achieve costs below $40, while four low-demand facilities are likely to exceed US$120 per test, somewhat challenging the conventional wisdom that POC technology is best suited to low-demand rural settings.
Conclusions: Building an efficient network to monitor VL suppression requires a cost-effective equipment mix to delivering timely test results, hastening ART assessments and linkages to care. VL-CL testing involves technology-intensive production but can realize economies of scale if working near full machine capacity. Reagents have potential for cost savings through negotiating volume-based procurement prices and pooling samples for testing. Decisions on which VL platform to deploy and where should be guided by evaluations of patient demand for testing, facility staffing and financial capacity to pay for same-day results.

TULBPED45

Brief didactic educational session increases willingness to prescribe HIV pre-exposure prophylaxis among health professionals

R. Patel[1], K. Ahsan[1], P. Chan[2], D. Krakower[3,4], K. Mayer[3,4], L. Harrison[1], S. Phillips[5], A. Nunn[6,7]
[1]Washington University in St. Louis, Infectious Diseases, St. Louis, United States, [2]Brown University, Infectious Diseases, Providence, United States, [3]Harvard Medical School, Medicine, Boston, United States, [4]The Fenway Institute, Boston, United States, [5]Midwest AIDS Training and Education Center of Missouri, Kansas City, United States, [6]Brown University School of Public Health, Behavioral and Social Sciences, Providence, United States, [7]The Rhode Island Public Health Institute, Providence, United States
Presenting author email: rupapatel@email.wustl.edu

Background: Pre-exposure prophylaxis (PrEP) is recommended for HIV prevention in at-risk populations as part of routine primary care services. However, awareness and prescribing of PrEP by health providers is low. We evaluated whether brief educational sessions for providers impacted their willingness to prescribe or discuss PrEP.
Methods: Between July 2014 and October 2016, we conducted 20-minute PrEP didactic educational sessions (components: local epidemiology, CDC guidelines, local patient/provider resources) at 18 organizations in four cities (Missouri, USA). Pre- and post-session surveys, completed by 244 attendees, assessed awareness, willingness to prescribe or discuss, and concerns regarding PrEP on 5-point Likert scales. Outcomes included changes in willingness to prescribe or discuss PrEP and predictors of unwillingness to prescribe or discuss. Wilcoxon signed-rank test and multivariable logistic regression were performed.
Results: A total of 343 health professionals attended sessions; 18% physicians and 12% nurse practitioners, physician assistants, or pharmacists (prescribers); 6% nurses and 43% social workers, case managers, or counselors (non-prescribers). Pre-session PrEP awareness was 89% among all participants, and 14% of prescribers had written a prescription for PrEP. More non-prescribers (95%) were comfortable discussing sexual health with patients than prescribers (77%). Willingness to prescribe or discuss PrEP increased from 64% to 84% overall ($p< 0.001$) and +28% among prescribers ($p< 0.001$). Twenty-one percent of all attendees changed their willingness to prescribe or discuss PrEP from unlikely (pre-session) to likely (post-session) (95% CI:16%-27%). Forty health professionals (16%) remained unwilling to prescribe or discuss post-session. Perceived organizational-level barriers to prescribing or discussing were low; perceived prescribing feasibility (82%) and support from administration for PrEP prescribing (66%) were high. When adjusting for organization type, location, and baseline PrEP awareness, perceived support from administration was a predictor (Adjusted OR=0.06; 95% CI:0.00-0.81; p=0.04) for unwillingness to prescribe or discuss (post-session) among attendees. The main post-session concern was poor patient follow-up (35%).
Conclusions: A brief educational session for health professionals significantly improved their willingness to prescribe or discuss PrEP. However, perceived lack of support at an organizational level was identified as a barrier. These findings suggest future educational interventions should be aimed at both providers and administrators in order to strengthen PrEP implementation.

TULBPED46

Scale-up of antiretroviral therapy was associated with decreased community HIV incidence in Rakai, Uganda, 1999-2016

X. Kong[1,2], F. Nalugoda[3], G. Nakigozi[3], G. Kigozi[3], J. Ssekasanvu[2], A. Ndyanabo[3], K. Grabowski[2], S. Reynolds[4], L. Chang[4], D. Serwadda[5], M. Wawer[2], R. Gray[2], Rakai Health Sciences Program
[1]University of Massachusetts, Biostatistics and Epidemiology, Amherst, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Rakai Health Sciences Program, Kalisizo, Uganda, [4]Johns Hopkins University School of Medicine, Baltimore, United States, [5]Makerere University School of Public Health, Kampala, Uganda
Presenting author email: sjr@jhmi.edu

Background: There are limited data on the impact of ART scale-up on HIV incidence at the community level. We assessed associations of community ART coverage with community HIV incidence in Rakai, Uganda.
Methods: Using population-based surveys (1999-2016) in 30 communities, community-level ART coverage, sociodemographics, sexual behaviors, and HIV incidence was estimated over four time periods: prior to ART availability (1999-2004), early ART and medical male circumcision (MMC) program (2004-07), mature program (2007-13), and further ART scale-up (2013-16). To isolate the effect of ART and exclude the impact of MMC scale-up on community HIV incidence, the outcomes are community-level incidence *in uncircumcised men* and *in women* who would not benefit from MMC, respectively. Multivariable Poisson regression with generalized estimating equations was used to estimate adjusted incidence rate ratios (adjIRR) associated with ART coverage in the opposite sex.
Results: From period 1 to 4, median community ART coverage rose from 0 to 47% in men and to 57% in women. Median community HIV incidence declined from 1.31 to 0.31 per 100-person-years (PYs) in uncircumcised men, and from 1.25 to 0.80 per 100-PYs in women. For uncircumcised males, each 10% increase in female community ART coverage was associated with an adjIRR of 0.88 (95%CI 0.83-0.93, p<0.001), suggesting 100% female ART coverage could reduce community HIV incidence by 73% compared to zero ART coverage. For females, the adjIRR associated with each 10% increase in male community ART coverage was 0.92 (CI 0.86-0.98, p=.006), and 100% male ART coverage could reduce female community incidence by 59%. Table 1 shows the adjIRRs associated with categorized ART coverage.

ART coverage in women	adjIRR (95%CI) associated with community incidence in uncircumcised men		ART coverage in men	adjIRR (95%CI) associated with community incidence in women	
≤10%	ref	P-value	≤10%	ref	P-value
10-20%	0.89 (0.65- 1.23)	0.48	10-20%	1.09 (0.88-1.36)	0.42
20-30%	0.79 (0.55-1.11)	0.18	20-30%	0.92 (0.68-1.25)	0.59
30-40%	0.73 (0.43-1.26)	0.26	30-40%	0.93 (0.74-1.17)	0.54
40-50%	0.54 (0.27-1.07)	0.08	40-50%	0.69 (0.50-0.96)	0.027
>=50%	0.42 (0.28-0.62)	<.001	>=50%	0.56 (0.36-0.88)	0.011

[Table 1.]

Conclusions: Increasing community ART coverage in the opposite sex was significantly associated with lower community HIV incidence in uncircumcised men and in women, but universal ART coverage alone could not reduce HIV incidence by 90% which is needed to end the HIV epidemic by 2030. Combination prevention including MMC, behavioural risk reduction is needed to end the HIV epidemic in Rakai.

TULBPED47

Acceptability of door-to-door rapid HIV testing among sub-Saharan African men and women living in the Paris region

J. Sondey[1], L. Fugon[1], S. Benayoun[1], V. Coquelin[1], L. Marty[2], V. Supervie[2], D. Rojas Castro[1,3,4], HERMETIC Study Group
[1]Association AIDES, Pantin, France, [2]Sorbonne Universités, UPMC Univ Paris 06, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique (IPLESP UMRS 1136), Paris, France, [3]Université Lyon 2 - GRePS EA 4163, Lyon, France, [4]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France
Presenting author email: jsondey@aides.org

Background: Recent modelling estimates indicate a high prevalence of undiagnosed HIV infections among individuals born in Sub-Saharan Africa (SSA) living in the Paris region (~1 per 100). To reduce undiagnosed HIV infections, innovative testing services are needed. Door-to-door HIV testing is often used in low- and middle-income countries, but rarely in high-income countries. A study was developed to evaluate the acceptability of door-to-door HIV testing among men and women born in SSA and living in the Paris region.
Methods: A pilot study was implemented to offer outreach rapid HIV testing in deprived neighbourhoods of three cities (Sevran, Bagnolet, Saint-Denis). The targeted population was SSA-born individuals. Field workers knocked on apartment doors and after oral consent asked the inhabitants to complete a short survey on country of birth and HIV testing. They offered rapid testing either at home or in a mobile van temporarily parked outside tower blocks. Reasons given for refusal were collected. Statistical comparisons between genders were performed using Pearson's chi-square test.
Results: Between November 2016 and February 2017, 290 SSA-born inhabitants (147 women, 143 men) were reached during 31 door-to-door outreach events. Sixty-two men (43.4%) and 55 women (37.4%) reported an HIV test in their lifetime (p=0.30). Fifty-six men (39.2%) and 48 women (32.7%) (p=0.25), were interested in getting tested for HIV. Among them (n=104), 46.4% of men (vs. 50.0% of women) were more interested in being tested at home and 41.1% (vs. 39.6% of women) in the van, with no significant gender differences. Among all, 24 men (16.8%) and 24 women (16.3%) were tested at home. One woman had a reactive test. Among individuals not interested in getting tested for HIV (n=186), most common reasons given for refusal were "not feeling at risk or not interested" (70.1% for men vs 66.7% for women, p=0.61) and "already tested" (42.5% for men vs 29.3% for women, p=0.06).
Conclusions: To our knowledge, this is the first time that door-to-door rapid HIV testing was implemented in Europe. It was an acceptable HIV testing strategy for individuals born in SSA. Implementation on a larger scale is necessary to study its potential impact on the HIV epidemic.

TULBPED48

Benchmarking 90-90-90 and HIV care continuum data and methodology in 9 Fast-Track Cities

S. Ravishankar, S. Gupta, R. Granich, J. Zuniga
International Association of Providers of AIDS Care, Washington, United States
Presenting author email: sravishankar@iapac.org

Background: The Fast-Track Cities initiative supports cities to achieve the UNAIDS 90-90-90 target by 2020. Grounded in the principle of data transparency, the initiative includes a public domain web-based monitoring and evaluation platform-the FTC Global Web Portal- which allows cities to measure and monitor progress towards the 90-90-90 target on city-specific dashboards.
Methods: HIV Care Continuum data and methodologies were considered for nine Fast-Track Cities that have reported data on their online dashboard, and were reviewed in accordance with IAPAC's 2015 Guidelines for Optimizing the HIV Care Continuum. Data were collected on the following indicators: estimated people living with HIV (PLHIV), PLHIV diagnosed, on antiretroviral therapy (ART) and virally suppressed. Based on the indicator rankings, the care continuum was graded as high, medium or low quality.
Results: Melbourne and Miami reported state and county data, respectively, in place of city data. Of the 9 Fast-Track Cities, two (Amsterdam, Melbourne) have achieved the 90-90-90 target in 2015. Five cities (Amsterdam, Melbourne, New York City, San Francisco, Denver) have achieved the "first 90" target; two (Amsterdam, Melbourne) have achieved the "second 90" target; and five (Amsterdam, Melbourne, New York City, Denver, Paris) have achieved the "third 90" target.
Along the care continuum, proportions ranged from 51-94% diagnosed, 23-85% on ART, and 19-79% virally suppressed among the estimated PLHIV. Majority of the cities had medium quality continuum, using standard surveillance methods, estimates and/or modeling to derive the indicators along the continuum.

[Continuum & 90-90-90 data for 9 Fast-Track Cities]

Conclusions: Fast-Track Cities are benchmarking 90-90-90 and care continuum data to address gaps across their HIV care continua. Two cities have attained the 90-90-90 target and four others have attained or surpassed one or more of the 90-90-90 targets. The Fast-Track Cities initiative supports cities to standardize metrics and strengthen methodologies for measuring the HIV care continuum, and to align programmatic efforts towards attaining 90-90-90.
