IAS2017

9TH IAS CONFERENCE ON HIV SCIENCE
PARIS, FRANCE – 23-26 JULY 2017

ABSTRACT BOOK

Conference Advisory Committee

IAS 2017 International Scientific Co-Chair & IAS President
Linda-Gail Bekker, South Africa

IAS 2017 Local Scientific Co-Chair
Jean-François Delfraissy, France

IAS Past President
Françoise Barré-Sinoussi, France

IAS President-Elect
Anton Pozniak, United Kingdom

IAS Regional Representative
Jürgen Rockstroh, Germany

Executive Director
Owen Ryan, Switzerland

Community Engagement Board Chair (CEB)
Bruno Spire, France

Track A Leads
Guido Silvestri, USA
Victor Appay, France

Track B Leads
Dominique Costagliola, France
Beatriz Grinsztejn, Brazil

Track C Leads
Jean-Michel Molina, France
Philippe van de Perre, France
Nyaradzo Mgodi, Zimbabwe

Track D Leads
Khuat Thi Hai Oanh, Vietnam
Ingrid Bassett, USA

Track Committees

Track A: Basic Science

Leads
Guido Silvestri, USA
Victor Appay, France

Members
Anthony Kelleher, Australia
Asier Saez-Cirion, France
Diana Finzi, USA
Elizabeth Connick, USA
Gustavo Reyes-Teran, Mexico
Nathalie Arhel, France
Penny Moore, South Africa
Takuya Yamamoto, Japan
Viviana Simon, USA

Track B: Clinical Science

Leads
Dominique Costagliola, France
Beatriz Grinsztejn, Brazil

Members
Allison Agwu, USA
Constance Delaugerre, France
Jintanat Ananworanich, USA
Joseph Eron, USA
Judy Currier, USA
Nathan Ford, Switzerland
Nicolas Meda, Burkina Faso
Saye Khoo, UK
Sharon Walmsley, Canada
Vanessa Rouzier, Haiti

Track C: Prevention Science

Leads
Jean-Michel Molina, France
Philippe van de Perre, France
Nyaradzo Mgodi, Zimbabwe

Members
Jacques Normand, USA
Jessica Justman, USA
Maria Prins, The Netherlands
Marie Préau, France
Nittaya Phanupak, Thailand
Sheena Mc Cormack, UK
Valdilea Veloso, Brazil

Track D: Implementation Science

Leads
Khuat Thi Hai Oanh, Vietnam
Ingrid Bassett, USA

Members
Adeeba Kamarulzaman, Malaysia
Benjamin Linas, USA
Cate Hankins, The Netherlands
Catherine Orrell, South Africa
Carlos Caceres, Peru
David Paltiel, USA
Fabio Mesquita, Brazil
Meghan Doherty, Switzerland
Yazdan Yazdanpanah, France

Abstract Mentor Programme

The Abstract Mentor Programme provides an opportunity for early-career investigators to receive feedback from more experienced researchers on their draft abstracts.
The programme links mentees to mentors within the same track to maximize the use of the mentors' expertise. Participants are required to take part in an online e-course on conference abstract writing in order to submit to the programme.

This year, 117 mentors reviewed 204 draft abstracts submitted by 156 researchers. One hundred and twenty-eight of them were submitted to IAS 2017 and the following were selected:

- 2 Oral Abstract
- 1 Poster Discussion Session
- 26 Poster Exhibition

We would like to thank all volunteer abstract mentors, listed below, who supported early-career HIV researchers improve the quality of their abstracts.

Alcides Troncoso, Argentina
Alexandra Ortiz, United States
Alfred Osoti, Kenya
Ali Judd, United Kingdom
Amara Frances Chizoba, Nigeria
Amos Laar, Ghana
Amy Corneli, United States
Andrew Etsetowaghan, Nigeria
Andrew Edmonds, United States
Andy Guise, United Kingdom
Anna Joy Rogers, United States
Annie Phoebe Kalyanasundaram, India
Archana Sarkar, India
Asa Radix, United States
Augustine Talumba Choko, Malawi
Axel Jeremias Schmidt, Switzerland
Barbara Burmen, Kenya
Bernadette Ndunge Ng'eno, United States
Bo Hønge, Guinea-Bissau
Boris Kevin Tchounga, Côte d'Ivoire
Brenda Asiimwe Kateera, Rwanda
Bright B. Drah, Canada
Brenda Crabtree-Ramírez, Mexico
Carmen Figueroa, Switzerland
Catherine Todd, United States
Cavin Epie Bekolo, Cameroon
Chandrakant Lahariya, India
Chen Zhang, United States
Chloe Teasdale, South Africa
Clare van Halsema, United Kingdom
Claudia Palladino, Portugal
Clotilde Allavena, France
Cristiane Menezes de Padua, Brazil
Daniel Murray, Australia
Daniel Elbirt, Israel
David Lubogo, Uganda
Deborah Brickley, United States
Denise Evans, South Africa
Diego Cecchini, Argentina
Douglas Kwon, United States
Ehimario Igumbor, South Africa
Elizabeth Irungu, Kenya
Ellen Tedaldi, United States
Elona Toska, South Africa
Elvis Tarkang, Ghana
Emily Hyle, United States
Erika Castro, Switzerland
François Dufrasne, Belgium
Giada Sebastiani, Canada
Giulia Marchetti, Italy
Godwin Aondohemba Timiun, Nigeria
Graciela Guaragna, Argentina
Guinevere Q. Lee, United States
Henning Drechsler, United States
Hsiaohsuan Kuo, United States
Huiru Dong, Canada
James Ndimbii, Kenya
Jean Joel Bigna Rim, France
Jennifer Ross, United States
Jessica Haberer, Uganda
Joel Francis, Tanzania
Justyna Kowalska, Poland
Kate Mitchell, United States
Kathleen Powis, Botswana
Kenneth Ngure, Kenya
Kévin Jean, France
Kok Keng Tee, Malaysia
Lauren Brinkley-Rubinstein, United States
Letitia Greener, South Africa
Lisa Hirschhorn, United States
Lucas Melo, Brazil
Lynn Matthews, South Africa
Marcel Yotebieng, United States
Maria Pando, Argentina
Mariana Esperanca Posse, Mozambique
Markella Zanni, United States
Martin Muhire, Uganda
Martin Herbas Ekat, Congo
Mauricio Carobene, Argentina
Mélanie Plazy, France
Milton Omondi, Kenya
Morna Cornell, South Africa
Mosepele Mosepele, Botswana
Myo Minn Oo, Myanmar
Nazneen Akhter, Bangladesh
Nicola Gianotti, Italy
Nikoloz Chkhartishvili, Georgia
Nyla Dil, United States
Oliver Laeyendecker, United States
Olumide Abiodun, Nigeria
Patricia Pérez-Matute, Spain
Patricia Agaba, Nigeria
Paul Otieno Yonga, Kenya
Paula Aulicino, Argentina
Pedrol Enric, Spain
Ragna Boerma, Netherlands
Raph Hamers, Netherlands
Roberto Santos, United States
Roger Reeves, United States
Russell Pierre, Jamaica
Ryan Westergaard, United States
Sai Ko Ko Zaw, Myanmar
Sara Gianella, United States
Seth Inzaule, Netherlands
Shu-Hsing Cheng, Taiwan, China
Stephanie Topp, Zambia
Stephen Okoboi, Uganda
Steve Innes, South Africa
Susannah Kamath, United States
Thierry Malebe, Zambia
Vanessa Veronese, Australia
Virginie Supervie, France
Wadzanai Samaneka, Zimbabwe
Weiming Tang, United States
William Christopher Mathews, United States
Yoav Keynan, Canada
Zulfa Abrahams, South Africa

International Abstract Review Committee

The 9th IAS Conference on HIV Science received more than 4,300 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

More than 800 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference:

Salim Abdool Karim, South Africa
Abu Abdul-Quader, United States
Sophie Abgrall, France
Elaine Abrams, United States
Lisa Abuogi, United States
Jeffry Acaba, Thailand
Kawango Agot, Kenya
Allison Agwu, United States
Atsushi Ajisawa, Japan
Ajaz Akhtar, Pakistan
Nazmul Alam, Canada
Jose Alcami, Spain
Grace Aldrovandi, United States
Todd Allen, United States
Ugo Amanyeiwe, United States
Rama Rao Amara, United States
Atul Ambekar, India
K. Rivet Amico, United States
Frank Michael Amort, Austria
Jintanat Ananworanich, Thailand
Petronela Ancuta, Canada
Jonathan Angel, Canada
Cristian Apetrei, United States
Victor Appay, France
Chris Archibald, Canada
Gabriele Arendt, Germany
Radka Argirova, Bulgaria
Nathalie Arhel, France
Jose Arribas, Spain
Judith Auerbach, United States
Santiago Avila-Rios, Mexico
Nwe Nwe Aye, Myanmar
Helen Ayles, Zambia
Ahidjo Ayouba, France
Tasnim Azim, Bangladesh
Alain Azondekon, Benin
Iskandar Azwa, Malaysia
David Back, United Kingdom
Andrew Badley, United States
Jared Baeten, United States
Rachel Baggaley, Switzerland
Andrew Ball, Switzerland
Stephen Banspach, United States
Stefan Baral, Canada
Giuseppe Barbaro, Italy
Francis Barin, France
Ruanne Barnabas, United States
Deborah Baron, South Africa
Dan Barouch, United States
Françoise Barré-Sinoussi, France
John A. Bartlett, United States
Simon Barton, United Kingdom
Emily Bass, United States
Ingrid Bassett, United States
Francisco Bastos, Brazil
Eduard Beck, Canada
Renaud Becquet, France
Josip Begovac, Croatia
Homira Behbahani, Sweden
Anne-Sophie Beignon, France
Linda-Gail Bekker, South Africa
Laurent Belec, France
Jorge Benetucci, Argentina
Eddas Bennett, United States
Philip Berger, Canada
Colm Bergin, Ireland
Ben Berkhout, Netherlands
Nicole Bernard, Canada
Daniela Bezemer, Netherlands
Sanjay Bhagani, United Kingdom
Paurvi Bhatt, United States
Adisak Bhumiratana, Thailand
Gunnel Biberfeld, Sweden
Julià Blanco, Spain
Joel Blankson, United States
Naomi Bock, United States
Christoph Boesecke, Germany
David Boettiger, Australia
Vicente Boix, Spain
Morgane Bomsel, France
Fabrice Bonnet, France
Peter Borges, India
Alberto Bosque, United States
Christine Bourgeois, France
Maria Belen Bouzas, Argentina
Mark Boyd, Australia
Ivana Bozicevic, Croatia
Patricia Bracamonte, Peru
Martine Braibant, France
Paula Braitstein, Kenya
Christian Brander, Spain
Sara Brewer, United States
Mark Brockman, Canada
Norbert Brockmeyer, Germany
Mario Bronfman, Mexico
John T Brooks, United States
Todd Brown, United States
Zabrina Brumme, Canada
Julie Bruneau, Canada
Cassia Maria Buchalla, Brazil
Elizabeth Bukusi, Kenya
Supranee Buranapraditkun, Thailand
Harold Burger, United States
Jenny Butler, Turkey
Maria Buzon, Spain
Maria Lorena Cabrera-Ruiz, Mexico
Carlos F. Caceres, Peru
Pedro Cahn, Argentina
Liliana Calanni, Argentina
Vincent Calvez, France
Bilali Camara, Nigeria
Cristina Camara, Brazil
Saulius Caplinskas, Lithuania
Irma Caplinskiene, Lithuania
Alex Carballo-Dieguez, United States
Patrizia Carrieri, France
José L. Casado, Spain
Isabel Cassetti, Argentina
Fabian Cataldo, Belgium
Marta Catalfamo, United States
Carina Cesar, Argentina
Lisa Chakrabarti, France
Joana Chakraborty, United States
Rana Chakraborty, United States
Thep Chalermchai, Thailand
Dick Chamla, United States
Larry Chang, United States
Jean-Marc Chapplain, France
Charlotte Charpentier, France
Manhattan Charurat, United States
Robert Chen, United States
Peter Cheung, Canada
Remi Cheynier, France
Benjamin Chi, United States
Frank Chimbwandira, Malawi
David Chipanta, Switzerland
Nicolas Chomont, Canada
Celia Christie, Jamaica
Gavin Churchyard, South Africa
Andrea Cimarelli, France

MOAA01 Hide and Seek: Biology of Reservoirs

MOAA0101

Assessing individual viral reactivations of the latent reservoir using a novel barcoded virus

C. Fennessey[1], M. Pinkevych[2], T. Immonen[1], C. Camus[1], G. Del Prete[1], J. Estes[1], J. Lifson[1], M. Davenport[2], B. Keele[1]

Background: An overwhelming obstacle to HIV cure is the presence of long-lived viral reservoirs that can reignite viral infection after removal of cART. Yet, our knowledge of the mechanisms of reservoir maintenance and persistence remains incompletely understood. Therefore, in this study, we generated a novel virus model for evaluating individual reactivation events following cART interruption to better understand key aspects of reservoir biology in vivo.
Methods: A genetically tagged virus (SIVmac239M) was generated with a 34-base molecular barcode stably inserted between vpx and vpr of SIVmac239. Rhesus macaques were infected intravenously and combination antiretroviral therapy (cART) administered, beginning either on day 6 for 82 days (n=4) (study 1), or day 4 for 305, 374, or 482 days (n=6) (study 2). Next-generation sequencing was used to evaluate the number of genetic variants in the stock and in plasma before and after treatment.
Results: In the viral stock, 9,336 individual barcodes, or clonotypes, were identified. During acute infection, an average of 1,247 barcodes were identified in each of the 10 animals. Plasma viremia was reduced to 15 vRNA copies/mL during treatment, and virus rapidly rebounded following treatment interruption. Between 87 and 136 distinct clonotypes were detected in plasma at peak rebound viremia in animals from study 1, and between 4 and 7 clonotypes in animals from study 2. Because the growth rate of each clonotype is equivalent once the virus reaches systemic infection, the measured relative proportions of each clonotype at rebound reflect the time between when each clonotype achieved systemic infection. The viral growth rate and the relative abundance of each clonotype in plasma during acute recrudescence was used to estimate a reactivation rate of 22.7 and 0.54 events per day in studies 1 and 2 respectively.
Conclusions: We conclude that identifying rebounding clonotypes may be used as a direct measurement of the latent reservoir that can successfully contribute to rebound viremia. Furthermore, the results confirm that the size of the post-cART recrudescence-competent viral reservoir is influenced by the timing of cART initiation and duration of treatment, enabling manipulation of these parameters to establish reservoirs of desired size for specific experimental purposes.

MOAA0102

Accumulation and persistence of deleted HIV proviruses following prolonged ART

E. Anderson[1], S. Hill[1], J. Bell[2], F. Simonetti[1], C. Rehm[3], S. Jones[4], R. Gorelick[2], J. Coffin[5], F. Maldarelli[1]

Background: HIV persistence during antiretroviral therapy (ART) is a substantial obstacle to HIV cure. HIV infected cells can undergo clonal expansion and specific clones may be highly expanded. We previously reported one provirus integrated in the HORMAD2 gene that accounted for 20-40% of all proviruses in one patient. Mechanisms by which clones emerge and persist over time are uncertain. To investigate the dynamics of HIV clonal expansion, we developed multiplexed droplet digital approaches (ddPCR) to quantify HIV proviruses, including specific integrants, prior to and following prolonged ART.
Methods: HIV infected ART-naïve individuals (N=11) underwent ART and were followed for a median of 13.7 years (range 4.3-16.4). Cell associated DNA (CA-DNA) from peripheral blood lymphocytes pre-ART, during first and second phase viral decay, and after prolonged ART was quantified using multiplexed ddPCR assays targeting HIV gag, LTR, and tat/rev regions, as well as a host gene (CCR5). We designed a specific ddPCR primer set overlapping the host-HIV junction to quantify the HIV integrant in HORMAD2.
Results: All patients had successful suppression of HIV RNA on ART to < 50 c/mL plasma within 5 months; HIV DNA copies/million CD4+ cells decreased for gag (average 15-fold), LTR (average 9.3-fold), and tat/rev regions (average 20-fold). In 10/11 patients the LTR:gag and LTR:tat/rev ratios increased progressively after second phase decay (average 6-fold and 6.4-fold respectively, p<0.01, paired T-test) demonstrating loss of full length proviruses; in 1/11 patients, LTR:gag and LTR:tat/rev ratios remained stable. The HORMAD2 integrant was undetectable at pre-ART, 1 month, and 2 months on ART (< 1 copy in 500,000 infected cells). After 1 year on suppressive ART, however, the HORMAD2 integrant was present at a frequency of 30% of all infected cells and persisted for 6 years on ART.
Conclusions: Progressive appearance of deleted proviruses is detectable in most, but not all patients undergoing ART. Substantial deletion did not appear during first or second phase viral decay, but only after 1-4 years during suppressive therapy. Clonal expansion of HIV infected cells can be rapid, and sustained at stable levels during prolonged ART, suggesting that both antigen-induced clonal expansion and homeostatic proliferation maintain HIV populations.

MOAA0103

A subset of extreme HIV controllers is characterized by a small HIV blood reservoir and a weak T cell activation level

E. Canoui[1,2], C. Lecuroux[2], V. Avettand-Fenoël[3], M. Gousset[3], C. Rouzioux[3], A. Saez-Cirion[4], L. Meyer[5], F. Boufassa[5], O. Lambotte[1,2], N. Noel[1,2,4], ANRS CO21 CODEX Study Group

Presenting author email: nicolas.noel@aphp.fr

Background: HIV controllers (HICs) form a heterogeneous group of patients with regard to formal definitions, immunologic characteristics and changes over time in viral load.
Methods: HICs with undetectable viral load (uHICs, i.e. for whom a viral load had never been detected with routine assays, n=52) were compared with 178 HICs with blips during the follow-up (bHICs). Clinical characteristics, ultrasensitive HIV-RNA and HIV-DNA loads, HIV1-Western blot (WB) profiles and immune parameters were analyzed.
Results: Relative to bHICs, uHICs had significantly lower ultrasensitive plasma HIV-RNA loads (median < 4 copies/ml [IQR < 2-< 4] vs. 21 [7-84] copies/mL, p<0.0001) and HIV-DNA levels in PBMC (< 10 copies per million PBMCs [< 10-11] vs. 21 [< 10-52], p=0.0004), higher CD4+ T cell count (790 [638-1038] vs. 711 [520-920], p=0.04) at enrolment, and lower T cell activation levels.
Half the uHICs were characterized by having a protective HLA allele (-B57/58/B27), a weak CD8+ T cell response and very small HIV-DNA reservoir. Between diagnosis and inclusion in the cohort, the CD4+ T cell count had not changed in uHICs but had significantly decreased in bHICs (-5.16 CD4/µL/year, p=0.001). 21% of the uHICs lacked specific anti-HIV IgG antibodies. These individuals also had very low levels of HIV-DNA, and 83% of these patients had both undetectable HIV DNA and us HIV RNA, compared with 40% of uHICs with full anti-HIV IgG responses.
Conclusions: We suggest that an optimal HIC phenotype combines protective HLA alleles, low level of HIV blood reservoirs and reduced immune activation. Such patients may have limited benefit from antiretroviral therapy.

MOAA0104

HIV integration sites in CD4 T cells from virally suppressed individuals show clonal expansion but no preferential location in oncogenes

J. Symons[1], A. Chopra[2], S. Leary[2], D. Cooper[2], J.L. Anderson[1], J.J. Chang[1], J. McMahon[3], S.G. Deeks[4], S. Mallal[2,5], P.U. Cameron[1,6], S.R. Lewin[1,6]

Presenting author email: jori.symons@unimelb.edu.au

Background: Assessing HIV integration site location and frequency in latently infected cells can inform how HIV persists on antiretroviral therapy (ART). We aimed to characterise HIV integration sites in CD4 T-cells from blood and tissue from HIV-infected individuals on suppressive ART.
Methods: Genomic DNA from 1 million CD4 T-cells obtained from blood, lymph node (LN) or rectal tissue from virologically suppressed participants on ART was enzymatically cut to random sized fragments, tagged and amplified by nested PCR with barcoded primers before Miseq sequencing. Chromosomal alignment was determined using Blat-UCSC Genome Browser (GRCH38/hg38). Clonal expansion of HIV integration sites was defined if identical HIV integration sites differed >2 base pairs in PCR-product length and ≥3 length polymorphisms were present.
Results: We assessed 1794 integration sites from 7 participants receiving ART for a median [range] of 14 [7-19] years with an undetectable viral load for 6 [4-16] years. Integration was enriched in genes vs non-genes (78 [58-87]% vs 23 [13-42]%, p<0.001). The majority of integration sites into genes were intronic (median 86 [72-97]% vs 13 [3-18]% exonic, p<0.001) and demonstrated preferential insertion in the opposite orientation relative to gene transcription (median 60 [47-68]% vs 40 [32-52]% same orientation, p=0.007). In blood we observed a median of 54 [25-70]% clonally expanded integration sites.
Interestingly, the frequency of clonal expansion was different in blood and tissue. In matched samples of 2 participants, the frequency of clonal expansion in LN was similar to blood, whereas rectal tissue showed the least amount of clonal expansion (table). Integration sites in expanded compared to non-expanded clones were enriched in genes (84% vs 69% respectively, p=0.04) but there was no enrichment in oncogenes (median 22% vs 25% respectively, p=0.74).

	CD4 count	HIV DNA /10^6 CD4 cells	% Clonal expansion in blood	% Clonal expansion in LN	% Clonal expansion Rectal tissue
Participant 6	578	1500	32	38	17
Participant 7	521	494	25	-	10

[Clonal expansion of HIV integration sites]

Conclusions: Expanded clones of infected cells in blood and tissues are common. HIV integration is preferentially detected in intronic regions but not oncogenes with orientations that are usually in opposite direction. The relative contribution of expanded clones to HIV persistence may differ in different tissue sites but analysis of further tissue samples are needed.

MOAA0105

The impact of treatment duration on defective and expanded identical HIV genomes in T cell subsets from peripheral blood and tissues

Presenting author email: eunok.lee@sydney.edu.au

Background: Understanding the impact of antiretroviral therapy (ART) duration on HIV-1 reservoirs is critical for implementing effective curative strategies. We studied the distribution of defective viral genomes in T cell subsets within blood and tissues over 3-18 years of effective ART. We also examined expansions of identical HIV-1 DNA sequences (EIS) to assess the contribution of cellular proliferation to viral persistence during ART.
Methods: Using single-genome/proviral sequencing, we performed inter-patient analysis of 479 HIV-1 p6-RT RNA sequences from pre- and early-ART plasma; and 2329 HIV-1 DNA sequences from naïve (N), central (CM), transitional (TM), effector (EM), gut homing and lymph homing memory CD4+ T cells sorted from peripheral blood (PB), lymph node (LN) and gut tissues from 14 participants who initiated ART during chronic infection (3-18 years on ART). Defective viral sequences had hypermutation, premature stops, frameshifts and large deletions. EIS were determined as ≥2 identical intact or defective HIV-1 DNA sequences across all cell types from all anatomic sites.
Results: Defective HIV-1 DNA sequences did not appear to accumulate substantially over 3-18 years of ART in any anatomic site (odds ratio=0.90-1.02/year, p=0.14-0.98). The viral sequences derived from pre- and early-ART plasma samples were more often genetically intact than sequences derived from PB and LN after several years of therapy (p≤0.004). The odds of an HIV-1 DNA sequence belonging to EIS increased in PB by 1.09-fold/year of ART (p=0.003). In tissues, the increase of the proportion in EIS during each additional year of ART was not statistically significant (p=0.15-0.25). Of note, 37-71% of identical HIV-1 DNA sequences were in EM sorted from PB and tissues. The odds that a viral sequence is part of an EIS in PB-derived EM increased by 1.11-fold/year (p=0.007), whereas other cell types showed no statistically significant trend (p=0.12-0.46).
Conclusions: The proportion of proviruses that were defective did not increase during effective therapy, suggesting that they are established in cells prior to viral suppression. Our data suggests that proliferation of HIV-infected T cells increased the proportion of sequences in EIS within peripheral blood over 3-18 years of therapy, and the EM cells were the major contributor.

MOAA02 Kill Me or Neutralize Me

MOAA0201

Sequential receptor-induced conformational states of native membrane-embedded HIV-1 Env

B. Ivan, N. Friedrich, Z. Sun, A. Trkola
University of Zurich, Institute of Medical Virology, Zurich, Switzerland
Presenting author email: ivan.branislav@virology.uzh.ch

Background: To fulfill its function of mediating virus attachment and entry, the HIV-1 envelope glycoprotein (Env) trimer undergoes a sequence of conformational changes. Due to their unstable nature, entry intermediates remain challenging to study, leaving several aspects of the entry process unresolved. This includes effects of CD4 and coreceptor engagement on the formation of successive Env intermediates and the stoichiometry of receptor and coreceptor binding. Knowledge on the different conformational states of native Env during the entry process is however crucial to understand its antigenic landscape and vulnerability to neutralization. While Env-directed broadly neutralizing antibodies (bNAbs) are thought to recognize Env preferentially in its closed, unliganded form, we currently lack information on their activity across different entry steps. As activity across intermediate Env conformations could increase the window of action, an antigenic profile of receptor-bound Env needs to be defined to select the best bnAbs for therapy and vaccine design.
Methods: We have developed a flow cytometry-based assay to assess and compare antigenic properties and conformational stability of fully native, cell surface-expressed Env trimers using an array of Env directed Abs and compounds. HIV-1 pseudovirus neutralization activity of a panel of NAbs was determined to explore links between open Env conformation and neutralization sensitivity.
Results: Our analysis provides a fine mapping of sequential exposure of shielded Env epitopes upon exposure to increasing doses of soluble CD4 (sCD4). Conformational changes induced by sCD4 binding proved consistent with a model where occupation of a protomer alters conformation of all three simultaneously. Increasing protomer occupancy by sCD4 promoted transition through intermediate, progressively more open Env conformations. According to our data, exposure of the coreceptor binding site may require at least two CD4 molecules to be bound per trimer. Most intriguingly, upon saturation of CD4 binding sites the trimer adopts a pre-hairpin conformation even in the absence of coreceptor interaction.
Conclusions: We provide here novel insights on antigenic characteristics of unliganded and receptor-bound conformations of native Env, that offer means to decipher critical steps of the entry process with high relevance for Env immunogen selection and design.

MOAA0202

Optimized Env trimer immunization parameters amplify onset, magnitude and consistency of autologous Tier 2 neutralizing antibody development in nonhuman primates

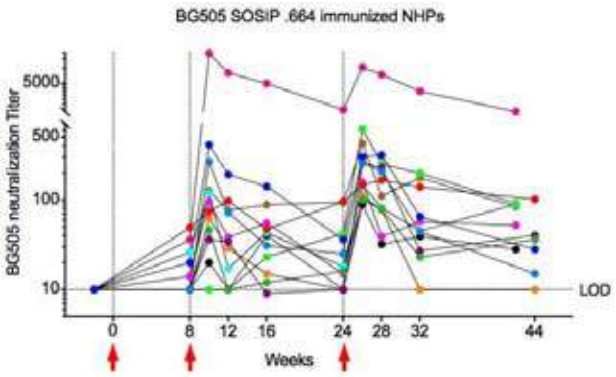
Background: The development of soluble native-like HIV Envelope trimers has reinvigorated hopes for protein-based vaccination strategies to induce protective antibody responses to HIV. However, unlike in rabbits, immunogens of this class have thus far induced only modest and inconsistent autologous neutralizing antibody (NAb) titers in rhesus macaques, raising concerns regarding the translatability of this approach. Moreover, Tier 2 NAbs have generally taken 6 months to develop in macaques.
Methods: Here, we investigated the effects of immunization schedule, route, dose and delivery on quantity, quality, and rapidity of NAb development in head-to-head comparisons, using 6-12 macaques per group. All 78 animals in the cohort were tightly matched for age, weight and gender.
Results: Major effects were observed. We identified strategies in which 100% of animals developed mean Tier 2 NAb titers of over 1:100 by wk 10. Geometric mean titers at wk 26 following two boosts were consistently higher than 1:200 (Figure 1). Effects of trimerization strategy (SOSIP vs. NFL) and immunization dose (100µg vs. 20µg) on autologous NAb titers were not significant. We further evaluated and compared novel SOSIP stabilization techniques (SOSIP v4.1, v5.2, Olio6), some of which significantly ($p < 0.001$) reduced induction of Tier 1 NAbs over previously reported strategies, while maintaining strong Tier 2 NAbs. Germinal center, T cell, and Ab responses were extensively analyzed in all animals through fine needle aspirates (FNAs), particularly those with BG505 NAb titers of 1:1000-1:20,000. Finally, high autologous Tier 2 neutralizing macaques also developed some neutralization breadth on a global Tier 2 viral panel.



[BG505 SOSIP .664 immunized NHPs]

Conclusions: In summary, this study provides a framework for preclinical and clinical vaccine studies targeting the elicitation of neutralizing antibodies by trimer immunization. We identified the when, where, and how of trimer immunogen delivery to maximize NAb titer induction in vivo.

MOAA0203

Germinal centers monitored by lymph node fine needle aspirates correlate with and predict HIV Tier 2 neutralizing antibody responses after HIV trimer immunization

Presenting author email: chavenar@lji.org

Background: The discovery of HIV broadly neutralizing antibodies in HIV+ individuals has re-galvanized efforts to develop a protective, antibody-based HIV vaccine. However, generation of neutralizing antibody (nAb) responses to clinically relevant strains of HIV (Tier 2) by immunization remains a challenging problem. Furthermore, the immunological barriers to induction of such responses by Env immunogens are unclear.
Methods: To directly study the germinal center (GC) responses induced after immunization, we have now performed over 1000 lymph node fine needle aspirates (LN FNA) of draining LNs in rhesus macaques immunized with native-like HIV-1 Env trimer proteins, such as BG505 SOSIP. LN FNA sampling captured GC cells and was highly representative of whole LN biopsies. Greater than 95% of samples provided sufficient cells for identifying the major cell types of the GC, GC B cells and GC T follicular helper (Tfh) cells. LN FNAs also afforded an opportunity for gene expression analysis of antigen-specific GC Tfh cells by RNAseq and longitudinal BCR sequencing to track evolution of the Env-specific B cell response.
Results: A majority of immunized animals developed autologous Tier 2 neutralizing antibodies. Tier 2 nAb development was most strongly associated with the magnitude of the GC response in an initial study ($p = 0.007$). In a subsequent study, the GC responses predicted Tier 2 nAb development ($p = 0.014$). Notably, Tier 2 nAbs did not correlate with BG505 SOSIP Ab binding titers. Thus, the GC responses distinguish between nAb responder and nAb non-responder monkeys, but ELISA binding titer does not.
Conclusions: Longitudinal LN FNA sampling has provided strong evidence that GC B and GC Tfh cell responses are central to generating HIV Tier 2 nAbs by immunization.

MOAA0204

Rapid elicitation of broadly neutralizing antibodies to HIV by immunization in cows

D. Sok[1], K. Le[2], M. Vadnais[2], K. Saye-Francisco[2], L. Kong[2], R. Stanfield[2], J. Jardine[2], J. Ruiz[1], A. Ramos[1], C.-H. Liang[2], P. Chen[3], M. Criscitiello[3], M. Waithaka[3], I. Wilson[2], V. Smider[2], D. Burton[2]

Presenting author email: dsok@iavi.org

Background: No immunogen to date has reliably elicited broadly neutralizing antibodies (bnAbs) to HIV in humans or animal models. Recent advances in the design of immunogens (BG505 SOSIP) that antigenically mimic the HIV envelope glycoprotein (Env) have improved the elicitation of potent isolate-specific Ab responses in rabbits and macaques, but so far failed to induce bnAbs. One possible contributor to this failure is that the relevant antibody repertoires are poorly suited to target occluded conserved epitope regions on Env relative to exposed variable epitope regions. The antibody repertoire of cows contains long third heavy chain complementary determining regions (HCDR3) with an ultralong subset that can reach nearly 70 amino acids in length.
Methods: Here we show that immunization of cows with BG505 SOSIP results in the rapid elicitation of broad and potent serum antibody responses. Four cows were immunized in total. Serum were collected over the course of immunization and evaluated for neutralization breadth and potency. Single memory B cells were then antigen-sorted with BG505 SOSIP and heavy and light chain variable genes were amplified by PCR.
Results: All immunized cows developed broad and potent neutralizing serum responses. Longitudinal serum analysis for one cow showed the development of neutralization breadth (19%, n = 114 cross-clade isolates) in 42 days and peak breadth (100%, n = 12 global isolates panel) at 217 days. A monoclonal antibody was isolated from this cow which harbored an ultralong HCDR3 of 64 amino acids and was able to recapitulate 69% of neutralization breadth with a potent median IC50 of 0.03 µg/ml. The antibody epitope mapped to the CD4 binding site of HIV Env.
Conclusions: Despite the inherent difficulty of eliciting broad and potent responses to HIV in most test animals, immunization with a trimer mimic in cows was able to show rapid responses in only 42 days, supporting the notion that the frequency of long HCDR3s is a critical factor in the ability to elicit HIV bnAbs. The results further suggest that immunization of cows may provide an avenue to quickly generate antibody prophylactics and therapeutics to address disease agents that have evolved to avoid human antibody responses.

Background: Anti-HIV-1 non-neutralizing antibodies (nnAbs) capable of antibody-dependent cellular cytotoxicity (ADCC) have been identified as a protective immune correlate in the RV144 vaccine efficacy trial. Broadly neutralizing antibodies (bNAbs) may also mediate ADCC and rely on their Fc region for optimal efficacy in animal models.
Methods: Here, we selected 10 bNAbs and 9 nnAbs, targeting various epitopes and conformations of the gp120/41 complex, and analyzed the potency of the two types of antibodies to bind and eliminate HIV-1-infected cells through NK engagement in culture. We tested their activity against 18 HIV-1 strains, including primary viruses.
Results: The landscape of Env epitope exposure at the surface and the sensitivity of infected cells to ADCC vary considerably between viral strains. The most potent bNAbs, and not the nnAbs, bound to reactivated infected cells from HIV-positive individuals and mediated effective ADCC against those cells. The nnAbs also modestly recognize cells infected with 8 different transmitted founder (T/F) isolates. Efficient ADCC requires sustained cell surface binding of bNAbs to Env proteins, and combining bNAbs allows a potent killing activity. Addition of a synthetic CD4 mimetic enhanced the binding and killing efficacy of some of the nnAbs in an epitope-dependent manner, without reaching the levels achieved by the most potent bNAbs.
Conclusions: Our study reveals important qualitative and quantitative differences between bNAbs and nnAbs, delineates the parameters controlling ADCC activity of bNAbs, and supports the use of the most potent antibodies to clear the viral reservoir.

MOAA0206

Allosteric regulation in human anti-HIV-1 Env ADCC-mediating antibodies upon immune complex (IC) formation enhances the binding to FcγRs for the activation of cytotoxicity against HIV-1 virus

C. Orlandi[1], D. Deredge[2], K. Ray[1], N. Gohain[1], W. Tolbert[1], M. Pazgier[1], A. Devico[1], P. Wintrode[2], G. Lewis[1]

Background: The field of HIV-1 vaccine research is in rapid development and a deeper knowledge of the mechanisms of defense against HIV-1 infection is urgent. In this regard, key insights about antibody-mediated immune response were provided by the RV144 vaccine trial that showed moderate protection correlating with Fc-effector functions. Historically, the activation of antibody-dependent cellular cytotoxicity (ADCC) has been considered dictated by two distinct and critical steps: optimal binding of viral antigens and engagement of FcγRs, respectively occurring in two distinguished mAbs regions (Fab and Fc domains). Only recently, few studies suggested a functional connection of Fab and Fc regions within the IgG.
Methods: Utilizing multiple approaches, such as ELISA, FCS (Fluorescence Correlation Spectroscopy), H/DX MS (Hydrogen/Deuterium Exchange Mass Spectroscopy) and crystallography, we studied whether the immune complex formation by antigen (Ag)-binding may impact the ability of IgG to consequently engage FcγRs and, in turn, activate the cytotoxic immune response against HIV-1 sensitized targets.
Results: Here we demonstrate a reciprocal allosteric regulation in anti-HIV gp120 Cluster A mAbs resulting from IC formation with a gp120-CD4 chimera antigen. We establish that the formation of ICs dramatically increases the efficiency of mAbs interaction to low affinity FcγRs compared to free IgG. Moreover, antigen-binding reverses the effect of FcγRs binding-attenuating LALA mutations in the Fc region, resulting in residual ADCC activity. HDX-MS analysis reveals an allosteric increase in conformational dynamics in the Fc domain of wildtype IgG upon Ag-binding, highlighting a putative mechanism for effective Fc receptors-engagement. In line with crystallographic data, H/DX MS showed a higher flexibility in the LALA mutant. However, antigen-binding further stabilized Fab and Fc regions of LALA mAbs, maintaining an adequate level of flexibility in the same crucial residues observed in the wt-IgG-Ag complex. Of note, the more mobile residues map to non-contact regions for FcγRs, but include residues that indirectly affect the IgG-FcγRs affinity and the induction of IgG-multimerization.
Conclusions: Collectively, these findings provide unique insights into reciprocal allosteric regulation between Fab and Fc domains, as IgG intrinsic factors that dictate the ability to tune selective Fc-effector functions, such as ADCC, in vaccine regimens or HIV-1 passive treatments.

MOAB01 Antiretroviral Therapy - ART: Season One

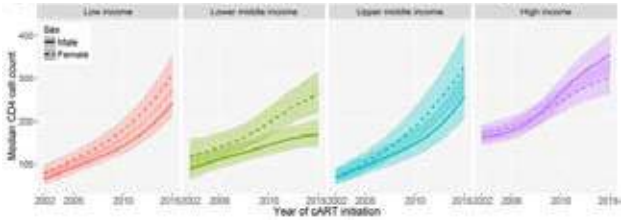
MOAB0101

Immunodeficiency at the start of combination antiretroviral therapy in low-, middle- and high-income countries

N. Anderegg[1], O. Kirk[2], for the IeDEA & COHERE collaborations
[1]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [2]University of Copenhagen, CHIP, Centre for Health & Infectious Diseases Research, Department of Infectious Diseases, Rigshospitalet, Copenhagen, Denmark
Presenting author email: nanina.anderegg@ispm.unibe.ch

Background: Early initiation of combination antiretroviral therapy (cART), at higher CD4 cell counts, prevents disease progression and reduces sexual transmission of HIV. Changes in guidelines are expected to result in increased CD4 cell counts at cART start. We describe temporal trends in the median CD4 cell count at cART start in adult men and women.

Methods: We used data from the International epidemiology Databases to Evaluate AIDS (IeDEA) sub-Saharan Africa, Latin America, Asia-Pacific and North America regions and from the Collaboration of Observational HIV Epidemiological Research in Europe (COHERE). We included all HIV-positive adults (≥16 years) initiating cART between 2002 and 2015. We aggregated data by calendar year, country and sex, and calculated median CD4 cell counts for each of the data cells. We used additive mixed models to analyze temporal trends in median CD4 cell counts. Sex, country income group and their interaction were included as fixed effects, and yearly trends were smoothed by sex and country income group.
Results: We included 652,728 adults from 14 low-, 11 lower middle-, 6 upper middle-, and 17 high-income countries. The Figure shows the modelled median CD4 cell count (cells/μL): from 2002-2015 there was an increase from 66 to 243 (+268%) in low-, from 88 to 170 (+93%) in lower middle-, from 69 to 257 (+272%) in upper middle- and from 163 to 355 (+118%) in high-income countries in males; and from 78 to 309 (+296%) in low-, 118 to 264 (+124%) in lower middle-, 70 to 328 (+369%) in upper middle- and 170 to 302 (+78%) in high-income countries in females.
Conclusions: Median CD4 cell count at cART start increased in all income groups, but generally remained below 350 cells/μL. Substantial additional efforts are needed to increase testing coverage with the aim of achieving earlier diagnosis, linkage, and initiation of cART globally.



[Figure. Modelled trends in CD4 cell count (cells/μL) at the start of cART, by sex and country income group]

ANRS 146 - GeSIDA 7211 OPTIMAL phase III trial: maraviroc plus cART in advanced HIV-1-infected individuals

Y. Levy[1,2], J.-D. Lelièvre[1,2], L. Assoumou[3], E. Aznar[4], F. Pulido[5], G. Tambussi[6], M. Crespo[7], A. Meybeck[8], J.-M. Molina[9], F. Cardon[10], A. Diallo[10], C. Delaugerre[9], R. Lancar[3], L. Béniguel[3], D. Costagliola[3], on behalf of the ANRS 146 - GeSIDA 7211 study group
[1]VRI/Inserm, U955, Equipe 16; Université Paris Est, Faculté de médecine, Créteil, France, [2]APHP, Hôpital H. Mondor, Créteil, France, [3]Sorbonne Universités, INSERM, UPMC Univ Paris 06, Institut Pierre Louis d'épidémiologie et de Santé Publique (IPLESP UMRS 1136), Paris, France, [4]Fundación SEIMC-GESIDA, Madrid, Spain, [5]Hospital 12 de Octubre, Madrid, Spain, [6]IRCCS-Ospedale San Raffaele, Milano, Italy, [7]Hospital universitario Vall d'Hebron, Barcelona, Spain, [8]Service Universitaire des Maladies Infectieuses et du Voyageur, Centre Hospitalier de Tourcoing, Tourcoing, France, [9]AP-HP, Hôpital Saint Louis, Paris, France, [10]ANRS, France Recherche Nord & Sud Sida-HIV Hépatites, Paris, France

Background: Late HIV diagnosis is associated with an excess risk of AIDS-Defining-Events (ADE) and mortality. We hypothesized that -due to its immunomodulating effect- the addition of maraviroc (MVC) to cART in naïve patients with low CD4 cell counts will decrease the risk of disease progression and death.
Methods: The ANRS 146 OPTIMAL trial (NCT01348308) was an European, multicentre, randomized, double-blind, phase III trial, in France, Spain and Italy, in ART-naïve HIV1-infected adults with CD4+ count < 200/μL or an ADE. Participants were randomized (1:1) to receive cART plus placebo or MVC for 72 weeks. The primary composite endpoint was any new ADE, serious non-AIDS-defining event, IRIS, or death from any cause. The primary endpoint and its components were compared using Kaplan-Meier estimates and Cox proportional-hazards models. In a post-hoc analysis, a Poisson regression model was used to analyse occurrence of all events and the interaction between the study period (0-24 versus 24-72 weeks) and the treatment effect.
Results: Between October 2011 and November 2014, 409 patients were included. At baseline, median HIV viral load was 5.39 $\log_{10}$ copies/mL, median CD4+ count 80 cells/μL and 42% of participants had an ADE. No difference was seen in CD4 cell increase (+258.3±8.9 vs +254.2±9.2/μL) (p=0.746). 74 events occurred in 53 participants: 42 events in 27 participants in the placebo group and 32 events in 26 participants in the MVC group. The incidence of the first event was 11.2 events per 100 person-years in the placebo group versus 11.1 events per 100 person-years in the MVC group with a hazard ratio of 0.97 (95% confidence interval [CI], 0.57-1.67). Poisson regression analysis showed that the incidence-rate-ratio (IRR) of the two groups differed significantly between periods 0-24 and 24-72 weeks with respective IRR of 0.61 (95% CI: 0.33-1.08) and 2.90 (95% CI: 0.86-12.49) (p=0.016).
Conclusions: The results of this large randomized trial showed that adding MVC to cART does not impact the occurrence of serious disease or death in advanced HIV1+ patients. However, post hoc analysis showed a trend for a beneficial effect of the addition of MVC in the first 24 weeks that disappeared thereafter.

MOAB0103

Safety, efficacy, and dose-response of GSK3532795/BMS-955176 plus tenofovir/emtricitabine (TDF/FTC) in treatment-naïve (TN) HIV-1-infected adults: week 24 primary analysis

J. Morales-Ramirez[1], J. Bogner[2], J.-M. Molina[3], J. Lombaard[4], I. Dicker[5], D. Stock[6], S. Min[7], C. Llamoso[5], S.R. Joshi[5], M. Lataillade[5]
[1]Clinical Research Puerto Rico Inc, San Juan, Puerto Rico, [2]Med IV, Hospital of the University of Munich, Munich, Germany, [3]Hôpital St Louis, Paris, France, [4]Josha Research, Bloemfontein, South Africa, [5]ViiV Healthcare, Wallingford, United States, [6]Bristol-Myers Squibb, Wallingford, United States, [7]ViiV Healthcare, Research Triangle Park, United States
Presenting author email: max.x.lataillade@viivhealthcare.com

Background: This Phase 2b study investigated the safety, efficacy and dose-response of GSK3532795 (formerly BMS-955176), a novel second generation MI, relative to Efavirenz (EFV) in treatment-naïve (TN), HIV-1-infected subjects.
Methods: AI468038 (205891) is a global, randomized, doubled blind, active-controlled trial. TN adults, with HIV-1 RNA ≥ 1000 c/mL and susceptibility to commercially available study medications, were randomized 1:1:1:1 to 60 mg, 120 mg or 180 mg of GSK3532795, or EFV 600mg once-daily with TDF/FTC. The primary endpoint was the proportion of subjects with HIV-1 RNA < 40 c/mL at Week 24 using the FDA Snapshot algorithm.
Results: A total of 210 subjects were randomized and 206 were treated. The mean age was 33.7 years; 85.4% were male. The mean baseline HIV-1 RNA and CD4+ T-cell counts were 4.3 log10 c/mL (17% >100,000 c/mL) and 444 cells/μl (5.8% < 200 cells/μl), respectively. At Week 24, 76-82.7% of subjects across the GSK3532795 arms (60, 120, and 180 mg) and 77.4% in the EFV arm achieved a HIV-1 RNA < 40 c/mL (mITT, FDA snapshot). More EFV (17%) than GSK3532795 (2-8%) subjects reported AEs leading to discontinuation. Few subjects reported SAEs on EFV (9%) or GSK3532795 (2-4%). The rates of GI AEs, predominately diarrhea and abdominal pain (all grades, regardless of relationship), in the GSK3532795 arms were 52-72.5%; the EFV rate was 24.5%. The rate of treatment emergent NRTI resistance in the GSK3532795 arms was 6.5%. The EFV arm did not contain any treatment emergent NRTI/NNRTI resistance.

Parameter, n (%)	GSK3532795 60 mg + TDF/FTC QD	GSK3532795 120 mg + TDF/FTC QD	GSK3532795 180 mg + TDF/FTC QD	EFV 600mg + TDF/FTC
Week 24 Snapshot (mITT)	(N = 50)	(N = 52)	(N = 51)	(N = 53)
HIV-1 RNA < 40 c/mL	38 (76.0)	43 (82.7)	42 (82.4)	41 (77.4)
HIV-1 RNA ≥ 40 c/mL	10 (20.0)	7 (13.5)	4 (7.8)	3 (5.7)
No virologic data at Week 24	2 (4.0)	2 (3.8)	5 (9.8)	9 (17.0)
Week 24 (Observed Data)	(N = 46)	(N = 47)	(N = 45)	(N = 44)
HIV-1 RNA < 40 c/mL	38 (82.6)	43 (91.5)	42 (93.3)	41 (93.2)

[Week 24 Efficacy Data]

Conclusions: The Week 24 primary endpoint showed similar efficacy results across GSK3532795 treatment arms relative to EFV when combined with TDF/FTC in TN HIV-1 infected adults. However the GSK-3532795 arms showed a higher rate of GI intolerability and treatment emergent resistance to the NRTI backbone relative to EFV.

Presenting author email: rmoh73@gmail.com

Background: Tolerance and efficacy data on third-line treatment are scarce in Sub-Saharan Africa, in a context where viral load and genotype test are limited. This study aims to assess the effectiveness of 48-week third line therapy after 3-month adherence reinforcement in HIV-infected adults who failed second-line ART.
Methods: Thilao is a cohort study conducted in Burkina Faso, Côte d'Ivoire, Mali and Senegal. HIV-1-infected adults with virological failure on a second-line protease inhibitor based regimen after a first-line non-nucleoside reverse transcriptase inhibitor were included.
Adherence reinforcement measures were proposed at baseline (V0). After 3 months (V3), a viral load (VL) was performed. The second-line therapy was maintained if VL from baseline to V3 decreases by more than 2 log or below 400 copies/ml and a switch to a third-line Darunavir/r 600/100 mg BID (DRVr) and Raltegravir 400 mg BID (RAL) regimen in case of virological failure without knowing genotypic resistance test results. Each patient was followed 64 weeks (W64) and 48 weeks (W48) after third-line initiation. We describe the virological outcomes at W48 for those initiated third-line therapy.
Results: 201 patients were included.
Women: 69%, median age: 41 years old [35-48]. Median CD4 count and VL at pre-inclusion were 242/mm^3 [113-400] and 4.5 log/ml [3.0-5.0]; median duration since ART initiation: 8 years [6-10] including median 3 years [2-6] of second-line protease inhibitor. The median of medication possession ratio between W0 and W64 was 97.1 [91.4-100.2].
After V3, 34% have initiated third-line ART. Among them, 64% received TDF 3TC/FTC-NNRTI regimen. At W48: 4 are deceased and 0 were lost-to-follow up. 62% had a VL < 50 copies/ml. The median of those with a detectable VL was 896 copies [176-24500].
The probability of eventually initiating a third-line therapy during follow-up at W64 was 39%.
No severe adverse event related to third line therapy were notified. Among patients who failed DRVr and RAL regimen (n=11), only one mutation E157q to RAL was detected.
Conclusions: Sequencing of third line regimen such as recommended by WHO based on Darunavir/r, Raltegravir and recycled NRTI, is well tolerated and efficient as salvage therapy.

MOAB02 Children and Adolescents: Issues in the First and Second Decade

MOAB0201

Maximizing targeted testing to improve HIV yield among children and adolescents in Rwenzori region, Uganda

H. Bitimwine[1], F. Musiime[2], P. Ajuna[2], P. Tumbu[2], P. Nahirya-Ntege[2], A. Kekitiinwa[2]
[1]Baylor College of Medicine Children's Foundation, Medical & Psychosocial, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda
Presenting author email: bitimwine@gmail.com

Background: Ugandan national Anti-retroviral therapy (ART) coverage among children (< 15 years) is low, at 42% (61,642/147,394) compared with the target of 90%. This arises from the low identification of HIV infected children and adolescents through HIV Testing Service (HTS) models, such as routine counselling and testing. In Rwenzori region, HIV testing yield is low for children (0.7%) and adolescents (1%). Baylor-Uganda implemented targeted HTS models to improve HIV yield among children and adolescents and thus close the ART gap in the Rwenzori region. We determined the HIV yield from these models.
Methods: In the period March-June 2016, we provided HTS to children and adolescents 18months -19 years using the following models: HTS outreaches to dwelling homes of orphans and vulnerable children (OVC); Know your child Status Campaigns (KYCS); HTS outreaches to children of female sex workers (FSWs), fisher folks (FFs) and tea plantation workers; and evening HTS points targeting adolescents after work/school hours. We summarized the HIV yield for the different models in proportions and frequencies.
Results: Of the 4,091 children and adolescents tested, 2,135 (52%) were females and 2,030 (50%) adolescents (10-19 years). The overall HIV yield from all models was 53/4,091(1.3%). The HIV yield among adolescents, children (5-9 years) and those under 5 years was 30/2,030(1.5%), 20/1,234(1.6%) and 3/824(0.4%) respectively. It was highest through outreaches at OVC dwelling homes 7/271 (2.6%) and lowest through outreaches to children of tea plantation workers 0/214(0%). The HIV yield through outreaches to children of FSWs, children of FFs, KYCS campaigns and evening HTS points was 10/610(1.6%); 3/283(1.1%) ; 16/836 (0.9 %) and 14/815 (1.7%) respectively.
Conclusions: A relatively high HIV yield was achieved through HTS at OVC dwelling homes, children of FSWs, FFs and Evening HTS; and a low yield through outreaches to children of tea plantation workers and KYCS campaign. Therefore, deliberate efforts should be made to scale up HTS to OVC dwelling homes, children of FSWs and fisher folks, and evening HTS for adolescents; and consider to discontinue HTS outreaches to children of tea plantation workers and scale down or modify KYCS campaigns.

Impacts of vitamin D and calcium supplementation on bone mineral density among perinatally HIV-infected adolescents: a 48-week randomized clinical trial

T. Sudjaritruk[1,2], L. Aurpibul[2], T. Bunupuradah[3], S. Kanjanavanit[4], T. Chotecharoentanan[2], S. Taejaroenkul[2], P. Ounchanum[5], P. Suntarattiwong[6], T. Puthanakit[3,7,8], CAL-D Study Group
[1]Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand, [2]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [3]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]Nakornping Hospital, Chiang Mai, Thailand, [5]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [6]Queen Sirikit National Institute of Child Health, Bangkok, Thailand, [7]Faculty of Medicine, Chulalongkorn University, Department of Pediatrics, Bangkok, Thailand, [8]Research Unit in Pediatric Infectious Diseases and Vaccines, Chulalongkorn University, Bangkok, Thailand
Presenting author email: tavitiya.s@cmu.ac.th

Background: This study aimed to identify the impacts of vitamin D and calcium (VitD/Ca) supplementation on bone mineral density (BMD) and bone metabolism among perinatally HIV-infected Thai adolescents.
Methods: An ongoing, randomized, open-label trial has been conducted. Adolescents aged 10-20 years who were stable on ART (HIV RNA< 400 copies/ml) were randomly assigned to receive either "high-dose": VitD/Ca (3200 IU/1.2 g daily) or "normal-dose": VitD/Ca (400 IU/1.2 g daily) supplementation for 48 weeks. Lumbar spine BMD and bone metabolism-related markers were evaluated at baseline and 48 weeks. BMD was measured by dual-energy X-ray absorptiometry, of which z-score ≤ -2 was defined as low BMD. Bone metabolism-related markers included 25-hydroxyvitamin D (25OHD), intact parathyroid hormone (iPTH), alkaline phosphatase (ALP), C-terminal telopeptide (CTX-bone resorption marker),

and procollagen type I amino-terminal propeptide (PINP-bone formation marker). An interim analysis, stratified by baseline BMD z-score ≤-2 (low BMD) vs. >-2 (normal BMD), was performed using the intention-to-treat analysis.

Results: Between April 2015 and October 2016, 166 adolescents were enrolled. The median age and ART duration were 16.0 and 10.0 years, respectively. The median baseline BMD z-score was -1.5 and 67 adolescents (40%) had low BMD. Overall adherence to VitD/Ca supplementation was 80%. At week 48, there was a significant increase in BMD z-scores in participants with low baseline BMD, particularly among those receiving "high-dose" compared with "normal-dose" supplementation (+0.74 vs. +0.49) (Table1). The increased 25OHD, and the declined iPTH, ALP, CTX and PINP levels were also observed in both treatment groups (P<0.001). No between-group differences in changes from baseline for BMD z-scores and all bone biomarkers (P>0.05), except for iPTH (P=0.007).

Parameters	Treatment group	Change from baseline to week 48*		Overall P†
		Low baseline BMD (n=67)	Normal baseline BMD (n=99)	
BMD z-score	High-dose	0.74 (0.31 to 1.14)‡	0.10 (-0.25 to 0.67)	0.07
	Normal-dose	0.49 (-0.4 to 1.19)‡	-0.07(-0.51 to 0.43)	
25OHD, ng/ml	High-dose	5 (-3 to 12)‡	5 (1 to 11)‡	0.81
	Normal-dose	6 (3 to 12)‡	6 (2 to 10)‡	
iPTH, pg/ml	High-dose	-10 (-21 to -2)‡	-6 (-22 to 1)‡	0.007
	Normal-dose	-16 (-23 to -6)‡	-13 (-22 to -3)‡	
ALP, U/l	High-dose	-24 (-128 to -14)‡	-45 (-83 to -11)‡	0.12
	Normal-dose	-65 (-95 to -27)‡	-49 (-119 to -21)‡	
CTX, ng/l	High-dose	-180 (-420 to 30)‡	-330 (-790 to 10)‡	0.09
	Normal-dose	-480 (-780 to -160)‡	-270 (-600 to 30)‡	
PINP, µg/l	High-dose	-49 (-193 to 13)‡	-87 (-208 to 11)‡	0.23
	Normal-dose	-170 (-331 to -36)‡	-71 (-225 to 16)‡	

*Data is presented as median change from baseline (interquartile range).
†P-value evaluates the overall difference in median change from baseline to week 48 between the two treatment groups (between-group difference), using Wilcoxon rank-sum test.
‡Indicates the median change from baseline to week 48 within the treatment groups (within-group difference) is a statistical significant (P <0.05), by Wilcoxon signed-rank test.

[Table 1. Changes of bone mineral density z-scores and bone metabolism-related biochemical markers from baseline among 166 perinatally HIV-infected Thai adolescents over the 48-week study follow-up.]

Conclusions: With the preliminary results, BMD were significantly ameliorated in adolescents with low baseline BMD who received VitD/Ca supplementation, regardless of dose, over 48-week follow-up. A prospective study with longer follow-up is warranted to confirm our findings.

MOAB0203

Inequality in mortality and access to antiretroviral therapy in adolescents living with perinatally-acquired HIV in sub-Saharan Africa: a Collaborative Initiative for Paediatric HIV Education and Research (CIPHER) cohort collaboration analysis

A. Slogrove[1], V. Leroy[2], A. Judd[3], CIPHER Global Cohort Collaboration Adolescent Project Team
[1]University of Cape Town, Centre for Infectious Disease and Epidemiologic Research, Cape Town, South Africa, [2]Universite Paul Sabatier Toulouse 3, INSERM U1027, Toulouse, France, [3]University College London, MRC Clinical Trials Unit, London, United Kingdom
Presenting author email: slogrove@gmail.com

Background: Eighty percent of adolescents living with perinatally- and behaviourally-acquired HIV live in sub-Saharan Africa (SSA), a continent with marked economic inequality. Extending our previous global description of adolescents living with perinatally-acquired HIV (APH), this analysis aimed to describe APH outcomes in SSA by country income group (CIG).
Methods: Through the CIPHER cohort collaboration, individual retrospective data from 12 cohort networks across 5 continents were pooled; 7 networks representing SSA were included here. APH included were HIV-infected children with entry into care at age <10 years (proxy for perinatally-acquired HIV), and follow-up at age >10 years. CIG was classified according to World Bank classification at median year of first visit by country.
Cumulative incidence functions were calculated by competing risks analysis for mortality, transfer-out and loss-to-follow-up.
Results: 30,296 APH were included; 75.7% resident in low income countries (LIC), 4.6% in lower-middle income countries (LMIC) and 19.8% in upper-middle income countries (UMIC). 64% of APH were born ≥2000. Median (interquartile range [IQR]) age at antiretroviral therapy (ART) start (8 [6;9] years) and at last follow-up (12 [11;14] years) were equivalent across CIG. 26,018 (85.9%) ever started ART and 3,352 (12.5%) started at age >10 years, both significantly different between CIG (p<0.001) (Table 1).
Individual CD4 count improved between ART start and last visit in all CIG (p<0.001). Half of APH had height-for-age Z-score (HAZ) <-2 at ART start that improved by last visit in LIC (p<0.001) and UMIC (p<0.001) but not LMIC (p=0.18). Mortality between age 10-15 years was lowest in UMIC however loss-to-follow-up was highest in UMIC.

	LIC N=22,925	LMIC N=1,386	UMIC N=5,985
Ever started ART - n (%)	19,114 (83.4)	1,207 (87.1)	5,697 (95.2)
Started ART age >10 years - n (%)	2,829 (14.8)	141 (11.7)	382 (6.7)
CD4 count (cells/µl) at ART start - median [IQR] (N=15,254)	310 [165; 520]	292 [174; 417]	318 [162; 558]
CD4 count (cells/µl) at last visit - median [IQR] (N=24,223)	668 [434; 945]	735 [532; 985]	729 [513; 971]
HAZ at ART start - median [IQR] (N=16,181)	-2.01 [-2.97; -1.08]	-2.08 [-2.95; -1.33]	-2.02 [-2.86; -1.17]
HAZ at last visit - median [IQR] (N=25,333)	-1.77 [-2.60; -0.95]	-2.02 [-2.77; -1.30]	-1.54 [-2.31; -0.77]
Cumulative incidence of mortality - % (95%CI)	3.5 (3.1; 3.8)	3.9 (2.7; 5.4)	1.1 (0.8; 1.4)
Cumulative incidence of transfer-out - % (95%CI)	17.5 (16.8; 18.3)	27.5 (24.2; 31.0)	23.7 (22.4; 25.1)
Cumulative incidence of loss-to-follow-up - % (95%CI)	13.1 (12.4; 13.8)	8.3 (6.3; 10.6)	14.0 (12.9; 15.3)

[Table 1: APH characteristics by CIG (N=30,296)]

Conclusions: Despite starting ART late, improvements in height and CD4 count were observed in most APH surviving to adolescence. Mortality rates are likely under-estimated. However, results highlight inequalities in mortality and access to ART according to CIG in SSA.

MOAB0204

Evaluation of the risk of birth defects among children exposed to raltegravir *in utero* in the ANRS-French Perinatal Cohort EPF

J. Sibiude[1,2], J. Warszawski[1,3], S. Blanche[4,5], O. Dialla[1], A. Faye[6,7], C. Dollfus[8], L. Mandelbrot[1,7,9], R. Tubiana[10,11], for the ANRS-EPF CO1/CO11 Study group
[1]INSERM, CESP 1018, Le Kremlin Bicêtre, France, [2]APHP-Hôpital Cochin Port Royal, Paris, France, [3]Université Paris Sud, Le Kremlin Bicêtre, France, [4]APHP Hôpital Necker, Paris, France, [5]Université Paris Descartes, Paris, France, [6]APHP Hôpital Robert Debré, Paris, France, [7]Université Paris Diderot, Paris, France, [8]APHP Hôpital Trousseau, Paris, France, [9]APHP Hôpital Louis Mourier, Colombes, France, [10]APHP Hôpital Pitié Salpétrière, Paris, France, [11]Sorbonne Universités, UPMC Université Paris 6, Paris, France
Presenting author email: jeanne.sibiude@gmail.com

Background: Raltegravir is an integrase inhibitor, largely used in the recent years, but tolerance data in pregnancy is scarce. Potential teratogenicity has not yet been evaluated for this molecule in a clinical context. We aimed to describe the rates and types of birth defects among children exposed to raltegravir in utero and to study the association with trimester of exposure.
Methods: EPF is a multicenter national cohort, which prospectively enrolls pregnant HIV-infected women delivering in 90 centers throughout France. Children are followed by pediatricians until two years of age. All births exposed to raltegravir were included. Birth defects were defined using the EUROCAT classification. Rates of birth defects were compared according to timing of exposure to raltegravir (1st trimester vs 2nd and 3rd trimester) using χ^2 tests.
Results: We included 479 fetuses born between 2008 and 2015, exposed to raltegravir, among which 6 stillbirths (1.3%) and 2 late miscarriages (0.4%). There were no terminations of pregnancies for birth defects. Rates of birth defects were 4.2% for all births (20/479, [95% CI 2.4%-6.0%]), and 4.2% among live births (20/471 [2.4%-6.1%]). This incidence was similar to that reported in a previous study in EPF for live births exposed to any ARV (4.4% [4.0%-4.7%]). Birth defect rates did not differ significantly between first trimester exposure to raltegravir (5.7%; 8/140) and 2nd or 3rd-trimester exposure (3.5%; 12/339; p=0.32). The anomalies did not follow any pattern and concerned various organs: 7 heart defects, 5 polydactylies, and 8 other defects. Other notable adverse outcomes were preterm births (14.2%), and 2 cases of HIV perinatal infection (0.4%). The follow-up was complete to 24 months for 63% of children. For 15% of children, only the birth questionnaire was available.
Conclusions: This is the largest prospective cohort of children exposed in utero to raltegravir with homogenous evaluation of birth defects. We did not find a significant association between 1st trimester exposure to raltegravir and birth defects. This finding is quite reassuring as this molecule is often prescribed to women of child-bearing age, and thus many children may be exposed in the first trimester of pregnancy.

MOAB0205

High prevalence of respiratory non-tuberculous mycobacteria respiratory infections in children living with HIV in South-East Asia

Presenting author email: lborand@pasteur-kh.org

Background: Data on burden of Non Tuberculous Mycobacteria (NTM) and related Pulmonary Diseases are limited in HIV-infected children in developing countries. We investigated NTM respiratory infections (RI) prevalence, species distribution, and associated factors in HIV-infected children with a suspicion of tuberculosis in four countries in South-East Asia and Africa.
Methods: From 2011 to 2014, HIV-infected children ≤13 years with a suspicion of tuberculosis were included in the ANRS 12229-PAANTHER 01 study in Burkina-Faso, Cambodia, Cameroun and Vietnam after parental consent. Children underwent respiratory and stool samples for mycobacterial culture and molecular identification of species. Children with ≥1 analyzable sample in culture were included. NTM-RI was defined as ≥1 sample culture-positive for any NTM. Logistic regression models were used to identify factors associated with respiratory NTM or Mycobacterium avium complex (MAC) infections.
Results: Of 438 children enrolled, 427 had ≥1 analyzable sample. Median age was 7.3 years, with 212 (49.7%) male, 245 (57.4%) Asian, 267 (63.9%) underweight, 212 (51.1%) severely immuno-depressed, and 258 (60.4%) ART-naïve. Prevalence of culture-confirmed tuberculosis was 13% (55/427), including 5 co-infections tuberculosis/NTM. Prevalence of NTM-RI was 10.8% (46/427), 16.7% (41/245), and 2.8% (5/177), in all, Asian, and African children, respectively. MAC were isolated in 21/427 (5%) children overall and 17/125 (13.6%) children from Asian origin with severe immune-depression (CDC classification 2014). Majority of NTM patients with severe immune-depression were infected by MAC (n=17/19). In contrast, Mycobacterium fortuitum, scrofulaceum, interjectum, and gordonae were the most frequent species in non or moderately immuno-depressed children. Overall, South-East Asian origin (OR 7.2; 95%CI 2.5-21.1), age 5-9 yo compared to 0-2 yo (OR 10.1; 95%CI 2.3-44.8), and severe immune-deficit (OR 3.3; 95%CI 1.5-7.2) were factors independently associated with NTM-RI. CD4-T Lymphocytes count <50/mm^3 (OR 9.8; 95%CI 3.6-26.5), and Asian origin (OR 16.5; 95%CI 2.2-126.1) were independently associated with MAC infection.
Conclusions: NTM-RI are frequent in HIV-infected children with presumptive tuberculosis in South-East Asia, not only as opportunistic infection in severe immuno-deficiency. NTM contribution to lung disease is unclear in a tuberculosis suspicion context. Empiric treatment for both tuberculosis and MAC may be relevant in most severely immuno-depressed HIV-children suspected of tuberculosis in South-East Asia.

MOAB0206

High-risk vaccine-specific HPV infection in HIV-infected and HIV-uninfected, vaccine-naïve Asian female adolescents

S. Sricharoenchai[1], T. Bunupuradah[2], R. Hansudewechakul[3], D.L.D. Hanh[4], D.N.H. Tran[5], S. Kerr[2], A. Chalermchockcharoenkit[1], N. Teeratakulpisarn[2], J. Achalapong[3], D.N.Y. Dung[4], W. Termrungruanglert[6], S. Chaithongwongwatthana[6], T. Singtoroj[7], T. Pankam[8], N. Phanuphak[8], A.H. Sohn[7], K. Chokephaibulkit[1], HPV in Adolescents Study team
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [4]Hung Vuong Hospital, Ho Chi Minh City, Vietnam, [5]Children's Hospital 1, Ho Chi Minh City, Vietnam, [6]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [7]TREAT Asia/amfAR - The Foundation for AIDS Research, Bangkok, Thailand, [8]Thai Red Cross AIDS Research Centre, Bangkok, Thailand
Presenting author email: sirintipsri@gmail.com

Background: Adolescents in resource limited countries have limited access to human papillomavirus (HPV) vaccination. We assessed the prevalence of 7 high-risk vaccine-specific HPV types (HRVS-7) in the nonavalent vaccine and identify factors associated with oral and anogenital HRVS-7 infection in perinatally HIV-infected female adolescents (PHIVA), and HIV-uninfected females (controls).
Methods: Sexually active PHIVA were enrolled in a prospective study in Thailand and Vietnam from 2013 to 2015. Controls were matched by age and lifetime number of sexual partners. All participants were naïve to HPV vaccination. HPV genotypic assay were performed on oral, anal, cervical and vaginal samples using the Roche Linear Array, and serum neutralizing antibodies (NAb) to HPV type 16 and 18 were measured. An audio-computer-assisted self-interview (ACASI) was performed to assess behavioral risks. Screening for sexually transmitted infections (STI) included Chlamydia trachomatis, Neisseria gonorrhea, herpes simplex virus-2 (HSV2) and syphilis. Multiple logistic regression analysis was used to assess factors associated with presence of any HRVS-7 genotypes (16, 18, 31, 33, 45, 52, 58) at any body sites.
Results: A total of 93 PHIVA and 99 controls were enrolled; median (IQR) age 19 (18-20) years, with 2 (1-3) lifetime sexual partners. At enrollment, median CD4 among PHIVA was 593 (392-808) cells/mm^3, and 62% had HIV-RNA < 40 copies/mL. HRVS-7 genotypes were found in 43 (46%) PHIVA and 39 (39%) controls (P=0.3). NAb were detected in 19 (22%) PHIVA and 26 (28%) controls (P=0.3). For the complete cohort, 20/33 (61%) adolescents 13-16 years, 50/105 (48%) 17-19 years, and 28/54 (52%) 20-24 years were positive for HRVS-7 DNA or NAb. A history of ≥3 lifetime partners (vs. 1; OR 3.34 [1.59-7.04]), and having any non-HPV STI (OR 3.39 [1.56-7.39]) were independently associated with increased risk of infection with an HRVS-7 genotype. Among PHIVA, HIV-RNA >40 copies/mL and having any non-HPV STI were independently associated with increased risk of infection with HRVS-7.
Conclusions: Half of Asian PHIVA and HIV-uninfected female adolescents in our cohort had high-risk HPV infection. Greater access to HPV vaccination is needed in the region to reduce future HPV-related cancer risk.

Hepatitis C care cascade for people living with HIV in the country of Georgia

N. Chkhartishvili[1], A. Abutidze[1], N. Bolokadze[1], O. Chokoshvili[1], N. Dvali[1], L. Sharvadze[1,2], T. Tsertsvadze[1,2]

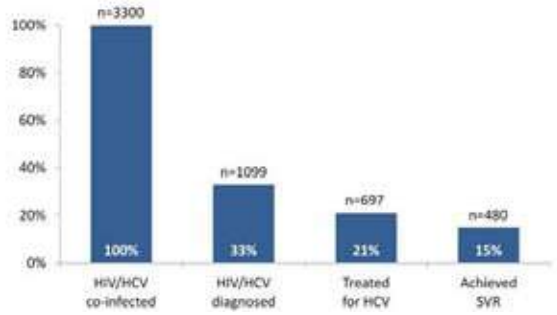
Presenting author email: nikoloch@yahoo.com

Background: Georgia made significant progress in addressing high burden of hepatitis C virus (HCV) infection among people living with human immunodeficiency virus (HIV). During 2011-2015 with the support of the Global Fund HIV positive persons in Georgia had access to free HCV treatment with pegilated interferon and ribavirin (PEG/RBV). In April 2015 in partnership with the U.S. CDC and Gilead Sciences the country launched a national hepatitis C elimination program, which provides free treatment with modern direct acting antivirals (DAAs).
Methods: The following steps of HCV care cascade were quantified:
1) HIV/HCV co-infected,
2) Diagnosed for both HIV and HCV,
3) treated for HCV infection,

4) achieved sustained virologic response (SVR).
Number of HIV/HCV co-infected persons was estimated using modeling and observed HCV prevalence. Data on diagnosed persons were extracted from the national AIDS health information system as of September 1, 2016.
Results: Among estimated 3300 persons living with HIV/HCV co-infection in Georgia, 2201 (67%) were not aware of their HIV status and 1099 (33%) were diagnosed both with HIV and HCV. Of those 1099 diagnosed persons 697 (63%) were treated for hepatitis C with either PEG/RBV or DAA-based regimen. 480 (69%) of those treated achieved SVR. Rates of SVR were 44% with PEG/RBV and 89% with DAA. Overall, because of gap in diagnosis stage only 15% of estimated number of HIV/HCV co-infected persons were cured.



[Hepatitis C care cascade]

Conclusions: The major gap in the HCV care cascade is at the stage of diagnosis resulting from deficiencies in HIV diagnosis. Reducing the number of people living with undiagnosed HIV/HCV co-infection will be critical for achieving population level impact of free HCV treatment program.

MOAB0302

Trends in cause-specific mortality in HIV-hepatitis C (HCV) co-infected patients in Canada (2003-2016): early impact of HCV therapy

N. Kronfli[1], S.R. Bhatnagar[2], M. Hull[3], E. Moodie[2], C. Cooper[4], N. Pick[3], S. Walmsley[5], M.-L. Vachon[6], V. Martel-Leferriere[7], J. Gill[8], M. Klein[1], on behalf of the Canadian Co-Infection Cohort Investigators
[1]McGill University Health Centre, Montreal, Canada, [2]McGill University, Epidemiology, Biostatistics & Occupational Health, Montreal, Canada, [3]University of British Columbia, Medicine, Vancouver, Canada, [4]Ottawa Hospital Research Institute, Ottawa, Canada, [5]Toronto General Research Institute, Toronto, Canada, [6]Universite de Laval, Laval, Canada, [7]Universite de Montreal, Montreal, Canada, [8]University of Calgary, Calgary, Canada
Presenting author email: nadine.kronfli@medportal.ca

Background: Hepatitis C treatment and an aging population may contribute to shifts in mortality, allowing other causes of death to emerge. We aimed to examine cause-specific mortality among HIV-HCV co-infected patients, evaluating changes in mortality trends over time.
Methods: The Canadian Co-infection Cohort is a prospective multicentre cohort of 1695 co-infected patients from 19 sites in Canada. All reported deaths, classified using a modified "Coding of Cause of Death in HIV" (CoDe) protocol, were analyzed from April 2003 to July 2016. Event rates per 1000 person-years before (2003-2009) and after (2010-2016) the availability of effective treatment stratified by age (20-50; 50-80) were calculated. Comparison of trends between periods was performed using Poisson regression. Multinomial regression was used to estimate the cause-specific hazard ratios (HR) and 95% confidence intervals (CIs) of time and age on cause of death.
Results: Overall, 1477 participants (72% men) contributed 6675 person-years of follow-up. Of the 203 (14%) patients who died (152 with assigned causes), end-stage liver disease (ESLD; 20%), smoking-related (17%) and drug overdose (16%) were the most common causes of death. All cause mortality decreased in both age groups over time (Table 1), while HCV treatment increased 2.8 times. Deaths due to ESLD declined by approximately 2-fold and were no longer the most common cause of death in the 2010-2016 time period for either age category. In contrast, smoking-related deaths increased with time and, among those aged 50-80, accounted for the greatest proportion of deaths from 2010-2016 (cause-specific HR 2.8; 95% CI, 1.5 - 5.4). Drug overdose accounted for the greatest proportion of deaths among individuals aged 20-50 from 2010-2016.
Conclusions: Increased HCV treatment uptake has coincided with decreased liver-specific mortality in HIV-HCV co-infected patients. However, these gains may be thwarted if modifiable risk factors (tobacco and drug use) are not addressed.

Outcome	Age	2003-2009	2010-2016
All cause	20-50	26.04 (13.91, 48.75)	19.29 (11.59, 32.11)

Presenting author email: karine.lacombe@sat.ap

Background: Pangenotypic, once-daily glecaprevir (identified by AbbVie and Enanta)/pibrentasvir (G/P) has demonstrated high rates of sustained virologic response at 12 weeks post-treatment (SVR12) in patients with hepatitis C virus (HCV) genotype (GT) 1-6 infection.
This phase 3 study evaluated the efficacy and safety of G/P in patients with chronic HCV GT1-6 infection and HIV-1 co-infection, including patients with compensated cirrhosis.
Methods: EXPEDITION-2 (NCT02738138) is a phase 3, multicenter, open-label study evaluating G/P (300 mg/120 mg) treatment in HCV/HIV-1 co-infected adults without or with compensated cirrhosis for 8 or 12 weeks, respectively. Patients were either HCV treatment-naïve or experienced with interferon (IFN), pegylated IFN ± ribavirin, or sofosbuvir + ribavirin ± pegylated IFN. GT3 treatment-experienced patients were excluded. The primary endpoint was the proportion of patients with sustained virologic response (HCV RNA < lower limit of quantification) 12 weeks post-treatment (SVR12).
Results: In total, 153 patients were enrolled, including 16 (10%) with cirrhosis. Baseline demographics are shown in **Table 1**. In patients with available data, rates of response at end of treatment and post-treatment week 4 were 98.7% (151/153) and 98.6% (144/146) respectively. To date, there is one (1/153; 0.65%) virologic failure: a breakthrough in a patient with GT3a infection and cirrhosis. The most common adverse events (AEs) were fatigue (16/153; 10%) and nausea (13/153; 8%).

Three patients (2%) had serious AEs, and one serious AE of stroke led to treatment discontinuation on Day 23 in one patient with cirrhosis; all were unrelated to G/P. All patients maintained HIV-1 suppression (< 200 copies/mL) during treatment.

Characteristic	Without Cirrhosis 8 Weeks N = 137	With Cirrhosis 12 Weeks N = 16
Male, n (%)	113 (83)	15 (94)
Genotype 1/2/3/4/5/6, n	84/12/22/16/0/3	10/1/4/1/0/0
Age, median (range), years	45 (23-74)	50 (35-62)
HCV treatment-experienced	26 (19)	2 (13)
HCV RNA, media (range), log_{10} IU/milliliter	6.2 (4.0-7.4)	6.1 (4.4-7.0)
Antiretroviral therapy-naive	9/137 (7)	0
Raltegravir anchor ARV, n (%)	39 (29)	6 (38)
Dolutegravir anchor ARV, n (%)	62 (45)	5 (31)
Rilpivirine anchor ARV, n (%)	27 (20	5 (31)
CD4+ cell count ≥500 cells/mm^3, n (%)	92 (67)	9 (56)

[Table 1. Baseline Demographics & Disease Characteristics]

Conclusions: G/P for 8 weeks in non-cirrhotic and 12 weeks in cirrhotic patients is a well-tolerated and highly efficacious pangenotypic treatment for HCV/HIV-1 co-infection, regardless of baseline HCV RNA or treatment experience. Full SVR12 rates and prevalence of baseline NS3 and NS5A polymorphisms will be presented.

Background: Metabolic syndrome (MetS) has become a common finding in HIV-infected patients. However the severity, risk factors and pathogenesis of liver fibrosis in this population have been poorly documented.
From a matched cohort of HIV-monoinfected patients with and without MetS, this study aimed 1) to assess the impact of MetS on the prevalence and severity of liver fibrosis and 2) to analyze the association between liver fibrosis and markers of adipose tissue, insulin resistance and macrophage activation.
Methods: Patients with immune-controlled HIV-1 infection under antiviral therapy (ART) were enrolled in the following exposed-unexposed study. The exposure was defined by the presence of MetS according to international criteria after exclusion of all other causes of chronic liver disease. Fibrosis was assessed using transient elastography (Fibroscan). Adipokines, HOMA index and soluble CD163 and CD14 were measured as markers of fat mass, insulin resistance and macrophage/monocyte activation, respectively.
Results: 468 HIV-monoinfected individuals were enrolled (male (89%), mean age 53 (9) years, mean BMI 24.6 (5.3) kg/m^2); 246 with MetS and 222 without MetS. Patients with MetS were older and 49% of them had insulin resistance i.e HOMA-IR≥2.5 (compared to 8.5% in patients without MetS). The mean value (SD) of LSM was 5.6 (2.2) kPa with a minimum and maximum value of 2.4 and 17.1 kPa. Mean LSM was higher in patients with MetS compared to those without MetS [6.3 (2.6) versus 4.9 (1.5) kPa, p<0.0001]. In multivariable analysis, obesity (OR: 3.9 (IC95% 2.1-7.1)) and insulin resistance (1.1 (1.06-1.2)) were independent factors of significant fibrosis (≥F2) and remained associated after adjustment on MetS. Serum levels of adipokines and sCD163 were significantly associated with the degree of liver fibrosis. When adjusted on MetS leptin and sCD163 remained strongly associated to fibrosis. HIV parameters and ART regimen were not associated fibrosis.
Conclusions: In HIV-monoinfected patients, MetS is an important risk factor of liver fibrosis. Obesity and insulin resistance are key factors in the development of liver fibrosis independently of HIV infection parameters. Adipose tissue and macrophage activation certainly play an important role in the development of fibrosis in HIV monoinfected patients but the exact mechanisms need to be elucidated.

MOAB0305

Predictor factors associated with liver fibrosis and steatosis by transient elastography in HIV-monoinfected patients under long-term combined antiretroviral therapy: the PROSPEC-HIV study

H. Perazzo Pedroso Barbosa, S. Cardoso, C. Yanavich, J.C. Soares, J. Fittipaldi, M. Morata, C. Cardoso, P. Simplicio, C. De Almeida, V. Veloso, B. Grinsztejn

Presenting author email: perazzohugo@gmail.com

Background: Liver disease remains one of the main causes of non-AIDS mortality in HIV-infected individuals. Transient elastography (TE) is an accurate imaging method to estimate liver fibrosis and steatosis. We aimed to evaluate the risk factors associated with liver fibrosis and steatosis in HIV mono-infected patients under long-term combined-antiretroviral therapy (c-ART).
Methods: This cross-sectional study prospectively included HIV-infected adult patients under c-ART (PROSPEC-HIV; NCT02542020). Liver stiffness measurement (LSM) and Controlled Attenuation Parameter (CAP) by TE were used to estimate liver fibrosis and steatosis, respectively. Exclusion criteria were hepatitis coinfection and c-ART naïve. Patients with an unreliable M probe LSM or CAP were excluded from the liver fibrosis and steatosis analyses, respectively. Clinical evaluation, fasting blood tests and TE were performed at the same day. TE exams were performed by a single experimented operator blinded to clinical and laboratory data. Metabolic factors were defined according to the International Diabetes Federation criteria. Alcohol consumption was quantified using the AUDIT score. Presence of liver fibrosis and steatosis were considered when LSM ≥ 8.0kPa and CAP ≥250dB/m, respectively. Age and gender-adjusted multivariate logistic regression was performed.
Results: A total of 348 HIV mono-infected patients [61% female, median (IQR) age=44 (34-52) years, BMI=25.4 (23.0-29.3) kg/m^2] were included. Median (IQR) time under c-ART and under the current c-ART regimen were 7.3 (4.1-12.8) and 4.3 (1.9-7.5) years, respectively. LSM and CAP were unreliable in 6% and 12%. Liver fibrosis and steatosis prevalence were 9% (n=30/326) and 33% (n=102/305). In age and gender adjusted multivariate analysis, factors associated [OR (95%CI)] with liver fibrosis were: age >45 years [2.91 (1.19-7.15); p=0.020]; CD4 count <200 cells [5.00 (1.38-18.21); p=0.014] and type-2 diabetes [3.04 (0.97-9.55); p=0.056]. Male gender [5.69 (2.68-12.04); p<0.001]; dyslipidemia [2.86 (1.46-5.60); p=0.002]; type 2 diabetes [6.00 (2.08-17.28); p=0.001] and central obesity [10.24 (4.11-25.50); p<0.001] were independently associated with liver steatosis.
Conclusions: Non-communicable diseases (NCD) can play a major role in the development of liver fibrosis and steatosis. NCD prevention and care services need to be integrated to HIV care to decrease the burden of hepatic events in HIV-infected individuals.

MOAB04 Tuberculosis in a Time of HIV

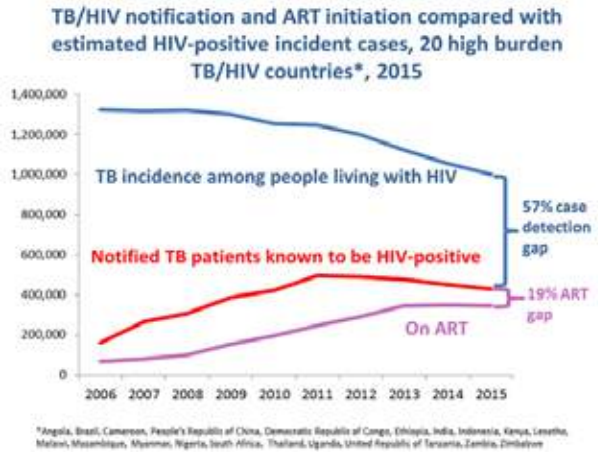
MOAB0401

Gaps and opportunities in policy and practice in 20 countries with the highest burden of HIV-associated TB

A. Baddeley[1], M. Doherty[2], A. Kanchar[1], Y. Hamada[1], H. Getahun[1]
[1]World Health Organization, Global TB Programme, Geneva, Switzerland, [2]World Health Organization, Department of HIV/AIDS & Global Hepatitis Programme, Geneva, Switzerland
Presenting author email: baddeleya@who.int

Background: Despite impressive scale-up of collaborative TB/HIV activities since 2004, TB is still the major cause of morbidity and mortality among people living with HIV (PLHIV). In June 2016 Member States adopted the UN Political Declaration on HIV and AIDS, including a target to reduce TB deaths among PLHIV by 75% by 2020. In order to achieve this, gaps in policy, implementation, and recording and reporting need to be identified and urgently addressed.
Methods: 20 countries were selected with the highest estimated burden of HIV-positive incident TB in 2015. Data on collaborative TB/HIV activities were extracted from the Global TB Programme Database and the UNAIDS online GARPR tool, and trends and progress analysed. Reviews were further conducted of the latest available policy documents, programme reviews, epidemiological assessments, Global Fund Concept Notes and GARPR reports to identify gaps and opportunities in policy and implementation.
Results: Cascade analysis revealed a 57% gap in notification of TB patients living with HIV, compared with estimated cases, and a 19% gap of ART started among notified HIV-positive TB patients (Figure 1). Half of countries did not report Isoniazid

preventive therapy (IPT). Case fatality among TB patients living with HIV was at least 3 times higher than HIV-negative TB patients in seven reporting countries. Document review revealed the following gaps and barriers: misalignment of policies on ART and IPT; poorly implemented TB screening and IPT; centralized or underuse of Xpert MTB/RIF; centralized ART provision; stock-outs in IPT, HIV testing kits and ART; and separate planning, supervision, health management information systems, and procurement and supply.
Conclusions: Considerable gaps and opportunities were identified in this analysis. Countries need to seek ways to resolve barriers, be they policy, implementation or health system-related to ensure access to evidence-based HIV-associated TB care and to end HIV-related deaths from this preventable disease.



[Figure 1]

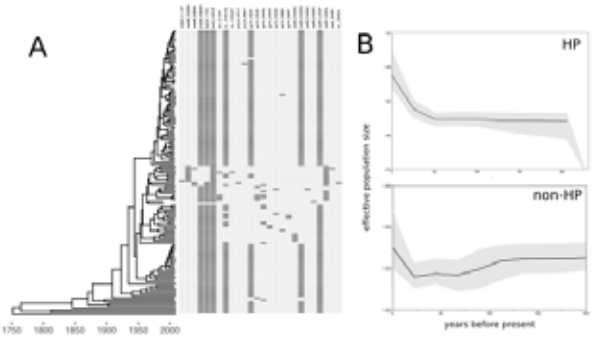
Presenting author email: tsb2126@columbia.edu

Background: Extensively drug-resistant tuberculosis (XDR-TB) has emerged over the last decade as a significant public health threat worldwide, particularly among people with HIV. South Africa first reported XDR-TB in 2005 and now has among the highest burden of XDR-TB worldwide, with >1000 cases diagnosed in 2015. The bacterial evolutionary determinants behind the rise of XDR-TB in South Africa are not well understood.
Methods: We enrolled persons with newly-diagnosed, culture-confirmed XDR-TB from 2011-2014 in KwaZulu-Natal province and performed whole genome sequencing of their Mycobacterium tuberculosis (Mtb) isolates. Lineage 4 isolates were selected for phylogenetic reconstruction, dating of drug-resistance mutations, and estimates of prior demographic history using Bayesian Markov chain Monte Carlo Methods (BEAST v1.8.3).
Results: Among 160 participants with XDR Mtb isolates included in this analysis, 127 (79%) were HIV co-infected. Half (51%) of XDR-TB cases were attributable to a single predominant clade of highly monomorphic isolates (Restriction Fragment Length Polymorphism type HP). There were no significant differences between the proportion of participants with HIV or with CD4 counts < 200 cells/µl in the HP vs. non-HP isolates. Both HP and non-HP Mtb populations exhibit evidence of rapid population expansion beginning 25-30 years ago (Figure, B). The emergence of key drug resistance mutations occurred near the historical dates of introduction for their corresponding antibiotics (Figure, A).



[IAS1]

(A) Dated phylogenetic tree for HP isolates annotated with known drug resistance mutations; (B) Bayesian Skyline reconstruction for HP and non-HP isolates
Conclusions: Mtb isolates from the predominant HP clade and from less prevalent XDR-TB strains underwent demographic expansion following the onset of the HIV epidemic in South Africa. Endemic strains in KwaZulu-Natal acquired drug resistance mutations across diverse strain groups and genetic backgrounds, corresponding to the introduction of new antituberculosis medications. The impact of HIV coinfection on pathoadaptive evolution in Mtb remains an important area for further investigation.

Presenting author email: boris_2022@yahoo.fr

Background: Despite evidence that isoniazid preventive therapy (IPT) reduces tuberculosis incidence and mortality, its uptake remains very limited in West Africa. Our objective was to assess tuberculosis incidence during the first year of antiretroviral therapy (ART) and identify associated factors in HIV-infected adults in West Africa to support policy decisions in these countries.
Methods: We conducted a retrospective observational cohort analysis using data collected in three HIV outpatient centers from Côte d'Ivoire, Burkina Faso, and Senegal participating in the IeDEA West Africa Collaboration. We included HIV-infected adults (≥16 years) initiating ART between 2010 and 2014, without tuberculosis diagnosis at ART initiation and with ≥1 follow-up visit. None of them received IPT. Tuberculosis new diagnoses were documented according to national recommendations. We analyzed incidence of tuberculosis and identified associated factors using Poisson regression models.
Results: Of 4,154 patients who started on ART, 3,404 had ≥1 follow-up visit after ART initiation. Of those, 191 (5.6%) had ongoing tuberculosis at ART initiation. Thus, we enrolled 3,213 patients in our analysis. Median age was 38.5 (IQR 32.0-45.4) years, 67.1% were female, and median CD4 count at ART initiation was 211 (IQR 95-343) cells/mm^3. Overall 170 new tuberculosis cases were reported for 2,360.5 person years (PY) at risk. The crude tuberculosis incidence rate during the first year on ART was 7.2 (95% CI 6.12-8.28) cases per 100 PY. The adjusted tuberculosis incidence rate was 1.42 (95% CI 0.55-3.20) per 100 PY in women, aged 16-30 years, without prior tuberculosis history, with CD4 ≥500 cells/mm3, and hemoglobin ≥11 g/dL, followed in Burkina-Faso. A higher tuberculosis risk was significantly associated with male gender (RR 1.87; 95% CI 1.28-2.74), previous history of TB (RR 4.22; 95% CI 2.70-6.42), hemoglobin < 9 g/dL (RR 2.26; 95% CI 1.61-4.31) and follow-up in Côte d'Ivoire (RR 4.32; 95% CI 2.90-6.50).
Conclusions: Tuberculosis incidence remains high during the first year on ART in the West African context in the absence of IPT. It is crucial to reinforce implementation of IPT in all HIV-infected adults starting ART especially in this part of the world.

MOAB0404

Time to treatment initiation for drug-resistant tuberculosis is delayed in a South African prospective cohort

B.J. Sullivan[1,2], J. Prvu Bettger[1,2,3], S. Silva[1], J. Humphreys[1], C.K. Cunningham[2,4], J.E. Farley[5]
[1]Duke University, School of Nursing, Durham, United States, [2]Duke Global Health Institute, Durham, United States, [3]Duke University School of Medicine, Orthopaedic Surgery, Durham, United States, [4]Duke University, School of Medicine, Department of Pediatrics, Durham, United States, [5]Johns Hopkins University, School of Nursing, Baltimore, United States
Presenting author email: brittney.sullivan@duke.edu

Background: Drug-resistant tuberculosis (DR-TB) is a growing threat to TB management and elimination globally. Early initiation of DR-TB treatment is critical to successful treatment outcomes (cure) and to prevent transmission. The South African National TB Program (NTP) recommends initiating treatment within five days of diagnosis. This study examined time to treatment initiation and its relationship with patient age among a prospective cohort of individuals living with DR-TB in South Africa.
Methods: Patients included subjects, age 13 years or older, enrolled in a DR-TB cluster-randomized trial in two South African provinces. Outcomes were treatment initiation within five days of DR-TB diagnosis and days from diagnosis to treatment initiation. Hierarchical mixed-effects models were employed to examine the association between age and these outcomes, adjusted for patient (sex, TB history, HIV coinfection) and site (rural/urban, province) characteristics and random effects of treatment center.
Results: Of 521 patients, there were 55% male, 75% with HIV coinfection, and 53% with prior history of TB. Only 82 patients (16%) received DR-TB treatment within five days of diagnosis. The median time to treatment was 11 days (range=0 to 180). Age was not associated with treatment initiation within five days (F=0.07, df=1,495, p=0.794) or days to treatment initiation (F=1.42, df=1,489, p=0.233). Individuals coinfected with HIV tended to have a greater likelihood of receiving treatment within five days relative to those without coinfection (17% vs 12%, p=0.104; Odds Ratio=1.749, 95% Confidence Interval=0.891-3.433).
Conclusions: Delays in DR-TB treatment increase harm to the patient and risk of disease spread. Only one in six patients with DR-TB received treatment within five days of being diagnosed as recommended by South African NTP guidelines. Further research is needed to examine what modifiable factors decrease treatment delay and how to most effectively implement treatment guidelines.

MOAB0405

High uptake of antiretroviral therapy among HIV-positive TB patients receiving co-located services in Swaziland

I. Pathmanathan[1], M. Pasipamire[2], S. Pals[1], E.K. Dokubo[1], P. Preko[3], T. Ao[3], S. Mazibuko[2], J. Ongole[4], S. Haumba[4]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]Ministry of Health, Swaziland, Swaziland National AIDS Programme, Mbabane, Swaziland, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Mbabane, Swaziland, [4]University Research Co, LLC, Mbabane, Swaziland
Presenting author email: ydi6@cdc.gov

Background: Swaziland has the highest adult HIV prevalence, the third highest tuberculosis (TB) incidence, and the highest rate of TB/HIV coinfection globally. In recent years, the Ministry of Health and partners have increased integration and co-location of TB and HIV services, but the timing of antiretroviral therapy (ART) initiation relative to TB treatment - a marker of program quality and predictor of outcomes - is unknown.
Methods: We conducted a retrospective review of programmatic data from 11 purposefully-sampled facilities to evaluate provision of timely ART for adult (≥15 years) HIV-positive TB patients seen and retained in care between July and September 2014. Timely ART was defined as initiated within two weeks of TB treatment initiation for patients with CD4< 50/µL or missing, and within eight weeks for others. Descriptive statistics were estimated and logistic regression was used to assess factors independently associated with timely ART.
Results: Of 466 HIV-positive TB patients, 51.5% were male, median age was 35 (interquartile range [IQR]: 29-42), and median CD4 was 137/µL (IQR: 58-268). 189 (40.6%) were on ART prior to, and five (1.8%) did not receive ART within, six months of TB treatment initiation. Median time to ART initiation after TB treatment initiation was 15 days (IQR: 14-28). Almost 90% started ART within eight weeks. 25 of 55 patients (45.5%) with CD4< 50/µL started within two weeks. Of 44 (16.1%) patients without a documented CD4, 47.7% began ART within two weeks, and 93.2% within eight. Patients with CD4 50-200/µL or ≥200/µL had significantly higher odds of receiving timely ART than patients with CD4< 50/µL, with adjusted odds ratios of 11.3 (95% confidence interval [CI]: 5.0-25.8) and 10.38 (95% CI: 4.89-22.03), respectively. 71.2% achieved TB cure or treatment completion at six months, but this was not associated with timely ART.
Conclusions: This study demonstrates the relative success of integrated and co-located TB/HIV services in Swaziland and shows that very high levels of timely ART uptake for HIV-positive TB patients can be achieved in integrated but resource-limited TB/HIV settings. However, gaps remain in getting patients with CD4< 50/µL to receive ART within the recommended two weeks post TB treatment initiation.

MOAB0406

Feasibility of using determine-TB LAM test in HIV-infected adults in programmatic conditions

S.C. Mathabire[1,2], L. Cossa[3], J. Mpunga[4], I. Manhiça[5], I. Amoros Quiles[6], L. Molfino[3], E. Szumilin[7], O. Telnov[8], H. Huerga[1]
[1]Epicentre, Clinical Research Department, Paris, France, [2]Medecins Sans Frontieres, Chiradzulu, Malawi, [3]Medecins Sans Frontieres, Maputo, Mozambique, [4]National TB Control Program (MoH), Lilongwe, Malawi, [5]National TB Program, Maputo, Mozambique, [6]Medecins Sans Frontieres, Lilongwe, Mozambique, [7]Medecins Sans Frontieres, Paris, France, [8]Medecins Sans Frontieres, Geneva, Switzerland
Presenting author email: chenai.mathabire@epicentre.msf.org

Background: We assessed the feasibility and described the operational aspects of using the Determine-TB LAM (LAM) test for diagnosis of tuberculosis (TB) in adult HIV infected patients.
Methods: This multi-centric study was conducted in Malawi and Mozambique from 2014 to 2016. LAM was used as a rule in screening tool for hospitalized adult HIV infected patients (Malawi) and for ambulatory patients with CD4 < 100 /µl (Mozambique), and as an additional diagnostic tool for adult HIV infected TB suspects with CD4 < 200 /µl (Malawi and Mozambique). Standard questionnaires were used to assess user acceptability of LAM; electronic databases used to calculate reader agreement between LAM users, and health centre registers to calculate workload. Supervision notes, minutes of meetings, training reports, and personal observations were used to assess training required, patient flow changes after LAM introduction, strengths and challenges of using the LAM test.
Results: Training of LAM users was performed in approximately 1.5 hours in Malawi and 4 hours in Mozambique. All users found the test easy to perform. Reader agreement for test interpretation was excellent: 98.9%, kappa=0.97, and 98.3%, kappa=0.94 for Malawi and Mozambique respectively. Time to results when LAM was performed in the consultation room was 2 to 7 times lower than when performed in the laboratory. LAM positive patients were started on TB treatment on same day. Introduction of LAM did not require additional space or staff. Strength of LAM was that overall, 98.7% and 99.6% of patients received a LAM result compared to 69.5% and 67.2% receiving a sputum result, and 31.7% and 46.0% receiving a chest X ray result in Malawi and Mozambique respectively. A challenge in Mozambique was the need for CD4 prior to the LAM test to identify LAM eligible patients.
Conclusions: Using the LAM test to diagnose TB among hospitalized or severely immune-suppressed ambulatory HIV patients was feasible, well accepted, and required minimal training. The LAM was a useful additional test for TB in this group because of the ease of providing the urine sample and the rapidity of the results which allowed immediate TB treatment for LAM positive patients.

MOAD01 What's Different about Differentiated Care and Service Delivery?

MOAD0101

Readiness for antiretroviral therapy: implications for linking HIV-infected individuals to care and treatment

B. Maughan-Brown[1], P. Smith[2], C. Kuo[3], A. Harrison[3], M. Lurie[4], L.-G. Bekker[2], O. Galárraga[5]
[1]Southern Africa Labour and Development Research Unit (SALDRU), University of Cape Town, Cape Town, South Africa, [2]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [3]Department of Behavioral and Social Sciences, Brown University School of Public Health, Providence, United States, [4]Department of Epidemiology, Brown University School of Public Health, Providence, United States, [5]Department of Health Services, Policy & Practice (HSPP), Brown University School of Public Health, Providence, United States
Presenting author email: brendan.maughanbrown@gmail.com

Background: ART readiness is a key predictor of ART initiation. However, there is a paucity of data on ART readiness among individuals at the time of HIV-diagnosis and ART eligibility assessment. Under a test-and-treat approach, understanding

factors associated with ART readiness can inform strategies to support early engagement in care and thereby maximize the benefits of ART. This study examined demographic and psychosocial factors associated with ART readiness and potential barriers to linkage to care among individuals referred for treatment from a mobile health clinic.
Methods: Between April 2015 and May 2016, 87 individuals (18 years and older) in a resource-limited setting in Cape Town, South Africa, completed a face-to-face survey immediately after referral for ART. ART readiness was assessed using key components of this concept identified in the literature (1) an awareness that treatment will be beneficial; (2) motivation to initiate treatment; and (3) the intention to start treatment soon. Multiple logistic regression analysis, controlling for age, gender and education, identified factors associated with ART readiness.
Results: Most participants were very ready (84%) and motivated (85%) to start ART, but 28% reported some uncertainty regarding ART initiation. Treatment readiness was lower among those surprised by their diagnosis (aOR:0.26,p< 0.05) and among healthier individuals (aOR:0.44,p< 0.01). In contrast, higher readiness was associated with better ART knowledge (aOR:4.31,p< 0.05) and knowing someone who had experienced positive health effects from ART (aOR:2.65,p< 0.05). The three most common self-reported barriers to linking to care were: (1) not wanting to be seen at the clinic (31%); (2) no money for transport (29%); and (3) not being able to get time off work (20%).
Conclusions: Results indicate that post-test counselling will need to be designed to deal with surprise at HIV diagnosis, and that health messaging needs to be carefully crafted for HIV-positive but healthy individuals to improve ART readiness and to increase likelihood of further linkage to treatment and care. Further research is needed on effective post-test counselling approaches (e.g., motivational-interviewing) and effective framing of health messaging to increase awareness of the positive benefits of early ART initiation and corresponding motivation to engage in treatment.

MOAD0102

Factors associated with loss to follow-up in a primary healthcare HIV clinic practising test and treat

J. Kiwanuka[1,2], N. Kiwanuka[3], F. Matovu Kiweewa[3], J. Gonzalez Perez[4], J. Kitonsa[2,5], J. Waila Mukulu[6]
[1]AIDS Healthcare Foundation, M&E, Kampala, Uganda, [2]Makerere University School of Public Health, Kampala, Uganda, [3]Makerere University School of Public Health, Epidemiology and Biostatics, Kampala, Uganda, [4]AIDS Healthcare Foundation, Kigali, Rwanda, [5]Medical Research Council-Uganda Virus Research Institute, Masaka, Uganda, [6]Makere University School of Public Health, Kampala, Uganda
Presenting author email: jkiwanuka74@gmail.com

Background: World health organisation (WHO) currently recommends all people diagnosed HIV positive to start antiretroviral therapy instantly (T&T) regardless of CD4 cell count and WHO stage. Currently however, a myriad of HIV treatment programs are plagued with the challenge of patients' loss to follow up. We set out to study factors associated with loss to follow up (LTFU) in a primary healthcare facility practising T&T.
Methods: We retrospectively drew and analysed a sample of patients from routine patients' data for HIV clients enrolled into HIV care from January 2012 to December 2014 at Masaka regional referral hospital -Uganda Cares clinic. We defined loss to follow up as failure of the client to show up at the Masaka clinic for at least 91 days from the date of their last appointment taking 31st December 2014 as the reference. We determined cumulative incidence of loss to follow up at differing time intervals and used multivariable cox proportional hazards regression model to determine factors associated with time to LTFU.
Results: We included 600 patients in the sample, 64.7% were females and the median (IQR) age at enrollment of 30.4 (23.8-37.1). The median (IQR) CD4 cell count at start of ART was 373 (204-570), and 15.2% were in WHO stage 3 or 4. By 31st December 2014, 55 cases of LTFU were observed, and the cumulative incidence of LTFU was 8.48% (95% CI=6.26-11.12) at 12 months into HIV care. In multivariable analysis, T&T (aHR=2.49, 95% CI=1.07-5.78), WHO stage 3&4 (aHR=3.78, 95% CI=1.70-8.41) TB suspect (aHR=3.42, 95% CI=1.19-9.81) were associated with an elevated risk of LTFU; whereas access to mobile phone (aHR=0.56, 95% CI=0.36-0.88) duration on ART 1-3 months (aHR=0.21, 95% CI=0.08-0.59), 3-6 months (aHR=0.03, 95% CI=0.01-0.11) and ≥6months (aHR=0.003, 95% CI=0.001-0.01) were independently associated with reduced risk of LTFU.
Conclusions: This study identified testing and initiating on ART instantly being associated with elevated risk of LTFU and as well TB suspicion and advanced disease at enrolment. In a bid to achieve the 90-90-90 campaign therefore, steep ART initiation should be backed by intensive pre-initiation and adherence counseling for better long term retention of patients.

MOAD0103

Pilot study of a multi-pronged intervention using social norms and priming to improve adherence to antiretroviral therapy and retention in care among adults living with HIV in Tanzania

Background: Interventions incorporating insights from behavioral economics and psychology have been successfully used in the private sector and have the potential to enhance HIV ‚treatment as prevention' (TasP). This approach recognizes that decisions are influenced by emotions, contexts, and decision-making shortcuts outside of conscious awareness. To test this hypothesis, we evaluated an intervention to improve antiretroviral therapy (ART) adherence and retention in care based on concepts of social norms and priming.
Methods: We used patient-centered design to develop a combination intervention using social norms and priming, which is when a stimulus subconsciously or indirectly influences another behavior. The intervention included visual feedback about clinic-level retention in care (social norms), a self-relevant prime, and useful take-home items with the priming image (calendar, pill box). The intervention was implemented at two HIV primary clinics in Shinyanga, Tanzania in 2-week intervals for six months.
We conducted a quasi-experimental pilot study (Clinicaltrials.gov: NCT02938533) by reviewing the medical records of a random sample of 438 adult patients living with HIV infection (PLHIV, 320 exposed and 118 unexposed) to compare retention and the proportion of patients achieving a medication possession ratio (MPR) ≥95% after six months. Intervention acceptability was determined through an in-person survey with a convenience sample of 405 PLHIV at baseline (n=189) and endline (n=216).
Results: In adjusted analyses, PLHIV exposed to the intervention were significantly more likely to be in care after 6 months (87% vs. 79%, adjusted odds ratio (OR_a)=1.73, 95% CI: 1.08, 2.78, p<0.05) and were more likely to achieve MPR≥95% (70% vs. 59%, OR=1.51, 95% CI: 0.96, 2.37, p=0.07). The intervention was associated with increases in staff support of treatment goals (100% vs. 95%, p=0.01) and life goals (66% vs. 50%, p<0.01), the perceived likelihood of other patients' adherence (54% vs. 32%, p<0.01), support from other patients (71% vs. 60%, p=0.03), and being very satisfied with care (53% vs. 35%, p< 0.01).
Conclusions: This novel intervention has the potential to improve the clinic experience, short-term retention in care, and ART adherence. Future studies are needed to expand the generalizability of the approach and evaluate effectiveness on clinical outcomes.

MOAD0104

Multi-month refills of antiretroviral drugs for stable patients in Malawi: assessing accuracy in the application of eligibility criteria at the health facility level

M. Prust[1], C. Banda[2], R. Nyirenda[3], F. Chimbwandira[3], T. Kalua[3], A. Jahn[4], M. Eliya[3], K. Callahan[5], P. Ehrenkranz[6], M. Prescott[7], E. McCarthy[7], E. Tagar[5], A. Gunda[2]
[1]Clinton Health Access Initiative, Applied Analytics Team, Boston, United States, [2]Cli, Lilongwe, Malawi, [3]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [4]Ministry of Health / I-TECH Department of Global Health, Department of HIV and AIDS, Lilongwe, Malawi, [5]Cli, HIV, TB and Health Financing Team, New York, United States, [6]Bill & Melinda Gates Foundation, Seattle, United States, [7]Cli, Applied Analytics Team, Boston, United States
Presenting author email: mprust@clintonhealthaccess.org

Background: The provision of three-month antiretroviral (ARV) refills, or multi-month scripting (MMS), for stable HIV patients on antiretroviral therapy (ART) can increase service efficiency and decrease congestion. Since 2008, Malawi has offered MMS to patients that are 18 years or older, have been on ART at least six months, are on first-line ART, have no adverse drug reactions or opportunistic infections, have a viral load less than 1000 copies/mL, and have good adherence according to pill counts. We assessed the extent to which patients are accurately differentiated as eligible or ineligible for MMS and explored potential causes of inaccurate patient differentiation.
Methods: Data were collected from 30 purposefully selected ART facilities in 2016. Participation and eligibility for MMS were determined based on 75,364 patient clinical records, which were analyzed using Stata version 13. Results were weighted and clustered by facility. The reasons for inaccurate patient differentia-

tion were explored using structured surveys with 136 health workers and 32 qualitative interviews with clinic management. Interviews were audio recorded, transcribed and thematically coded.
Results: A majority of patients (86.4%, 95% confidence interval [CI] 84.0-88.6) were eligible and 68.7% of patients (95% CI 62.5-74.6) were receiving MMS. Among patients eligible for MMS, 72.9% (95% CI 66.3-78.6) received MMS. However, 42.3% (95% CI 33.1-52.0) of ineligible patients (amounting to 5.7% of all patients) also received MMS. Results were similar based on sensitivity analyses using different eligibility criteria scenarios, but variation in the application of criteria existed across facilities. Among ineligible patients receiving MMS, 77% had viral load greater than 1000 copies/mL, and 39% had been on ART less than six months. Inaccurate patient differentiation was suggested to result from lack of health worker knowledge of the criteria for MMS, patient requests, health worker attempts to reduce workload, and perceived challenges with low stocks of medications.
Conclusions: MMS is being widely implemented in Malawi, but patient differentiation in many facilities is not happening according to the agreed upon definition of eligibility. Simplification of guidance, improvements in health worker mentorship, patient counseling, and alignment of patient record forms against eligibility criteria would improve patient differentiation in Malawi.

MOAD0105

Multi-month prescription of antiretroviral therapy and its feasibility: experiences from the Baylor International Pediatric AIDS initiative (BIPAI) in six southern African countries

M. Kim[1], R.S. Wanless[2], S. Ahmed[3], J. Mhango[3], D. Damba[4], A. Kayabu[5], M. Chodota[6], S. Dlamini[7], N. Chidah[8], M. Mokhali[9], N. Calles[2], A. Amzel[10], R. Golin[10], E.J. Abrams[11]
[1]Baylor International Pediatric AIDS Initiative, Children's Clinical Center of Excellence, Lilongwe, Malawi, [2]Baylor International Pediatric AIDS Initiative, Houston, United States, [3]Baylor International Pediatric AIDS Initiative, Lilongwe, Malawi, [4]Baylor International Pediatric AIDS Initiative, Kampala, Uganda, [5]Baylor International Pediatric AIDS Initiative, Mwanza, Tanzania, United Republic of, [6]Baylor International Pediatric AIDS Initiative, Mbeya, Tanzania, United Republic of, [7]Baylor International Pediatric AIDS Initiative, Mbabane, Swaziland, [8]Baylor International Pediatric AIDS Initiative, Gabarone, Botswana, [9]Baylor International Pediatric AIDS Initiative, Maseru, Lesotho, [10]United States Agency for International Development, Washington, United States, [11]International Center for AIDS Care and Treatment Programs, Mailman School of Public Health, Columbia University, New York, United States

Background: To improve antiretroviral coverage (ART) and help reach the 90-90-90 treatment targets, differentiated approaches to care are necessary, including reduced frequency of clinic visits for stable patients. Given the paucity of data regarding the impact of differentiated care models on pediatric outcomes, BIPAI conducted a retrospective analysis of clinical outcomes, comparing monthly (MS) with multi-monthly (MMS) ART prescription schedules for children and adolescents in Botswana, Lesotho, Swaziland, Malawi, Uganda and Tanzania.
Methods: MMS was introduced in each country in line with national policy. Patients were transferred to MMS when clinically stable and ART adherent, after 6-9 months of monthly prescriptions. For analysis patients were allocated to the MMS group after three consecutive visits at intervals of greater than 56 days. Adherence, lost-to-follow up rates, CD4 counts and viral load were compared between MS and MMS patients by two-sample tests for binomial proportions. Mortality was compared by log rank test. To avoid bias against the MS groups, deaths in the first 6 months of MS therapy were excluded, given the known, high early rates of mortality. To avoid immortal time bias, MMS patients contributed person-time to the MS group between ART initiation and the start of MMS. The analysis was conducted according to an IRB approved protocol.
Results: There were 11,421 MS and 18,137 MMS patients aged between 0 and 19 years. Comparison of clinical outcomes is displayed in table 1.

Variable	MS patients	MMS patients	p value
Mean interval between visits (SD)	39 days (27.5)	61 days (34.9)	
% of patients with good adherence by pill count (95 to 105%)	68.7% (7,846/11,421)	78.5% (14,238/18,137)	< 0.0002
Lost-to-follow up (%)	7.1% (811/11,421)	1.8% (326/18,137)	< 0.0002
Mortality (deaths per 100 patient years)	2.9	0.4	< 0.0001
CD4 counts (% reaching >350 or >25 % for under age 5	78.0% (8,312/10,653)	92.8% (16,767/18,067)	< 0.0002
Viral load (% undetectable)	63.3% (2,976/4,703)	78.9% (10,787/13,678)	< 0.0002

[Table 1: Clinical outcomes of MS and MMS patients]

MMS patients had statistically lower mortality and lost-to-follow up rates, as well as superior ART adherence rates and response to ART by CD4 counts and viral load measurements.

Conclusions: This study, representing data from six African countries, provides reassurance that patients 0-19 years of age who are clinically stable and ART adherent, can do well with reduced clinical visits via MMS. The consequent reduction in visits can yield additional benefits by decreasing the burden on health systems and patient time.

MOAD02 Unlocking the Epidemic with Key Populations

MOAD0201

Why don't key populations access HIV counselling and testing centres in Nepal? Findings based on national surveillance survey

R. Shrestha[1], S. Philip[2], H.D. Shewade[3], B. Ojha[1], K. Badal[4], B.B. Rawal[5], K. Deuba[6]
[1]Public Health and Environment Research Center, Kathmandu, Nepal, [2]Government T.D Medical College, Kerala, India, [3]International Union Against Tuberculosis and Lung Disease (The Union), New Delhi, India, [4]UNAIDS, Kathmandu, Nepal, [5]National Center for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [6]Karolinska Institutet, Stockholm, Sweden
Presenting author email: rachanashrestha2@gmail.com

Background: UNAIDS proposed the 90-90-90 targets, i.e., that by 2020, 90% of PLHIV will know their HIV status, 90% of PLHIV who know their HIV status will receive HIV treatment, and 90% of PLHIV on ART should be virally suppressed. It is estimated that three million new HIV infections and three million AIDS-related deaths could be averted if these targets are achieved. HIV Testing and Counselling (HTC) is the entry point for HIV care services in Nepal and is provided free of cost to all. This study assesses the demographic, psychosocial and structural factors associated with non-utilization of HTC by female sex workers (FSW) and men who have sex with men/ transgender (MSM/TG) in Nepal.
Methods: We analysed data from the national surveillance survey which included 610 FSW and 400 MSM/TG recruited from 22 and three districts of Nepal respectively. Adjusted prevalence ratio (PR) using modified Poisson regression was used to assess the association between independent and outcome variables (non-utilization of HTC in last year).FSW was recruited using two-stage cluster sampling whereas MSM/TG was recruited using respondent driven sampling.
Results: Non-utilization of HTC in last one year was 54% for FSW and 55% for MSM/TG. The prevalence of depression among study populations was very high (≥50%). About 2 of every 10 FSW experienced forced sex in the last 12 months. The significant factors for FSW related to non-utilisation of HTC were: depression[PR=**1.4(1.1-1.6)**], injection of drugs (ever)[PR=**1.4(1.1-1.8)**],episode of forced sex in previous year [PR=**1.1(1.0-1.3)**], presence of dependents in the family [PR=**1.1(1.0-1.3)**], andparticipation in HIV awareness programmes(ever) [PR=**1.2(1.0-1.4)**]. Non-utilisation of HTC among MSM/TG had significant association with age 16-19 years [PR=**1.4(1.1-1.7)**],physical assault in previous year [PR=**1.6(1.3-2.0)**], condom use [PR=**1.2(1.0-1.4)**],experience of forced sex [PR=**0.5(0.3-0.9)**]and participation (ever) in HIV awareness programs [PR=**1.6(1.3-2.0)**].
Conclusions: HIV prevention programmes in Nepal need to go beyond condom promotion. Creative strategies should be envisaged for effective behavioural change communication. Psychosocial and structural interventions should be integrated with HIV prevention programmes to support key populations.

Presenting author email: tertiero81@yahoo.fr

Background: Since September 2015, the World Health Organization (WHO) has recommended to initiate antiretroviral treatment (ART) in all adults living with HIV, regardless of WHO clinical stage and at any CD4 cell count. In Africa, few programs focused on men who have sex with men (MSM). We therefore assessed the feasibility and acceptability of immediate ART initiation in MSM in four West African countries.
Methods: A prospective cohort study has been conducted since June 2015 in community-based clinics in Bamako (Mali), Abidjan (Côte d'Ivoire), Lomé (Togo) and Ouagadougou (Burkina Faso). MSM eligibility criteria were as follows: aged 18 years or older, reporting at least one episode of anal intercourse with another man within the previous 3 months, and either HIV-seronegative or discovering their HIV infection at study enrolment. HIV-seronegative MSM were offered a quarterly follow-up including clinical examinations, screening for HIV, screening and treatment for sexually transmitted infections, individualised peer-led support for prevention, condoms and lubricants. MSM who discovered their HIV infection at study enrolment and those who seroconverted during the follow-up were offered ART initiation immediately after HIV diagnosis.
Results: As of January 16, 2017, 679 MSM were enrolled in the study. Of them, 120 were HIV-seropositive at study enrolment and 35 seroconverted during follow-up. The median age of these 155 HIV-infected MSM was 24.5 years (interquartile range [IQR]: 21.8-28.1). A total of 134 (86.5%) MSM initiated ART. The median time from HIV diagnosis was 7 days (IQR: 3-16). Only 15 (11.2%) MSM initiated ART more than 1 month after HIV diagnosis, and 6 (4.5%) MSM after 3 months. The median CD4 cell count at ART initiation was 433 cells/µL (IQR: 324-535). Few discrepancies were observed between the study sites. MSM mainly received EFV+TDF+3TC (85.1%) or EFV+TDF+FTC (13.4%). Of 57 MSM with available data, 5 were resistant to EFV, of which 2 were also resistant to 3TC/FTC.
Conclusions: These preliminary results indicate that immediate ART initiation is feasible and well accepted by MSM in West Africa, strengthening the recent WHO-recommendation.

MOAD0203

Don't get lost: how peer navigation can link HIV-positive key populations to care and treatment and re-engage those lost to follow-up

T. Lillie[1], S. Nemande[1], H. Gbais[2], S. Kersten[2], D. Levitt[1,3], F. Ndonko[2,4]
[1]FHI360, District of Columbia, United States, [2]CARE, Yaounde, Cameroon, [3]CARE, Atlanta, United States, [4]LINKAGES, Washington, DC, United States
Presenting author email: ndonko@carecameroun.org

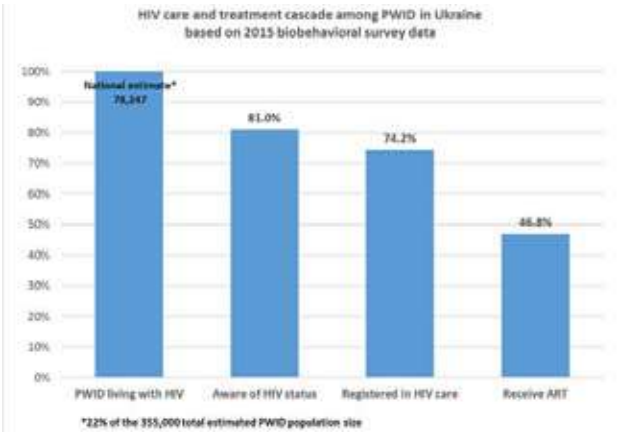
Background: Linking key populations (KP), including men who have sex with men (MSM) and sex workers (SW) to HIV care and treatment programs, and ensuring they adhere to treatment to reach viral suppression is a challenge in many developing countries. The peer navigation system in Cameroon was initiated to support enrollment and retention of HIV-positive KPs in the HIV service cascade and to remain adherent to treatment. Peer Navigators (PN) are HIV-positive, medication-adherent role models who understand and can convey clearly how to access and utilize key services for people living with HIV and their partners, loved ones, and children.
Methods: Through the USAID- and PEPFAR-funded LINKAGES and CHAMP projects, we pilot tested the peer navigation system in Yaoundé, Cameroon. Working with two community-based organizations, twenty-four PN were trained to provide quality support to HIV-positive KP. PN are usually HIV positive, may be a member of the KP community, trained and full-time staff. Programmatic data collected between November 2015-July 2016 before PN was introduced was compared to data collected between August-December 2016 after PN initiation. For the analysis, linkage to HIV treatment before and after PN was reviewed.
Results: A total of 838 HIV-positive FSW and 557 HIV-positive MSM accessed services from the two CBOs between November 2015 to December 2016. Preliminary data showed increases in client linkage to care and treatment, which went from roughly 39% of newly diagnosed HIV-positive clients before PN to as high as 82% after PN was introduced. Also, 38% of MSM and 71% of SWs living with HIV that were lost to follow-up before PN were recovered in just four months of PN implementation and linked to treatment.
Conclusions: While data are preliminary, they demonstrate the potential effectiveness of Peer Navigation programs that are being initiated in sixteen countries where LINKAGES is working. More widespread implementation of PN with high risk populations could accelerate progress toward 90-90-90 goals.

MOAD0204

HIV treatment cascade analysis for people who inject drugs in Ukraine: identifying the correlates of continuum

K. Dumchev[1], O. Varetska[2], T. Salyuk[2], C. Vitek[3]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Alliance for Public Health, Kyiv, Ukraine, [3]US Centers for Disease Control and Prevention, Kyiv, Ukraine
Presenting author email: dumchev@uiphp.org.ua

Background: PWID constitute over 50% of PLWHIV and continue driving HIV incidence in Ukraine, but data on HIV care continuum are scarce. Integrated bio-behavioral surveys (IBBS) among PWID are conducted biannually since 2007 to evaluate the effectiveness of HIV response. The aim of this study was to identify gaps in the HIV treatment cascade among PWID and identify correlates of receiving HIV care and ART.
Methods: This is a secondary analysis of 2015 IBBS data collected in all 27 regions of Ukraine using RDS. Results of rapid HIV testing and self-reported data on HIV status awareness, enrollment into HIV care and treatment were used to construct the cascade. Socio-demographic variables, drug use patterns, risk behaviors, receiving of prevention and other interventions were evaluated as potential correlates of being registered in HIV clinic and receiving ART. Logistic regression was used to test significance of association.
Results: 9,405 PWID were recruited (25% females), 22% tested positive for HIV. Of those, 81% reported being aware of their status. Among PWID who agreed to disclose HIV+ status, 74.2% were registered in HIV care and 46.8% received ART (see Figure).



[PWID Cascade]

Being female (aHR=1.9, 95%CI 1.02-3.33), age>35y.o. (aHR=4.05, 95%CI 1.95-8.41), being a harm reduction client (aHR=2.03, 95%CI 1.19-3.46) were positively associated with HIV care registration. Age>35y.o. (aHR=2.54, 95%CI 1.49-4.32), being a harm reduction client (aHR=1.68, 95%CI 1.26-2.24), current case-management (aHR=1.75, 95%CI 1.04-2.97) were positively associated with receiving ART. Past history of case-management was negatively associated with both outcomes (aHR=0.09, 95%CI 0.04-0.2 and aHR=0.44, 95%CI 0.22-0.88, respectively). Opioid agonist treatment, drug and alcohol use, risk behaviors were not associated with either outcome.
Conclusions: The study confirmed existence of significant gaps in HIV cascade among PWID in Ukraine, especially in access to ART. Services provided at harm reduction programs, including case-management, are important interventions that may improve access to care and treatment.

MOAD0205

Effectiveness of comprehensive HIV and stimulant use prevention intervention with Cambodian female entertainment and sex workers

K. Page[1], A. Carrico[2], E. Stein[3], J. Evans[3], M. Sokunny[4], S. Ngak[4], C. Sophal[5], Y. Neak[6], L. Maher[7], C. McCulloch[3]
[1]University of New Mexico, Albuquerque, United States, [2]University of Miami, Miami, United States, [3]University of California, San Francisco, San Francisco, United States, [4]FHI 360 Cambodia, Phnom Penh, Cambodia, [5]Ministry of Health, Department of Mental Health and Substance Abuse, Phnom Penh, Cambodia, [6]National Authority for Combating Drugs, Phnom Penh, Cambodia, [7]UNSW Australia, Kirby Institute for Infection and Immunity, Syndey, Australia
Presenting author email: pagek@salud.unm.edu

Background: HIV prevention services for female entertainment and sex workers (FESW) could serve as a platform for targeting key risk factors for HIV infection, including amphetamine-type stimulant (ATS) use and economic distress. We examined sequentially delivered interventions to decrease ATS use and improve economic well-being to boost HIV risk reduction with FESW.
Methods: This cluster randomized stepped-wedge trial in 10 Cambodian provinces enrolled 1,198 FESW to test the effectiveness of a comprehensive HIV and ATS use prevention package leveraging SMARTGirl, an existing HIV prevention platform for Cambodian FESW. The intervention included a conditional cash transfer with cognitive-behavioral aftercare (CCT+AC) intervention to reduce ATS use followed by a microenterprise (ME) opportunity. The co-primary outcomes assessed in 600 FESW purposively targeted for the 18-month follow-up were: 1) self-reported number of sexual partners (past three months); and 2) positive urine toxicology results for ATS (ATS Tox+). After baseline, FESW with problematic patterns of ATS use were allocated to receive a 4-month CCT+AC intervention. All FESW who were abstinent from ATS at six months were allocated to receive a ME opportunity.
Results: At six months, relative to baseline participants had 60% lower odds of ATS Tox+ (Adjusted Odds Ratio [AOR]=0.40; 95%CI 0.25-0.65; p<0.001) and non-significant decreases in number of sexual partners (Adjusted Risk Ratio [ARR]=0.65; 95%CI 0.38-1.11; p=0.11). At 12 months, FESW reported 50% fewer sexual partners (ARR=0.50; 95%CI 0.25-0.95; p=0.035) and non-significant reductions in the odds of ATS Tox+ (AOR=0.58; 95%CI 0.30-1.14; p=0.11). Although FESW continued to display reductions in both primary outcomes at 18 months, these were not statistically significant (p's< 0.09).

	# of Sexual Partners (3 Mo)	ATS Tox+
	ARR (95% CI)	*AOR (95% CI)*
Follow-up Assessment		
6 Months	0.65 (0.38 - 1.11)	**0.40 (0.25 - 0.65)***
12 Months	**0.50 (0.25 - 0.95)***	0.58 (0.30 - 1.14)
18 Months	0.45 (0.18 - 1.14)	0.44 (0.18 - 1.07)

[Intent-to-treat analyses (N = 1,198 at Baseline)]

Conclusions: Findings support the robust, short-term effectiveness of the sequentially delivered CCT+AC and ME interventions for optimizing HIV prevention services for Cambodian FESW. Further implementation science research is needed to inform the scale up and improve the durability of this comprehensive approach to boost HIV risk reduction with FESW in Southeast Asia.

MOAD0206

Viral suppression at the first integrated methadone and antiretroviral therapy program for people who inject drugs in sub-Saharan Africa

B.H. Lambdin[1,2,3], S. Hassan[4], D. Mushi[5], A. Cooke[6], J. Mbwambo[5]
[1]RTI International, Behavioral and Urban Health, San Francisco, United States, [2]University of California, San Francisco, United States, [3]University of Washington, Seattle, United States, [4]Yale University, School of Medicine, New Haven, United States, [5]Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of, [6]University of California, Los Angeles, United States
Presenting author email: blambdin@rti.org

Background: The prevalence of HIV among people who inject drugs (PWID) in Dar es Salaam is 42%, compared to 7% in the general population. In 2011, an opioid treatment program (OTP), using methadone, was established in Tanzania to reduce HIV risk behaviors and transmission. Enrollment of PWID into the OTP program surged, but linking and sustaining HIV-positive, eligible OTP patients in antiretroviral therapy faced many obstacles. We report the results from the first integrated methadone and antiretroviral therapy (IMAT) program to improve sustained ART access for PWID in sub-Saharan Africa.
Methods: A community engagement process with patients, providers, and government stakeholders helped us to collaboratively define an integrated model, including: opt-out HIV screening, OTP providers trained in HIV clinical management and monitoring, multiple ART dispensing models from the OTP clinic, and intensive case management for people who were not virally suppressed. We assessed viral suppression 6 and 12-months after implementation of the integrated model, and used logistic regression to assess predictors of viral suppression (< 1,000 copies/mL) at 12 months.
Results: Of the 126 people receiving HIV treatment at OTP, the median age was 35 years old, and 17% were female. Overall, 72% (95% Confidence Interval (CI): 60-82%) of patients had achieved viral suppression after 6 months of receiving HIV care at the OTP clinic, and after 12 months, 81% (95% CI: 69-88%) had achieved viral suppression. Regarding ART dispensing models, 79% received monthly supplies while 21% received directly administered ART (DAART) at the pharmacy or by a nurse. Age (p=0.323), sex (p=0.814), time in treatment (p=0.683) and ART regimen (p=0.263) were not significantly associated with viral suppression. Intensive case management was associated with a 16% (95% CI: 1-32%; p=0.0362) increase in viral suppression within 3 months of the case management session.
Conclusions: Our findings show a high level of viral suppression among people accessing HIV treatment within the IMAT program. The success of IMAT was driven by early engagement of OTP patients and providers. Future work will develop differentiated models of care for people receiving ART to achieve sustained viral suppression among HIV-positive PWID without overburdening the region's health system.

MOAX01 Just Do It Yourself: Preferences and Performances of HIV Self-testing

MOAX0101

Self-testing: an effective means of increasing HIV-testing and status awareness

A. Moore[1], T. Cassidi[2], S.J. Steele[2], A. Shroufi[2], N. Ntuli[2], L. Ndani[2], C. Metcalf[2], T. Ellman[2], E. Goemare[2], L. Trivino Duran[2]
[1]MSF, Medical, Cape Town, South Africa, [2]MSF, Cape Town, South Africa
Presenting author email: msfocb-khayelitsha-doc2@brussels.msf.org

Background: HIV self-testing (HST) could potentially improve HIV testing uptake and awareness of serostatus, especially if targeted towards patients who refuse routinely-offered facility-based HIV counselling and testing (HCT) due to privacy concerns. We conducted a pilot study of HST at two health facilities in Khayelitsha, South Africa, among patients who refused HCT, and assessed their HST uptake and linkage to care.
Methods: Patients who refused HCT were offered HST using OraQuick ADVANCE HIV1/2. Participants were asked to report their HST result by pre-paid text message (SMS), or by returning to the facility. Participants who did not report their result within 7 days were contacted telephonically.
Results: From 1 March 2016 to 31 October 2016, 537 patients were offered HST, of whom 422 (78%) accepted. Those who accepted HST, had a median age of 28 years; 409 (97%) were female; and 313 (74%) reported their HST result. Of the 422 participants, 245 (58%) reported their result within 7 days, and the median time to reporting the result was 1 day. Of those who reported their result, 269 (86%) reported by SMS. Reporting of results varied by facility, being 60% at the facility where many patients did not carry a cell phone due to security concerns, compared to 83% at the other facility. Among participants who reported their HST result, 19 (6%) were positive, compared to 7% HCT at same facilities. Of the 19 participants reporting a positive HST result, 10 (53%) returned for confirmatory testing. Of the 294 participants who reported a negative HST result, 53 (18%) returned for confirmatory testing. All confirmatory tests agreed with the reported HST results.
Conclusions: Offering HST in public-sector clinics is an effective way of increasing HIV testing uptake among those who refuse HCT, but ensuring that those with positive HST results return for confirmatory testing is challenging. As the majority of patients attending clinics are female, the effectiveness of providing HST in other settings needs to be assessed as a means of increasing HIV testing uptake among males.

HIV self-testing: feasibility and acceptability of a large scale national service delivered by a community organisation

C. James, D. Edwards, W. Harris, M. Brady
Terrence Higgins Trust, Health Improvement, London, United Kingdom
Presenting author email: cary.james@tht.org.uk

Background: The UK needs a dramatic increase in HIV testing to reduce undiagnosed HIV and late diagnoses. HIV self-testing offers the potential to significantly increase the number and frequency of tests.
Methods: : We piloted a national HIV self-testing service, which was delivered online to men who have sex with men (MSM) and Black Africans living in the UK. A dedicated website was created and the service was promoted through social media. Participants provided demographic information, contact details and answers to HIV risk assessment questions. An HIV self-testing kit was then posted to them. Service users were asked to log onto a secure page on the website to inform us of their result. Anyone with a reactive result was called for support or advice and to ensure access to care for confirmatory testing. An online satisfaction survey was sent to everyone who gave consent.
Results: The pilot ran from 24th June - 5th Aug 2016. A total of 4,879 kits were ordered. 3,021 people (62%) informed us of their result. 19% had never had an HIV test before and a further 37% had last tested >1 year ago. 68% reported condomless anal sex in the previous 3 months with 28% reporting this with 2 or more partners. 28 people (0.92%) reported a reactive result. 3 (10.7%) people already knew they were HIV positive and one result was confirmed as a false positive. Of the remaining 24 all were MSM. 15/24 (62.5%) identified as white British. Contact was made with 22 (92%) all of whom had accessed confirmatory testing and HIV services. 602 people responded to the survey. 98% would use the service again, 91% felt self testing encouraged them to test and 91% were happy with the support they received.
Conclusions: We have demonstrated the feasibility and acceptability of HIV self-testing in the UK. It also demonstrated a high percentage were willing to report their results which allowed for confirmation of linkage to care. We believe that an investment in HIV self-testing will compliment existing options and provide a cost-effective way to scale up our approach to testing.

MOAX0103

The impact of HIV self-testing among internet-recruited MSM, eSTAMP 2015-2016

R.J. MacGowan[1], P.R. Chavez[1], C.B. Borkowf[1], P.S. Sullivan[2], J.H. Mermin[1]
[1]Centers for Disease Control and Prevention, NCHHSPT/DHAP, Atlanta, United States, [2]Emory University, Atlanta, United States

Background: Knowledge of HIV status is essential for accessing antiretroviral therapy and effective prevention services. Providing HIV rapid diagnostic tests (RDTs) for self-testing to persons at risk of HIV infection, such as men who have sex with men (MSM), could increase frequency and timeliness of HIV testing. The "Evaluation of HIV self-testing among MSM Project" (eSTAMP) is a 12-month randomized controlled trial (RCT) that evaluates the impact of this strategy.
Methods: MSM in the US were recruited online from March through August 2015 and enrolled into eSTAMP. Participants were asked to complete online surveys at baseline, 3, 6, 9, and 12 months. The intervention group was mailed 4 RDTs at baseline with the option of replenishing the ones used after interim assessments. At the end of the study, all participants who completed the 12-month survey were mailed 2 RDTs and a dried blood spot (DBS) card. We compare the percentage of participants who tested ≥ 3 times, mean number of all HIV tests, percentages who accessed clinic-based HIV testing services, mean number of sex partners over 12 months, and newly identified cases of HIV infection by intervention and control groups.
Results: We randomly assigned 2665 MSM to the Intervention (n=1325) and Control (n=1340) arms. Mean age was 30.4 years; 58% were white, 10% black, 23% Hispanic, and 9% other or mixed race; 17% had never been tested for HIV. 72% completed at least one follow-up survey; retention rate at 12 months was 58%. There was significantly more HIV testing in the intervention group. 42 cases of HIV infection were identified, 21 were linked to care.

Results over 12 month follow-up period	Intervention	Control	P value
Number of newly identified HIV cases*, n/N (%)	25**/966 (2.6%)	11**/958 (1.2%)	0.03
MSM reporting ≥3 HIV tests, n/N (%)	761/965 (79%)	217/958 (22%)	< 0.01
Number of HIV testsa, mean (SD)	5.3 (3.6)	1.5 (1.8)	< 0.01
MSM reporting clinic-based HIV tests, n/N (%)	395/966 (41%)	614/958 (64%)	< 0.01
Number of sex partners, mean (SD)	9.1 (17.0)	9.7 (19.7)	0.57
*includes RDT and clinic-based testing among study participants. **Additional cases (Intervention: n=3, Control: n=3) were identified from the DBS testing after the 12 month survey.			

[Table 1]

Conclusions: Implementing internet-based HIV screening programs with free HIV RDT increased HIV testing and diagnosis among MSM, including those who have not previously accessed traditional HIV testing services.

MOAX0104

Feasibility of HIV self-test programming among female sex workers in Zimbabwe

S. Mavedzenge[1], E. Sibanda[2], J. Dirawo[2], K. Hatzold[3], O. Mugurungi[4], F. Cowan[2,5]
[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [3]Population Services International, Harare, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom
Presenting author email: smavedzenge@rti.org

Background: Female sex workers (FSW) are disproportionately affected by HIV, yet their engagement in HIV services does not reflect this heightened risk. Increasing HIV testing is the first step towards prevention and care services. There is little research on HIV self-testing (HIVST) among FSW, which may be particularly appropriate for this population. We conducted a pilot study offering HIVST for 6 months to FSW in Zimbabwe to evaluate programmatic feasibility.
Methods: Adult FSW of unknown HIV status presenting for testing at a dedicated FSW clinic were given the option of provider-delivered testing or HIVST. Those opting for HIVST and who had a mobile phone were invited to enroll. Participants received self-test kits and validated instructions. They were contacted after 2 weeks to complete a questionnaire about their experience.
Results: 607 FSW presented for testing and 325 (54%) opted for HIVST (p< 0.01). Among self-testers, mean age was 29 years (range 18-62). Most (94%) had previously tested for HIV. 100% reported the test was not difficult to use, and 98% were comfortable learning their result without a provider present. 30% had a reactive result, and of those, 99% had attended post-test services by the 2-week post-test questionnaire. 100% indicated they would want HIVST to be available to them, and would recommend HIVST to family/friends. 81% would recommend HIVST to their clients. Though no participants were forced to self-test, 38% thought coercive testing might happen if HIVST became more widely available. FSW thought HIVST distribution should be via clinic (62%), pharmacy (18%), peer (14%) and/or workplace (13%). FSW indicated they would be willing to pay $0.50-$25 for self-tests, with 35% willing to pay $1 and 30% $5.
Conclusions: FSW found HIVST highly acceptable, and wanted HIVST to be available to them. A high proportion had a reactive self-test, and importantly, virtually everyone had linked to post-test services by the 2-week follow-up questionnaire. Some expressed concern about potential for coercive testing. FSW were willing to pay for HIVST, and provided useful insight into how to distribute and promote HIVST during future implementation research. HIVST represents a promising strategy to promote regular re-testing among FSW in Zimbabwe.

MOPDA01 Getting to the HAART of Immune Activation

MOPDA0101

A higher fraction of drug resistant proviruses express unspliced HIV RNA during ART compared to the archival wild-type proviruses that comprise the HIV-1 reservoir

A. Musick[1], J. Spindler[1], M. Sobolewski[2], M. Bale[1], B. Keele[3], W. Shao[3], A. Wiegand[1], S. Hughes[1], J. Mellors[2], J. Coffin[4], F. Maldarelli[1], M. Kearney[1]

Presenting author email: kearneym@mail.nih.gov

Background: The fraction of proviruses persisting during ART that are latent vs. transcriptionally active has not been determined. To address this question, we investigated the expression of unspliced HIV RNA in vivo in single cells carrying either wild-type (WT) proviruses or those with drug resistance (DR) mutations.
Methods: PBMC were analyzed from Patient #1 in Maldarelli, et al., 2014. The fraction of the proviruses expressing HIV RNA was determined by single-genome sequencing of cell-associated HIV RNA and DNA from single cells. Intact proviruses, capable of infectious virus production, were identified using viral outgrowth assays (VOA). The levels of viral RNA present in infected cells were determined for the archival drug sensitive population, the recently infected DR population, and for clones carrying intact and defective proviruses.
Results: We analyzed a total of 77 million PBMC, of which 10,450 contained HIV pro-pol sequences: 7137 were WT, 1714 were DR, and 1599 were defective (contained stop codons). The median fraction of proviruses that expressed RNA in cells more recently-infected with DR virus was 25%, whereas in cells with WT or hypermutant proviruses, it was 14% (p=0.0008). Levels of expression in single cells with DR proviruses were higher than in cells with WT proviruses (p=0.002). The median fraction of cells in apparent clonal populations carrying intact proviruses (N=3) expressing HIV RNA was 2.3% (1.2%-8.8%). For clones carrying defective proviruses (N=5), the median fraction expressing was 3.5% (0.9%-7.0%), and for clones carrying proviruses that did not have obvious defects in the pro-pol region but were not recovered in the VOA (N=26), the median was 6.6% (1.3%-66.7%).
Conclusions: A small fraction of the proviruses in clones of HIV infected cells expressed HIV RNA. The fraction and levels of proviral expression were significantly higher in more recently infected cells than in those that persisted during long-term ART. These findings show that ART can select both for cells infected before ART initiation that either do not express HIV RNA or express at low levels and for cells infected recently with drug-resistant viruses that express higher levels of HIV RNA.

MOPDA0102

Evidence of production of HIV-1 proteins from "defective" HIV-1 proviruses in vivo: implication for persistent immune activation and HIV-1 pathogenesis

H. Imamichi[1], M. Smith[1], A. Pau[1], C.A. Rehm[1], M. Catalfamo[1,2], H.C. Lane[1]
[1]NIAID, NIH, Laboratory of Immunoregulation, Bethesda, United States, [2]Georgetown University School of Medicine, Department of Microbiology and Immunology, Washington, United States
Presenting author email: himamichi@nih.gov

Background: Greater than 95% of proviruses detected in circulating PBMCs are referred to as "defective" and are unable to encode intact viruses. They have been thought to represent a silent graveyard of viruses with little contribution to HIV-1 pathogenesis. We have recently shown that these "defective" proviruses are capable of transcribing novel mRNA species. In the present study, we demonstrate that these "defective" proviruses are also capable of producing HIV-1 proteins.
Methods: CD4+ T cell clones were obtained from an HIV-infected individual who had recently been placed on suppressive combination antiretroviral therapy (cART). The CD4+ T cells were initially plated in 96-well cell culture plates at a cell density of 100 cells/well and expanded for 2 weeks in the presence of autologous feeder cells. Positive wells by HIV-DNA PCR were further expanded in 48-well plates for another week. The identification of single-cell clones harboring "defective" proviral DNA was confirmed by combining 5´LTR-to-3´LTR single-genome amplification and direct amplicon sequencing of the genomic DNA. Cellular expression of HIV-1 proteins was analyzed by western blot and flow cytometry.
Results: Two months after suppression of plasma viremia to <40 copies/ml, the estimated frequency of CD4+ T cells containing HIV-DNA was 1%. Multiple cell lines harboring defective proviruses ranging from 6.5-8.2 kb in length were derived from the CD4+ T cells. Most prominent among these were cells containing an identical 6.5 kb provirus. Sequencing of this 6.5 kb provirus revealed a 2.4 kb internal deletion affecting the region encoding the HIV-1 accessary proteins and the gp120 portion of Env protein. The Gag, Pol and Nef regions remained intact in the 6.5 kb provirus. Consistent with the DNA data, western blots revealed the presence of the Gag and Nef proteins.
Conclusions: These data indicate that "defective" proviruses in successfully treated HIV-infected patients are not silent dead-end products but rather capable of producing HIV-1 proteins in vivo. The proteins encoded by these defective "zombie" proviruses may be responsible for persistent seropositivity and immune activation in most patients with controlled HIV-1 infection during suppressive cART.

MOPDA0103

HIV reservoirs in the brain and association with sex and neurocognition

M.F. Oliveira[1], M. Nakazawa[1], A. Vitomirov[1], M. Zhao[1], B. Gouaux[1], D. Moore[1], R. Ellis[1], D. Smith[1,2], S. Gianella[1]
[1]University of California San Diego, La Jolla, United States, [2]Veterans Affairs San Diego Healthcare System, La Jolla, United States
Presenting author email: d13smith@ucsd.edu

Background: Although antiretroviral therapy (ART) reduces plasma HIV-RNA below the detection limit, HIV reservoirs persist in anatomic compartments, as the central nervous system. The clinical and biological factors that influence HIV reservoirs in brain are unknown.
Methods: Paired autopsy tissues from frontal cortex [FC, N=61], occipital cortex [OCC, N=60], basal ganglia [BG, N=31] and peripheral lymphoid tissue (N=37) from 63 HIV+ adults were selected from the National NeuroAIDS Tissue Consortium. All participants died with virologic suppression on ART (< 50 or 400 copies/ml, assay-dependent) without evidence of CNS opportunistic disease, between 1999-2014. Genomic DNA was extracted by magnetic beads; HIV-DNA levels were measured by ddPCR and normalized by RPP30. Neurocognitive (NC) functioning was assessed at the last visit (median 3 months before death) by Clinical Rating based on 7 neuropsycological abilities. Bayesian hierarchical regression model was used to evaluate the relationship between brain regions, sex and NC functioning. The model used a zero-inflated negative-binomial family with a logit link function.
Results: The study cohort consists of 12 females and 51 males (median age: 55 years). Median CD4+ at the last visit was 164 [IQR: 80-390] and median estimated duration of infection was 14 years [IQR: 10-19]. HIV-DNA was detected in 62.5% of brain and 100% of lymphoid tissue. Lymphoid tissue has higher HIV-DNA levels than brain (85.6 vs. 14.2, p<0.001). BG has higher HIV-DNA levels (20.3 copies/10^6 cells) compared to FC (13, p=0.018) and OCC (9.3, p=0.005). Female sex and younger age are associated with higher HIV-DNA in brain (p=0.026, p=0.06, respectively), but not in lymphoid tissue (p=0.31). When evaluating NC sub-domains, higher HIV-DNA (any brain region) was associated with worse speed of information processing (p=0.012) and better verbal fluency (p<0.05). No sex-differences in Clinical Rating was observed.
Conclusions: HIV-DNA was detected in most of brains despite virologic suppression. While levels of HIV-DNA were comparable in lymphoid tissue, women had higher brain HIV-DNA levels than men. Higher brain HIV-DNA levels negatively affected the speed of information in both sexes. The negative association between HIV-DNA and verbal fluency requires more investigation.

MOPDA0104

Monocyte-derived reactive oxygen species impair CD4+ T cell restoration in HIV-1 patients under therapy

M. Younas[1], Y.-L. Lin[1], S. Gimenez[1], P. Portalès[2], M. Morchikh[1], D. Maiorano[1], J. Reynes[2], P. Pasero[1], C. Psomas[1], P. Corbeau[1,3]
[1]Institute of Human Genetics, CNRS, Montpellier University, UMR9002, Montpellier, France, [2]University Hospital, Montpellier, France, [3]University Hospital, Nîmes, France
Presenting author email: pierre.corbeau@igh.cnrs.fr

Background: Antiretroviral therapy is highly efficient at suppressing viral replication in over 90% of HIV-1-infected patients. However, 5-25% of these virologic responders do not restore correctly their CD4 count. This suboptimal immunologic response is often correlated with a persistent hyperactivity of the immune system. However, the molecular mechanisms linking residual immune activation to impaired CD4 cell recovery remain to be identified. We tested the hypothesis that periph-

eral blood mononuclear cells (PBMC) from aviremic HIV adults might induce DNA damage in CD4+ T cells resulting in their apoptosis.
Methods: We probed by immunofluorescence the presence of g-H2AX, 53BP1 and 8-hydroxy-2-deoxyguanosine, markers of genostress, DNA double-strand break and oxidation, respectively, in primary fibroblasts co-cultured in transwells with PBMC from virologically suppressed patients. PBMC subpopulations were sorted using magnetic beads. The amount of reactive oxygen species (ROS) expressed in the monocytes and CD4+ T cell apoptosis were measured by flow cytometry using dichloro-dihydro-fluorescein diacetate and fluorescent Annexin V, respectively. DNA-dependent protein kinase (DNA-PK) and p53 phosphorylation was analyzed by western blot.
Results: PBMC of 56 out of 103 virologic responders (54%) induced g-H2AX nuclear foci in cocultured fibroblasts. Cell sorting and inhibition of this phenomenon by a ROS scavenger and an NADPH oxidase-inhibitor established that this genostress, characterized by DNA oxidation and double-strand break, was due to ROS released by monocytes. In cocultured CD4+ T cells, this resulted in DNA-PK as well as p53 phosphorylation, and finally in apoptosis. Patients with PBMC able to damage DNA, a phenotype that we found stable over time, presented with lower CD4 recovery than patients whose PBMC did not induce DNA damage ($p = 0.003$). Patient CD4 slopes were inversely correlated with the intensity of DNA damage induced by their PBMC ($r = -0.419$, $p = 0.006$).
Conclusions: ROS are persistently produced by monocytes in half of virologic responders, inducing DNA damage, cell death in CD4+ T cells, and impaired CD4 restoration. This phenomenon could pave the way for oncogenesis and could be an important driver of CD4 loss in non-treated persons. ROS inhibitors deserve to be tested in non-immunologic responders.

MOPDA0105

HIV-1-mediated induction of Hypoxia Inducible Factor-1 alpha activity in CD4+ T cells modifies immunometabolic phenotype and decreases cell survival

G.A. Duette[1], J. Rubione[1], P. Pereyra Gerber[1], F. Erra Diaz[1], A. Varese[1], C. Palmer[2], M. Ostrowski[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, UBA-CONICET, Buenos Aires, Argentina, [2]Burnet Institute, Melbourne, Australia
Presenting author email: gabriel.duette@gmail.com

Background: Chronic T cell activation and dysfunction are hallmarks of HIV infection. Taking into consideration that T cell metabolism influences T cell functionality, we hypothesized that CD4+T cell dysfunction during HIV infection could be associated to virus-induced metabolic alterations. A critical transcription factor in the coordination of T cell metabolism, differentiation and effector function is Hypoxia Inducible Factor-1α (HIF-1α). Herein, we analyzed the expression, activity and function of HIF-1α in CD4+T cells.
Methods: CD4+T cells isolated from the blood of healthy donors were activated with anti-CD3/CD28 antibodies and infected in vitro with HIV. HIF-1α activity was evaluated by using a reporter cell line, expressing GFP under the control of the Hypoxia-Responsive-Element. Cytokine production was evaluated by CBA kit. Cell viability was evaluated by 7-AAD staining and Annexin V binding. Silencing of HIF-1α expression was achieved by transduction with lentivirus-encoded shRNAs. To analyze ex vivo the relationship between HIF-1α levels and cell death in CD4+T cells a total of 7 HIV-1-infected patients on cART and 6 healthy donors were recruited.
Results: We show that HIV-1 infection triggers HIF-1α expression and activity, promoting aerobic glycolysis and the production of proinflammatory cytokines in CD4+T cells infected in vitro. We also observed that the promotion of aerobic glycolysis by HIV is associated with a higher rate of CD4+T cell death. Remarkably, silencing HIF-1α expression in CD4+T cells reverted the promotion of cell death and production of proinflammatory cytokines induced by HIV-1 infection. Finally, we also analyzed HIF-1α expression in samples from HIV-1-infected patients on cART. Interestingly, these patients also exhibit higher levels of HIF-1α expression compared to healthy donors. Moreover, the expression levels of this transcription factor presented a negative correlation with CD4+T cell counts.
Conclusions: In conclusion, we show that HIV infection induces the activity of HIF-1α in productively infected cells promoting glycolytic activity, a proinflammtory phenotype and cell death. These results pave the way to explore the possibility of targeting HIF-1α and/or T cell metabolism to restore CD4+T cell physiology in HIV-1 infected individuals.

MOPDA0106

Toll-like receptor activation modulates inflammation and HIV-1 infection in the female reproductive tract (FEMINIVI study)

F.D. Benjelloun[1,2], H. Quillay[1,3], C. Cannou[1,2], R. Marlin[1,2,4], Y. Madec[5], H. Fernandez[6], F. Chrétien[7], R. Le Grand[2,4], F. Barré-Sinoussi[8], M.-T. Nugeyre[1,2,4], E. Menu[1,2,4]
[1]Institut Pasteur, MISTIC Group - Virology, Paris, France, [2]CEA, U1184 ImVA-IDMIT, Fontenay aux Roses, France, [3]University paris diderot, Paris, France, [4]Vaccine Research Institute (VRI), Creteil, France, [5]Institut Pasteur, Research Unit Epidemiology of Emerging Diseases, Paris, France, [6]Bicêtre Hospital AP-HP, Gynecology-Obstetrics, Le Kremlin Bicêtre, France, [7]Institut Pasteur, Research Unit Human Histopathology and Animal Models, Paris, France, [8]Institut Pasteur, Paris, France
Presenting author email: fahd.benjelloun@pasteur.fr

Background: The female reproductive tract (FRT) mucosae are the main sites of exposure and entry of sexually transmitted infections (STIs) including HIV-1. The Toll-Like receptors (TLRs), widely expressed in the FRT, recognize pathogenic motifs and modulate immune responses. TLR stimulation induces an immune activation and/or a local production of inflammatory markers. This inflammation has a controversial impact on the antiviral activity. The aim of this project is to determine in vitro the impact of the TLR activation in the control of HIV-1 infection and on the inflammation in the major mucosal sites of the human FRT
Methods: Samples from different compartments of the FRT (vagina, cervix and uterus) were obtained from HIV-1 negative non-menopausal women who gave their written informed consent. To test the potential antiviral effect of the TLRs, mononuclear cells isolated from the samples were stimulated by TLR agonists 72h prior to HIV-1 infection: PolyI:C (TLR3), LPS (TLR4), R848 (TLR7/8) and the CpG ODN (TLR9). Viral production was measured in cell culture supernatants by p24 Ag ELISA. Prior to HIV-1 BaL infection, the modulation of cytokine production was quantified by Luminex assay and evaluated by confocal microscopy in tissue sections of TLR pre-stimulated biopsies
Results: Each compartment of the FRT presents a specific composition in immune cells. Among CD45+ cells, CD3+ T cells (30-56%), and CD14+ cells (9-16%) are the major populations in the FRT. The NK cells (CD56+) are more abundant in the uterus (4%). The stimulation of TLR3, 7/8 and 9 controls more efficiently HIV-1 infection in the uterus than in other compartments, while TLR4 stimulation does not have a major impact. TLR stimulation also modulates the production of pro and anti-inflammatory cytokines such as IL-6, IL-8 and IL-10
Conclusions: Our results show that the TLR stimulation modulates the cytokine expression and impacts the HIV-1 infection according to compartments in the FRT. Our aim is now to determine if a synergetic effect is obtained by stimulating more than one TLR at the time. The effect of induced inflammation on HIV-1 infection in the FRT is under investigation. Our findings will give clues for developing novel strategies against STIs

MOPDB01 Comorbidities in an Ageing Era

MOPDB0101

More and earlier cardiovascular events (CVE) and shorter overall survival (OS) in HIV-positive patients (HIV+) compared to the general population differ by sex

S. Esser[1], M. Arendt[2], C. Schulze[1], V. Holzendorf[3], N.H. Brockmeyer[4], K.-H. Jöckel[2], R. Erbel[2], N. Reinsch[5], HIV HEART Study Group and Heinz Nixdorf Recall Investigative Group
[1]University Hospital Essen, Clinic of Dermatology, Department of Venereology, Essen, Germany, [2]University Hospital Essen, Institute for Medical Informatics, Biometry and Epidemiology (IMIBE), Essen, Germany, [3]University Leipzig, Clinical Trial Centre Leipzig - Coordination Centre for Clinical Trials (ZKS Leipzig - KKS), Leipzig, Germany, [4]Ruhruniversity Bochum, Germany Clinic of Dermatology, Venerology and Allergology, Center for Sexuell Health and Medizin, Bochum, Germany, [5]Alfried Krupp Hospital, Department of Internal Medicine I and Cardiology, Devision of Electrophysiology, Essen, Germany

Background: The OS of HIV+ should be adapted to the general population by antiretroviral treatment. But in the aging HIV+ CVE and strokes became more frequent.
Methods: We compare CVE, stroke and OS of HIV+ outpatients of the HIV HEART study (HIVH) and of HIV-negative controls of the population-based Heinz Nixdorf Recall study (HNR), both recruited from the German Ruhr area. HIVH cases with HNR controls are matched in a 1:2 ratio by sex and age. CVE are defined

by myocardial infarction and sudden cardiac death. Cox proportional hazard models are used to investigate the impact of study affiliation on OS, CVE and stroke with time from study start to event or last contact. We adjust for age, active smoking and for men additionally for diabetes.
Results: Descriptions are shown in table 1. We observe adjusted Hazard ratios (HR) of 3.5 (95%-CI: 2.2; 5.5) for CVE for male HIVH vs. HNR and for stroke of 1.8 (0.8; 3.9) for male and 2.2 (0.1; 42.9) for female HIVH vs. HNR. The OS in male and female HIVH vs. HNR has an HR of 3.9 (2.5; 6.1) and 1.7 (0.2; 12.3), respectively. The smoking status is different in male subjects (p< 0.0001) and the Framingham Risk score (FRS) is different in female subjects (p< 0.0001). Men differ highly in variables related to blood fats and BMI, women differ in terms of blood pressure and heartrate which is also displayed in the highly different FRS.

	HNR male	HIVH male	p-value	HNR female	HIVH female	p-value
N (%)	950 (66.7)	475 (33.3)		124 (66.7)	62 (33.3)	
Age mean±SD	54.5 ± 6.7	54.5 ± 6.7		51.3 ± 6.1	51.3 ± 6.1	
Cardiovascular events N (%)	40 (4.2)	47 (9.9)	<0.0001	0	2 (3.2)	0.0443
Stroke N (%)	16 (1.7)	12 (2.5)	0.2803	1 (0.8)	1 (1.61)	0.6152
Deceased N (%)	49 (5.2)	52 (11.0)	<0.0001	2 (1.6)	2 (3.2)	0.4747
Never smoker N(%)	278 (29.3)	111 (23.4)		51 (41.5)	22 (36.1)	
Former smoker N(%)	371 (39.1)	126 (26.5)		38 (30.9)	10 (16.4)	
Active smoker N(%)	299 (31.5)	238 (50.1)	<0.0001	34 (27.6)	29 (47.5)	0.0157
FRS mean ± SD	12.6 ± 7.3	11.8 ± 3.1	0.0295	5.5 ± 5.6	14.6 ± 4.7	<0.0001

[Description of the matched study population of 537]

Conclusions: HIV+ males had an increased incidence of CVE compared with HIV-negative controls in spite of similar FRS at baseline in contrast to HIV+ females with higher FRS than controls but comparable rates of CVE. HIV+ males had the highest mortality rate and a higher risk to die or to get CVE at younger age than the general population.

MOPDB0102

Incidence of renal Fanconi syndrome in patients taking antiretroviral therapy including tenofovir disoproxyl fumarate

N.A. Medland[1], E.P.F. Chow[2], R.G. Walker[3], M. Chen[2], T.H.R. Read[2], C.K. Fairley[2]

Presenting author email: nmedland@mshc.org.au

Background: Fanconi syndrome (FS) is a well recognised complication of use of the antiretroviral agent of tenofovir disoproxyl fumarate (TDF).
Despite millions of patient years of TDF use, the incidence and predictors of FS are not known. The aim of this study was to determine the incidence and predictors of FS in a clinic cohort of patients taking TDF.
Methods: Clinical records and laboratory investigations from patients receiving ART between January 2002 and March 2016 at the Melbourne Sexual Health Centre, Australia, were extracted. FS was defined as new onset normoglycaemic glycosuria and proteinuria and at least one other marker of renal dysfunction. Kaplan-Meier survival curves were performed using duration of exposure to ART: not containing TDF, or containing TDF, with or without ritonavir co-administration. Cox regression analysis was performed on TDF exposures with using the covariates ritonavir co-administration, age, sex, co-morbidities (hypertension, hyperlipidemia, diabetes, viral hepatitis), CD4 cell count nadir and baseline eGFR.
Results: 1537 patients received ART, including 1260 who received TDF, of whom 398 patients received TDF co-administered ritonavir, representing 10401 patient years (PY) of ART, 5327 PY of TDF and 1641 PY of TDF ritonavir co-administration. 13 cases of FS were identified. All cases were taking TDF and the mean duration of exposure was 55 months (12-98) before developing FS. The incidence of FS was 1.09/1000PYs (95% CI 0.54-1.63) of TDF exposure (without ritonavir) and 5.48/1000PYs (3.66-7.33) of TDF-ritonavir co-administration (p=0.0057). The adjusted hazards ratio for ritonavir co-administration was 4.71 (1.37-16.14, p=0.014). Known risk factors for chronic kidney disease were not associated with an increased risk of FS.
Conclusions: In this first published study of the incidence of Fanconi syndrome, we find that ritonavir co-administration but not other factors is associated with a greater risk of FS. FS developed late. Out study supports ongoing renal monitoring in long term supressed patients with twice yearly urinalysis, particularly if serum laboratory monitoring is not available.

MOPDB0103

Higher HDL, better brain? Higher HDL cholesterol is associated with better cognition in a cohort of older persons living with HIV infection

A. Makanjuola[1,2,3], K. Wu[4], K. Tassiopoulos[4], B. Berzins[3], A. Ogunniyi[1,2], K. Robertson[5], B. Taiwo[3], F. Chow[6]

Presenting author email: felicia.chow@ucsf.edu

Background: Despite effective combination antiretroviral therapy (ART), neurocognitive impairment (NCI) remains prevalent in persons living with HIV (PLWH). The contribution of cardiovascular comorbidities to NCI may increase as PLWH age. We investigated the association of cardiovascular risk factors with prevalent NCI in a prospective cohort of older PLWH at entry into the AIDS Clinical Trials Group A5322 study.
Methods: Participants who underwent a brief neurocognitive screen (Trailmaking Tests A and B, HVLT-R, Digit Symbol) at entry into A5322 were eligible. Primary outcomes were overall cognitive performance summarized by mean z-scores of the 4 tests (NPZ-4) and presence of NCI, defined as ≥1 SD below the mean on 2 or more tests or ≥2 SD below the mean on 1 test. We used linear and logistic regression models to determine the association between cardiovascular risk and the primary outcomes.
Results: Of 988 participants (30% black, 21% Hispanic/Latino, 20% women), mean age was 52 years and education 14 years. Median ART duration was 8 years, mean CD4 count 661 cells/mm^3, and 90% of participants had viral load < 40 copies/mL. Current smoking (26%), statin (27%) and anti-hypertensive (36%) use were common, while stroke (2%), myocardial infarction (3%) and injection drug use (< 1%) were uncommon. Mean LDL and HDL cholesterol were 109 and 49 mg/dL, respectively, and systolic blood pressure was 126 mmHg. 180 participants (18%) had NCI. In demographics and education-adjusted models, higher HDL was associated with better NPZ-4 (+0.04, p=0.040) and lower odds (OR 0.88, p=0.043) of NCI per 10 mg/dL higher HDL, as was statin use (+0.15 NPZ-4, p=0.037). An association between smoking and worse NPZ-4 (-0.15, p=0.053) became non-significant after controlling for anti-depressant use and hepatitis C. In a multivariable model including factors significant at p< 0.10 in demographics and education-adjusted analyses, older age, female sex, Hispanic/Latino ethnicity, high school education or less, and anti-depressant use were associated with worse NPZ-4. Longer ART duration and higher HDL were associated with better NPZ-4.
Conclusions: Among older PLWH with well-controlled cardiovascular risk factors, higher HDL was associated with better cognition. Investigation into the impact of modifying HDL cholesterol on cognition in PLWH is merited.

The combination of Tai Chi, cognitive behavioral therapy and motivational text messaging improves physical function, reduces substance use and improves pain in older HIV-infected adults

J.E. Lake[1,2], M.C. Reid[3], S.G. Edwards[4], A. Kuerbis[5], J. Candelario[6], D. Liao[7], L. Tang[7], A.A. Moore[8], for the STOP PAIN Study
[1]University of Texas Health Science Center Houston, Medicine/Infectious Diseases, Houston, United States, [2]University of California, Los Angeles, Medicine/Infectious Diseases, Los Angeles, United States, [3]Cornell University, New York, United States, [4]University of California, Los Angeles, Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [5]Hunter College, New York, United States, [6]APAIT, Special Service for Groups, Los Angeles, United States, [7]University of California, Los Angeles, Los Angeles, United States, [8]University of California, San Diego, San Diego, United States
Presenting author email: jordan.e.lake@uth.tmc.edu

Background: Chronic pain is common among older HIV-infected (HIV+) adults and contributes to substance use, reduced physical function and disability. We designed a pilot randomized controlled trial of cognitive behavioral therapy (CBT) + tai chi + motivational texting vs standard of care to reduce pain, disability and substance use in older HIV+ adults.
Methods: Evidence-based chronic pain and substance abuse CBT protocols were adapted and combined with group tai chi and motivational text messaging (EXP). HIV+ adults ≥50 years of age with chronic pain and substance use (n=55) were randomized to EXP (n=18), support group control (cINT, n=19) or no intervention (noINT, n=18) for 8 weeks plus a 4-week post-study follow-up. All participants also completed daily diary assessments. Effects were compared within and between groups. Linear regression models assessed factors, including treatment assignment, associated with physical function, pain, substance use and quality of life.

Results: Participants had mean age 55, 17 years HIV+, 11 years chronic pain; 84% were non-white, 76% male and 9% transgender women. Approximately 1/3 each reported alcohol, marijuana and stimulants as their preferred substance. At baseline, all participants had physical and mental health (SF-12) scores below population means, and 87% had reduced physical function (short physical performance battery [SPPB] ≤10). After 8 weeks, only EXP participants had significantly improved SPPB scores (+31%, within-group p<0.001, between-group p=0.04) and physical function (60% less reduced physical function) that persisted at the post-study follow-up visit and after controlling for age, education, HIV and baseline pain severity. After 12 weeks, both EXP (-55%, p=0.04) and cINT (-120%, p=0.03) participants demonstrated reduced 30-day preferred substance use. However, only EXP participants experienced reduced overall substance use (-51%, p=0.02) and improved percent pain relief (-76%, p=0.03).
Conclusions: An 8-week combined CBT, tai chi and motivational text messaging intervention significantly improved physical function in older HIV+ adults with chronic pain and substance use. After 12 weeks, substance use decreased and achievable pain relief also improved, possibly reflecting delayed onset of improvement in these outcomes. Further study will determine whether CBT + tai chi + motivational texting can provide sustained improvements in this vulnerable population.

Background: Mental disorders are prevalent among people living with HIV (PLWH) and are associated with inferior HIV treatment outcomes, including poor adherence to antiretroviral therapy and lack of viral suppression. Integrating interventions to treat mental disorders into HIV care is a key strategy to improve HIV treatment outcomes in low- and middle-income countries (LMIC), but data on HIV treatment sites' capacities to screen and manage mental disorders is limited.
Methods: We report preliminary findings from an ongoing survey among a stratified random sample of 142 HIV treatment sites in 36 LMIC that participate in the International epidemiologic Databases to Evaluate AIDS (IeDEA). This analysis focuses on depression, posttraumatic stress disorder (PTSD), and substance use disorders (SUD) screening and management in the 53 adult HIV treatment sites that have completed the survey so far.
Results: Most sites (n=40, 75%) were in urban areas. Although 34 sites (64%) reported screening for depression, only 14 (26%) sites had guidelines for screening. Screening for depression and PTSD was more common in low-income countries than middle-income countries. This trend was reversed for SUD screening (Table). Depression, PTSD, and SUD were managed on site (defined as having services provided at the HIV clinic or the same health facility) in 62%, 43%, and 36% of sites, respectively. Selective serotonin reuptake inhibitors (SSRIs) were available in all sites from upper-middle income countries, but only in 22% and 35% of low-income and lower-middle income countries, respectively.

	Low Income Countries N=18 n(%)	Lower middle income countries N=23 n(%)	Upper middle income countries N=12 n(%)	Total N=53 n(%)
Depression screening	13(72)	14(61)	7(58)	34(64)
Guideline available for depression screening	8(44)	3(13)	3(25)	14(26)
Depression management on site	10(56)	12(52)	11(92)	33(62)
PTSD screening	8(44)	2(9)	2(17)	12(23)
Guideline available for PTSD screening	7(39)	2(9)	1(8)	10(19)
PTSD management on site	8(44)	5(22)	10(83)	23(43)
Substance use disorders screening	8(44)	18(78)	8(67)	34(64)
Guideline available for substance use disorders screening	6(33)	4(17)	4(33)	14(26)
Substance use disorders management on site	6(33)	5(22)	8(67)	19(36)

[Screening and management of mental disorders]

Conclusions: Interim findings suggest that most of the HIV treatment facilities surveyed have integrated some mental health services and that screening for depression is commonly reported in low-income countries. However, on site management of depression is less common in these settings. Additional research is needed to understand individual, organizational, and contextual factors that may influence availability of mental health interventions in LMIC.

Methods of gestational age (GA) assessment influence the observed association between ART exposure and preterm delivery (PTD): a prospective study in Cape Town, South Africa

T. Malaba[1,2], M.-L. Newell[3], H. Madlala[1,2], A. Perez[1,2], C. Gray[4], L. Myer[1,2], for the PIMS Study
[1]*University of Cape Town, Division of Epidemiology and Biostatistics, Cape Town, South Africa,* [2]*University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa,* [3]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom,* [4]*University of Cape Town, Division of Immunology, Cape Town, South Africa*
Presenting author email: thokomalaba@gmail.com

Background: The association between antenatal ART and PTD in HIV+ women is controversial and has not been reliably quantified. Measuring GA is challenging in resource-limited settings; different methods could explain heterogeneous findings. We examined impact of GA estimation methods on observed PTD deliveries rates, by maternal ART.
Methods: Between 4/2015-10/2016 we enrolled women regardless of HIV status attending a large primary care antenatal clinic. Midwives estimated GA by last menstrual period (LMP) and symphysis-fundal height (SFH); separately, obstetric ultrasound was performed by a research sonographer blinded to midwife GA assessment if clinical GA was < 24w. Analyses compared GA estimated by ultrasound, SFH and LMP; the association between HIV/ART status and PTD was examined by GA assessment method using multivariable logistic regression.
Results: Of 1060 women (median age 28y; 46% HIV+ of whom 48% initiated ART pre-conception vs 52% during pregnancy), 82% had LMP-based GA, 71% SFH-based GA, 58% ultrasound-based GA and 54% (n=576) had GA based on ultrasound and at least one other method. At first ANC visit, estimated median (IQR) GA was 18w (12-23w) by LMP, 23w (18-28w) by SFH and 17w (13-21w) by ultrasound. Overall PTD < 37w was observed in 41% by LMP, 27% by SFH and 12% by ultrasound. In 1037 live-singleton births (mean birthweight 3124g; 10% SGA < 10th centile), PTD risk was doubled for HIV-infected compared to uninfected women for ultrasound-based GA (OR=2.01, 95%CI=1.15-3.51); but for LMP/SFH-based GA the association was not significant (Figure). These differences between GA assessment methods persisted after adjustment for age, parity, height and previous PTD; PTD risk did not vary by ART initiation timing for any GA method.
Conclusions: Findings for an association between HIV/ART and PTD are substantially influenced by GA assessment method. With growing scientific interest in this association, future research efforts should seek to standardize optimal measures of gestation.

Presenting author email: sufia@jhu.edu

Background: In the era of universal HAART, concerns remain that triple-therapy may increase adverse pregnancy outcomes. We compared low birth weight (LBW), preterm birth (PTB), and survival in infants born to ART-experienced women and to uninfected women in Blantyre, Malawi, where first-line ART includes tenofovir, lamivudine, and efavirenz.
Methods: We enrolled HIV-infected and uninfected women and their babies at delivery into a one-year prospective study at four health-facilities. Eligibility included confirmed HIV status, consent, singleton births, CD4>350 cells/mL^3, and no stage 3/4 HIV. We documented sociodemographic data, clinical and reproductive history, maternal and infant survival, birth weight and gestational age using Ballard score. We applied logistic regression to measure the association between HIV and LBW and PTB. Odds ratios and 95% CIs are presented.
Results: We enrolled 459 HIV-uninfected and 335 HIV-infected women on ART from January to December 2016; 1.4% were virally suppressed at baseline (< 40 copies per/ml). Rates of LBW among HIV-infected and uninfected women were 4.2% and 3.4%, respectively; p=0.69. 11.9% of HIV-infected women and 12.0% of uninfected women delivered PTB; p=0.99. In multivariate analyses for LBW and PTB (Table 1), there was no association between HIV status and adverse outcomes. Among all women, having more than one pregnancy (OR=0.36, 95% CI (0.18, 0.73)) or more than one birth (OR=0.39, 95% CI (0.19, 0.82)) was protective against LBW. PTB was 8.9% among women starting ART before or during first trimester; 15.5% among those starting in second trimester; and 17.9% among women starting in third trimester (p=0.06 for trend). Two infants died: one HIV-exposed and one HIV-unexposed. No maternal deaths were observed.

Baseline Characteristics		Low Birth Weight		Gestational Age	
		OR (95% CI)	Adjusted OR (95% CI)	OR (95% CI)	Adjusted OR (95% CI)
HIV Status (reference = HIV-, n=408)	HIV+ (n=310)	1.23 (0.57, 2.66)	2.08 (0.88, 4.90)	0.99 (0.63, 1.57)	1.18 (0.69, 1.98)
Maternal age	Per year of age	0.96 (0.89, 1.03)	0.95 (0.88, 1.03)	0.98 (0.95, 1.02)	0.99 (0.94, 1.03)
Body Mass Index at delivery (kg/m2) (reference = 18.5-24.9, n=426)	<18.5 (n=15)	1.83 (0.23, 14.78)	2.12 (0.25, 17.83)	1.92 (0.52, 7.05)	2.26 (0.59, 8.63)
	≥25 (n=267)	1.00 (0.45, 2.25)	0.99 (0.43, 2.32)	1.05 (0.65, 1.68)	1.11 (0.67, 1.82)
Estimated work load during pregnant (reference = In house only, n=569)	In house + outdoor (n=43)	0.63 (0.83, 4.79)	0.71 (0.09, 5.58)	1.10 (0.42, 2.91)	1.33 (0.49, 3.63)
	Moderate to heavy (n=92)	0.27 (0.04, 2.00)	0.24 (0.03, 1.84)	0.62 (0.28, 1.40)	0.54 (0.22, 1.29)
Electricity at home (reference = Yes, n=337)	No (n=382)	1.29 (0.59, 2.82)	1.33 (0.59, 2.99)	1.13 (0.72, 1.78)	1.30 (0.80, 2.12)
Hemoglobin (reference = ≥10 mmHg, n=522)	<10 mmHG (n=151)	2.28 (0.68, 7.71)	2.81 (0.81, 9.75)	1.20 (0.67, 2.14)	1.33 (0.72, 2.46)

[Table 1: Adverse Pregnancy Outcomes by HIV Status]

Conclusions: It is reassuring to observe that adverse outcomes were not different between healthy HIV-infected women and HIV-uninfected women. It appears that near-universal ART can eliminate mother-to-child transmission of HIV without significant negative impact on other pregnancy outcomes.

MOPDC0103

ARV drug concentrations in breastmilk, viral load, and HIV transmission to the infant

N. Davis[1], A. Corbett[2], J. Kaullen[2], J. Nelson[2], C. Chasela[3], D. Sichali[4], M. Hudgens[2], W. Miller[5], D. Jamieson[1], A. Kourtis[1], BAN study team
[1]Centers for Disease Control and Prevention, Division of Reproductive Health, Atlanta, United States, [2]University of North Carolina at Chapel Hill, Chapel Hill, United States, [3]University of Witwatersrand, Johannesburg, South Africa, [4]UNC Project Malawi, Lilongwe, Malawi, [5]Ohio State University, Columbus, United States
Presenting author email: dwg4@cdc.gov

Background: Concentration of antiretroviral (ARV) drug found in plasma, as well as the amount of drug excreted into breastmilk, may affect the rate at which ARVs suppress viral replication, and/or the duration of viral suppression, affecting HIV viral load and potentially HIV transmission from mother to infant.
Methods: A case cohort study was conducted using data from the Breastfeeding, Antiretrovirals and Nutrition study to 1) examine correlation between plasma and breastmilk ARV drug concentration, 2) estimate associations between ARV drug concentration and HIV viral load, and 3) compare time to breastmilk HIV transmission by plasma drug concentration status. We included mothers randomized to 28 weeks of postpartum maternal ARVs or infant nevirapine who had ≥1 plasma or breastmilk (maternal ARV arm only) specimen available 2-24 weeks postpartum. Among these, we included all mothers who transmitted HIV to their infants between 2-28 weeks and 15% of mothers who did not (n=27 and 227, respectively). Plasma and breastmilk drug concentrations for nevirapine, nelfinavir, and lopinavir were dichotomized using the median effective concentration (EC50) as a cutoff (>EC50 vs ≤EC50). Plasma and breastmilk viral load were dichotomized as detectable (plasma: >40 copies/ml, breastmilk: >56 copies/ml) or undetectable. Spearman correlation coefficients were used to assess correlation between plasma and breastmilk ARV concentration. Associations between drug concentration and viral load cutoffs were assessed using mixed effects models. Cox models were used to estimate the association between plasma drug concentration and breastmilk HIV transmission between 2-28 weeks.
Results: All ARV compounds exhibited substantial correlations between maternal plasma and breastmilk concentrations (rho: 0.85-0.98, p-value < 0.0001). Having plasma drug concentration above the EC50 was associated with lower odds of having detectable HIV RNA (plasma OR 0.69, 95%CI 0.49-0.98; breastmilk OR 0.23, 95% CI 0.15-0.37) and a reduced rate of breastmilk HIV transmission (HR 0.42, 95% CI 0.18-0.98). Having breastmilk drug concentration above the EC50 was also associated with lower odds of having detectable HIV RNA (plasma OR 0.65, 95%CI 0.47-0.89; breastmilk OR 0.44, 95% CI 0.31-0.62).
Conclusions: Ensuring adequate drug concentration in both plasma and breastmilk is important for reaching and maintaining viral suppression, and preventing breastmilk HIV transmission.

MOPDC0104

Stillbirth in HIV-infected women delivering in UK/Ireland between 2007 and 2015

G. Favarato, H. Bailey, H. Peters, K. Francis, A. Horn, R. Sconza, P. Tookey, C. Thorne, National Study of HIV in Pregnancy and Childhood (NSHPC)
UCL Great Ormond Street Institute of Child Health, Faculty of Population Health Sciences, London, United Kingdom
Presenting author email: graziella.favarato@ucl.ac.uk

Background: Stillbirth (SB) has multifactorial and incompletely understood causes. We aimed to assess the SB rate and associated risk factors in HIV-infected women delivering in UK/Ireland between 2007-2015.
Methods: We analysed data from singleton deliveries and defined a SB as a baby delivered at ≥24 gestational weeks (GW) showing no signs of life. We performed multivariable logistic regression of SB risk factors, adjusted for maternal age and country of origin (grouped, see Table), year, IDU history, parity, first antenatal CD4 count ≤350cells/μL, antenatal ART regimen, late antenatal care start (≥13GW) and newborn gender with random effect for repeated pregnancies in the same mother.
Results: There were 10157 pregnancies (in 7951 mothers) and 87 (0.9%) SB; MTCT was reported in 41 (0.4%) cases. Compared to live births (LB) SB were more likely to be male (58.7% vs 50.6%), delivered pre-term (median 33.5GW vs 39GW) and be SGA (55.2% vs 20.4%); 7/87 (8.1%) SB had congenital abnormalities versus 295/10070 (2.9%) LB. Compared to mothers delivering a LB, those delivering a SB were more likely to be primiparous (46.5% vs 32.7%), older (56.3% vs 47.2% of age ≥33yrs), from Eastern Africa (47.1% vs 41.4%), more likely to book antenatal care at ≥13GW (93.1% vs 86.8%), have first antenatal CD4 count ≤350cells/μL (50.8% vs 34.5%) and more likely to receive no antenatal ART (5.8% vs 1.6%). Multivariate analysis suggested that significant risk factors associated with SB were antenatal CD4 count ≤350cells/μL and delivering a male newborn; women whose country of origin was not Europe or Africa were also at higher risk (Table).

Maternal age (per 1year increase)	1.04 (0.98, 1.10)
Area of origin: Europe	1.00
Eastern Africa	1.63 (0.55, 4.80)
Western Africa	1.35 (0.40, 4.57)
Middle/South Africa	2.24 (0.68, 7.39)
Other	4.33 (1.31, 14.26)
CD4 cells/µL: ≤350	1.00
>350	1.96 (1.09, 3.53)
Newborn : Female	1.00
Male	1.95 (1.06, 3.58)

[Adjusted OR (95%CI) for stillbirth]

Conclusions: SB rate in HIV-infected women in UK/Ireland was 0.9% in 2007-2015, around twice that in the general population (< 0.5%). Further research is needed to understand circumstances around SB in this population in order to identify possible interventions.

Usefulness of HBV rapid tests to identify pregnant women at high-risk of HBV mother to child transmission: the pilot ANRS 12328 study in Cambodia

O. Segeral[1], D. N'Diaye[2], S. Prak[3], W. Khamduang[4], J. Nouhin[3], M. Ek[5], K. Chim[5], S. Hout[6], A.-M. Roque-Afonso[7], P. Piola[2], N. Ngo-Giang-Huong[4], F. Rouet[3]

Presenting author email: oliseg@hotmail.com

Background: Mother-to-child transmission (MTCT) of HBV is mainly associated with high maternal HBV DNA viral load (VL) levels. International guidelines recommend the use of antiviral drugs (such as tenofovir [TDF]) during pregnancy if maternal VL is >200,000 IU/mL. In Southeast Asia (SEA), many pregnant women are not screened for hepatitis B surface antigen (HBsAg) and VL testing is not accessible for those who are HBsAg-positive. Here, we report among pregnant women from Cambodia, the performance of a serial algorithm using two HBV rapid diagnostic tests (RDTs), in which samples reactive for HBsAg were further tested for hepatitis B e antigen (HBeAg), as a surrogate marker for HBV replication.
Methods: In 2015, we prospectively collected plasma samples of 250 pregnant women from the Calmette Hospital (Phnom Penh), including women with a known positive HBsAg status. All specimens were initially tested with the SD BIOLINE HBsAg RDT (Standard Diagnostics), and results were compared to the Murex HBsAg ELISA v3.0 (Diasorin) (gold standard). HBeAg status was then blindly assessed among all ELISA HBsAg-positive samples using the SD BIOLINE HBeAg RDT, and results were compared to HBV DNA levels (PUMA HBV kit, Omunis) (gold standard). Analysis was done according to thresholds of 200,000 and 2,000,000 IU/mL.
Results: Overall, 128 pregnant women tested positive for HBsAg with ELISA (51.2%). The sensitivity and specificity of the HBsAg RDT, compared to ELISA, were 99.2% (95% confidence intervals, 95.7-99.9) and 100% (97.0-100), respectively. Among the 128 ELISA HBsAg-positive samples, 29 (23%) tested positive with the HBeAg RDT, 34 (26%) showed HBV viremia >200,000 IU/mL and 29 (23%) >2,000,000 IU/mL. The sensitivity and specificity of the HBeAg RDT in detecting HBV replication were 76.5% (60.0-87.6) and 96.8% (91.0-98.9) for VL > 200,000 IU/mL and 89.7% (73.6-96.4) and 97.0% (93.6-100.0) for VL >2,000,000 IU/mL.
Conclusions: Our results strongly suggest that a combination of HBsAg and HBeAg RDTs in a serial algorithm is an efficient strategy to identify highly viremic HBV-infected pregnant women in need of TDF to prevent HBV MTCT. RDTs-based strategies can significantly improve HBV screening coverage among pregnant women, notably in SEA where HBV is highly prevalent.

MOPDD0101

HIV treatment and care services for adolescents: a situational analysis of 218 facilities in 23 sub-Saharan African countries

D. Mark[1,2], A. Armstrong[3], C. Andrade[1], M. Penazzato[4], L. Hatane[1], L. Taing[1], T. Runciman[1], N. Sugandhi[5], J. Ferguson[6]
[1]PATA, Cape Town, South Africa, [2]University of Cape Town, Psychology, Cape Town, South Africa, [3]Consultant, London, United Kingdom, [4]World Health Organisation, HIV Department, Geneva, Switzerland, [5]ICAP at Colombia University, New York, United States, [6]Africa Centre for Population Health, Health Adolescents & Young Adults Research Unit, Mtubatuba, South Africa
Presenting author email: luann@teampata.org

Background: In 2013, 2.1 million adolescents (age 10-19 years) were living with HIV globally. The extent to which health facilities provide appropriate treatment and care was unknown. To support understanding of service availability in 2014, Paediatric-Adolescent Treatment Africa (PATA), an NGO supporting a network of health facilities across sub-Saharan Africa, undertook a facility-level situational analysis of adolescent HIV treatment and care services in 23 countries.
Methods: Two hundred and eighteen facilities , responsible for an estimated 80,072 HIV-infected adolescents in care, were surveyed. Sixty percent of the sample were from PATA's network, with the remaining gathered via local NGO partners and snowball sampling. Data were analyzed using descriptive statistics and coding to describe central tendencies and identify themes.
Results: Respondents represented three sub-regions: West and Central Africa (n=59; 27%), East Africa (n=77, 35%) and Southern Africa (n=82, 38%). Half (50%) of the facilities were in urban areas, 17% peri-urban and 33% rural settings. Insufficient data disaggregation and outcomes monitoring were critical issues. A quarter of facilities did not have a working definition of adolescence. Facilities reported non-adherence as their key challenge in adolescent service provision, but had insufficient protocols for determining and managing poor adherence and loss to follow-up. Adherence counselling focused on implications of non-adherence rather than its drivers. Facilities recommended peer support as an effective adherence and retention intervention, yet not all offered these services. Almost two-thirds reported attending to adolescents with adults and/or children, and half had no transitioning protocols. Of those with transitioning protocols, 21% moved pregnant adolescents into adult services earlier than their peers. There was limited sexual and reproductive health integration, with 63% of facilities offering these services within their HIV programmes and 46% catering to the special needs of HIV-infected pregnant adolescents.
Conclusions: Results indicate that providers are challenged by adolescent adherence, and reflect an insufficiently targeted approach for adolescents. Guidance on standard definitions for adherence, retention and counselling approaches are needed. Peer support may create an enabling environment and sensitize personnel. Service delivery gaps should be addressed, with standardized transition and quality counselling. Integrated, comprehensive sexual reproductive health services are needed, with support for pregnant adolescents.

MOPDD0102

Factors associated with viral suppression among adolescents living with HIV in Cambodia

S. Yi[1,2], C. Ngin[1], S. Tuot[1], P. Chhoun[1], K. Pal[1], S. Sau[3], K. Chhim[1], S.C. Choub[1], G. Mburu[4], P. Ly[3]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]Touro University California, Center for Global Health Research, Vallejo, United States, [3]National center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia, [4]Lancaster University, Division of Health Research, Phnom Penh, United Kingdom
Presenting author email: ckolab@khana.org.kh

Background: Adolescents living with HIV on antiretroviral therapy (ART) have poorer rates of treatment adherence and viral suppression as well as higher mortality rates compared to their adult counterparts. This study investigated factors associated with viral suppression among adolescents living with HIV in Cambodia.
Methods: A cross-sectional study was conducted in August 2016, among adolescents living with HIV aged 15-17 years randomly selected from 11 ART clinics in the capital city and 10 provinces, utilizing a structured questionnaire. The most recent viral load test result was retrieved from medical records obtained from the ART clinics. Adolescents were categorized as having viral suppression if the viral load count was < 1,000 copies/ml. Multivariate logistic regression analysis was performed.
Results: This study included 328 adolescents with a mean age of 15.9 years (SD= 0.8); of whom, 48.5% were female. Mean duration on ART was 97 months (SD= 40.2). Proportion of adolescents with viral load suppression was 76.8%. In bivariate analyses, viral suppression was significantly associated with older age, duration on

ART, higher CD4 count, better family socio-economic status, living with parents, parental education, having parents as main caregivers, no experience of negative attitude from healthcare providers, being aware that they were receiving ART, knowing that HIV is transmitted through unprotected sex with people living with HIV, understanding that there is no cure for AIDS, receiving treatment from a pediatric clinic and type of ART (first or second line). After adjustment, viral suppression remained significantly associated with longer duration on ART, higher CD4 count, receiving treatment from a pediatric clinic, being aware that they were receiving ART and better HIV-related knowledge including knowing that HIV is transmitted through unprotected sex with people living with HIV and understanding that there is no cure for AIDS.
Conclusions: Viral load suppression rates among adolescents living with HIV in this study were considerably high, but fall short of the global target of 90% viral suppression among people living with HIV on ART. Our findings indicate the need to strengthen treatment literacy and understanding of HIV among adolescents as they prepare for transition from pediatric to adult HIV care.

MOPDD0103

Evaluating the implementation and impact of the adolescent package of care at health facilities in former Nyanza province, Kenya

M. Mburu[1], P. Ongwen[1], M. Guze[2], N. Okoko[1], S.B. Shade[3], C. Blat[2], J. Kadima[1], J.P. Otieno[1], N. Tuma[1], W. Muriu[4], E.A. Bukusi[1], C.R. Cohen[1], H.T. Wolf[5]

Presenting author email: megmburu@gmail.com

Background: Youth represent 40% of new HIV infections worldwide including in sub-Saharan Africa. Young people respond better to HIV and sexual health services tailored for their developmental stage. In 2015, Kenya's National AIDS and STD Control Program (NASCOP) introduced an adolescent package of care (APOC) to provide standardized adolescent services to HIV infected adolescents. We conducted this evaluation to assess the impact of APOC on: visit adherence, family planning (FP) uptake, and viral load (VL) suppression.
Methods: Beginning in November 2015, staff at Family AIDS Care & Education Services (FACES)-supported sites were trained in APOC, which included utilizing adolescent checklists and adolescent tailored services i.e. support groups, home re-fills, adolescent clinic days. At 16 sites utilizing electronic medical records, data for adolescents (9-19 years) was extracted on demographic characteristics, clinic appointments, FP, and VL from November 2015-December 2016. At these same sites, chart audits were conducted on a random sample of encounters per site every quarter to assess APOC checklist utilization (0-10) as a proxy for APOC implementation. Generalized estimating equations for logistic regression, accounting for repeated measures, were used to assess effect of checklist utilization on outcomes from November 2015-Decemeber 2016.
Results: We assessed visit adherence and FP uptake in 19,301 encounters for 2,739 HIV-infected adolescents and 1,372 VL tests for 1,305 adolescents. Median age was 13 years (IQR 11, 17). Females comprised 60% (n=1,646) and 61% (n=794) of the clinical encounters and VL tests, respectively. FP uptake (aOR=1.50; 95% CI: 1.19-1.89) and VL suppression (aOR=1.54; 95% CI: 1.09-2.20) increased over time, as did APOC checklist utilization (aOR=2.18; 95% CI: 1.54-3.08). Increased APOC checklist utilization was not associated with change in visit adherence and was inversely associated with FP uptake (aOR= 0.93; 95% CI: 0.89-0.98) and VL suppression (aOR=0.87; 95% CI: 0.89-0.95) over time.
Conclusions: We observed increased FP uptake and VL suppression during scale-up of the APOC. However, increased utilization of the APOC checklist was not associated with these improved outcomes. The checklist is only one element of APOC. Further investigation of additional elements are needed to assess full implementation and impact of APOC on adolescent outcomes.

Economic context and HIV vulnerability in adolescents and young adults living in urban slums in Kenya: a qualitative analysis-based on scarcity theory

L. Jennings[1], M. Muthai[2], S. Linnemayr[3], A. Trujillo[1], M. Mak'anyengo[4], B. Montgomery[5], D. Kerrigan[6]
[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]University of Nairobi, College of Health Sciences, Department of Psychiatry, Nairobi, Kenya, [3]RAND Corporation, Santa Monica, United States, [4]National Health and Development Organization (NAHEDO), Kenyatta National Hospital, Nairobi, Kenya, [5]Univertiy of Arkansas for Medical Sciences, Fay W. Boozman College of Public Health, Health Behavior and Health Education, Little Rock, United States, [6]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior, and Society, Baltimore, United States
Presenting author email: ljennin6@jhu.edu

Background: Urban slum adolescents and young adults have disproportionately high rates of HIV compared to rural and non-slum urban youth. Yet, few studies have examined youth's perceptions of the economic drivers of HIV. This study applied principles from traditional and behavioral economics, in particular the theory of scarcity as defined by Mullainathan & Shafir (2013), in understanding the duality that impoverished youth face in making sexual decisions both in response to direct money shortages and under the cognitive load of financial distress.
Methods: Twenty focus group discussions were conducted with 120 adolescents, aged 15 - 17, and young adults, aged 18 - 22, living in one of two urban slums in Nairobi, Kenya. Using a semi-structured discussion guide, we asked youth to describe how their economic scarcity, in the form of financial, material, and physical deprivation, contributed to sexual risk behaviors and influenced their capacity to prevent HIV acquisition. All discussions were conducted in Kiswahili and translated and transcribed into English. Data were then coded and analyzed using interpretive phenomenology.
Results: Results indicated that slum youth made many sexual decisions considered rational from a traditional economics perspective, such as acquiring more sex when resources were available, maximizing wealth through sex, being price-sensitive to costs of condoms or testing services, and taking more risks when protected from adverse sexual consequences. Youth's engagement in sexual risk behaviors was also motivated by scarcity phenomena explained by behavioral economics, such as compensating for sex lost during scarce periods (i.e., risk-seeking), valuing economic gains over HIV risks (i.e., tunneling, bandwidth tax), and transacting sex as an investment strategy (i.e., internal referencing). When scarcity was alleviated, young women additionally described reducing the number of sex partners to account for non-economic preferences (i.e., slack). These findings further revealed two implications for prevention interventions relating to gender-specific economic interests and reduced perceived costs of HIV infection.
Conclusions: Scarcity theory draws attention to the role of financial insecurity in altering how individuals and couples approach sexual decision-making. Combination prevention interventions, including biomedical technologies relying on adherence, should not ignore traditional and behavioral economic drivers of sexual decisions in urban poor settings.

MOPDD0105

The effectiveness and cost-effectiveness of community-based support for adolescents receiving antiretroviral treatment in South Africa

G. Fatti[1], N. Shaikh[1], O. Oyebanji[1], F. Chirowa[2], D. Jackson[3,4], A. Goga[5,6], T. Magubu[7], J.B. Nachega[8,9,10], B. Eley[11], A. Grimwood[1]

Presenting author email: ashraf.grimwood@khethimpilo.org

Background: Adolescents receiving antiretroviral treatment (ART) in sub-Saharan Africa are at particular risk of suboptimal adherence, inadequate viral suppression and high loss to follow-up (LTFU). Sub-Saharan Africa also has critical shortages of professional healthcare workers. Community-based support (CBS) programs

are task-shifting interventions to address these shortages. Effectiveness and cost-effectiveness data of interventions improving ART outcomes amongst adolescents are very limited. We measured the effectiveness and cost-effectiveness of a large CBS program in South Africa, the country having the highest HIV burden globally.
Methods: A cohort study including ART-naïve adolescents and youth (ages 10-24 years) who initiated ART at 47 facilities. CBS workers conducted regular home visits providing ART-related and adherence education, psychosocial support, symptom screening for opportunistic infections and traced patients defaulting clinic appointments. Outcomes were compared between adolescents who received CBS plus standard clinic-based care vs. adolescents who received standard care only. Cumulative incidences of LTFU, mortality, CD4 count increases, viral suppression, and pharmacy refill data using the medication possession ratio (MPR) were analysed using multivariable competing-risks regression, generalized estimating equations and multilevel mixed-effects models over five years of treatment. Costs of CBS were compiled and incremental cost-effectiveness ratios (annual cost per additional patient retained in care for patients receiving CBS vs. not receiving CBS) were calculated.
Results: Of 6706 patients included, 2100 (31.3%) received CBS. 5523 (82.4%) were female and 1810 (27.0%) were aged 10-19 years. LTFU was 36% lower amongst adolescents who received CBS; being 29.9% vs. 39.0% amongst adolescents with and without CBS after 5 years, respectively; adjusted subhazard ratio (asHR)=0.64 (95% CI: 0.55-0.76); P<0.0001). Mortality was 32% lower amongst adolescents with CBS, asHR=0.68 (95% CI: 0.53-0.88; P=0.004). Virological suppression (adjusted risk ratio=1.04 [95% CI: 0.94-1.16]), annual CD4 count increases (coefficient=11.7 [95% CI: -13.0 to 36.6; P=0.35]) and mean MPR (81.9% vs. 82.7%; P=0.16) were not significantly different. The average cost of CBS was US$49.54/patient/year. The cost per additional patient retained due to CBS was US$828 and US$594 after one and two years, respectively.
Conclusions: CBS for adolescents receiving ART is a low-cost intervention associated with substantially reduced LTFU and mortality, and can be scaled-up in low income countries.

MOPDD0106

HIV risk behavior, risk perception and experiences in accessing HIV and sexual reproductive health (SRH) services among adolescent key populations in Kenya: a situational analysis

A. Ikahu[1], R. Kimathi[1], M. Kiragu[1], S. Njenga[1], M. Mireku[1], M. Muthare[1], G. Ombui[1], J. Kyongo[1], R. Karuga[1], E. Gitau[2], U. Gilbert[2], H. Musyoki[3], L. Digolo[1], W. Mukoma[1], L. Otiso[1]
[1]LVCT Health, Nairobi, Kenya, [2]UNICEF, Nairobi, Kenya, [3]NASCOP, Nairobi, Kenya
Presenting author email: annrita.ikahu@lvcthealth.org

Background: Men who have sex with men, sex workers, and people who inject drugs are considered key populations (KPs) due to their high risk of HIV infection and transmission. Adolescent KPs (less than 19 years) are at higher risk of HIV than their older counterparts yet programs have not prioritized them. Legal barriers affect their access to SRH and HIV services. A study was conducted to identify risk perceptions and experiences that heighten risk of HIV among adolescents aged 10-19 years who engage in either sex work, same sex relationships or intravenous drug use and their uptake of SRH services.
Methods: A qualitative exploratory study was conducted between October 2015 and April 2016 in Nairobi, Mombasa and Kisumu Counties. Nine (9) focus group discussions and 18 in depth interviews were conducted with 37 adolescent girls reporting sex work, 36 adolescent boys in same sex relationships, and 35 adolescents involved in intravenous drug use. The participants were purposively selected from various KP community based organizations. Data were coded thematically and analyzed using Nvivo 10. Ethical approval was obtained from AMREF ESRC.
Results: 108 adolescent KPs (51 female and 57 male) ranging from 10 to 19 years were interviewed. They reported similar experiences that placed them at heightened HIV risk; being forced to have "condomless" sex for more money, selling sex to sustain themselves and their dependents (22 of the 37 adolescent FSWs had children), sexual abuse and physical abuse from clients and police. Self-perceptions of HIV risk were mixed; those practicing sex work and had multiple sexual partners perceived themselves to be at high risk while those having one partner perceived themselves at low risk. All groups preferred accessing SRH services in private unlike public facilities due to stigma and discrimination.
Conclusions: The findings demonstrate the challenges faced by the often forgotten adolescent KPs highlighting the need for adolescent KP friendly policies, services and structural interventions to address poverty, legal barriers to service access, violence, stigma and discrimination. HIV prevention interventions should address knowledge of and self-perception of HIV risk to prevent HIV acquisition and transmission.

Evidence of substantial HIV-1 genetic evolution in vivo during suppressive therapy

L. Bertoni Giron[1], J. Galinskas[1], S. Tenore[1], M.C. Araripe Sucupira[1], L.M. Ramos Janini[1], S. Pillai[2], R. Sobhie Diaz[1]
[1]Federal University of Sao Paulo, Infectious Diseases, São Paulo, Brazil, [2]Blood Systems Research Institue/ University of California San Francisco, San Francisco, United States
Presenting author email: rsdiaz@catg.com.br

Background: Although antiretroviral therapy (ART) suppresses HIV to undetectable levels in plasma, it is unclear if treatment fully suppresses viral replication. We aimed to determine if current ART is fully suppressive by investigating HIV genetic diversification during therapy as a proxy for ongoing viral replication.
Methods: Peripheral blood cells from 30 HIV-infected individuals were evaluated immediately before starting therapy and after four years of continuous ART with undetectable viral loads. Ultra-deep sequencing of the gp41 and C2V3 regions of HIV gp160 was performed. Low-frequency viral variants were filtered based on an error rate of 0.5% derived from misincorporations in the HIV BAL plasmid, which was amplified and sequenced with the samples. HIV divergence and diversity at each time point were calculated using average pairwise distance. Genetic compartmentalization analyses between time points based on tree topologies and pairwise distance were also performed. Correlations between genetic divergence and elapsed time between sampling points were evaluated using linear regression, implemented using TempEst software (root-to-tip analysis).
Results: There was no correlation between read depth and the number of viral variants recorded (p=0.74). gp41 sequences after four years of ART demonstrated significant increases in viral genetic divergence from the most recent common ancestor sequence as compared to baseline sequences from the same individual (p=0.0004). Viral divergence values exhibited significant negative correlations with the CD4/CD8 ratio (p=0.02). No difference was observed in viral diversity between time points. Compartmentalization analyses indicated the presence of distinct virus populations emerging at each time point in 20 out of 30 individuals based on both tree topologies and pairwise distance analysis tests. Root-to-tip analyses yielded R^2 values ranging from 0.01 to 0.96 at gp41 and 0.15 to 0.74 at C2V3 region, indicating high correlation between genetic divergence and time and therefore viral evolution.
Conclusions: Ongoing viral genetic evolution was detected in the majority of individuals on continuous ART. These results suggest that current ART regimens do not completely suppress viral replication. Residual replicating virus may replenish the viral reservoir and sustain inflammatory responses, especially in sanctuaries. These findings suggest that ART intensification should be considered as part of HIV eradication strategies.

MOPEA0002

CRF19_cpx variant emergence in a cluster in naive patients of Southern Spain

I. Viciana[1], C.M. González-Domenech[2], M. Mayorga[3], J. de la Torre[4], F. Jarilla[5], M. Castaño[3], M. Márquez[1], E. Clavijo[1], R. Palacios[1,2], J. Santos[1,2]
[1]Hospital Virgen de la Victoria, Málaga, Spain, [2]IBIMA, Málaga, Spain, [3]Hospital Carlos Haya, Málaga, Spain, [4]Hospital Costa del Sol, Marbella, Spain, [5]Hospital de Antequera, Málaga, Spain
Presenting author email: iadomenech@gmail.com

Background: HIV CRF19_cpx has been described as a highly pathogenic recombinant from Cuba. We describe the emergence of this CRF19_cpx variant in southern Spain, clustering in MSM.
Methods: The study was undertaken at the Hospital Virgen de la Victoria (Málaga, Spain) a reference center for the analysis of HIV-1 genotypic drug resistance. The subtype for each FASTA sequence provided was assigned through REGA v3.0. Sequences consigned as a CRF19_cpx variant were confirmed by phylogenetic analysis with other 195 reference sequences retrieved from LANL. Protease and reverse transcriptase (RT) genes were aligned by ClustalX and the phylogenetic reconstruction inferred by maximum likelihood method (RAxML). The reliability of the clades was supported on bootstrapping, with 1,000 replications. For analysis of RT and protease resistance mutations Stanford algorithm v7.1.1 was used. Epidemiological, clinical and immunological data were collected.
Results: Genotypic test was performed in 2340 naive patients from four hospitals during 2011-2016, finding the CRF19_cpx variant in 52 (2.2%). These recombinants, except one, were clustered together (bootstrap=88%), with phylogenetic relation to CRF19_cpx from Israel, Bulgaria and Cuba. Seven well-supported subclusters with different number of patients were also found: A (n=9); B, C, D and G (n=2); E (n=10); and F (n=4). Non-nucleoside RT inhibitor G190A resistance mutation was found in 26 patients (50.0%), among them, clades C, D, E and F. All the patients were MSM, twenty-two of them (42,3%) had a prior negative HIV test, with a median time of seroconversion of 15,7 months. All were Spanish, except one patient from Argentine and one from France. The median age was 32.5 years, baseline CD4 count was 369/µL and VL 5.05 Log (4.4-5.5), being lower in patients with G190A mutation (4.6 vs 5.1, p=0.02). Three cases of AIDS (5,7%) and one death occurred (acute myocardial infarction). All the patients treated with first-line combination ART responded
Conclusions: CRF19_cpx variant has emerged affecting MSM naive patients from southern Spain; all cases but one are related to a local cluster. Half of patients showed the G190A resistance mutation. Unlike previous studies, the variant from Malaga seems less pathogenic, with few cases of AIDS and excellent response to ARV.

MOPEA0003

Impact of HLA-associated HIV adaptation on disease progression in Mesoamerica

[1]National Institute of Respiratory Diseases, Center for Research in Infectious Diseases, Mexico, Mexico, [2]Microsoft Research, Redmond, United States, [3]Roosevelt Hospital, Infectious Diseases Clinic, Guatemala, Guatemala, [4]Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama, Panama, [5]Hospital Metropolitano Vivian Pellas, Managua, Nicaragua, [6]Hospital Roberto Calderón, Managua, Nicaragua, [7]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, [8]Hospital Escuela Universitario, Tegucigalpa, Honduras, [9]Ministry of Health, Belmopan, Belize, [10]Hospital Nacional Rosales, San Salvador, El Salvador, [11]Simon Fraser University, Vancouver, Canada
Presenting author email: santiago.avila@cieni.org.mx

Background: Transmission of HIV pre-adapted to HLA class I-restricted CD8+ T cell responses can accelerate disease progression. HLA-associated adaptation of circulating HIV can vary significantly in populations with different immunogenetic backgrounds. We assessed the impact of HLA-associated HIV adaptation in Mesoamerica.
Methods: We estimated HLA-associated autologous, heterologous and circulating HIV adaptation distributions in gag and pol sequences from 3,208 HLA-typed, antiretroviral treatment-naïve individuals from Mexico, Guatemala, Belize, Honduras, El Salvador, Nicaragua and Panama using a published probabilistic framework.
Results: Autologous and heterologous HIV adaptation distributions overlapped substantially in Mesoamerica compared to other cohorts, suggesting a relatively high degree of pre-adaptation of the circulating virus to HLA alleles in the population. CD4 counts were significantly lower in individuals harboring HIV displaying high adaptation to the autologous HLA profile (p<0.0001 1st vs. 4th quartile). This effect was observed when considering adaptation to HLA-A (p=0.0012) and -B (p< 0.0001), but not -C alleles. Moreover, autologous adaptation could partially explain HLA-specific effects on plasma viral load (pVL): individuals with protective HLA alleles with non-adapted viruses showed lower pVL than individuals with highly adapted viruses (p=0.0482). Interestingly, HLA-specific circulating adaptation positively correlated with HLA-specific pVL (r=0.3276, p=0.0018) and HLA frequency (r=0.2990, p=0.0025), consistent with a general detrimental effect of HIV pre-adaptation on viral control in the Mesoamerican epidemic. Notably, risk HLA alleles showed significantly higher median circulating adaptation than protective alleles (p<0.0001). When considering only protective and risk HLA alleles, we observed a positive correlation between viral replicative capacity and HLA-specific circulating adaptation (r=0.4543, p=0.0442). Additionally, we identified pairs of same-locus HLA alleles with high adaptation similarity and observed that individuals with more compatible HLA pairs had significantly higher pVL (p=0.0386).
Conclusions: Our observations corroborate the negative impacts of HLA-associated HIV adaptation on HIV disease progression. We also provide evidence that adaptation of circulating viruses to frequent HLA alleles negatively impacts viremia control. Moreover, allele-specific circulating adaptation could explain some differential HLA effects on HIV disease progression in different populations. These observations underscore the importance of considering HIV adaptation in vaccine design in a population-specific manner.

MOPEA0004

Heterogeneous age and genetic distribution of within-host HIV-1 reservoirs revealed by a novel phylogenetic dating strategy

B.R. Jones[1], N.N. Kinloch[2], J. Horacsek[1], P. Mwimanzi[2], J. Huang[3], R. Truong[3], B. Ganase[1], M. Harris[1], P.R. Harrigan[1,4], R.B. Jones[3], M.A. Brockman[1,2], J.B. Joy[1,4], A. Poon[5], Z.L. Brumme[1,2]

Presenting author email: bjones@cfenet.ubc.ca

Background: HIV's ability to persist within latent cellular reservoirs represents a major barrier to cure. Since HIV reservoir establishment begins early following transmission, and HIV evolves continually within a host, viral reservoir sequences sampled during chronic infection should range in both age and divergence from the founder virus. However, methods to infer these parameters from HIV reservoir sequences remain limited. We developed a phylogenetically-informed regression method to date HIV sequences sampled within-host, and apply it to infer the ages of reservoir sequences sampled from the blood of an individual after nearly 10 years of suppressive cART.
Methods: The method involves inference of a maximum-likelihood phylogeny from longitudinal within-host plasma HIV RNA sequences, followed by optimal rooting of the tree using root-to-tip regression. Root-to-tip distances of presumed latent reservoir sequences are then mapped to the optimal regression line to estimate their establishment (integration) dates. The method was first validated on simulated and published HIV sequences. Then, it was applied to empirical data from a single participant comprising 65 Nef sequences isolated by single-template amplification from 14 archived pre-cART plasma samples spanning 1996-2006, and 16 unique putative reservoir sequences isolated in 2016 from PBMC during suppressive cART.
Results: Our phylogenetically-informed regression approach reliably recovered sampling dates from simulated longitudinal sequence datasets with and without latent lineages. Validation on published HIV RNA sequences was similarly successful and provided more realistic error estimates. Application of the method to „date" published HIV DNA sequences from phylogenies inferred from longitudinal datasets of paired HIV RNA and DNA sequences yielded age estimates consistent with latency. Application of the model to the study participant yielded a realistic estimated Nef evolutionary rate of 2.0 X 10^{-5} substitutions/base/day. Reservoir sequences were genetically diverse with estimated establishment dates ranging from 1999-2013, consistent with a heterogeneous reservoir pool.
Conclusions: Dates of establishment of individual HIV reservoirs can be recovered from phylogenetic analysis of within-host HIV RNA sequence variation. Our novel method illuminates HIV reservoir dynamics and contributes to the ongoing debate surrounding the extent of HIV evolution on suppressive cART.

MOPEA0005

Subtype-specific constraints on HIV-1 adaptation to host cellular immunity revealed through statistical and functional analyses

N.N. Kinloch[1], G.Q. Lee[2], J.M. Carlson[3], C.J. Brumme[2], H. Byakwaga[4,5], C. Muzoora[4], K.D. Cobarrubias[1], M.A. Brockman[1,2], P.W. Hunt[5], J.N. Martin[5], M. Carrington[6], D.R. Bangsberg[7], P.R. Harrigan[2,8], Z.L. Brumme[1,2]

Presenting author email: nkinloch@sfu.ca

Background: The extent to which viral genetic context constrains HLA-driven immune escape pathways in HIV remains incompletely understood. We combine phylogenetically-informed statistical analyses with in vitro functional assessments to investigate HLA-driven adaptation in a host population where multiple HIV-1 subtypes co-circulate (Uganda).
Methods: HLA-associated polymorphisms in HIV-1 Gag, Pol and Nef were identified in 200 antiretroviral-naive individuals infected with subtype A1 and 135 infected with subtype D. Their strengths of selection were then compared across HIV-1 subtypes using a phylogenetically-informed logistic regression approach to identify instances of differential selection between subtypes. Multiple testing was addressed using q-values. Infectious molecular clones expressing consensus and mutant subtype A1 or D gag/protease sequences in an HIV-1 NL4.3 backbone were constructed using Gibson Assembly and used to produce VsVg-pseudotyped virus stocks. In vitro replication of these viruses was assessed using a 7-day GFP-reporter-based assay.
Results: A total of 83 Gag, 198 Pol and 105 Nef HLA-associated polymorphisms were identified in subtype A and/or D at q< 0.2 (all p< $9x10^{-4}$). Of these, 34% (Gag), 39% (Pol) and 27% (Nef) exhibited significant differential selection between subtypes (p< 0.05; q< 0.1). For example, HLA-B*57:03 strongly selected Gag-T242N in subtype D (Odds Ratio [OR]=250; p=$2x10^{-10}$), but not subtype A1 (OR=1.8; p=0.8)(inter-subtype comparison p=$8x10^{-6}$; q=0.001). This raised the hypothesis that the subtype A1 consensus proline at adjacent Gag codon 243, which differs from the consensus leucine observed in subtype D, is incompatible with T242N. Indeed, a subtype A1 virus carrying 242N/P243 exhibited >10-fold poorer in vitro replication compared to consensus A1, confirming HIV-1 subtype-specific constraints on immune escape at this position.
Conclusions: Statistical analyses applied to linked HIV-1/HLA datasets can illuminate HIV-1 codons where mutational immune escape pathways may be constrained in certain HIV-1 subtypes. Functional validation of these incompatible mutation combinations may help identify subtype-specific mutationally-constrained viral regions for vaccine design.

MOPEA0006

Pre-existing tuberculosis infection and associated immune reconstitution inflammatory syndrome affects the HIV-1 reservoir

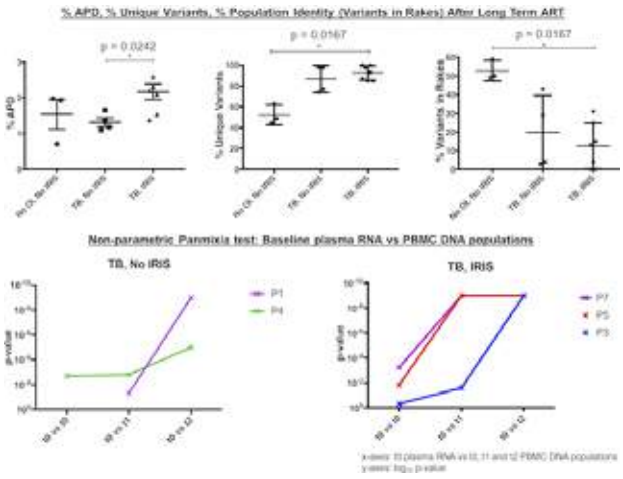
C. Lange[1], M. Manion[2], G. Roby[2], R. Gorelick[3], V. Sheikh[2], J. Adelsberger[4], F. Maldarelli[1], I. Sereti[2]
[1]NCI/NIH, Clinical Research Section, DRP, Frederick, United States, [2]NIAID, NIH, Laboratory of Immunoregulation, Bethesda, United States, [3]NIH, AIDS and Cancer Virus Program, Frederick, United States, [4]Leidos Biomedical Research, Inc, AIDS Monitoring Laboratory, Clinical Service Program, Frederick, United States
Presenting author email: camille.lange@nih.gov

Background: Tuberculosis (TB)-associated immune reconstitution inflammatory syndrome (IRIS) is an aberrant inflammatory response of TB patients starting antiretroviral therapy (ART), especially with severe CD4 lymphopenia or disseminated TB. Previous studies show TB-IRIS driving rapid expansion of activated TB-specific CD4+ T-cells. We hypothesized that pre-ART (baseline) TB and IRIS in HIV-1 infected patients have long-term effects on viral reservoirs.
Methods: A single copy assay measured HIV viremia in baseline lymphopenic (BL) patients +/-IRIS to assess if IRIS affected HIV replication after long term ART (1-2y). CD4+ T-cell associated (CA) gag RNA:DNA ratios quantified the CD4+ reservoir of patients +/-TB and IRIS. Single genome sequencing (SGS) of HIV-1 p6-pol (1.3kb) characterized proviral populations of peripheral blood mononuclear cells at baseline, 2-8w of ART, during IRIS; and after long-term ART as well as pre-ART viral plasma RNA.
We measured genetic diversity as percent average pairwise distances (%APD), %unique population variants, and determined %population identity. Non-parametric panmixia tests assessed shifts between populations and intra-population neutrality was computed. Mann-Whitney p-values< 0.05 were indicative of statistically significant observations. Patient characteristics - Table 1.

TB, IRIS	7 patients	57% Male; 43% Female	Median = 41 years old	Median CD4 count = 49c/mm3	1040 sequences
TB, No IRIS	4 patients	75% Male; 25% Female	Median = 35 years old	Median CD4 count = 50.5c/mm3	661 sequences
No TB, No IRIS	3 patients	67% Male; 33% Female	Median = 40 years old	Median CD4 count = 23/mm3	427 sequences

[Table 1 - Patient Characteristics]

Results: After long-term ART, there was no difference in viremia between patient groups. TB patients without IRIS had lower ratios of CA gag RNA:DNA than those without TB or IRIS (p=0.02). TB-IRIS patients had higher %APD and more unique variants than TB patients without IRIS (p=0.02), and less population identity than patients with no TB or IRIS (p=0.02). Preliminary analyses revealed shifts in HIV populations during ART in TB infected patients. Graph 1 - Sequence Analyses.



[Graph 1 - Sequence Analyses]

Conclusions: TB-IRIS patients had higher frequencies of HIV infected cells, higher HIV genetic diversity, less population identity and less evidence of panmixia after long term ART, suggesting that IRIS may alter the HIV reservoir permanently.

MOPEA0007

Evolution of HIV-1 groups M and O: genetic comparative analysis of 19 HIV-1/MO inter-group recombinant forms

A. Moisan[1,2], F. De Oliveira[1], P. Cappy[1,2,3], P.A. Ngoupo[2,4], R. Njouom[4], J.-C. Plantier[1,2]

Presenting author email: alice.moisan@chu-rouen.fr

Background: HIVs are characterized by a high genetic diversity, due to their simian origins and their replication mode, enhanced by recombination events. Despite the great genetic divergence between pandemic HIV-1/M and HIV-1/O (endemic in Cameroon), dual infections between the two groups can generate HIV-1/MO inter-group recombinants. Only three cases were described before 2004. The consequences of the emergence of these forms on diagnosis and treatment are currently unknown, but the presence of group O fragments in their genome may have a strong impact due to the strong divergence between these variants. The aim of this work was to analyze the recombination patterns and genetic peculiarities of all HIV-1/MO recombinants currently characterized.
Methods: Between 2006 and 2016, the implementation of a sero-molecular algorithm in Cameroon and the exploration of atypical HIV-1 infection profiles in France allowed the description of new HIV-1/MO infections. In addition to the first three cases described, 16 new recombinants or putative forms, all found in patients of Cameroonian origin, were identified in Cameroon and France. Recombination and phylogenetic analysis covered 19 distinct HIV-1/MO recombinants, partially or completely sequenced.
Results: The results showed the complexity of screening and molecular characterization of these forms, but also that these recombinants could be detected with a suitable sero-molecular strategy or following discordances between detection and/or follow-up of results. The genetic diversity of the mosaic fragments matched the molecular epidemiology in Cameroon, with a clear predominance of HIV-1/M CRF02_AG (48%) and of HIV-1/O sub-group H (84 %). Phylogenetic analysis showed that the 19 recombinant forms corresponded to 19 URFs. Analysis of the genomic profiles and of the breakpoints frequency revealed hotspots in the „central" accessory genes (vif, vpr, vpu), reverse transcriptase and gp41, and no recombination event in protease, gp120 and nef. This work also highlighted a variable degree of complexity in profiles, with on average two to three breakpoints per recombinant genome.
Conclusions: In conclusion, this work allowed us to describe and analyze a unique series of HIV-1/MO recombinants, highlighting a greater diversity and complexity than originally supposed, and offering new research perspectives on the conditions of emergence and virological properties of these recombinant forms.

MOPEA0008

Proposal for an improved classification of the HIV-1 M subtype A sub-subtypes

N. Désiré[1], L. Cerruti[2], Q. Le Hingrat[3], M. Perrier[3], S. Emler[2], V. Calvez[1], D. Descamps[3], A.-G. Marcelin[1], B. Visseaux[3]
[1]Laboratoire de Virologie - Hôpital Pitié Salpétrière, Paris, France, [2]SmartGene, Lausane, Switzerland, [3]Laboratoire Virologie Bichat Claude Bernard - APHP - IAME, UMR 1137, INSERM, Paris, France
Presenting author email: benoit.visseaux@aphp.fr

Background: The extensive genetic diversity of HIV-1 subtype A has let, to date, to the description of 6 sub-clades comprising 4 sub-subtypes (A1 to A4), a putative A5 and a distinctive cluster from former Soviet Union (FSU). The current classification only retains A1 and A2 as official sub-subtypes and does not reflect the real diversity of HIV-1 A, leading to classification difficulties for subtyping tools. We aimed to re-analyse subtype A diversity and propose a more accurate classification.
Methods: Pairwise genetic distances between all HIV-1 A near full genome sequences available in the LANL database were calculated, excluding clonal, sequential or potential recombinant sequences (n=201). A maximum of likelihood phylogenetic tree (FastTree 2.1) was reconstructed and compared to clades and distances observed between previously established and candidate sub-subtypes. These analyses were also done on the pol, gag and env genes separately.
Results: Based on the tree topology and the genetic distance analysis of A subtype and previously well-established sub-subtypes, a full genome minimal mean genetic distance of 0.10 substitution/site was necessary to distinguish between major A clades, hence to define sub-subtypes. This proposal maintained most of previous sub-subtype candidates still not including in the extant classification system. Two new sub-subtypes are added, A6 (the FSU cluster) and A7. Another potential sub-subtype was rejected as only one full genome sequence is available and no partial sequences clustered with it in our separate-genes analysis. The A5 sub-subtype, whose existence is only supposed from the CRF26 analysis but was never retrieved outside this recombinant virus, was not retained in this proposal to avoid any potential confusion.
Conclusions: This proposal provides a more accurate view of subtype A diversity and will allow a more precise and rapid identification of emergence or diffusion of these particular subtype A variants, the cornerstone of HIV classification.

MOPEA0009

High frequency of non-subtype B infections and clustering in new HIV-1 diagnoses in Spain

E. Delgado[1], Y. Vega[1], M.T. Cuevas[1], H. Gil[1,2], S. Benito[1], V. Montero[1], E. García-Bodas[1], C. Carrera[1], M. Sánchez[1], L. Pérez-Álvarez[1], M.M. Thomson[1], the Spanish Group for the Study of New HIV Diagnoses

Presenting author email: delgade@isciii.es

Background: HIV-1 sequences generated for analysis of drug resistance and tropism, combined with epidemiological data, contain valuable information to be used for molecular epidemiologic surveillance of HIV infection. Since 1999, we have phylogenetically analysed samples from 10,257 HIV-1-infected individuals attended at Spanish hospitals. Here, we update molecular epidemiological data of new HIV-1 diagnoses in Spain in 2016.
Methods: We have analysed 439 HIV-1 infections diagnosed in 2016 in 38 Spanish hospitals from 13 regions. Sequences of protease-reverse transcriptase, integrase and env V3 region were analysed with phylogenetic trees using FastTree, including all sequences generated in our laboratory since 1999 and similar sequences retrieved from databases through BLAST searches. Recombination was analysed by bootscanning with SimPlot
Results: 80% subjects were men. Geographic origin, available for 80% individuals, was Spain in 70%, Latin America in 14%, Africa in 10%, Europe in 4%, and other in 2%. Transmission route in men, available for 71%, was 49.6% men who have sex with men (MSM), 20.8% unspecified sexual, 25.6% heterosexual, 3.6% parenteral, and 0.4% mother-to-child transmission (MTCT); and in women, available for 67%, was 96.6% heterosexual, 1.7% parenteral, and 1.7% MTCT.
The distribution of HIV-1 genetic forms was 64% subtype B, 8.7% CRF02_AG, 5.7% subtype F, 4.1% subtype A1, 3.2% subtype G, 3% subtype C, 1.4% CRF47_BF, 0.9% CRF01_AE, 3.4% other CRFs, 2.3% unique BF recombinants, and 3.6% other unique recombinant forms. Non-subtype B infections (36%) were more frequent among non-Spaniards (49.6% vs 27.8% in Spaniards).
187 (42.6%) infections grouped in 89 transmission clusters (TCs) of ≥4 individuals. 93% individuals belonging to clusters were men, among which transmission route, available for 75.9%, was 56.1% MSM, 19.7% unspecified sexual, 22.7% heterosexual, and 1.5% parenteral. Among women, 7% belonged to TCs, and transmission

route, available for 76.9%, was heterosexual in all cases. Geographic origin in TCs, available for 85%, was Spain in 84.6%, Latin America in 9.9%, Africa in 2.5%, and Europe in 2.5%.
Conclusions: New HIV-1 diagnoses in Spain are dominated by sexual transmission in men, with 42.6% infections clustering in TCs and 36% corresponding to infections with non-subtype B genetic forms, including 27.8% in Spaniards.

MOPEA0010

Relative resistance of HLA-B for downregulation by Nef is a fundamental property across lentiviral lineages

F. Mwimanzi[1], M. Mahiti[1], M. Toyoda[1], J. Mann[2], T. Ndung'u[2], T. Ueno[1]
[1]Kumamoto University, Center for AIDS Research, Kumamoto, Japan, [2]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa
Presenting author email: uenotaka@kumamoto-u.ac.jp

Background: HLA-B plays a dominant role, compared to HLA-A and HLA-C, in immune control of HIV-1 infection. Such differential roles have been shown to be attributable to relative resistance of HLA-B for downregulation by primary HIV-1 Nef sequences. However, the previous study was performed with only subtype B Nef clones and thereby it remains elusive whether this Nef property is conserved across various lentiviral lineages.
Methods: The Nef's ability to downregulate HLA was analyzed using Jurkat T cells engineered to express HLA-A*02:01 or chimeric HLA-A*02:01 molecule whose cytoplasmic tail was replaced with HLA-B*35:01. A panel of diverse Nef sequences (N=270 in total) across lentiviruses including SIVs, HIV-2 and a pandemic group M (subtypes A, B, C and D) as well as a relatively rare group O of HIV-1 was tested for HLA downregulation functions.
Results: Despite a diverse genetic diversity, all lentiviral Nef clones tested exhibited reduced downregulation activity to the HLA-B, compared to the HLA-A ($p<0.001$). Specifically, Nef clones from HIV-1 subtypes (A, B, C, and D) were comparably resistant to HLA-B for downregulation. However, although the amino acid residue at Nef-202 in subtype B was important for this phenomenon, the pairwise analysis of HIV-1 subtype C Nef sequences revealed that the amino acid at Nef-9, but not Nef-202, was solely associated with resistance to HLA-B, a finding corroborated by Nef mutational studies for downregulation of various HLA alleles.
Conclusions: Taken together, these results indicate that, though mediated by different Nef residues among viral lineages, relative resistance to HLA-B, compared to HLA-A, for downregulation is a fundamental functional property among naturally occurring Nef sequences of diverse lentiviruses.

MOPEA0011

Characterization of a novel dolutegravir monotherapy-associated S230R Mutation in HIV

H.T. Pham[1], I. Wijting[2], S. Hassounah[1], L. Labrie[1], T. Mesplède[1], K.Y. Lok[1], I. van der Ende[2], C. Boucher[2], B. Rijnders[2], M.A. Wainberg[1], J.J. van Kampen[2]
[1]McGill AIDS Centre, Lady Davis Institute, McGill University, Montreal, Canada, [2]Erasmus Medical Center, Rotterdam, Netherlands
Presenting author email: phamhanh792005@gmail.com

Background: The integrase strand-transfer inhibitor (INSTI) Dolutegravir (DTG) has a higher barrier to resistance than other approved INSTIs. In treatment-experienced individuals and in vitro, DTG can select for several primary mutations that have not been observed in patients undergoing first-line triple therapy, possibly due to the fact they significantly impair viral replicative capacity. DTG monotherapy has been considered as a possibility for HIV-infected patients. We report the emergence of a S230R substitution in two patients who experienced virological failure after switching to DTG monotherapy from triple therapy and the effects of S230R on integrase (IN) activity, viral infectivity and drug resistance.
Methods: IN-resistance associated mutations were evaluated by sequencing both prior to and at the time of virologic failure. Strand-transfer and tissue culture assays were performed to characterize enzyme activity, viral infectivity and to measure resistance to different INSTIs.
Results: The first case of S230R was found in the DOMONO study (NCT02401828) in a patient who experienced virologic failure at week 30 (HIV-1 RNA was 1570 copies/mL). The patient had a CD4 nadir of 330cells/mm^3 and had been virologically suppressed on EFV/TDF/FTC for 25 months before switching to DTG 50 mg once daily. A second case involved a patient who had been virologically suppressed on DTG/ABC/3TC for 8 months before switching to DTG monotherapy. Viral load remained < 20 copies/mL but increased to 700 copies/mL with the presence of S230R in IN at week 29.
The results of cell-free assays showed that, compared to the WT-IN (Km = 8.8 ± 0.95), the S230R-IN had a 2.22-fold increase in Km (19.9 ± 2.3). In the presence of DTG, the S230R-IN had a 2.6- fold decrease in DTG susceptibility (Table 1). A slight decrease in susceptibility to other INSTIs was observed in S230R-IN compared to WT-IN (Table 1). The infectivity of S230R virus was also impaired by about 50% compared to WT.

Recombinant enzyme	DTG - Ki (mean ± SD nM)/Fold change	CAB - Ki (mean ± SD nM)/Fold change	BIC - Ki (mean ± SD nM)/Fold change	RAL - Ki (mean ± SD nM)/Fold change	EVG - Ki (mean ± SD nM)/Fold change
WT	1.27 ± 0.13 - 1	1.76 ± 0.4 - 1	1.84 ± 0.30 - 1	6.40 ± 0.5 - 1	2.30 ± 0.13 - 1
S230R	3.33 ± 0.22 - 2.62	3.38 ± 0.55 - 1.92	2.70 ± 0.49 - 1.47	13.8 ± 5.5 - 2.16	7.34 ± 0.47 - 3.19

[Table 1. Susceptibilities of recombinant integrase]

Conclusions: Virological failure involving DTG monotherapy can occur due to replication of a virus containing a novel S230R substitution that confers modest-level resistance to DTG and other INSTIs.

MOPEA0012

HIV-1 resistance to dolutegravir is modulated by epigenetic signals

K.R.A. Anstett, T. Mesplede, N. Osman, M. Wainberg
McGill AIDS Center, Lady Davis Institute, Montreal, Canada
Presenting author email: tibo_mes@hotmail.com

Background: Integrase strand transfer inhibitors (INSTIs) act by inhibiting the HIV integrase enzyme (IN). The INSTI raltegravir (RAL) selects for drug resistance substitutions within the catalytic site of IN. The R263K dolutegravir (DTG) INSTI resistance substitution, however, is located in the C-terminus of IN and has an unknown resistance mechanism. The C-terminus is post-translationally modified by the acetylation of three lysine residues by the histone acetyltransferase enzyme (HAT) p300. We hypothesized that the R263K substitution interferes with some function of IN through dysregulation of the acetylation of nearby residues.
Methods: TZM-bl cells were infected with NL4.3 viruses in the presence of INSTIs, with or without the addition of HAT inhibitors (HATi) or histone deacetylase (HDAC) inhibitors (HDACi) 2 or 12h post-infection. PM1 cells were infected with NL4.3 viruses produced under different conditions (HATi or HDACi) and followed for 14 days post-infection. Co-IP was performed with 293T cells transfected with pACGFP-1C$_{IN}$ constructs and western blots to detect KAP1 were performed.
Results: Treatment of cells with HATi resulted in a decrease in the IC$_{50}$ for DTG and Cabotegravir for NL4.3$_{WT}$ but not NL4.3$_{R263K}$. However, no change in IC$_{50}$ was seen for RAL or Lamivudine and experiments are currently underway with the novel INSTI Bictegravir. NL4.3$_{WT}$ and NL4.3$_{R263K}$ produced in the presence of HATi or HDACi displayed different parameters over the course of infection. HDACi reduced the peak of replication for NL4.3$_{WT}$ but not NL4.3$_{R263K}$, whereas HATi had no effect on NL4.3$_{WT}$ but greatly enhanced the peak replication for NL4.3 $_{R263K}$. Using Co-IP, we were also able to show that IN$_{R263K}$ binds with a higher affinity to KAP1 (a component of the HDACI complex) as compared to IN$_{WT}$.
Conclusions: This is the first report of the influence of post-translational modifications on HIV drug resistance. Both the replication and resistance to DTG of NL4.3$_{WT}$ and NL4.3$_{R263K}$ are differentially affected by acetylation, likely through altered interactions with the HDACI complex. Many "shock and kill" strategies to eradicate HIV employ HDACi to reactivate latent HIV; however our results suggest that some drug resistant viruses may differentially respond to HDACi, which may complicate the advancement of this concept.

MOPEA0013

Impact of immune-driven sequence variation in Pol on viral replication capacity and disease progression in HIV-1 subtype C infection

D.B.A. Okanda[1], T. Ndungú[1,2,3], J. Mann[1]
[1]HIV Pathogenesis Programme,Doris Duke Medical Research Instutute,University of KwaZulu-Natal, Laboratory Medicine and Medical Science, Durban, South Africa, [2]Ragon Institute of MGH, MIT and Harvard, Massachusetts General Hospital and Harvard Medical School, Boston, United States, [3]Max, Berlin, Germany
Presenting author email: dtyachieng@hotmail.com

Background: CD8+ T cell responses to epitopes, particularly conserved Gag epitopes, in which immune escape mutations result in lower viral replication capacity is a hypothesised mechanism of protection in HIV-1 infected individuals with certain clinically favourable HLA class I alleles. Therefore, a possible vaccine strategy is to direct immune responses to vulnerable HIV regions, aiming to limit immune escape

due to fitness constraints or slow virus replication. Substantial replication costs and clinical relevance of several immune escape mutations in the HIV-1 Gag have been demonstrated, however, less is known about consequences of immune-driven mutations in other proteins. We investigated the impact of immune-driven sequence variation in Pol, a highly conserved and immunogenic protein essential for viral replication, on viral replication capacity and disease progression in a large population of individuals chronically infected with HIV-1 subtype C, the most prevalent subtype world-wide.
Methods: 414 patient-derived RT-integrase NL4-3 recombinant viruses were generated by electroporation of a green fluorescent reporter cell line (GXR cells) with plasma-derived RT-integrase PCR products and pNL43ΔRT-integrase and RT-integrase sequences were generated for 369 of these thus far. The replication capacities of recombinant viruses were determined by calculating the slope of increase in percentage infected cells, as measured by flow cytometry, from days 3-6 following infection.
Results: The mean replication capacity of these viruses, normalised to the growth of wild-type NL4-3, was 0.92 (interquartile range; 0.87 to 0.97). RT-integrase driven replication capacity correlated significantly with log viral load (r= 0.2571 p=< 0.0001) and CD4 count (r= -0.2580 p= < 0.0001). A preliminary sequence analysis of RT-integrase HLA-associated polymorphisms previously described to reduce replication capacity of subtype B viruses, showed that the HLA-A*33 restricted polymorphism G163E in integrase was associated with significantly reduced replication capacity in subtype C viruses (p=0.02).
Conclusions: The data suggest that RT-integrase-driven replication capacity is clinically relevant. Preliminary sequence analyses suggest that immune-driven mutations in Pol may significantly attenuate HIV. Further comprehensive sequence analysis may inform which Pol epitopes are the most vulnerable for an attenuation-based vaccine.

Presenting author email: matthew.hernandez@icahn.mssm.edu

Background: The extensive HIV diversification throughout infection complicates effective antiretroviral treatment and facilitates immune escape. Both viral (e.g., reverse transcriptase) and host factors (e.g., APOBEC3G restriction factor) contribute to viral evolution in vivo. The advent of humanized mouse models combined with powerful next generation sequencing approaches provides new opportunities to dissect the dynamics and mechanisms driving HIV evolution with unprecedented precision.
Methods: We generated isogenic HIV molecular clones that differed in their ability to counteract APOBEC3G (A3G) due to point mutations in Vif (HIV-WT: 100%; HIV-45G: 10%, HIV-SLQ: 1%). Humanized mice were infected with HIV-WT, HIV45G and HIV-SLQ. One month post-infection, some of the mice were treated with the RT inhibitor, lamivudine (3TC) (HIV-WT+3TC, N=11; HIV-45G+3TC, N=11; HIV-WT no treatment, N=12; HIV-45G no treatment, N=7, HIV-SLQ no treatment, N=4). Plasma viremia was quantified throughout the infection by RT-qPCR.
Using molecular barcodes (UMID) in conjunction with deep sequencing, we determined the viral quasi-species at single-molecule resolution in plasma and tissue compartments. Custom bioinformatics pipelines were developed to generate consensus sequences and analyze viral diversity over time within individual animals and across groups.
Results: Both HIV-WT and HIV-45G resulted in robust infection of humanized mice, but over time the fitness of HIV-45G was significantly reduced compared to HIV-WT (p=0.0039). In contrast, in the presence of 3TC, replication of HIV-45G was superior to that of HIV-WT (p=0.0045). We sequenced a total of 146,781 single HIV genomes, 24,606 single HIV transcripts and 2,293 single HIV proviruses. We found that the 3TC drug-resistance mutation RT-M184I appeared at a 10-fold faster rate than RT-M184V in HIV-45G infected, 3TC treated mice (p=0.0008). Of note, the proviral pool of both HIV WT and HIV 45G infected mice, revealed extensive mutagenesis, suggestive of A3G deaminase activity.
Conclusions: We show in this study that A3G accelerates emergence of 3TC drug resistance in vivo using deep sequencing on the Illumina platform. Furthermore, while HIV population dynamics between plasma and tissue transcripts were comparable, the HIV proviral pool in tissues was highly divergent due to extensive A3G driven mutagenesis.

Background: HIV-1 infection can be clinically managed using combination antiretroviral therapies (cART). However, accumulation of drug resistance mutations leads to treatment failure in a subset of patients, necessitating changes of therapy. Emergence and accumulation of resistance mutations follow certain patterns, which have been mostly studied on the basis of HIV-1 subtype B infections. Also, most therapeutic strategies are based on research and clinical studies of this subtype, although non-B subtypes represent the majority of global HIV infections. Clinical research on the basis of subtype B may not generalize to other subtypes, as host and environmental factors may be confounding. Here, we used a probabilistic model to describe the temporal progression of drug resistance mutations in a large cross-sectional dataset of South African individuals infected with HIV-1 subtype C, which accounts for nearly half of all HIV infections worldwide, under the selective pressure of lopinavir (LPV) boosted cART with low-dose ritonavir (LVP/r).
Methods: We collected and genotyped virus populations from 1065 South African individuals infected with HIV-1 subtype C. We used the continuous time conjunctive Bayesian network (CT-CBN) model for analyzing the accumulation of LPV-associated mutations. In addition, we contrasted our results on HIV-1 subtype C with a dataset of 254 HIV-1 subtype B genotypes from patients treated with LPV, obtained from the Stanford HIV Drug Resistance Database.
Results: We focused on 22 LPV-associated mutations according to the Stanford HIV Drug Resistance Database. We found 4 major protease inhibitors resistance mutations with high abundance in both datasets, namely M46I, I54V, L76V and V82A. Furthermore, we identified I54V as an early event in HIV-1 subtype C infections, whereas L24I, I50V and V82C were consistently identified as genetic changes occurring at later times. For subtype B, on the other hand, the early events consist of mutations M46I and I54V, with I84V being a later event. Differences in the inferred progressions of subtypes B and C suggest different evolutionary pathways.
Conclusions: CT-CBNs provide insights on the evolution of drug resistance in HIV-1 subtype C infections and allow comparisons to other subtypes.

Background: Persistent HIV can be found in a range of CD4+ T cells such as long lived naïve and central memory (CM) cells; as well as short lived transitional (TM) and effector memory (EM) cells in individuals on combination antiretroviral therapy (ART). These cells express vastly different viral receptor levels and we sought to determine if the envelope protein (Env) was genotypically and phenotypically different amongst the subsets which would indicate adaptation to these different environments.
Methods: HIV-infected 8 individuals on ART for at least 3 years with a plasma HIV RNA< 50 c/ml were studied. Single genome amplification for the env gene was performed on genomic DNA extracts from CM, TM, effector memory (EM) and naïve CD4+ T cell subsets. 10-30 envs were selected, sequenced and any variants containing hypermutation removed. Phylogenetic trees were created based of the V1-V5 region of env. Coreceptor usage was predicted using the geno2pheno prediction algorithm based on V3 amino acid sequence.

Results: The cohort was male with a mean age of 58 years, mean CD4 count of 607 cells/ul and nadir CD4 of 275 cells/ul. A total of 535 env sequences with intact reading frames were generated from 8 individuals. Phylogenetic analysis showed envs did not cluster based on the CD4+ T cell subset from which it was derived, however envs did form phylogenetically distinct clusters based on coreceptor tropism. CXCR4-using variants were detected in 5 of 8 individuals ranging from 34-62% of envs. Where CXCR4 usage was detected, it was most prevalent in envs derived from naïve (CXCR4 prevalence; mean 87.47% ± 2.5% SEM) and central memory CD4+ T cells (60.0% ± 7.9%); whilst less prevalent in transitional (34.8% ± 4.5%) and effector memory CD4+ T cells (16.8% ± 3.1%).
Conclusions: There is distinct compartmentalisation of viruses in short and long lived cells on ART as determined by co-receptor use and CXCR4-using strains appear to replace CCR5-using strains in the long lived but not short lived viral reservoir. Our results suggest direct infection of each individual cell type helps form and maintain the viral reservoir.

Background: Macrophages are cellular targets of HIV-1 and participate in virus dissemination and establishment of persistent virus reservoirs in host tissues, but the mechanisms of virus cell-to-cell transfer to macrophages remain largely unknown.
Methods: An experimental approach was developed to investigate the mechanisms of virus cell-to-cell transfer from infected T cells to macrophages. 36 h after infection, infected T cells were co-cultured for a maximum of 6 h with macrophages derived from primary monocytes, and virus transfer and dissemination in macrophages was then analyzed by flow cytometry, ELISA, immunofluorescence, live-cell imaging and transmission electron microscopy.
Results: We reveal a very fast and efficient mechanism involved in cell-to-cell transfer from infected T cells to macrophages and subsequent virus spreading between macrophages. We show that tight contacts between infected T lymphocytes and monocyte-derived macrophages lead to cell fusion for transfer of viral material to macrophage targets. This cell-to-cell fusion transfer is very efficient, restricted to CCR5-tropic viruses, and mediated by viral envelope-receptor interactions. Transferred viruses can then accumulate in cytoplasmic compartments of newly formed lymphocyte/macrophage fused cells. Moreover, early viral assembly and budding events, resulting from the merge of viral material between infected T cells and macrophages, are also observed at the plasma membrane of the lymphocyte/macrophage fused cells. These cells thus acquire the ability to fuse with neighboring non-infected macrophages for virus dissemination. Together, these two-sequential envelope-dependent cell fusion processes lead to the formation of highly virus-productive multinucleated giant cells.
Conclusions: These two-step cell fusion processes reveal the mechanisms for virus transfer and dissemination in macrophages and the formation of the infected multinucleated giant macrophages detected in vivo in lymphoid organs and the central nervous system of HIV-1-infected patients and SIV-infected macaques. These mechanisms contribute to a better understanding of virus dissemination from infected T cells toward macrophages and formation of long-lived macrophage viral reservoirs in host tissues during HIV-1 infection.

Investigation of tandemers activities against cell-associated HIV-1 and against viruses with decreased sensitivity to griffithsin

K.B. Alexandre[1], T. Moulaei[2], K. Buckheit[3], K. Palmer[4], B. O'Keefe[2]
[1]Council for Scientific and Industrial Research, Pioneering Health Sciences, Pretoria, South Africa, [2]National Cancer Institute, Molecular Targets Laboratory, Frederick, United States, [3]ImQuest Biosciences Inc, Frederick, United States, [4]University of Louisville, School of Medicine, Department of Pharmacology and Toxicology, Louisville, United States
Presenting author email: aalexandre@csir.co.za

Background: The lectin griffithsin (GRFT) is a homodimer and each of its monomers has three binding sites for glycans on HIV-1 envelope. GRFT showed potent and broad anti-HIV-1 activity and is one of the leading microbicide candidates. Tandemesrs 2MG, 2MG3, 3MG and 4MG are GRFT derivatives made of arrays of two, three and four monomeric units, respectively. Since the bond between monomers in GRFT is rigid while being flexible in tandemers, also given that some tandemers have more than two monomers, we hypothesized that these derivatives will be more active than GRFT against HIV-1.
Methods: We evaluated HIV-1 subtype A, B and C against 2MG, 2MG3, 3MG, 4MG and GRFT using the TZM-bl neutralization assay. GRFT derivatives were also tested for their inhibition of the cell-to-cell transmission of HIV-1. The 234 and 295 glycans, shown to be important in GRFT binding to HIV-1, were introduced in the virus by site directed mutagenesis, and their effects on 2MG, 2MG3, 3MG and 4MG binding studied. GRFT resistant viruses were generated by culturing HIV-1 under escalating concentrations of the lectin. These resistant viruses were then tested for sensitivity to 2MG, 2MG3, 3MG and 4MG.
Results: In general 2MG and 2MG3 were as potent as GRFT against all the viruses tested while 3MG and 4MG were more potent against HIV-1 subtype A and C. GRFT was also less potent than these two derivatives in the inhibition of cell-to-cell transmission of HIV-1. Similar to GRFT, the introduction of the 234 and 295 glycans affected HIV-1 sensitivity to 2MG and 2MG3; while it did not affect 3MG and 4MG neutralization of the virus. Lastly, GRFT resistant viruses showed sensitive to 3MG and 4MG.
Conclusions: We found that 3MG and 4MG were more potent than GRFT. Also viruses that showed resistance to GRFT remained sensitive to these compounds. It is possible that 3MG and 4MG binding sites on the viral envelope are different from that of GRFT given that GRFT resistant viruses remained sensitive to these tandemers. Our study suggests that linking GRFT monomers into arrays of more than two units increases potency against HIV-1.

Background: Macrophages are heterogeneous and functionally important immune cells that contribute to HIV pathogenesis by promoting viral spread, forming viral reservoirs and mediating neurological disorders. Macrophage phenotype and function vary depending on their location and tissue of origin, and these conditions influence also their susceptibility to HIV infection. Indeed, GALT macrophages are relatively resistant to HIV infection, whereas lung macrophages are relatively more susceptible. While these different phenotypes can be recapitulated in vitro with monocyte-derived macrophages (MDMs) (susceptible) or the M1- or M2- polarized macrophages exposed to pro- or anti-inflammatory cytokines (more refractory), the host factors responsible for these varying phenotypes are not entirely defined. Herein, we investigated the role of microRNAs in regulating the susceptibility of macrophages to HIV infection.
Methods: MDMs were infected with GFP-encoding HIV-1; infected (GFP+) and bystander (GFP-) cells were sorted by FACS and microRNA expression profiles determined using RNA-seq. The effect of miR-221/222 on CD4 expression was assessed by Q-RT-PCR and flow cytometry, while the impact on viral entry was analyzed by viral fusion assay. Myeloid cells from gut biopsies and blood from healthy volunteers were isolated by FACS and miR-221 levels determined by Q-RT-PCR.
Results: We examined the microRNA expression profile of over 400 microRNAs in HIV-infected MDMs and compared their expression profile in HIV non-producing bystander and uninfected cells. Among these microRNAs, we identified miR-221 and miR-222 as two negative regulators of the CD4 viral receptor expression, which are up-regulated in the bystander population. Functional analyses of miR-221/miR-222 in MDMs revealed that these microRNAs, which are efficiently induced by the pro-inflammatory cytokine TNF-α, inhibit HIV entry by down-regulating CD4. Inhibition of miR-221/miR-222 enhanced HIV replication and spread in infected macrophage cultures by limiting TNFα-mediated up-regulation of miR-221/222 in non-infected bystander cells. Consistent with a role of these microRNAs in the resistance of GALT macrophages to HIV infection, we found that miR-221 was significantly enhanced in myeloid cells from the gut as compared to those of peripheral blood.
Conclusions: MiR-221/222 represent pivotal host factors activated during inflammation that are capable of modulating permissiveness to HIV infection by restricting viral entry via CD4 down-regulation.

Presenting author email: dominique.mahe@univ-rennes1.fr

Background: Endogenization of SIV was demonstrated in lemur primates, suggestive of infection of the germinal lineage, and HIV/SIV nucleic acids detected in situ within testicular germ cells (TGCs) from men and macaques. In this context, we aimed to decipher the nature of the interactions between primary human TGCs and HIV-1.
Methods: TGCs isolated from normal human testes comprised haploid spermatids, tetraploid primary spermatocytes and diploid spermatogonia/ secondary spermatocytes. TGCs preparation purity (>94%) was assessed by flow cytometry using specific germ cell markers (DDX4, MAGEA4) as well as leukocyte/somatic markers (CD45, HLA class I, vimentin). HIV receptors and co-receptors expression was measured by flow cytometry. R5-, X4-tropic and Denv HIV-1 binding to TGCs was assessed by p24 ELISA. Viral entry, early steps of replication and viral proteins expression were investigated upon cell-free or cell-associated infection of primary TGCs and testicular germ cells T-cam2 using wild type HIV, or HIV-1 nef-ires-gfp infected Jurkat as donor cells. Viral entry was detected by confocal microscopy while new viral protein expression was evaluated by microscopy, FACS and ELISA. Integrated HIV-1 DNA was measured by PCR on FACS sorted TGC populations (CD45-DDX4+MAGEA4+).
Results: TGCs expressed the alternate HIV-1 receptors CD206, galactocerebroside and heparan sulfate proteoglycans, as well as CCR3. R5- and X4- tropic HIV-1 bound to isolated TGCs in a dose dependent manner, and this binding was inhibited by inhibitors/competitors for heparan sulfate proteoglycans, CD206 and HIV gp120. HIV-1 entry was more efficient with cell-associated HIV than with free virus. Integrated HIV-1 DNA was found in both TGCs and Tcam2 cells following cell-associated infection, as well as in T-cam2 cells exposed to cell free HIV pseudotyped with VSV-G.
Conclusions: Our results indicate that HIV-1 can enter testicular germ cells and integrate into the human germ line genome. The close proximity within the testis of stem germ cells to HIV-infected leukocytes, along with their high daily generation rate, may favor such events. These findings imply that HIV has the potential to integrate into the male gamete genome, which might ultimately lead to HIV nucleic acids endogenization in the progeny.

Presenting author email: anne.brelot@pasteur.fr

Background: The chemokine receptor CCR5 is the main coreceptor for entry of R5 HIV-1 strains into target cells. It plays a prominent role during HIV transmission, progression of infection, and evolution to AIDS. One allosteric non-peptidic inhibitor targeting CCR5, maraviroc, has already been approved for treatment of HIV infection. Like other G-protein coupled receptors, CCR5 forms homo-dimers at the cell surface, which could affect receptor physiology and HIV pathogenesis. However, the structural properties and dynamics of CCR5 homo-dimers are still unknown.
Methods: We combined computing approaches with cross-linking, energy transfer, and a new functional assay (based on the RUSH system) to characterize residues involved in CCR5 dimerization interface.
Results: We show that unliganded CCR5 exists in two dimer conformations, involving residues of the transmembrane helix 5. Binding of maraviroc stabilizes a third dimeric conformation that has not yet been described in a GPCR crystal structure. Functionally, we show that CCR5 dimerization occurs in the endoplasmic reticulum and regulates receptor cell surface targeting.
Conclusions: This study supports that dimerization contributes to the conformational diversity of CCR5. The three dimer models of CCR5 described constitute an essential step for future exploration of the role of CCR5 dimerization in HIV infection. Their involvement in receptor export also offers a new possibility to inhibit HIV entry by playing directly on CCR5 dimerization and cell surface expression.

HIV-1 subtype C may possess extended coreceptor utilization in peripheral blood and the central nervous system of patients experiencing cryptococcal meningitis

K. Sojane[1], M. Roche[2], C. Chang[3], R. Kangethe[1], M. French[4,5], S. Lewin[2,3], P. Gorry[6], T. Ndung'u[1,7]
[1]*University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa,* [2]*University of Melbourne and Royal Melbourne Hospital, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia,* [3]*Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia,* [4]*University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia,* [5]*Royal Perth Hospital and PathWest Laboratory Medicine, Department of Clinical Immunology, Perth, Australia,* [6]*RMIT University, School of Health and Biomedical Research, Melbourne, Australia,* [7]*University of KwaZulu-Natal, Africa Health Research Institute, Durban, South Africa*

Background: Limited evidence suggests that HIV-1 clones obtained ex vivo without culture may have expanded coreceptor utilization. However, it is widely reported that for HIV-1 subtype C (HIV-1C), the predominant genotype in the global epidemic, the switch to coreceptors other than CCR5 is infrequent. Here, we sought to determine the entry phenotype of uncultured HIV-1C circulating in plasma and cerebrospinal fluid (CSF) of patients with late stage HIV infection and cryptococcal meningitis co-infection.
Methods: Matched plasma and cerebrospinal fluid (CSF) was collected from eight antiretroviral therapy naive HIV-infected South Africans (median CD4 count of 17 cells/μL), experiencing cryptococcal meningitis. Following RNA extraction and cDNA synthesis, HIV-1C envelope gene fragments were amplified, sequenced and cloned into the pSVIII-Env expression vector. Pseudoviruses capable of single-round replication were produced in 293T cells and serial dilutions of these were used to infect NP2-CD4 or U87-CD4 cells expressing CCR5, CXCR4 or CCR3. Pseudovirus entry into target cells was quantified by assaying luciferase activity in cell lysates. Background (culture medium), negative and positive (lab-strain) controls were included in the assays.
Results: From eight study participants, 28 unique (median of 3 per participant) plasma-derived and 29 (median of 1.5 per participant) CSF-derived pseudoviruses were produced. Four of eight participants had exclusive CCR5-utilizing variants only in plasma and CSF, and one had a CCR5-utilizing variant that also utilized CCR3 in plasma and CSF. Notably, three other participants had variants which utilized CXCR4 in plasma and not CSF, but one had a CXCR4-utilizing variant in both plasma and CSF.
Furthermore, CCR3-utilization in combination with CXCR4 or CCR5 was identified in the plasma and CSF of these three participants.
Conclusions: Uncultured HIV-1 subtype C circulating in plasma and CSF is capable of utilizing more than one coreceptor for entry in advanced disease. CCR5 alone or in combination with CCR3 was frequently utilized in plasma and CSF of study participants. CXCR4 usage by CSF-derived clones was infrequent. Our study shows that coreceptors other than CCR5 may be important for cell entry in the central nervous system in late stage disease. We will next explore the importance of CCR3-utilization in ex vivo models.

MOPEA0023

Alternative splicing of human APOBEC3G in HIV infection

P. Colson[1], O. Glazunova[1], I. Ravaux[1], E. Baptiste[1], C. Boileau[1], E. Decroly[2], C. Tamalet[1], D. Raoult[1]
[1]*IHU Méditerranée Infection, Marseille, France,* [2]*Aix-Marseille University, CNRS AFMB Laboratory, UMR 7257, Case 925, Marseille, France*
Presenting author email: didier.raoult@gmail.com

Background: We recently identified two individuals seemingly cured of HIV. Indeed, they exhibit confirmed HIV-seropositivity since 30 and 5 years, respectively, but kept normal LT-CD4-counts and had no HIV-related illness despite they never received antiretrovirals. In addition, they persistently displayed undetectable plasma HIV-RNA and PBMC HIV-DNA with standard assays, while HIV culture was negative. Scarce short PBMC HIV-DNA sequences were only laboriously obtained using hundreds of nested-PCR and next-generation sequencing. These sequences showed a high level of gene inactivation by G-to-A mutations generating stop-codons. As this is a signature of deamination by human-APOBEC3G, we se-

quenced APOBEC3G-mRNA from the blood of these two patients to gain a better understanding of their infection outcome.
Methods: RNA was extracted from plasma using the EZ1-Virus Mini kit (Qiagen). Reverse transcriptase-PCR amplification and Sanger population sequencing were performed by in-house protocols. Next-generation sequencing was performed on two HIV-DNA fragments overlapping APOBEC3G gene exons 2-6 and 2-7 using Illumina paired-end technology on MiSeq instrument.
Results: Sequences corresponding to APOBEC3G-mRNA obtained from the two patients showed presence of the complete form (1,132 nucleotides generated from 8 exons). Strinkingly, three truncated isoforms were identified by Sanger sequencing, one from patient#1 (isoform1) and two from patient#2 (isoform2, isoform3). Isoform1 contained only five exons;exons 3-4-5 lacked. Isoform2 and isoform3 contained only 6 exons; exon3 and exon6 were truncated and of different lengths. Importantly, isoform1 lacked exon3 region encoding amino-acids targeted by HIV-Vif protein that triggers APOBEC3G degradation, whereas exon6 region encoding the deamination active site was present. Regarding isoform2 and isoform3, they both lacked the Vif-interacting site-encoding region. Preliminary analysis of sequence-reads obtained by next-generation sequencing confirmed isoforms 1-3 presence and identified several additional putative APOBEC3G-mRNA isoforms.
Conclusions: These results indicate an alternative splicing of APOBEC3G gene in these two patients in whom no live HIV and no full-length HIV-DNA with untruncated genes were retrieved. This could be notably related to APOBEC3G resistance to Vif-triggered degradation and enhanced APOBEC3G activity. This deserves additional studies of APOBEC3G gene alternative splicing and further characterization of sensibility to Vif and activity of these APOBEC3G isoforms.

MOPEA0024

The role of CCR5 structural diversity in HIV infection

P. Colin[1,2], Z. Zhou[1,2], I. Staropoli[1,2], J. Jin[1,2], J. Alcami[3], H. Lortat-Jacob[4], F. Arenzana-Seisdedos[1,2], A. Brelot[1,2], B. Lagane[1,2,5]
[1]Institut Pasteur, Paris, France, [2]INSERM U1108, Paris, France, [3]ISCIII, Madrid, Spain, [4]IBS, Grenoble, France, [5]INSERM U1043, Toulouse, France
Presenting author email: bernard.lagane@inserm.fr

Background: CC chemokine receptor 5 (CCR5) plays a key role in innate immunity and HIV infection. It acts as a CD4-associated coreceptor for entry of R5-tropic strains of HIV-1 into CD4+ T-lymphocytes and macrophages. CCR5 interacts with the CD4-bound form of the HIV-1 envelope glycoprotein gp120, leading to fusion between the viral and host cell membranes. R5 strains of HIV-1 are preferentially transmitted and predominate in the asymptomatic stage of infection. Recent data identified that CCR5, similarly to other G protein-coupled receptors (GPCR), exists in an ensemble of structurally diverse forms at the cell surface, but how this affects the functional properties of the receptor and its role in HIV infection is not known.
Methods: We performed binding assays of envelope glycoproteins (gp120) from ten different R5 HIV-1 strains to CCR5-expressing cell lines and primary cells. Virus-cell fusion experiments were also carried out to characterize whether a link exists between the cellular tropism of R5 HIV-1 isolates and their ability to recognize specific CCR5 populations. Finally, competition experiments of gp120 binding by anti-CCR5 monoclonal antibodies and site directed mutagenesis of CCR5 were set up to identify factors contributing to multiplicity of the CCR5 populations.
Results: Results revealed that distinct subsets of the CCR5 molecules differentially bind distinct envelope glycoproteins isolated from different primary HIV-1 isolates. The divergent binding levels of gp120 to CCR5 do not result from impaired binding to CD4 or incorrect folding when they are bound to CD4. The distinct binding capacities of these envelope glycoproteins to CCR5 are related to differential recognition of antigenically distinct populations of CCR5 and sensitivity to CCR5 homodimerization. Finally, the nature/quantity of the CCR5 populations to which the HIV-1 envelope glycoproteins may bind differs between different target cells and critically controls the cell tropism of R5 viruses.
Conclusions: This study sheds light on the relationship between CCR5 structural diversity and physiopathology of HIV-1 infection and provides important clues for developing future CCR5 entry inhibitors against HIV-1.

Loss of SUN2 impairs CD4 T cell proliferation and alters sensitivity to HIV-1 infection in a cyclophilin A-independent manner

D.A. Donahue, F. Porrot, N. Couespel, O. Schwartz
Institut Pasteur, Paris, France
Presenting author email: ddonahue@pasteur.fr

Background: Linker of nucleoskeleton and cytoskeleton (LINC) complexes bridge the nucleus and the cytoskeleton in eukaryotic cells. Previously, we demonstrated that overexpression of the inner nuclear membrane protein and LINC complex component, SUN2, inhibits HIV infection between reverse transcription and nuclear import, and that this depends on the viral capsid. We also showed that in several cell lines, SUN2 silencing does not alter HIV infection. SUN2 silencing in primary CD4 T cells was recently reported to decrease HIV infection, which was suggested to result from modulation of Cyclophilin A (CypA)-dependent steps of HIV infection.
Methods: To better understand the role of SUN2 in HIV infection, we used lentiviral shRNA transduction to silence SUN2 in primary CD4 T cells from many donors, in which cell proliferation and health were monitored. Several HIV strains (lab-adapted, transmitted/founder, and non-lab-adapted) were used for spreading infections in these cells. Single-round infections in the presence of Cyclosporin A were performed to address the potential role of CypA. Analysis of viral gene expression levels was performed by flow cytometry.
Results: Consistent with previous data, we found that HIV infection of primary CD4 T cells is reduced upon SUN2 silencing, and we extend these results to additional viral strains. However, we found that endogenous SUN2 was dispensable for the well-documented positive effects of CypA during HIV infection. Conversely, CypA was not required for the reduction in HIV infection observed in the absence of endogenous SUN2. In contrast, primary CD4 T cells lacking SUN2 exhibit a striking proliferation defect, as well as lower expression of activation markers and decreased viability. Furthermore, we found that levels of viral protein expression were reduced in SUN2-silenced CD4 T cells that did become infected. Future work will determine whether SUN2 might also act directly on the virus.
Conclusions: Our results suggest that SUN2 does not promote CypA-dependent steps of HIV replication. Rather, we demonstrate that SUN2 is required for efficient activation and proliferation of primary CD4 T cells. Therefore, disruption of these processes can explain the role of endogenous SUN2 in HIV infection of primary lymphocytes.

MOPEA0026

Insights into the domains of IFITM3 involved in the negative imprinting of HIV-1 viral particles infectivity

R. Appourchaux[1], K. Tartour[1], J. Gaillard[2], X.-N. Nguyen[1], G. Savidis[3], A. Brass[3], P. Roingeard[4], A. Cimarelli[1]
[1]CIRI, INSERM U 1111, CNRS UMR 5308, UCBL, ENS-L, Lyon, France, [2]Plateforme des Microscopies, PPF ASB, Université F. Rabelais et CHRU de Tours, Tours, France, [3]University of Massachusetts Medical School, Department of Microbiology and Physiological Systems, Worcester, United States, [4]INSERM U 966, Université F. Rabelais et CHRU de Tours, Tours, France
Presenting author email: acimarel@ens-lyon.fr

Background: The Interferon-induced transmembrane proteins 1, 2 and 3 (IFITMs) are innate defense proteins that inhibit a broad range of viruses, including HIV-1. Thus far, IFITMs have been associated to two distinct mechanisms of viral inhibition, at least in the case of HIV: the endosomal trapping of incoming viral particles by the pool of IFITM molecules present in target cells; the interference with the production of infectious HIV-1 viral particles in virus-producing cells.
In the latter, we and others have demonstrated that IFITMs coalesce with the structural protein Gag during virion assembly, leading to the production of virion particles that package IFITMs and that display a consistent infectivity defect. At present, it is unclear whether the physical incorporation of IFITMs into virions can be dissociated from the negative effects on the viral infectivity, and the domains(s) of IFITMs driving this defect remain poorly characterized.
Methods: Using IFITM3 as a paradigm for the IFITM family, we have examined a panel of point mutants spanning the entire length of the protein and we have determined the effects of these mutants on both HIV-1 assembly and virion particle infectivity.
Results: In so doing, we have identified domains that enhance the antiviral effects of IFITM3, as well as domains that relieve the infectivity defect. We have then measured and correlated several parameters as quality and quantity of Envelope incorporated into virions, intracellular localization of IFITM mutants, cholesterol level changes etc to the infectivity data, to pinpoint to key parameters at the basis of the antiviral role of IFITMs against HIV-1.

Conclusions: Overall our results indicate that changes in envelope maturation and processing are unlikely to be major determinants of the antiviral effects of IFITM3 and that cholesterol modifications are similarly not involved in these effects. These and other results on the characterization of the action of IFITM3 on the production of infectious HIV-1 virion particles will be presented.
With the support of ANRS and Sidaction.

Apolipoprotein E is an HIV-1-inducible restriction factor of HIV-1

R. Siddiqui[1], S. Suzu[1], R. Koba[1], K. Kawano[1], M. Yasuda-Inoue[1], S. Matsushita[1], K. Shimotohno[2], Y. Ariumi[1]

Presenting author email: ariumi@kumamoto-u.ac.jp

Background: Apolipoprotein E (ApoE) is a secretory protein that plays an important role in various biological processes, including lipid metabolism, cardiovascular diseases, Alzheimer's disease, immunoregulation and HCV infection. ApoE has three major isoforms, ApoE2, ApoE3 and ApoE4 with isoform-specific functional properties and is produced by liver and macrophages. Notably, we noticed that HIV-1 infection specifically and strongly induces endogenous ApoE expression in primary human monocyte-derived macrophages by micro array and Western blot analysis. Therefore, ApoE might affect life cycle of HIV-1.
Methods: To test this possibility, we first analyzed the HIV-1 kinetics in ApoE knockdown primary human macrophages. Then, we performed the overexpression study of ApoE. 293T cells were co-transfected with ApoE-expressing plasmid and HIV-1 molecular clone (R9, NL4-3, JR-FL, and AD8) and we examined the HIV-1 replication and HIV-1 infectivity in their culture supernatants. Furthermore, we observed subcellular localization of HIV-1 proteins and ApoE.
Results: We observed that HIV-1 production is enhanced in the ApoE knockdown primary human macrophages, indicating that ApoE restricts HIV-1 life cycle. In contrast, overexpression of ApoE significantly reduced the expression levels of both HIV-1 capsid and envelope (Env) proteins. In this context, the HIV-1 production was strongly suppressed in the ApoE-overexpressing cells. Indeed, all three different isoforms of ApoE could suppress the HIV-1 infectivity.
Furthermore, ApoE failed to suppress the expression level of HIV-1 capsid protein from HIV-1ΔEnv, an HIV-1 molecular clone lacking Env. As well, all isoforms of ApoE unable to suppress the expression of other virus envelope glycoprotein like vesicular stomatitis virus (VSV-G), suggesting that ApoE specifically targets the HIV-1 Env. In fact, ApoE colocalized with HIV-1 Env in cytoplasm and immunoprecipitation result showed that both proteins bind each other, indicating an interaction of ApoE with HIV-1 Env.
Moreover, we also observed that ApoE sequesters HIV-1 Env in early (Rab5) and late (Rab7) endosomes. Finally, ApoE hijacked HIV-1 Env into lysosome, a protein degradation site, resulting in degradation of HIV-1 Env.
Conclusions: Altogether, ApoE seems to be a novel HIV-1-inducible restriction factor of HIV-1 in macrophage. These findings have important implications for further understanding of HIV-1 life cycle as well as development of novel antiretroviral strategies.

MOPEA0028

A structural study of UNG2 and its interaction with the HIV protein Vpr

H. Kara[1], S. Bouaziz[1], L. Ponchon[1], S. Benichou[2]
[1]Laboratoire de Cristallographie et RMN Biologiques (LCRB) CNRS UMR 8015, Paris, France, [2]UMR_S 1016 UMR 8104 - Institut Cochin, Paris, France
Presenting author email: hasna.kara@etu.parisdescartes.fr

Background: Antiretroviral treatments cause the emergence of resistances and side effects that prompted us to look for new therapeutic targets against HIV. Vpr controls the integration of viral DNA into the genome of the host cell, the activation of the transcription of the LTR (long terminal repeat) and the cell cycle arrest in G2 phase of the host cell, which are essential steps for viral multiplication. UNG2 is involved in DNA repair and reduces the viral genome mutations enabling it to evade the immune system. Vpr, by interaction with UNG2, appears to facilitate its ubiquitination and its degradation by the proteasome. The interaction between the uracil DNA glycosylase (UNG2) and the HIV-1 viral regulatory protein (Vpr), which has no equivalent in humans, is a potential target against HIV replication. Our first objectif is to understand the factors governing that interaction at the atomic level. Our second objective is to target that interaction with ligands that have been identified against Vpr.
Methods: We expressed the UNG2 in E. coli and synthesized Vpr and several of its fragments in order to characterize their interaction by NMR, crystallography, circular dichroism, and other physico-chemical methods. Peptides containing the WxxF motif and chemical compounds have been selected by screening against Vpr.
Results: First NMR experiments allowed us to confirm in vitro, the mode of interaction between these two proteins. The same experiments carried out on the fragment of Vpr (containing W54) and a fragment of UNG2 (containing the WxxF pattern) showed similar results. Peptides containing the WxxF pattern or WW motif were studied by the two-hybrid system. One of these peptides interacts with Vpr and by biochemical tests, we have shown that it disrupts the interaction between Vpr and UNG2. On the other hand, a primary screening of a small molecules library was used to select chemical compounds, potential Vpr inhibitors and a secondary NMR screening will identify those disrupting the interaction between Vpr and UNG2.
Conclusions: The interaction between the two proteins was demonstrated by NMR and pool down, and one of the peptides containing the WxxF motif (the petide P6) we tested, can totally inhibit this interaction.

MOPEA0029

Regulation of retroviral integration by RNA polymerase II associated factors and chromatin structure

V.N. Parissi
CNRS, UMR 5234, Bordeaux, France
Presenting author email: vincent.parissi@u-bordeaux.fr

Background: HIV-1 integration occurs in highly Pol II transcribed and spliced regions of the chromatin thanks to the interaction between the retroviral intasome and the cellular tethering factor LEDGF/p75. These regions of the host genome are enriched in transcription and remodeling factors that are expected to modulate the chromatin access to the incoming intasome and its functional association with the targeted nucleosome.
Methods: This final step has been shown to be regulated by both intasomes and chromatin structure we investigated these regulation processes focusing on the analysis of the IN/nucleosome interaction and on the role of the cellular proteins associated with the Pol II transcription apparatus.
Results: We show here that histone tails are required for optimal association between HIV-1 IN and the nucleosome and efficient integration on it. Interactions between IN and the amino-terminal tail of human histone H4 was reported in vitro. Structure/function studies enabled us to identify HIV-1 IN amino-acids important for this interaction in the carboxy-terminal domain (CTD) of the viral protein. Functional analyzes confirmed the importance of this interaction for efficient replication and integration of the virus. Additionally the analysis of the role of Pol II associated remodeling factors on this functional association led us to found that FACT (facilitates chromatin transcription) complex, a chromatin remodeler associated with Pol II and recently reported to bind LEDGF/p75, can regulate the access to the nucleosome and histone tails to the incoming intasomes. Mechanistic studies indicate that FACT generates partially dissociated nucleosomes structures that are highly favored substrates for HIV-1 integration. This partial nucleosome dissociation decreases the chromatin density in the vicinity of the integration site and, thus, allows the final association between intasomes and the targeted nucleosome.
Conclusions: Consequently, our work highlights new host/pathogen interactions that could constitute novel and attractive targets for future potential therapeutic applications in addition to provide a better understanding of this crucial integration step of the retroviral replication.

Autophagy does not influence HIV replication in productively infected dendritic cells (DCs)

C. Richetta[1], P.-G. Coulon[1], A. Rouers[1], S. Cardinaud[1], A. Urrutia[1], F.P. Blanchet[2], S. Graff-Dubois[1], A. Moris[1]
[1]CIMI U 1135, Paris, France, [2]CNRS, UMR 5236, UM 1/UM 2, Centre d'Études d'Agents Pathogènes et Biotechnologies pour la Santé, Montpellier, France
Presenting author email: clemence.richetta@upmc.fr

Background: Macroautophagy, thereafter referred to as autophagy, is a lysosomal degradation process essential for the maintenance of cellular homeostasis. Since few years, autophagy is emerging as an important factor of immunity. Indeed, autophagy can directly degrade intracellular pathogens but it is also involved in the regulation of both innate and adaptive immune responses. To escape from autophagy degradation, several viruses have evolved strategies to inhibit or even hijack autophagy. In this work, we focused on Human Immunodeficiency Virus (HIV-1) which targets cells from the immune system such as CD4 T lymphocytes, macrophages and dendritic cells (DCs). Whereas interactions between HIV and au-

tophagy have been studied in CD4 T cells and in macrophages, it is less described in DCs. We previously reported that during viral entry in DCs, incoming HIV particles could be degraded by autophagy and that HIV-1 induces a rapid shutdown of autophagy. However, involvement of autophagy during viral replication was unknown.
Methods: In this study, we analysed the impact of autophagy modulation by drugs or shRNA on HIV replication in productively infected DCs.
Results: We show that in DCs, the HIV Gag protein does not colocalize with the protein LC3, a marker of autophagosomes, suggesting that newly-produced HIV-1 particles are not sequestrated into autophagosomes. Moreover, the induction of autophagy using drugs, CD46-trigerring or TLR ligands does not lead to a targeting of Gag in autophagosomes. The use of HIV-1 mutants lacking Env or Nef proteins (that have been shown to impact early and late steps of autophagosome formation, respectively) suggest that the absence of Gag uptake into autophagosomes is not the result of an escape mechanism developed by HIV-1. Interestingly, we also demonstrate that the HIV Env protein does not colocalize with autophagosomes. Moreover, shRNA-mediated inhibition of autophagy in DCs does not impact HIV-1 replication and propagation.
Conclusions: Our work reveals, in DCs, two distinct phases in HIV and autophagy interactions: whereas viral incoming particles are targeted to autophagosomes during viral entry contributing to the induction of cellular responses, HIV does not interact with the autophagy pathway after the establishment of a productive infection.

p21 restricts HIV-1 replication in dendritic cells through the synergistic reduction of dNTP biosynthesis and the regulation of SAMHD1 antiviral activity

J.C. Valle Casuso[1], A. Allouch[1], A. David[1], G. Lenzi[2], F. Barré-Sinoussi[1], M. Müller-Trutwin[1], B. Kim[2], G. Pancino[1], A. Sáez-Cirión[1]

Presenting author email: jose-carlos.valle-casuso@pasteur.fr

Background: Dendritic cells (DCs) play a key role in the induction of immune responses against HIV. Immature myeloid DCs allow HIV-1 replication, but mature myeloid DCs are strongly resistant to HIV infection. $p21^{cip/waf}$, a cyclin-dependent kinase inhibitor involved in cell cycle regulation and monocyte differentiation and maturation, and SAMHD1 are cellular factors that regulate the size of the dNTPs pool and can block HIV replication in myeloid cells. We used the different HIV-1 susceptibility of immature and mature DCs to shed light on the intermingled antiviral activities of p21 and SAMHD1 and their impact on the intracellular dNTP pool.
Methods: Dendritic cells were obtained after differentiation of freshly isolated primary human monocytes in the presence of GM-CSF and IL-4. Monocytes derived to DCs were then cultured in the absence (immature) or the presence (mature) of IFNγ, CD40L with a His-tag and His6x. mRNAs of the genes of interest were quantified by qRT-PCR and proteins by western blot under different experimental conditions. Intracellular dNTP concentrations were measured with a single-nucleotide incorporation assay.
Results: We found that the inhibition of HIV-1 replication in mature DCs was related to a strong increase in the expression of p21. p21 decreased the size of the intracellular dNTP pool by suppressing several enzymes involved in dNTP synthesis (i.e., RNR2, TYMS, and TK-1). In parallel, we show that p21 prevented SAMHD1 phosphorylation and promoted SAMHD1 antiviral activity. Both activities were complementary and differently contribute to block HIV-1 replication. The antiviral activity of SAMHD1 in our primary cell model appeared to be, at least partially, independent of its dNTPase activity. The reduction in the pool of dNTPs in DCs was rather due to p21-mediated suppression of dNTP biosynthesis.
Conclusions: This study shows that p21 expression resulted in conditions that allowed the effective inhibition of HIV-1 replication in DCs through complementary/synergistic mechanisms affecting differently dNTPs synthesis and the phosphorylation of SAMHD1. Overall our results point to p21 as key regulator of HIV infection in myeloid cells.

Expression of native HIV-1 antisense protein (ASP) in chronically infected T cells (ACH-2) following stimulation with TNF-α

A. Mancarella[1], E. De Crignis[2], G. Corradin[3], C. Fenwick[1], G. Pantaleo[4], C. Graziosi[1]
[1]Centre Hospitalier Universitaire Vaudois (CHUV), Medicine, Epalinges, Switzerland, [2]Erasmus Medical Center, Biochemistry, Rotterdam, Netherlands, [3]Université de Lausanne, Biochemistry, Epalinges, Switzerland, [4]Centre Hospitalier Universitaire Vaudois (CHUV), Medicine, Lausanne, Switzerland
Presenting author email: antonio.mancarella@chuv.ch

Background: HIV-1 Antisense protein (ASP) is an antisense (-2) open reading frame encoding for a highly hydrophobic protein of 20 kDa encompassing Env at the junction of gp120-gp41. Existence of ASP was initially suggested by Miller in 1988 and ASP transcripts demonstrated shortly thereafter. Expression of recombinant ASP has been widely shown in various cell lines, although its cellular localization remains controversial. In this study we report expression of native ASP in the membrane fraction of TNF-α-stimulated ACH2, a T cell line chronically infected with $HIV\text{-}1_{HXB2}$.
Methods: ACH2 cells and their uninfected counterpart A301, were stimulated with recombinant TNF-α at intervals of 12h and up to 72h. Cells were lysed and the proteins from the membrane and cytoplasmic cell fractions separated by SDS-PAGE and analyzed by Western blot using ACH-2-derived anti-ASP polyclonal antibody. Western blot competition assay was performed with synthetic ASP peptide in the membrane fraction of both ACH2 and A301 at 48h post TNF-α stimulation.
Results: A band similar in size to ASP (20 kDa) was reproducibly observed in the membrane fraction of TNFα-stimulated ACH2 using anti-ASP polyclonal antibody. In contrast, no band was observed in A301. The intensity of the 20 kDa band increased in a time-dependent manner up to 48h post TNF-α stimulation. In ASP peptide competition assays, the 20 kDa band was specifically competed out by free, soluble ASP peptide. In contrast, it could be clearly observed in ACH2 in absence of competition. No band could be observed in A301 with or without competition.
Conclusions: Our data indicate that anti-ASP antibodies recognize a band of 20 kDa, the ASP expected molecular weight. Detection of this protein by anti-ASP antibodies and its presence only in ACH2 clearly indicate its specificity for HIV, whereas its finding only in the membrane fraction is in good agreement with the hydrophobic nature of the ASP protein as predicted by bioinformatic analysis. Finally, the 20 kDa band was inhibited by free ASP peptide, suggesting that this protein is indeed ASP. Further experiments to formally prove the identity of the 20 kDa band and its cellular localization are on the way.

Inhibition of HIV-1 gene transcription by KAP1: a new CTIP2 interactant

A. Ait Ammar[1], V. Gautier[2], C. Van Lint[3], C. Schwartz[4], O. Rohr[4]
[1]Strasbourg University, EA7292, DHPI, Institut de Parasitologie et Pathologies Tropicales, Strasbourg, France, [2]University College Dublin (UCD), Centre for Research in Infectious Diseases (CRID), School of Medicine and Medical Science (SMMS), Belfield, Ireland, [3]Université Libre de Bruxelles (ULB), Service de Virologie Moléculaire, Institut de Biologie et de Médecine Moléculaires (IBMM), Gosselies, Belgium, [4]Strasbourg University, EA7292, DHPI, Institut de Parasitologie et Pathologies Tropicales, 3 rue Koeberlé, Strasbourg, France
Presenting author email: amina.aitammar@gmail.com

Background: HIV-1 post-integrative latency generates reservoirs which prevent the eradication of the virus with the current therapies. We have demonstrated that the transcriptional co-repressor CTIP2 recruits multi-enzymatic complexes to promote the establishment and the persistence of HIV-1 latency in microglial cells (Marban et al., 2007), the major viral cellular reservoir in the central nervous system. The control of the HIV-1 Tat transactivator is crucial to the persistence of these long-life reservoirs (Cherrier et al., 2013).
Methods: In the present work, the protein partners of CTIP2 were investigated. Nuclear protein extracts from HEK cells expressing Flag-CTIP2 were submitted to immunoprecipitation using an anti-Flag antibody. Co-immunoprecipitated proteins were identified by quantitative mass spectrometry. KAP1, a newly identified partner of CTIP2, has been studied for its function on the control of HIV-1 gene transcription by classical methods: Luciferase assays, co-immunoprecipitation assays, SDS-PAGE and Western blot analysis.
Results: 888 proteins interacting with CTIP2 ($p < 0.05$) were identified, including the transcriptional regulatory factor, KAP1 / TRIM28. KAP1 has been shown to control viral gene expression and viral latency of KSHV, Murine Leukemia Virus (MLV) and human T-cell lymphotropic virus-1 (HTLV-1) (Chang et al., 2009; Wolf et al., 2008a, 2008b).

We found that the transcriptional repressor KAP1 contributes to HIV-1 gene silencing by repressing the initiation and the Tat-dependent steps of the viral gene transcription.
Moreover, we report that KAP1 cooperates with CTIP2 to silence HIV-1 gene transcription and the viral expression. KAP1 functions are closely linked to SUMO-mediated post-transcriptional regulations. Our results suggest that KAP1 induces Tat degradation via a SUMO-sensitive pathway. Indeed, favoring SUMOylations promotes Tat association with KAP1 and the resulted degradation. Logically, over-expressing the SUMO protease SENP1, abrogates KAP1-mediated degradation of Tat.
Conclusions: Altogether, our results suggest that KAP1 contributes to the establishment and the persistence of the latently infected HIV-1 reservoirs. Nevertheless, these results suggest that targeting the SUMO pathways may be a new field of investigation to develop new classes of Latency Reversing Agents for cure strategies.

Translational regulation of APOBEC3G mRNA by Vif requires its 5'UTR and contributes to restoring HIV-1 infectivity

S. Guerrero[1], C. Libre[1], J. Batisse[1], G. Mercenne[1], D. Richer[1], G. Laumond[2], T. Decoville[2], C. Moog[2], R. Marquet[1], J.-C. Paillart[1]
[1]CNRS - Université de Strasbourg, Architecture et Réactivité de l'ARN, Strasbourg, France, [2]INSERM UMR 1109 - Université de Strasbourg, Laboratoire d'Immuno Rhumatologie Moléculaire, Strasbourg, France
Presenting author email: jc.paillart@ibmc-cnrs.unistra.fr

Background: The HIV-1 requires the concerted contribution of many cellular factors to achieve efficient replication. Similarly, mammalian cells express a set of proteins called restriction factors to suppress viral replication. Among these factors, the family of APOBEC3 (A3) proteins and in particular A3G and A3F are the most efficient against HIV-1. They belong to a large family of cytidine deaminases that catalyze the deamination of cytidines to uridines during retrotranscription. The antiviral activity of A3G/F is counteracted by the HIV-1 Vif protein. Vif significantly reduces their expression in cell and their incorporation into viral particles by
1) recruiting an E3 ubiquitin ligase complex to induce their degradation by the proteasome, and;
2) regulating their translation. Up to now, mechanisms by which Vif regulates the translation of A3G are unknown.
Methods: We tested the importance of the untranslated regions (UTRs) of A3G mRNA in the translational inhibition. HEK293T cells were transfected with wild-type and mutated constructions of A3G mRNAs in presence or absence of Vif. These experiments were also performed with proteasome inhibitors in order to distinguish the proteasomal degradation from the translational inhibition.
Results: Although the translation of wild-type A3G mRNA is significantly reduced by Vif, the deletion of its 5'UTR suppressed its regulation by Vif, suggesting the importance of this region for translational repression. Moreover, its replacement by heterologous 5'UTRs prevents translation inhibition. Within this 5'UTR, the two distal stem-loops are required for the inhibition. Interestingly, we found that A3G is also translationally regulated by Vif in HIV-1 chronically infected lymphoid cells (H9). This effect of Vif on A3G translation is conserved amongst HIV-1 isolates, whereas CBF-b an essential factor in Vif-induced A3G proteasomal degradation does not seem to be required. Finally, we observed a strong correlation between the level of A3G protein translation in cell, their incorporation into viral particles, and the infectivity of released virions.
Conclusions: Experiments are in progress to identify with precision the mechanisms and partners of A3G translational regulation. Regulating the translation of A3G could thus be considered as a new target to restore a functional expression of A3G and viral restriction.

MOPEA0035

TILRR is a potential enhancer of inflammation and HIV-1 vaginal infection through interacting with NFκB signaling pathway

M. Kashem[1,2], P. Lacap[2], H. Li[1,2], W. Omange[1,2], N. Toledo[1,2], F. Plummer[1,3], M. Luo[1,2]
[1]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]National Microbiology Laboratory, National HIV and Retrovirology Laboratory, Winnipeg, Canada, [3]National Microbiology Laboratory, Winnipeg, Canada
Presenting author email: kashemm@myumanitoba.ca

Background: TILRR (Toll like IL1 Receptor Regulator), a transcript variant of FREM1, is a novel regulatory component, which stimulates host defense against infection through binding to IL-1R1 and TLR complex and enhancing the recruitment of MYD88 in the Ras-dependent NFκβ signal transduction pathway. Our previous study identified FREM1 as a novel candidate gene in correlation with HIV-1 resistance/susceptibility in the Pumwani Sex worker cohort. In this study, we investigated the effect of TILRR on the global gene expression profile of the NFκB signaling pathway by over-expressing it into human cell lines.
Methods: TILRR was overexpressed in HeLa and VK2 cells using eGFP tagged plasmid construct. Transfection efficiency was confirmed by Confocal microscopy and Flow cytometry. TILRR RNA overexpression was confirmed by qRT-PCR and Western blot analysis. The effect of TILRR on the expression of 84 genes linked to NFκB pathway was subsequently investigated by qRT-PCR. Conditioned media were also tested for the protein level expression of important pro- and anti-inflammatory cytokines/chemokines using Bioplex multiplex cytokine/chemokine bead assay.
Results: Overexpression of TILRR significantly up-regulated 32- and 52-genes, as well as down-regulated 15- and 4-genes in IL-1β treated and non-treated cells, respectively. We observed that most of the pro-inflammatory cytokine/chemokine encoded genes, like IL-1β, IL-6, TNFα, and IL-8 (chemokine) were significantly increased at mRNA level expression. We further noticed that cytokines/chemokines, those were assessed for mRNA level expression by qRT-PCR, were also increased at the protein level expression in conditioned media using multiplex bead assay. Data described here are the representative of three independent experiments using female genital tract cell lines, which suggest a potential link of TILRR in HIV-1 vaginal infection through enhancing the NFκB and inflammatory responses.
Conclusions: Although how TILRR influence the expression of these genes needs to be further studied, our study is the first to show that TILRR may influence the expression of genes directly involved in HIV-1 infection in addition to its role in enhancing NFκB and inflammatory responses. NFκB and inflammatory response pathways are extremely important in HIV-1 transmission; therefore, further study of the role of TILRR may identify novel intervention targets and strategies against HIV-1 vaginal infection.

HIV-1 Vpr counteracts CTIP2-mediated cellular response to viral infections

F. Forouzanfar[1], S. Ali[2], H. El Mekdad[1], A. Ait-Ammar[1], C. Van Lint[3], C. Schwartz[1], O. Rohr[1]
[1]University of Strasbourg, Strasbourg, France, [2]University of Faisalabad, Faisalabad, Pakistan, [3]Université libre de Bruxelles, Gosselies, Belgium
Presenting author email: olivier.rohr@unistra.fr

Background: Mammals have developed innate and acquired immune responses to combat infections. Several host factors such as APOBEC3G, Tetherin, TRIM5a or SAMHD1 have been described to restrict HIV-1 expression. Interestingly, none of them targets the transcription step of the viral life cycle. We have previously reported that the cellular transcription factor CTIP2 contributes to the establishment and the persistence of HIV-1 post-integration latency. CTIP2 restricts HIV-1 gene transcription by recruitments of multi-enzymatic complexes at the viral promoter. Since CTIP2 is widely expressed in HIV-1 target cells, we investigated how the virus counteracts this transcriptional block to allow its expression in permissive cells.
Methods: Microglial and T cell lines have been used to study the molecular mechanisms underlying the HIV-1 counteractions of CTIP2 functions. Classical but focused and complementary methods have been used to investigate the functional and biochemical interplays between the response of the host cells and the role of the viral factors.
Results: We report that CTIP2 expression is favored by interferon treatments making this transcription factor a contributor of the innate cellular response against viral infections. HIV-1 infection induced a biphasic control of CTIP2 expression. CTIP2 was overexpressed at early time points and reduced during the productive phase of the viral expression. Since the overexpression of CTIP2 resulted from an interferon sensitive increase of CTIP2 mRNA, the reduced expression of CTIP2 resulted from a degradation of the protein through the proteasome pathway. We report that the viral accessory protein Vpr promoted this degradation through the association of CTIP2 with the CULL4-DDB1-DCAF1 complex. Vpr induced the degradation of CTIP2 and of its associated-chromatin modifying enzymes at the HIV-1 promoter. These events favor an efficient HIV-1 gene transcription and the subsequent viral replication.
Conclusions: Our results suggest that the transcriptional repressor CTIP2 contributes to the cellular response against HIV-1 infections. In HIV-1 permissive cells, the virus counteracts this cellular restriction through a Vpr-mediated degradation of CTIP2. Through modulations of CTIP2 expression, the transcription step of the HIV-1 life cycle is for the first time targeted by host factors to restrict the viral expression and by the viral factors to counteract this restriction.

BRD4 inhibitor, JQ1, but not HDAC inhibitors, stimulate accumulation of spliced HIV RNA

T.M. Mota[1,2], G. Khoury[1,2], S. Li[1,3], S.R. Lewin[1], D.F. Purcell[1,2]
[1]University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [2]University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, [3]Peking University, School of Life Sciences, Beijing, China
Presenting author email: taliamm13@gmail.com

Background: Understanding HIV transcription is critical to developing new strategies to eliminate latency. HIV Tat protein augments transcriptional transactivation by facilitating viral RNA elongation and splicing. Tat proteins are highly acidic and undergo different posttranslational modifications on lysine residues which modify the behaviour of Tat. We aimed to determine the effects of these lysine residues on HIV transcription and splicing in the presence and absence of latency reversing agents (LRAs), including histone deacetylase inhibitors (HDACi).
Methods: Wildtype (WT) Tat101 (AD8) was mutated by site-directed mutagenesis to generate K28A, K50A, K50/51A, K71A, and R53A. Expression of these mutants was confirmed by Western Blot. TZM-bl cells were used to measure the effect of each mutant on transcriptional transactivation compared to WT Tat and luciferase expression was quantified. Effects on splicing were quantified by flow cytometry using a fluorescent splicing reporter system, where unspliced transcripts expressed green fluorescent protein (eGFP) and spliced transcripts expressed dsRed. We transfected HEK293T cells with the reporter constructs in the presence of WT and mutant Tat using a panel of LRAs (vorinostat, panobinostat, JQ1, chaetocin, and disulfiram), DMSO and PMA.
Results: In TZM-bls, transfection of the Tat mutants K28A, K50A and K50/51A, and to a lesser extent, R53A, significantly reduced luciferase expression compared to WT, while there was no difference between K71A and WT. In the splicing reporter system, the impact of Tat mutations on eGFP expression (unspliced product) was similar to our findings in TZM-bl cells, and the addition of HDACi and JQ1 but not chaetocin or disulfiram, resulted in increased expression of eGFP compared to DMSO for all Tat mutants. In contrast, only JQ1 significantly increased the level of dsRed (spliced product) compared to DMSO. Finally, in the absence of Tat, JQ1 was the only LRA to significantly increase dsRed to levels similar to wildtype Tat.
Conclusions: JQ1, a BRD4 inhibitor that promotes pTEF-b formation, drives accumulation of spliced HIV RNA, even in the presence of Tat mutants while HDACi, only increased the levels of unspliced HIV RNA. JQ1 may have increased potency as an LRA in latently infected resting T-cells where Tat levels are low.

Generation of HIV latency reporter cell lines by targeted genome engineering to explore effects of proviral integration site choice

U.C. Lange[1,2,3], T. Walther[1], J.K. Bialek[1], J. Hauber[1,3]
[1]Heinrich Pette Institute, Hamburg, Germany, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]German Center for Infection Research (DZIF), Hamburg, Germany
Presenting author email: ulrike.lange@hpi.uni-hamburg.de

Background: Infection with Human Immunodeficiency Virus (HIV) leads to non-random integration of proviral sequences into the human host genome. Irrespective of antiretroviral therapy, this results in a genomic burden of virus-derived sequences. It is thought that only a small proportion of these sequences code for intact, replication-competent HIV genomes. They have been claimed to be the source of a latent reservoir in infected and treated individuals. In such individuals, recent reports highlight the existence of preferred genomic integration sites for provirus-derived sequences. These findings prompt the question of whether the site of genomic proviral integration impacts on proviral activity or indeed if there is an effect vice versa.
Methods: T cell-derived Jurkat cells were targeted using CRISPR/Cas9 technology to introduce an HIV-derived reporter cassette. The workflow for targeting and screening of clonal lines will be demonstrated.
Results: In this study, we have used targeted genome engineering to generate T cell-derived lines that carry an HIV-derived fluorescent reporter at defined genomic loci. These defined loci have been reported as preferred integration sites in HIV-infected subjects under therapy. We demonstrate thorough characterization of the novel reporter lines by Southern blotting, qPCR and flow cytometry and show how stimulation with various latency reversing agents (LRAs) affects LTR-dependent reporter expression.
Conclusions: Our study shows how genome engineering techniques can be exploited to generate new in vitro models for HIV latency. Focusing on recurrent proviral integration sites found in vivo, these reporter models provide unique tools to study the link between genomic integration site and provirus activity.

Background: RNA interference (RNAi) is a post-transcriptional gene process in eukaryotes that controls cell differentiation, development, and immunity. RNAi in mammals occurs via micro RNAs (miRNA), which are small ~22 base pair non-coding double-stranded RNAs that hybridize to a specific target mRNA for cleavage or translational repression. This process requires the RNA Induced Silencing Complex (RISC), which is composed of Dicer, TRBP and Ago2. We and others have shown that HIV-1 does not shut off the RNAi pathway but, HIV-1 proteins and RNAs act at discrete steps. Here, we identify an interaction between the HIV-1 structural protein Gag and Dicer and analyze its impact on Dicer activity and miRNA selection in the RISC.
Methods: We identified an interaction between Gag and Dicer by indirect immunofluorescence, Proximity Ligation Assay (PLA) and co-immunoprecipitation (co-IP). In addition, we determined the cleavage capacity of Dicer using a catalytic activity assay with miRLet7-c and mir29a. Finally, we evaluate miRNAs bound to Dicer by using RNA immunoprecipitation and sequencing (RIP-seq).
Results: We show that Gag co-localizes with Dicer by confocal microscopy. We show that Dicer co-IPs with Gag in an RNA-independent fashion. By PLA we quantify ($P< 0.001$) and determine that Gag-Dicer interaction occurs mainly in the cytoplasm. Additionally, we developed a catalytic assay for Dicer to evaluate its function. Our results show that Dicer catalytic activity is not impaired by Gag for the amount or size of two produced miRNAs, Let7-c and miR29a. We are on the process of acquiring results from ongoing RIP-seq analyses to evaluate the miRNAs produced by Dicer in the presence of Gag.
Conclusions: We have demonstrated HIV-1 Gag interacts with Dicer. The importance of this discovery relies on the fact that pre-miRNAs must pass through Dicer to complete their function whether they have been produced by a canonical or non-canonical pathway. Subtle modifications by Gag could affect miRNAs binding and processing by Dicer and consequently the mRNA expression.

Microglial cells that are latently infected by HIV are activated by inflammatory stimuli and induce neuronal damage

D. Alvarez-Carbonell, Y. Garcia-Mesa, C. Dobrowolski, J. Karn
Case Western Reserve University, Molecular Biology and Microbiology, Cleveland, United States
Presenting author email: dxa150@case.edu

Background: The major reservoirs for HIV in the CNS are in the microglia, perivascular macrophages, and to a lesser extent, astrocytes. We hypothesized that toll-like receptor (TLR) responses to inflammatory conditions by microglial cells induce latent HIV proviruses and that these activated microglial cells, in turn, are responsible for the neuronal damage seen in HIV-associated neurodegeneration.
Methods: Primary human cells, including cells obtained from adult brain tissue, were transformed with lentiviral vectors expressing a combination of SV40 T antigen and hTERT. These newly developed human microglial cell lines (hμglia) were used to generate latently infected cells using a single-round HIV virus carrying a green fluorescence protein (GFP) reporter (hμglia/HIV, clones HC01 and HC69). Neuronal viability was assessed through time-lapse digital images recording of live cells, MAP-2 immunohistochemistry, and Western blot analysis.
Results: The immortalized cells have microglia-like morphology, demonstrate the expected migratory and phagocytic activity, express key microglial surface markers (CD11b, TGFβR, and P2RY12), and have RNA expression profiles characteristic of primary microglial cells. The inflammatory cytokines TNF-α and IL-1β stimulated HIV transcription. Surprisingly, two TLR3 agonists, poly (I:C) and bacterial ribosomal RNA (rRNA) also potently reactivated HIV in hμglia/HIV cells using a previously unreported mechanism mediated by IRF3. The selective induction of IRF3 by poly (I:C) was confirmed by chromatin immunoprecipitation (ChIP) analysis. LPS (TLR4 agonist), flagellin (TLR5 agonist), and FSL-1 (TLR6 agonist) reactivated HIV to a lesser extent through transient NF-κB induction. Pam3CSK4 (TLR2/1 agonist) and HKLM (TLR2 agonist) only weakly reversed HIV latency. When LUHMES cells or mouse primary neurons were co-cultured with HIV infected microglia, extensive neurodegeneration was observed as shown by the significantly reduced MAP-2 staining of neuronal axons (dendritic damage), decreased level of synaptophysin, GluR1 AMPA and synaptophysin (synaptic damage), and increased levels of phosphor-Tau (neuronal microtubules damage).

Conclusions: The cell lines developed and rigorously characterized will provide an invaluable resource for the study of HIV infection in microglial cells. Since HIV patients characteristically have chronic inflammation due to the release of microbial components into the circulation, the TLR responses that we have documented are likely to contribute to CNS-disease progression.

MOPEA0041

A single-cell method to detect early activation of the latent HIV provirus

J.P. Svensson
Karolinska Institutet, Biosciences and Nutrition, Huddinge, Sweden
Presenting author email: peter.svensson@ki.se

Background: The reservoir of latently infected cells is the main obstacle to cure HIV. The cellular mechanisms that are responsible for the initial activation and transcriptional elongation of the latent provirus remain unclear. To better understand the factors that affect the proviral activation in the heterogenous population of the latent reservoir, there is a need for new tools.
Methods: We have developed a technique to identify early proviral activation in single cells. The technique relies of detection of proximity of a single viral Tat protein to the HIV promoter in an engineered Jurkat-derived cell model.
Results: We are able to detect early activation in a sensitive and robust manner without increasing the background signal relative to standard assays. The results were compared to a J-lat model, 5A8, with a latent reporter HIV-GFP contruct. Up to three-fold higher activation were observed using our technique compared to the GFP signal in the same cell. The signal for activated provirus could be detected a few hours after stimulation of T-cell receptor signaling.
Conclusions: This technique can be used to delineate the cellular pathways that promote or restrict proviral activation.

MOPEA0042

The nuclear pore orchestrates HIV-1 nuclear import and sculpts the chromatin landscape near integration sites

Background: Nuclear pore complexes (NPCs) are dynamic structures embedded in double lipid layer of the nuclear envelope, which act as guardians of nucleocytoplasmic transport, genome organization, genome stability and gene expression regulation. Some of these cellular functions orchestrated by NPCs are usurped by viruses that replicate in the nucleus. In recent years, research regarding multiple aspects of the early steps of HIV-1 life cycle highlights dynamic and concerted mechanisms between viral components, NPC, chromatin state. Recently, we unraveled the distinct roles of two nuclear basket Nups, Nup153 and Tpr, in HIV-1 infection. We observed that Nup153 participates in HIV-1 nuclear import, while Tpr maintains a chromatin environment favorable for HIV-1 replication.
Methods: We generated stable knockdown cells using lentivectors carrying shRNA specific for a single nucleoporin and using HIV-1 mutants. We analyzed HIV-1 integration sites by high throughput pyrosequencing and RNA sequencing. Functional enrichment analysis has been performed using DAVID and ToppGene Suite, both including defined gene sets for Gene Ontology categories and biological pathways like KEGG.
Results: We investigate how critical is the passage through the NPC for HIV-1 replication and if the pore is the exclusive pathway used by the virus to reach the chromatin. To understand whether HIV-1 integration sites in particular chromatin regions depends on the NPC passage we performed high throughput pyrosequencing in different viral conditions. We observe divergences in the distribution of integration sites in host chromatin regions and in particular chromatin features. Bioinformatics analysis show changes in cluster of genes involved in cell cycle, DNA repair and transcription. We previously observed that cells depleted for Tpr have a defect in HIV genes expression. In order to identify cluster of genes that could be involved in viral silencing due to the absence of Tpr, we compare the transcription level of 36,064 genes on Tpr depleted Jurkat cells vs control cells infected and not with HIV-1.
Conclusions: Taken together these results could help the comprehension of how Nups, chromatin factors and genes are concerted to orchestrate HIV-1 replication. Nucleoporins may be another "cellular code" for specifying HIV-1 fate through the underlying chromatin.

Presenting author email: marcial_g_a@hotmail.com

Background: Latency remains the biggest barrier to HIV eradication. Elite controller (EC) patients, who are able to spontaneously control viral replication, could have molecular mechanisms against HIV-reservoir. In this study, we seek for correlates of HIV reservoir control in the CD8-T cells and resting memory CD4-T cells (TRM) transcriptional profile of these patients.
Methods: Thirty HIV-patients were included according to plasma viral load (pVL) and cART status: 10 EC (pVL< 50 without cART); 10 TX (pVL< 50 on cART); 10 TP (pVL>50 without cART). Ten healthy controls (HC) were also included. HIV reservoir size was analyzed measuring cell-associated total HIV-DNA by digital droplet PCR in TRM cells. Transcriptional profile of purified CD8 and TRM cells was analyzed with human whole genome Agilent microarray platform. Limma test was used for the analysis of genes with differential expression; genes were considered significant with false discovery rate (FDR) below 0.05 (P< 0.05).
Results: The smallest HIV reservoir size was seen in EC among HIV-patients (p< 0.0001). CD8 T-cells transcriptional profile revealed that HIV induces deregulation of 5153 genes in TP patients; viral suppression with cART (TX patients) led to a normalization with only 24 genes differentially expressed compared to HC. Surprisingly, EC had 368 genes differentially expressed compared to HC, many of these related to immune response. Otherwise, TRM cells transcriptional profile revealed 256 genes differentially expressed in EC but not in TX compared to TP. Again, many of these were related to immune system, and interestingly some were associated to infection control: MICA (fold change 3.38 EC vs. TP; p=0.04) a NK cell-activating ligand, and CD96 (fold change 4.39 EC vs. TP; p=0,006) a T cell-specific receptor.
Conclusions: EC patients present a better control of proviral HIV-DNA in TRM cells, the main component of cellular HIV reservoir. Interestingly, both CD8 T-cells and TRM cells transcriptional profiles reveal molecular mechanisms specifically associated to the status of EC and potentially involved in the better control of reservoir size observed in these patients, and different to those potentially associated to control throughout treatment. These data provide important findings to improve clinical strategies that could help to achieve HIV remission.

MOPEA0044

Peripheral T follicular helper cells make a difference in HIV reservoir size between elite controllers and patients on successful ART

M. García[1,2], A. Cabello[3], M. Górgolas[3], C. Restrepo[1,2], M. Montoya[4], V. Estrada[5], F.J. De la Hera[3], C. Barros[6], M. Fernández[3], J.C. López-Bernaldo[7], J. Ligos[4], J.M. Benito[1,2], N. Rallón[1,2]
[1]Instituto de Investigación Sanitaria-FJD, UAM, Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [3]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [4]CNIC, Celomics Unit, Madrid, Spain, [5]Hospital Universitario Clínico San Carlos, Madrid, Spain, [6]Hospital Universitario de Móstoles, Móstoles, Spain, [7]Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: HIV latency is the main barrier to HIV eradication. At cellular level, long-term persistent virus has been mainly described in resting memory CD4+ T-cells. Recently, peripheral T follicular helper (pTfh) cells have taken a prominent role in HIV persistence.
Herein, we analyzed the HIV reservoir size in memory CD4+ T-cell subsets in patients with HIV replication control.
Methods: Twenty HIV-infected patients were included according to plasma viral load and ART status: 10 elite controller (EC) and 10 treated (TX) patients. Size of HIV reservoir was analyzed by ultrasensitive digital droplet PCR assay to measure total cell-associated HIV-DNA in resting memory CD4+ T-cells, peripheral T follicular helper cells and non-peripheral T follicular helper cells. Inter-group and intra-group differences were tested using non-parametric tests.

Results: Compared to TX patients EC patients had lower reservoir size in resting memory CD4+ T-cells (p=0.059) and in pTfh cells (p=0.025), but not in non-pTfh cells (p=0.17). Moreover, pTfh and non-pTfh cells harbored similar levels of HIV reservoir both in EC (p=0.60) and in TX patients (p=0.17).
Conclusions: Our data shows that compared to patients on successful ART, Elite Controller patients have a lower HIV reservoir size in memory CD4+ cells, and this is consequence of the HIV-DNA content in pTfh cells, a population of memory cells with a pivotal role in anti-viral immune response, suggesting a potential link between low level of infection of pTfh cells and ability of EC to spontaneously control HIV replication.

Background: Current antiretroviral therapy (ART) does not allow for the eradication of the human immunodeficiency virus (HIV) due to the presence of latent proviruses in rare, long-lived resting CD4+ T cells. The main research efforts to eliminate the viral reservoir are focused on the use of latency reversing agents (LRAs) to force the reactivation of the latent provirus, while maintaining ART to prevent de novo infections. Subsequently, reactivation of HIV expression would kill reservoir cells via viral cytopathic effects and/or immune clearance ("shock and kill" strategy). So far, no LRAs tested in clinical trials have succeeded in reducing the viral reservoir.
Methods: We used an improved dual-fluorescent HIV reporter (GKO), which distinguishes productively infected cells from the latent population, to investigate the efficacy of the "shock and kill" strategy. In addition, GKO provides a unique opportunity to:
(1) explore the impact of HIV integration site specificity on the fate of the infection, and to;
(2) characterize the inducible subpopulation of latently infected cells, since it allows the isolation of inducible latent and non-inducible latent populations from the productively infected majority.
Results: We first showed that our patients' data was consistent with previously published studies. However, we found that at most 5% of GKO latent proviruses were reactivated, and that these reactivated cells were resistant to virus-induced cytopathic effects, thus preventing their elimination. Moreover, the analysis of HIV-1 integration sites from productively, non-inducible and inducible latently infected populations reveals heterogeneity within the latent infections. In contrast to non-inducible latent infections, the integration sites of inducible latent proviruses have similar features to those of productive proviruses, thus demonstrating a prominent role for the site of integration and its chromatin context for the fate of the initial infection as well as for latency reversal.
Conclusions: Our study shows an important roadblock for the "shock and kill" approach to reservoir eradication. Differences between reactivatable and permanently latent reservoir cells suggest that complete reservoir reactivation and eradication with LRAs may prove impossible, and that a multipronged "functional cure" approach may be necessary.

MOPEA0046

HIV reservoir size and composition, after antiretroviral treatment initiation, is related to HIV-specific CD8+ T-cell responses developed during primary HIV infection

Y. Ghiglione[1], C. Trifone[1], J. Salido[1], A. Solomon[2], M.J. Ruiz[1], M.L. Polo[1], H. Salomón[1], N. Laufer[1,3], O. Sued[3,4], S.R. Lewin[2,5], G. Turk[1]

Presenting author email: hsalomon@fmed.uba.ar

Background: The persistence of latently infected T-cells remains the major obstacle to cure HIV. Understanding the early events that occur after infection and establish HIV latency will be fundamental for potential eradication. We aimed to determine the relationship between CD8+ cytotoxic T lymphocyte (CTL) function and HIV persistence on antiretroviral therapy (ART).
Methods: Twenty-one individuals were enrolled during acute/early HIV infection (median 2 month post-infection, mpi) and started ART within 12 mpi. Blood samples were obtained at enrollment (baseline sample, pre-ART) and every 3 months (on-ART) during 2 years. Cell-associated HIV DNA and unspliced (US) RNA were quantitated by real-time PCR, in samples on-ART. HIV-specific CTLs were identified based on cytokines/CD107 production upon peptide stimulation. Phenotypic (CD45RO, CCR7, PD-1) markers were studied in baseline samples on bulk and HIV-specific CTLs by flow cytometry. Data was analyzed using non-parametric statistics
Results: HIV DNA and US RNA rapidly diminished after ART initiation, reaching a plateau by 30 weeks post-ART (median total HIV DNA 159 copies/10^6 cell equivalents; unspliced (US)-RNA 14 copies/10^6 18S copies). HIV-specific CTLs profile at baseline was: 52% terminal effectors (T_{TE}); 20% naïve-like; 13% effector memory (T_{EM}) and 5% central memory. PD-1+ HIV-specific CTLs were 24.7%. Also, high intensity PD-1 (PD-1^{High}) expression was measured in 1.2% CTLs.
Spearman's correlations showed that the proportion of baseline naïve CTLs was inversely correlated with levels of cell-associated US-RNA measured at 12 month post-ART (mp-ART) (r=-0.6321, p=0.005). A higher proportion of bulk and HIV-specific CD8+ T_{EM} cells at baseline correlated with higher levels of US-RNA measured at 12 mp-ART (r=0.6746, p=0.002 and r=0.5752, p=0.017; respectively). The percentage of HIV-specific CD8+ T_{TE} cells positively correlated with total HIV DNA levels at 12 mp-ART (r=0.6888, p=0.011).
Finally, a strong positive correlation was observed between the proportion of bulk and HIV-specific PD-1^{high} CTLs measured at baseline and total HIV DNA levels at 12 mp-ART (r=0.5005, p=0.034 and r=0.7349, p=0.006; respectively).
Conclusions: Results suggest that higher proportion of terminally differentiated CTLs and higher CTL exhaustion are related to higher HIV reservoir size. Thus, the quality of early CTL immune responses may serve as a predictor of HIV persistence on ART.

Urethral tissue macrophages are genuine viral reservoirs in HIV-1-infected individuals under suppressive antiretroviral therapy

Presenting author email: yonatan.ganor@inserm.fr

Background: HIV-1 eradication, or at least functional cure, requires the elimination/reduction of the HIV-1 reservoir pool. The best-characterized HIV-1 reservoir resides within peripheral blood resting memory CD4+ T-cells. Yet, residual viremia in HIV-1-infected HAART-suppressed individuals originates not only from T-cells

but also from macrophages, which could therefore comprise an additional long-lived HIV-1 reservoir. Indeed, macrophages are tissues-resident cells that resist the cytopathic effects of HIV-1 infection, survive for long periods, have the capacity of self-renewal, and accumulate infectious virus in intracellular virus-containing compartments (VCCs). Moreover, latency-reverting agents (LRAs) re-activate HIV-1 production in-vitro from both latently infected CD4+ T-cells and macrophages. Currently, a clear demonstration that macrophages actually comprise genuine HIV-1 reservoirs is lacking, as no studies showed that tissue macrophages recovered from HIV-1-infected HAART-suppressed individuals produce infectious virus only following re-activation.
Methods: Using whole penile tissues, obtained upon transgender surgery, from HIV-1-infected HAART-suppressed individuals with undetectable plasma viral loads, we evaluated whether urethral macrophages serve as a yet unrecognized cellular reservoir for HIV-1. Such assumption was based on our previous results showing that urethral macrophages are the first cells targeted by HIV-1 during sexual transmission.
Results: We found that urethral macrophages, but not urethral T-cells, contain HIV-1 proteins, intact virions in VCCs, RNA and R5-tropic integrated DNA. Moreover, in a sensitive quantitative viral outgrowth assay (sQVOA), urethral cells release infectious HIV-1 following stimulation with the macrophage-specific activator lipopolysaccharide (LPS), but not the T-cell-specific activator phytohaemagglutinin (PHA). HIV-1 reservoirs form preferentially in a newly identified subset of polarized urethral macrophages we term transitional M1/M2. Such cells highly express IL-1-receptor, CD206 and IL-4-receptor, but lack CD163, and are increased in urethral tissues from HIV-1-infected HAART-suppressed individuals. Finally, HIV-1 in urethral macrophages does not result from phagocytosis / internalization of T-cells.
Conclusions: Our results show for the first time that despite suppressive HARRT, HIV-1 persists in urethral macrophages, which can be re-activated to release infectious virus. Hence, urethral macrophages are genuine HIV-1 reservoirs. These findings are determinant for therapeutic strategies aimed at HIV-1 eradication.

Stimulation of the HIV T-cell reservoir leads to expression of genetically intact but functionally impaired Env glycoproteins

A. Huard de Verneuil, J. Migraine, J. Dutrieux, C. Delaugerre, J.-M. Molina, S. Gallien, F. Mammano, A.J. Hance, F. Clavel
Inserm U941, Hôpital Saint-Louis, Paris, France
Presenting author email: anne.huard-de-verneuil@inserm.fr

Background: The HIV T-cell reservoir harbors only a small percentage of intact HIV genomes, but little is known of the functional capacity of viral proteins expressed by these sequences. We have focused here on the HIV envelope glycoprotein, a major target for the host immune response and a strong effector of HIV cytopathicity.
Methods: Resting CD4+ T-cells were collected from 4 HIV-infected subjects in whom viral replication had been fully suppressed by ART for more than 4 years. After in vitro T-cell stimulation, Env sequences were obtained from two sources : clonal replicative virus isolated by qVOA, and cell-associated Env mRNAs isolated by limiting-dilution PCR. Env sequences were cloned in a Rev-independent expression vector. Env expression was examined quantitatively by FACS flow cytometry and Western Blotting. Env function was tested using both a quantitative cell-cell fusion assay and a pseudotype infectivity assay.
Results: All qVOA-derived Envs were intact, while 26% of mRNA-derived Envs carried lethal mutations. Only clones with intact sequences were tested. As expected, clusters of identical sequences were seen in all 4 patients. Env diversity was widest in patients with longest HIV history. Env fusogenicity was highest in qVOA viruses, with 90% of them expressing fusion values above 50% of that of NLAD8 control. By comparison, among mRNA-derived Envs, only 41% reached fusogenic levels above 50% of control, 31% had fusogenic levels below 25% of control, and 14% had no detectable fusion activity. Similar findings were made when Env sequences were expressed and tested in a pseudotype infectivity assay, with a significant correlation between results from the two assays. Flow cytometry and Western-Blot analyses revealed that defects in Env function were essentially related to defects in Env expression, maturation and/or stability.
Conclusions: The discovery of apparently intact, yet functionally defective, Env sequences in the HIV reservoir has two implications. First, Env fusogenicity and cytopathicity could be one important factor driving selection of defective HIV genomes in the reservoir. Second, the presence of poorly expressed and poorly functional Env sequences in the reservoir could preclude elimination of cells harboring these sequences in « kick and kill » HIV eradication attempts.

MOPEA0049

Early initiation of antiretroviral treatment post SIV infection does not resolve lymphoid tissue activation

J.J. Hong[1], E. Silveira[2], P. Amancha[3], S. Byrareddy[4], S. Gumber[5], K.-T. Chang[1], A. Ansari[5], F. Villinger[3]
[1]Korea Research Institute of Bioscience and Biotechnology (KRIBB), Cheongju, Republic of Korea, [2]University of São Paulo, São Paulo, Brazil, [3]New Iberia Research Center, Lafayette, United States, [4]University of Nebraska Medical Center, Omaha, United States, [5]Emory University, Atlanta, United States
Presenting author email: gowest2@hanmail.net

Background: Germinal center (GC) resident follicular helper T (TFH) cells in lymphoid follicles are a potential sanctuary for HIV/SIV replication. But the dynamics of GCs upon early initiation of antiretroviral therapy (ART) and their potential role in the formation of viral sanctuaries post SIV infection are not fully understood.
Methods: Sequential lymph node biopsies (n=10) were collected from SIVmac239-infected rhesus macaques at time points corresponding to pre infection, 5 weeks post infection/pre ART, 6 and 12 weeks after ART initiation time points for frequencies of TFH cells and the evaluation of GC scores.
Results: Post-acute SIV infection (wk 5/pre ART), modest but significant increases in TFH cells and hyperplastic follicles with large GCs were noted. In contrast, 6 weeks after ART initiation, substantial increases in GC TFH cells, hyperplastic follicles with large GCs and abundant local IL-21 production were observed, while levels of SIV RNA and DNA of lymph nodes had decreased to barely detectable values, as well as circulating SIV antibody producing plasmablasts. An additional 6 weeks of ART did not appreciably decrease GC TFH numbers or GC scores.
Conclusions: Thus, early ART rapidly control SIV replication, but not lymphoid activation, which may be potentially dictating the seeding and magnitude of viral reservoirs.

MOPEA0050

A humanized mouse-based HIV-1 viral outgrowth assay with higher sensitivity than in vitro VOA in detecting latently infected cells from patients on ART with undetectable viral loads

P. Charlins[1], L. Mulder[1], T. Henrich[2], R. Akkina[1]
[1]Colorado State University, Microbiology, Immunology and Pathology, Fort Collins, United States, [2]University of California, Medicine, San Francisco, United States
Presenting author email: akkina@colostate.edu

Background: With the current emphasis on achieving a complete cure for HIV/AIDS it is important to develop assays that can verify full viral clearance. Currently, in vitro viral out growth assays (VOA) are the gold standard compared to PCR based-tests which cannot distinguish between defective and replication competent viruses. However, the VOAs failed to detect latent virus in cases such as the Boston patients prior to treatment interruption during which virus rebounded. Thus more sensitive latent viral detection methods are needed.
Methods: With a goal of developing a potentially more sensitive in vivo-based VOA, we employed humanized mice shown to be permissiveness for HIV infection, latency and viral reactivation. Purified resting CD4 T cells were obtained from patients on long term ART and no detectable viral loads. These cells were first tested by the standard in vitro quantitative VOA (qVOA). Patient samples that gave negative viral outgrowth by this method were injected i/p into hu-mice and these mice were followed for 8 weeks to detect any viral outgrowth.
Results: Of the five in vitro VOA negative patient samples tested, four showed viral outgrowth in the hu-mouse based viral outgrowth assay (hmVOA) indicating its higher sensitivity. In positive samples, those injected with higher numbers of cells became virus positive sooner and in some, only mice receiving the largest numbers of cells showed viral outgrowth consistent with the distribution of minute levels of latent cells present in aviremic patients on effective ART.
Conclusions: Our results suggest that in vivo-based hmVOA is more sensitive than the standard in vitro qVOA in detecting the latently infected cells. The reasons for better sensitivity are attributed to a more physiological in vivo environment in present in hu-mice versus in vitro culture for the longer term cell survival as well as potent xenograft reaction possibly resulting in better viral induction. These findings set the stage for further improvement and refinement of the hmVOA in HIV latency and cure research.

Background: Despite viral control in antiretroviral therapy (ART)-treated individuals, HIV persists in anatomic reservoirs. We demonstrated the presence of HIV DNA in the testes of individuals receiving ART. In animal models, the testis is described as a site of immune privilege where immune responses are suppressed, notably through the expression of indoleamine 2,3-dioxygenase (IDO) in macrophages and dendritic cells (DCs). Herein, we characterized human testicular myeloid cells and evaluated their immunosuppressive properties that may contribute to HIV persistence.
Methods: Matched testis and blood samples were collected from 9 uninfected individuals undergoing sex reassignment surgery. Peripheral blood mononuclear cells (PBMCs) were isolated by ficoll gradient density centrifugation and testicular cell suspensions were obtained by enzymatic digestion. Myeloid (mDCs), plasmacytoid (pDCs) dendritic cells and myeloid-derived suppressor cell (MDSCs) were assessed using multicolor flow cytometry. In situ localization of testicular immune cells was evaluated by immunostaining of frozen sections. IDO mRNA expression was quantified by qPCR.
Results: Testicular cell suspensions contained 9% of leukocytes, of which 30% were myeloid cells. Testicular myeloid cells harbored a higher expression of MHC class II molecules than their peripheral counterparts (p=0.004). Immunosuppressive macrophages (lin$^-$ HLA-DR$^+$ CD14$^+$ CD163$^+$) represented 20% of the testicular leukocytes.
The majority of testicular DCs (lin$^-$ CD14$^-$ HLA-DR$^+$) were mDCs (CD11c$^+$), contrasting with rare pDCs (CD123$^+$). MDSCs were not detected in the testis while representing 0.5% of PBMCs. IDO-secreting macrophages and mDCs as well as T cells were detected in the testicular interstitium but not pDCs. Importantly, IDO mRNA levels were remarkably higher in the testis than in PBMCs (p<0.001).
Conclusions: Our results show for the first time the existence of an immune privilege mediated by immunosuppressive myeloid cells in the human testis, which creates a „safe harbor" for HIV. Such findings will contribute to orient tissue-specific viral eradication strategies.

MOPEA0052

Analysis of microRNA differential expression patterns during HIV-1 reactivation to identify new molecules involved in HIV-1 latency

Background: Despite antiretroviral treatments, HIV-1 remains integrated in reservoir cells. Non-productive expression after viral integration may result from insufficient levels of transcriptional activators, chromatin silencing, and specific microRNA activity etc. Indeed, some data show that microRNAs could contribute to the establishment of latency. Several therapeutics approaches are investigated to achieve HIV-1 eradication from the reservoirs by using latency-reversing agents (LRAs) to disrupt the latency. The use of LRAs, targeting multiple pathways combined with anti-retroviral therapy may accelerate viral reservoirs exhaustion. To find markers and new targets of HIV-1 latency, we have analyzed microRNA/mRNA expression patterns during HIV-1 reactivation.
Methods: We used a HIV-1 latent model in lymphocytes, monocytes and macrophages that expresses HIV-1 Gag protein fused with the Green Fluorescence Protein (GFP). By using Western-blot, fluorescence, cell viability assay, flow cytometry and RT-qPCR we have set up and characterized the conditions for HIV-1 reactivation. We used several LRAs including Histone deacetylase inhibitors, Histone Methyltransferase inhibitors, Bromodomain inhibitors, and Akt/PKC agonists. Reactivated cells were sorted by FACS and the RNA expression profiles were analyzed by RNA Sequencing.
Results: We set up and characterized the HIV-1 latent model by using different LRAs. We showed that the drugs: JQ1, HMBA, Chaetocin, SAHA, prostratin and Disulfiram reactivate viral expression by different mechanisms. The reactivation patterns are different for each LRA and also for each cell type (lymphocytes, monocytes and macrophages). Based on the reactivation and the cell viability, we determined the best days of reactivation for each LRA and each cell type. We also observed that the combination of two LRAs, Prostratin and SAHA, was the best reactivator treatment. We then decided to use these treatments to analyse the RNA expression profiles. In this model, we can distinguish reactivated cells by the expression of GFP. We isolated the reactivated and the non-reactivated cells after the reactivation treatments and then purified RNAs. We are currently analyzing the microRNA expression profiles of the reactivated and non-reactivated cells.
Conclusions: We expect to identify novel microRNA-based latency mechanisms. These results will help to identify strategies to eliminate the virus from the reservoirs.

Background: The proportion of replication-competent HIV-1 genomes in memory CD4$^+$ T cell subsets, including cells considered resting or activated, during antiretroviral therapy (ART) is unclear. To address this issue, we used a novel full-length HIV-1 sequencing assay to examine the distribution of intact proviruses within memory CD4$^+$ T cell subsets during ART.
Methods: Naïve, central (CM), transitional (TM) and effector (EM) memory CD4$^+$ T cells, as well as CD45RA$^-$HLA-DR$^+$ and CD45RA$^-$HLA-DR$^-$ CD4$^+$ T cells, were sorted from the peripheral blood of six participants who initiated ART during either acute (n=3) or chronic (n=3) infection. Cellular DNA was subjected to nested PCR, using LTR-specific primers at the limiting dilution, to isolate near complete individual genomes. The resulting 30-40 amplicons per cell subset were subjected to next-generation sequencing, and proviruses were characterized as defective (containing INDELs, stop codons or APOBEC3G hypermutation) or intact (lacking defects).
Results: All cell subsets contained intact proviruses except for the CM subset, which contained only defective proviruses (0/125 isolated sequences intact). The number of HIV-1 positive cells varied significantly across T cell subsets ($p < 0.001$), with the highest infection frequency in HLA-DR$^+$ cells. The proportion of intact provirus was also significantly different across the cell subsets ($p = 0.001$), with HLA-DR$^+$ and EM cells containing the highest proportion of intact genomes. The HLA-DR$^+$ subset contained the highest frequency of cells infected with a genetically intact provirus (48 versus < 10 infected cells/million cells in HLA-DR$^+$ versus all other subsets).The proportion of genetically intact virus isolated from participants treated during acute (5.6 ± 2.4 %) or chronic (3.8 ± 0.90 %) infection was similar ($p = 0.73$).
Conclusions: The HLA-DR marker identifies cells containing a high frequency of intact HIV-1 genomes, therefore assays quantifying the HIV-1 reservoir should include cells expressing HLA-DR. The lack of observable replication-competent proviruses in CM indicates that the majority of rebound virus is not derived from these cells. Similar proportions of intact genomes in participants treated during acute or chronic infection indicates that the replication-competent HIV-1 reservoir is established during acute infection, further supporting the need to initiate ART as early as possible.

MOPEA0054

Inhibition of HIV-1 replication in macrophages by the neuropeptides VIP and PACAP: analysis of the inhibitory potential and mechanisms

[1]Oswaldo Cruz Institute - FIOCRUZ, Laboratory on Thymus Research, Rio de Janeiro, Brazil, [2]Oswaldo Cruz Institute - FIOCRUZ, Laboratory of AIDS and Molecular Immunology, Rio de Janeiro, Brazil, [3]Oswaldo Cruz Institute - FIOCRUZ, Laboratory of Inflammation, Rio de Janeiro, Brazil
Presenting author email: dumith.chequer@gmail.com

Background: VIP and PACAP are high similar members of Secretin/Glucagon family of peptides, sharing immunoregulatory functions, besides other systemic actions. We have reported that VIP and PACAP treatment of HIV-1-infected macrophages reduces viral production (Temerozo et al, 2013). Here, we show their potential to confer resistance to HIV-1 infection and identify molecular mechanisms engaged in macrophages.
Methods: Monocyte-derived macrophages (MDM) from healthy donors were infected with HIV-1, exposed to VIP or PACAP under different conditions, and viral replication was assessed by ELISA to p24 antigen. Statistics were done using One or Two-way ANOVA, with Bonferroni's or Sidak post test, respectively.
Results: VIP or PACAP (10 nM) inhibited HIV-1 replication (38% inhibition) when added to MDMs before infection, likewise neuropetide treatment after infection (51% inhibition). Viral replication was also inhibited in infected macrophages exposed to multiple sub-optimal input (1 nM) (47% inhibition for VIP and 66% inhibition for PACAP), comparable with a single optimal dose (58% for VIP and 45% for PACAP). Upon sequencing the provirus, we found that treatment with neuropeptides promoted mutations, similar to those induced by IFN-α. VIP and PACAP receptors were identified in both infected and uninfected macrophages by immunofluorescence. We detected, in signaling studies, that VIP effect was impaired by PKA or PKC inhibition, whereas PACAP effect diminished only with PKC blockage. Through immunoblotting, we observed that VIP induced activation of PKA and PKC, and that PACAP activated only PKC. Next, VIP and PACAP induced CREB activation and inhibition of NF-kB, and down modulated the levels of Cyclin D1 in HIV-1-infected macrophages.
Conclusions: Our study shows that VIP and PACAP render MDM more resistant to HIV-1 replication in different treatment protocols, and promote mutations in the provirus, indicating that these neuropeptides can modulate key regulators of HIV-1 replication. We found that HIV-1 inhibition by VIP and PACAP is mediated by PKA and PKC, and some of the molecular mechanisms could involve the activation of CREB and the down modulation of NF-kB activity and Cyclin D1. The action on transcription factors and its regulators implicates that, at some level, mechanisms related to HIV-1 proviral transcription/latency could be involved in our model.

Presenting author email: chiraz_hamimi@hotmail.com

Background: Recently two minor peripheral blood subsets of memory-stem cells (SCM) and T follicular helper CD4 T-cells (TfH) have been shown to harbor HIV provirus. While low levels of HIV-reservoir achieved in some treated patients appears to be necessary, though probably not sufficient, to reach functional cure, the relative contribution of SCM and TFH to these low HIV-reservoirs remains unknown. The Resachron study aims to decrypt the contribution of SCM and TfH subsets to these low HIV-reservoirs compared to major memory CD4 T cell subsets.
Methods: The Resachron cross-sectional study enrolled 17 patients under-cART with CD4 counts >400/mm^3, pVL< 50 copies/mL and low HIV-DNA< 200 copies/10^6 PBMCs. The CD4 T-cells were sorted as total naïve cells (TN) and TN depleted of CD95+SCM (TN-SCM), total central-memory (CM) and CM depleted of CXCR5+TfH (CM-TfH), transitional-memory (TM) and effector-memory (EM) subsets. HIV-reservoirs were quantified as total HIV-DNA in PBMCs and sorted subsets using ultrasensitive PCR and analyzed for correlation with cell activation. Results were expressed as subset contribution to total HIV-reservoirs and blood concentrations of subsets reservoirs.
Results: The total CM and TM subsets were the major HIV-reservoirs by contributing up to 50.8% and 19.9%, respectively to the total blood HIV-reservoirs. The total CM reservoir concentration in blood was 76 copies/mL. After CM depletion in TfH (TfH represented 32% of total CM), the CM-TfH reservoir dropped down to 19 copies/mL (p=0.03) with a CM-TfH contribution to HIV-reservoirs falling down to 11.7% (p=0.01 vs total CM). In total TN, HIV-DNA was below limit of detection (< 66 copies/10^6 PBMCs) in 65% cases and TN contributed only to 6.6% of reservoirs. After TN depletion in SCM (SCM represented 2.5% of TN), changes in undetectable reservoir levels were not interpretable. Finally, proportions of CD4+ CD25+ activated T-cells correlated with HIV-DNA levels in CM (r=0.732, p=0.004).
Conclusions: In virologically-suppressed cART-treated patients with low HIV-reservoirs, TfH represent a major reservoir for HIV, at least equivalent to the reservoirs contained in bona fide CM cells. These results point to the key contribution of TfH issued from lymph nodes to these low HIV-reservoirs, opening new perspectives for strategies towards HIV remission.

Presenting author email: amelie.cattin44@gmail.com

Background: Antiretroviral therapy (ART) controls HIV-1 replication to undetectable levels; however, HIV eradication is not achieved. The persistence of HIV reservoirs during ART is well established in CD4+ T-cells, but the contribution of myeloid cells remains controversial. While monocytes are resistant to HIV, monocyte-derived dendritic cells (MDDC) and macrophages (MF) are well-established HIV targets. Herein, we investigated the contribution of myeloid cells obtained from the blood and colon to HIV persistence during ART.
Methods: Total monocytes, CD16+/CD16- monocyte subsets, and/or CD1c+ DC were isolated from leukapheresis (n=2-12), while matched myeloid cells (lineage-HLA-DR$^+$) and CD4+ T-cells were isolated from sigmoid biopsies of ART-treated individuals (HIV+ART) (n=13), using magnetic and/or flow cytometry sorting. The presence of early (RU5), late (Gag), and integrated HIV-DNA was measured by nested real-time PCR in 3-10 replicates of 10^5 cells / test. Co-cultures of monocytes (10^6) with TCR-activated CD4+ T-cells (10^6) from HIV-uninfected individuals allowed detection of replication-competent HIV.
Results: RU5 but not Gag/integrated HIV-DNA was detected in total monocytes of 3/12 HIV+ART individuals. Low/undetectable levels of HIV replication were detected upon co-culture of monocytes of HIV+ART individuals with heterologous activated uninfected CD4$^+$ T-cells, indicative of low levels of replication-competent HIV persistence in monocytes. CD16+ but not CD16- monocytes sorted from 1/2 individuals carried Gag HIV-DNA (63 HIV-DNA copies/10^6 cells), while RU5 but not Gag/integrated HIV-DNA was detected in blood CD1c+ DC of 1/2 individuals (341 HIV-DNA copies/10^6 cells). Finally, in sigmoid mucosa biopsies, Gag HIV-DNA was detected in myeloid cells of 1/13 individuals (1562 HIV-DNA copies/10^6 cells), while CD4+ T-cells from 11/13 donors tested carried high levels of Gag HIV-DNA (303-7124 HIV-DNA copies/10^6 cells).
Conclusions: These results support a minor role played by myeloid cells from blood and colon to HIV reservoir persistence during ART relative to CD4+ T-cells. However, CD16+ monocytes and CD1c+ DC from blood of certain individuals may fuel viral reservoirs considering their tissue recirculation potential. Assessment of lymphoid tissues and other anatomic sanctuaries will be required to consider or not myeloid cells as relevant cellular reservoirs for HIV.

MOPEA0057

Ultrasensitive HIV-1 p24 detects single infected cells and differences in reservoir induction by latency-reversal agents

Presenting author email: cpassaes@gmail.com

Background: The existence of HIV reservoirs in infected individuals under cART represents a major obstacle towards cure. Viral reservoirs are assessed by quantification of HIV nucleic acids, which does not discriminate between infectious and defective viruses, or by viral outgrowth assays, which requires large number of cells and long-term cultures.
Methods: Here, we used an ultrasensitive p24 digital assay, which we report to be 1000 fold more sensitive than classical ELISA in the quantification of HIV-1 Gag p24 production in HIV-infected individuals samples. Results from ultrasensitive p24 were compared to conventional viral RNA RT-qPCR based assays, and outgrowth assays readout by flow cytometry.
Results: Using serial dilutions and flow-based single cell sorting, we show that viral proteins produced by a single infected cell can be detected by ultrasensitive p24. This unique sensitivity allowed the early (as soon as day 1 in 49% of cases) and more efficient detection and quantification of p24 in PHA-stimulated $CD4^+$ T cells from individuals under effective cART. When testing seven different classes of latency reversal agents (LRA) in resting $CD4^+$ T cells from HIV-infected individuals, ultrasensitive p24 revealed differences in the extent of HIV reactivation. Of note, HIV RNA production was infrequently accompanied by p24 protein production (19%). Among the drugs tested, prostratin showed a superior capacity in inducing viral protein production.
Conclusions: In summary, the ultrasensitive p24 assay allows the detection and quantification of p24 produced by single infected-$CD4^+$ T cells and provides a unique tool to assess early reactivation of infectious virus from reservoirs in HIV-infected individuals.

Presenting author email: delphine.planas@gmail.com

Background: Gut-associated lymphoid tissues (GALT) are enriched in CCR6+ Th17-polarized CD4+ T-cells that orchestrate immunity against pathogens but also support HIV-1 replication and reservoir persistence during antiretroviral therapy (ART). Th17 cell frequency/functions are not restored by ART, thus raising the need for additional Th17-targeted therapies. In an effort to identify mechanisms governing HIV-1 permissiveness in gut-homing Th17 cells, we analyzed the transcriptome of CCR6+ versus CCR6- T-cells exposed to retinoic acid (RA), a gut-homing inducer, and performed functional validations in colon biopsies of HIV-infected individuals receiving ART.
Methods: Memory (CD45RA-) CCR6+/CCR6- T-cells were sorted from PBMCs using magnetic beads (Miltenyi) and FACS (BDAriaII). Cells were stimulated via CD3/CD28 in the presence/absence of RA and RNA was extracted for microarrays analysis (Illumina). Validations of microarrays were performed using RT-PCR and/or FACS. HIV replication was monitored in the presence/absence of mTOR inhibitors by HIV-DNA real-time PCR and ELISA/FACS HIV-p24 quantifications. HIV reactivation from T-cells of ART-treated individuals was measured using a RA-based viral outgrowth assay. Levels of CCR5, integrin β7 and phosphorylated mTOR expression were monitored by FACS on CCR6+/CCR6- T-cells from matched blood/colon biopsies of ART-treated individuals (n=7).
Results: Although both CCR6+ and CCR6- T-cells responded to RA in terms of RA-induced gene 1 and integrin α4β7 up-regulation, the modulation of unique sets of genes coincided with preferential HIV-1 replication in RA-treated CCR6+ T-cells. The RA-induced transcriptional signature in CCR6+ versus CCR6- T-cells included the up-regulation of HIV-dependency factors and the down-regulation of transcripts involved in viral restriction acting via entry/post-entry mechanisms. Noteworthy, the PI3K-Akt-mTORC1 signaling pathway and the mTOR expression/phosphorylation were selectively modulated by RA in CCR6+ T-cells. The mTOR inhibitors rapamycin and INK128 counteracted the effect of RA on HIV replication/reservoir reactivation by mechanisms independent on CCR5-mediated entry but depended on RORγt activity. Finally, higher CCR5 and integrin α4β7 expression, as well as mTOR phosphorylation, were observed in CCR6+ versus CCR6- T-cells infiltrating the colon of ART-treated individuals.
Conclusions: Together, our results identify mTOR as a druggable key regulator of HIV permissiveness in gut-homing CCR6+ T-cells and propose the use of mTOR inhibitors for mucosal immunity restoration during ART.

Massive full-length, next generation sequencing identifies clonally-expanded, genome-intact replication-competent HIV-1 in Th1 cells

G.Q. Lee[1], N. Orlova-Fink[1], E. Serrao[2], K. Einkauf[1], F. Chowdhury[1], X. Sun[1], S. Harrington[1], H. Kuo[1], S. Hua[1], H. Chen[1], G. Sowd[2], Z. Ouyang[1], E.S. Rosenberg[3], A.N. Engelman[2], X.G. Yu[1], M.D. Lichterfeld[1,3,4]
[1]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [2]Dana-Farber Cancer Institute, Boston, United States, [3]Massachusetts General Hospital, Infectious Disease Division, Boston, United States, [4]Brigham and Women's Hospital, Infectious Disease Division, Boston, United States
Presenting author email: klee54@mgh.harvard.edu

Background: HIV-1 remains an incurable disease due to long-lasting reservoirs of infected cells that are unaffected by suppressive antiretroviral therapy. However, the mechanisms that maintain long-term stability of such viral reservoirs are not well understood. Here, we used a near-full-genome deep sequencing approach to characterize HIV-1 DNA content in highly purified CD4 T cell subsets with distinct functional polarization.
Methods: Highly purified CD4 T cells secreting IFN-g (Th1), IL-4 (Th2), IL-9 (Th9), IL-17 (Th17), cytokine-negative control cells and unstimulated autologous CD4 T cells were sorted or enriched from ~500million PBMC obtained from chronically-infected ART-suppressed patients; these were matched with autologous longitudinally archived PBMC. Total DNA extracted from each sample/population was subjected to ddPCR HIV-1 DNA quantification (5'LTR-gag 127bp) and/or to single-template near-full-genome nested PCR (HXB2 coordinates 638-9632) followed by Illumina MiSeq deep sequencing. Viral outgrowth assays were performed according to standard protocols, followed by near-full length HIV-1 sequencing of MOLT cells co-cultured in transwells.
Results: Little variation was found between total HIV-1 gag DNA levels among the different polarized
T cell populations in ten study subjects. In subsequent full-genome sequencing assays from three patients, 1378 HIV-1 DNA amplicons were obtained; only 5% (70/1378) were genome-intact. Of these, 622/1378 were from polarized CD4 T cell populations; 26 (4%) were sequence-intact. The proportion of genome-intact sequences relative to the pool of all viral species was highest in Th1 cells 11% (17/158), followed by cytokine-negative-Th 3% (6/171), Th2 2% (2/85), Th17 1% (1/78), and Th9 0% (0/120) (Fisher $p=1x10^{-5}$, Th1 vs non-Th1). In seven distinct cases, groups of two to nine genome-intact viruses that shared 100% sequence identity over ~9000bp were detected from autologous polarized Th1 cells and/or unfractionated CD4 T cells and/or archived total PBMC, suggestive of clonal expansion of cells harboring intact provirus. Viral replication competence of an eight-member clonal cluster was confirmed by the detection of a 100% homologous sequence from viral outgrowth assays.
Conclusions: Th1-polarized cells seem to represent an important reservoir of cells harboring genome-intact and replication-competent HIV-1 sequences during antiretroviral therapy. Proliferation of such cells may contribute to maintaining and expanding the HIV-1 infected cell pool.

MOPEA0060

Role of peroxisome proliferator activated receptor-gamma in regulating inflammatory signalling in HIV-1 associated brain inflammation

A. Omeragic, T. Hoque, S. Choi, R. Bendayan
University of Toronto, Toronto, Canada
Presenting author email: r.bendayan@utoronto.ca

Background: Despite the use of combination antiretroviral therapy for the treatment of HIV-1 infection, cognitive impairments remain prevalent due to persistent viral replication and associated brain inflammation. Primary cellular targets of HIV-1 in the brain are microglia and astrocytes which in response to infection release inflammatory markers, viral proteins [i.e., glycoprotein 120 (gp120)] and exhibit impaired glutamate uptake. Peroxisome Proliferator-Activated Receptors (PPARs) are members of the nuclear receptor superfamily of ligand-activated transcription factors.
Compelling evidence suggests that PPARs exert anti-inflammatory properties in neurological disorders. The goal of this study was to examine the role of PPARgamma in the context of HIV-1 gp120 induced inflammation in vitro, in primary cultures of rat astrocytes and in vivo, in a rodent model of HIV-1-gp120-associated brain inflammation.
Methods: Primary mixed cultures of rat astrocytes and microglia were treated with PPARgamma agonists (rosiglitazone or pioglitazone) and exposed to $gp120_{ADA}$. Inflammatory and oxidative stress markers (TNFalpha, IL-1beta, iNOS) were measured using qPCR and glutamate transporter (GLT-1) was quantified by immunoblotting. In vivo, rats were administered an icv injection of gp120 and an intraperitoneal (ip) injection of PPARgamma agonist (rosiglitazone) or co-administration with PPARgamma antagonist (GW9662). qPCR and immunoblot analysis were applied to measure inflammatory markers, GLT-1 and PPARgamma.
Results: In primary mixed cultures of rat astrocytes and microglia, $gp120_{ADA}$ exposure resulted in a significant elevation of inflammatory markers, and a decrease in GLT-1 expression which were significantly attenuated with rosiglitazone or pioglitazone treatment. Similarly, in vivo, treatment with rosiglitazone reversed the gp120 mediated inflammatory response and downregulated GLT-1 in the rodent brain. Co-administration with PPARgamma antagonist (GW9662) abolished the anti-inflammatory effects of rosiglitazone.
Conclusions: To date, we have established an acute in vivo rodent model of $gp120_{ADA}$ induced brain inflammation and demonstrated the role of PPARγ activation in reversing this effect. Our data suggest that targeting PPARγ signaling may provide a therapeutic option for preventing/treating HIV-associated brain inflammation.

Background: Asymptomatic replication of Cytomegalovirus (CMV) and Epstein Barr Virus (EBV) is frequent during HIV-infection and is associated with chronic inflammation and slower decay of HIV DNA during antiretroviral therapy (ART). We investigated the frequency and distribution of unique integration sites (UIS) of HIV DNA within the human genome in the setting of CMV and EBV replication.
Methods: We evaluated 25 longitudinal PBMC samples from 5 CMV/EBV-seropositive, recently HIV-infected men. Participants started ART within 5 months from estimated date of infection (EDI) and sustained viral suppression for >4 years thereafter. Levels of HIV, CMV and EBV DNA were measured by ddPCR at each time-point. Genomic DNA was fragmented by sonication, amplified by ligation-mediated PCR targeting the HIV 3LTR and sequenced using the MiSeq Platform. Individual reads were mapped to the human genome using BLAT and RefSeq.
For IS located within a gene, we determined annotation and enrichment of biological functions using the DAVID Functional Annotation Tool. The effect of EBV and CMV replication on the number of UIS was evaluated using mixed-effect regression analyses (R statistical software). Additional covariates were current and nadir $CD4^+$ counts, EDI, time from EDI to ART start, HIV DNA and peak HIV RNA.
Results: We identified 459 UIS among all participants (median: 4, IQR [1-12]). HIV DNA was enriched into genes associated with biological processes, e.g. alternative splicing, ATP and nucleotide binding proteins, intercellular organelles, transcription, and protein kinases. Higher numbers of UIS during ART were significantly associated with (i) higher levels of HIV DNA, (ii) higher levels of EBV, (iii) lower current and nadir $CD4^+$ T-cells, (iv) shorter EDI (v) lower levels of CMV (all $p<0.001$). In a multivariate analysis, higher levels of EBV ($p<0.001$), lower CD4 Nadir ($p=0.008$) and shorter EDI ($p<0.001$) remained significantly associated with increased UIS ($P<0.001$) after adjusting for HIV DNA, while CMV and current CD4 did not ($p>0.2$).
Conclusions: Presence of EBV replication, lower Nadir $CD4^+$ and shorter time from EDI were associated with higher frequencies of UIS during suppressive ART. How these factors may be associated with HIV integration or clonal expansion should be investigated further.

Background: Latently-infected cells have been postulated as the main barrier to fully eliminate HIV-1 from the human body. The "active viral reservoir" has been found in both, treated and untreated HIV-infected patients, and encompasses cells actively transcribing HIV-RNA, representing a portion of the entire HIV reservoir. Here we have validated and used a novel single cell FISH methodology that detects intracellular HIV-1 RNA molecules by flow cytometry with the aim to characterize the cell subpopulations actively transcribing HIV. Moreover, we used the RNA FISH/flow method to assess viral reactivation of primary $CD4^+$ T cells from antiretroviral treated HIV-infected patients.
Methods: The Human PrimeFlow® RNA Assay (eBioscience) was performed with a high sensitivity target-specific set of 50 probes targeting the Gag-Pol HIV-mRNA sequence. The proportion of cells expressing HIV-RNA was quantified in 15 millions of unfractionated PBMCs samples from untreated and treated HIV-infected patients. Viral reactivation was evaluated after stimulation of primary $CD4^+$ T cells with PMA/Ionomycin. Quantification of HIV-DNA and intracellular HIV-RNA was performed by qPCR using genetic material obtained from purified $CD4^+$ T cells.
Results: Effector memory $CD4^+$ T cells were identified as the main subset supporting HIV-RNA transcription during treated and untreated HIV infection. In patients with high viral load, HIV-RNA transcription was also detected in central memory cells. There was a direct correlation between the proportion of cells expressing HIV transcripts and either, plasma viral load, proviral DNA and intracellular HIV-RNA measured by qPCR. On the contrary, an inverse correlation was observed with absolute $CD4^+$ T cell counts, percentage of $CD4^+$ T cells and CD4/CD8 ratio. In addition, this novel RNA FISH/flow assay detected increased numbers of primary cells expressing viral transcripts and protein after ex-vivo viral reactivation with an activating stimulus.
Conclusions: This study identifies effector memory CD4+ T cells as the main cellular source of the "active viral reservoir" during both untreated and treated HIV-infection. Furthermore, this technique might be useful to evaluate the effectiveness of different latency-reversing agents in primary HIV-infected samples.

The lungs as anatomical reservoirs of HIV: enrichment in HIV-infected cells and skewed T-cell distribution in the lungs of HIV-infected adults under suppressive ART

C.T. Costiniuk[1,2], O. Farnos[3], S. Salahuddin[1,3], R. Olivenstein[2,4], J.-P. Routy[1,2], A. Pagliuzza[5], C. De Castro[1], J. Bourbeau[2,4], B. Lebouché[1,6], P. Ancuta[5,7], N. Chomont[5,7], M.-A. Jenabian[3]

Presenting author email: cecilia.soctiniuk@mcgill.ca

Background: Despite the success of antiretroviral therapy (ART), HIV reservoirs remain the primary impediment to HIV eradication. The lungs represent important but almost neglected HIV reservoirs in the ART era. Here, we characterized pulmonary T-cells and their contribution to HIV reservoirs compared to blood in ART-treated adults.
Methods: Bronchoscopies were performed to obtain bronchoalveolar lavage (BAL) fluid and matched blood samples were drawn from 15 ART-treated individuals (suppressed viral load for ≥3 years and CD4 count ≥350 cells/mm^3) without any active respiratory symptoms. Pulmonary mucosal cells were purified from BAL and the frequency of T-cell subsets, the expressions of immune activation and senescence markers were assessed using multicolor flow cytometry. The frequency of cells harboring total and integrated HIV DNA was measured by real-time PCR in total BAL cells and PBMCs.
Results: Participants with detectable levels of total HIV DNA in both PBMCs and BAL cell pellets displayed greater frequencies of infected cells in the lung compared to blood (p=0.04). A substantial decrease in naïve and central memory T-cells and a massive increase in effector-memory CD4 and CD8 T-cell subsets were observed in lungs vs. blood (p<0.001, p≤0.03, p<0.001, respectively). Importantly, total, central and effector memory pulmonary CD4 T-cells expressed higher levels of the activation marker HLA-DR when compared to their circulating counterparts (p<0.01 for all comparisons). Interestingly, the lungs were enriched in senescent CD4 T-cells (CD28-CD57+, p=0.003) and double negative T-cells, previously proposed as potential cellular reservoirs for HIV (CD4-CD8α-CD8β- and CD4-CD8α-TCRαβ-TCRγδ-; p<0.001, p=0.008, respectively). No difference in the frequencies of regulatory T-cells and Th17 cells was noted between the 2 compartments. However, a higher frequency of two recently described HIV reservoirs, Th1/Th17 and CXCR3-CCR4+CCR6+ T-cells, was observed within the lungs (p=0.004, p=0.003, respectively).
Conclusions: Compared to blood, higher HIV burden within the lungs is accompanied with a higher CD4 T-cell immune activation and greater frequencies of various T-cell subsets known as cellular reservoirs of HIV including effector memory CD4 T-cells, double negative T-cells, Th1/Th17 and CXCR3-CCR4-CCR6+ cells. Our results suggest the potential contribution of distinctive T-cells distribution in lungs as anatomical reservoir for HIV during ART.

Presenting author email: hanilylia@gmail.com

Background: c-ART cannot fully eradicate HIV-1 due to persistence of the reservoir. We have reported the presence of memory CD4$^+$ T-cells that display low levels of SAMHD1 (SAMHD1^{low}), are enriched in T-regulatory, Th17 and T-follicular helper cells and are productively infected in vitro (Ruffin et al. AIDS, 2015). Here we investigated whether SAMHD1^{low} cells are characterized by a distinct gene expression profile and contain high levels of HIV-1 DNA with distinct HIV-populations.
Methods: Patients (pts; n=36) on c-ART (median: 7y) with median CD4+ counts and nadir of 549 cells/ul and 210 cells/ul, respectively and 6 elite-controllers (HIC) (CD4+: 900 cells/ul) were studied. Memory CD4$^+$CD45RO$^+$SAMHD1^{low} and CD45RO$^+$SAMHD1^{high} together with naive CD45RO$^-$SAMHD1^{high} cells were sorted. Gene expression analyses were performed using Illumina Human-HT-12 V4-BeadChips. Cell-associated HIV-1 DNA levels were quantified (HIV-DNA Cell, Biocentric) and ultra-deep-sequencing (UDS, 454/Roche) of partial env (C2/V3) HIV-1 DNA was performed. Sequenced reads were quality-filtered and assembled using an in-house data processing-pipeline to characterize the HIV-DNA populations in sorted subsets.
Results: Memory SAMHD1^{low} cells exhibited a distinct gene profile with significant up-regulation (Fold change 3; p< 0.03) of activation, proliferation and phagocytosis pathways. Memory SAMHD1^{low} from c-ART pts showed high levels of DNA compared to SAMHD1^{high} cells (Median: 4.5 [3.1-6.2] vs 3.8 [2.9-5.7] log/10^6 cells, respectively, p=0.02), while naïve CD45RO$^-$SAMHD1^{high} showed lower levels (3.1 [1.6-4.4]). HIC exhibited low HIV-1 DNA in both SAMHD1^{low} and SAMHD1^{high} cells (1.6 and 2.3 log/10^6 cells, respectively, p>0.05). Naïve CD45RO$^-$SAMHD1^{high} from HIC showed lower DNA compared to naïve CD45RO$^-$SAMHD1^{high} from c-ART pts (1.6 and 3.1 log/10^6 cells, respectively, p=0.01). Phylogenetic analyses of UDS data revealed well segregated HIV-DNA populations between subsets. FST and Slatkin Maddison approaches confirmed significant compartmentalization between SAMHD1^{low} and SAMHD1^{high} cells in all but 2 participants (p< 0.001) with limited viral exchange, predominantly directed from CD45RO$^-$SAMHD1^{high} toward CD45RO$^+$SAMHD1^{high}.
Conclusions: Our data contribute to characterize the landscape of HIV reservoir. We show that memory SAMHD1^{low} cells exhibit distinct genes profile which segregates them from the SAMHD1^{high} counterpart, and contain the highest level of HIV-DNA. Moreover, we reveal distinct/well-segregated HIV DNA populations in both subsets, suggesting minimal viral exchange.

MOPEA0065

2LTR circle dynamics during integrase inhibitor monotherapy in the presence and absence of CD8$^+$ cells

B. Policicchio[1,2], E. Fabian Cardozo[3], P. Sette[2], T. Joshi[2], G. Haret-Richter[2], T. Dunsmore[2], C. Apetrei[2], I. Pandrea[2], R. Ribeiro[3,4]

Presenting author email: bbp6@pitt.edu

Background: 2LTR circles are extrachromosomal products generated upon failed integration of HIV/SIV into the host genome. It is predicted that 2LTR circle levels will increase during therapy including integrase inhibitors, but little is known about fluctuations of these isoforms during integrase inhibitor monotherapy (INT). To this end, we explored the effects of raltegravir (RAL) monotherapy on SIV-infected rhesus macaques (RMs) in the presence or absence of CD8$^+$ T cells.
Methods: Twenty RMs were intravenously-infected with SIVmac251 and were given the CD8$^+$ T-cell depleting antibody M-T807R1, RAL monotherapy, or a combination of both, with RAL treatment interrupted after 23 days. Blood was routinely sampled and lymph nodes (LNs) were biopsied. Plasma viral loads (VLs) and 2LTR circles from PBMCs and lymphocytes from LNs were measured with qRT-PCR, with 2LTR circles normalized by co-quantifying CCR5 expression.
Results: The CD8 depletion group had an immediate 1 log increase in VLs and a slower increase in PBMC 2LTR levels following depletion, with a noticeable increase in 2LTR circles 30 days after complete CD8$^+$ T-cell suppression. The INT group had an overall sharp decline in VLs (between 0.5-2.5 logs) upon RAL initiation but did not exhibit a change in 2LTR levels in PBMCs. The RAL + CD8 depletion group exhibited a similar increase in VLs following CD8$^+$ T-cell depletion and a weaker decline following RAL initiation, but showed a strong increase in 2LTR circles immediately following RAL initiation that remained elevated throughout RAL treatment and after CD8$^+$ T-cells recovered. Interestingly, only the RAL + CD8 depletion group exhibited a strong increase in 2LTR circles in the LNs following RAL treatment, while the other two groups' LNs maintained steady 2LTR levels.
Conclusions: We have shown for the first time that INT does not significantly increase levels of 2LTR circles in PBMCs or in LNs, likely due to the rapid decrease in VLs and subsequent infection events following INT initiation. However, CD8$^+$ T-cell depletion increases 2LTR levels, which are enhanced in the presence of INT. This data suggests a potential role of CD8$^+$ cells in controlling the levels of 2LTR isoforms during HIV/SIV infection.

HIV reservoirs in developing countries: implication for HIV CURE strategies

C. Kityo Mutuluuza[1], F. Ssali[2], J. Chipman[3], G. Beilman[4], F. Mbamanya[2], P. Mugyenyi[5], K. Nganou[6], D. Douek[7], T. Schacker[4]
[1]Joint Clinical Research Centre, Research and Clinical, Kampala, Uganda, [2]Joint Clinical Research Centre, Kampala, Uganda, [3]University of Minnesota, Minnesota, United States, [4]Minnesota, Minnesota, United States, [5]Joint Clinical Research Center (JCRC), Kampala, Uganda, [6]NIH Vaccine Research Centre, Washington, United States, [7]NIH, Vaccine Research Centre, Washington, United States
Presenting author email: ckityo@yahoo.com

Background: We measured the size of HIV RNA and DNA reservoirs in lymphatic tissue (LT) before and during ART in a group of HIV chronically infected Ugandans.
Methods: Cross-sectional and longitudinal quantification of HIV RNA/DNA (vRNA & vDNA) positive cells was done by in situ-hybridization with probes specific for HIV clades A & D in tissues from lymph node(LN) and rectal biopsies from HIV-infected Ugandans at the Joint Clinical Research Centre (JCRC), Uganda before and during prolonged ART.
Results: We enrolled 20 HIV+ people, mean age 32years, 50% were women, and mean CD4 T-cell count was 174 cells/mm^3(range 30-309 cells/mm^3). The mean plasma viral load was 81,827 copies/ml(range 736-908,930 copies/ml). A subset of 14 participants were followed for a mean of 4years (range 2-6years) after starting ART with multiple repeat LN and rectal biopsies. The mean frequency of vRNA+ cells in LN prior to ART was 9.4x10^4 cells/gram (range 6.3x10^3-3.5x10^5 cells/gram) and 2.0x10^5 cells/gram(range 2.3x10^4-9.6x10^5 cells/gram) in the rectum, similar to measures made in Clade B HIV infection. Before ART, the mean frequency of vDNA+ cell in LN was 6.2x10^7 cells/gram LT(range 8.3x10^6-1.3x10^8) vDNA+ cells/gram. The impact of ART on the LT reservoir in subjects who had been treated for >2 years (range 2-6 years) was surprisingly modest. ART only reduced the mean frequency of vDNA+ cells by about 1 log, to 2.3x10^6 cells/gram (range 1.1x10^5-7.3x10^6 cells/gram). This decrease is substantially less than we previously documented after six months of ART, albeit in a patient population from the US with a mean CD4 T-cell count of 467 cells/ul at entry. However, in gut tissues we did not document any decrease in the size of the vDNA reservoir. Prior to ART the frequency of vDNA+ cell was 3.8x10^5 cells/gram LT(range 1.8x10^5-8.4x10^5) and after >2 years of ART (range 2-6 years) the mean was 2.6 x 10^5 cells/gram (range 1.0x10^5-4.5x10^5 cells/gram).
Conclusions: ART had modest effect on the viral reservoir in this Ugandan cohort. The large size and stability of the DNA reservoir underscores the challenges to eradicating chronic HIV infection with current approaches, especially in the developing world.

MOPEA0067

In vivo massive expansion of a T-cell clone carrying a defective HIV genome: implication for the measurement of the HIV reservoir

Presenting author email: fromentin.remi@gmail.com

Background: HIV persists as an integrated genome in memory CD4$^+$ T cells during ART. Infected cells have the ability to survive and to proliferate, thereby ensuring the long-term stability of the viral reservoir. Here we report the unique case of an HIV-infected individual on suppressive ART with a massive expansion of an HIV infected T-cell clone.
Methods: The participant (57 year-old African American man) received suppressive ART for more than 3 years at the time of leukapheresis.
Results: Measurement of HIV DNA in isolated CD4$^+$ T cells by Alu-qPCR revealed that an unusually high frequency of cells carrying integrated genomes (31,070 copies per million cells). In contrast, the frequencies of CD4$^+$ T cells harbouring inducible HIV RNA by TILDA and replication competent virus by mQVOA were in the normal ranges of virally suppressed individuals (45 and 0.87 cells per million respectively), suggesting that the vast majority of the proviruses detected by Alu-PCR was defective. Circulating CD4$^+$ T cell subsets (Naïve, Central, Transitional, Effector memory and Terminally differentiated cells (N, CM, TM, EM and TD, respectively)) were sorted by flow cytometry. Strikingly, 44% of EM cells harboured integrated HIV DNA, representing 97% of all integrated viral genomes in the blood of this participant. Single-genome sequencing of the envelope gene revealed a unique sequence in the EM subset. This was consistent with the identification of the massive overrepresentation of a specific integration site in chromosome 14, gene RPS6KA5. The massive expansion of a defective provirus suggested proliferation of a particular clone of EM cells, which was confirmed by TCR sequencing, with 60% of EM cells sharing the same rearranged TCR.
Conclusions: These results indicate that massive clonal expansion of defective genomes can occur in vivo, leading to a >35,000 fold difference between PCR and QVOA measurements. These proliferation events may contribute to the weak association between DNA measurements and replication competence in some individuals.

MOPEA0068

Inhibition of HIV-1 infection by bi-specific immunoadhesin-IgA in humanized mice

M.Y. Niu, H.Y. Tang, Z. Chen
AIDS Institute, Department of Microbiology, University of Hong Kong, Hong Kong, Hong Kong

Background: Human immunodeficiency virus type one (HIV-1) is mainly a sexually transmitted virus. However, there is no effective vaccine to prevent HIV-1 mucosal transmission. IgA antibody may play a determinant role in mucosal protection yet few broadly neutralizing antibody (bNAbs)-IgA have been reported thus far.
Methods: In this study, we generated two bi-specific immunoadhesin-IgAs, BiIA-IgA$_1$ and BiIA-IgA$_2$, trying to improve their breath and potency against HIV-1 mucosal infection by combining single-chain variable fragment(ScFv) of bNAbs. They were characterized in vitro by ELISA, FACS and neutralization assays. Moreover, we evaluated their efficacy in humanized NSG mice against HIV$_{JR-FL}$ challenge. Viral load and p24+ T cell were measured in mouse blood by Q-PCR and FACS. P24$^+$ T cells in spleen, lung, intestine and rectum were stained by immunohistochemistry.
Results: BiIA-IgA$_1$ and BiIA-IgA$_2$ were successfully expressed as soluble antibodies after transfection into human 293 T cells. Both of them were able to bind their corresponding target antigens specifically. They displayed anti-HIV activities yet the potency was slightly weaker than the parental BiIA-IgG$_1$. The half-life was similar between BiIA-IgA$_1$ and BiIA-IgA$_2$ but was shorter than that of BiIA-IgG$_1$ after intramuscular injection in mice. Interestingly, intramuscular BiIA-IgA$_2$ resulted in mucosal distribution and displayed more potent protection against intraperitoneal challenge by HIV$_{JR-FL}$ when compared with BiIA-IgA$_1$.
Conclusions: Our findings indicated that BiIA-IgA$_2$ is effective against systemic HIV-1 infection, which warrants ongoing investigation for mucosal prophylaxis.

The male organs source of AIDS virus in semen uncovered through phylogenetic analysis

L. Houzet[1], M. Pérez-Losada[2], G. Matusali[1], C. Deleage[1], N. Dereuddre-Bosquet[3], A.-P. Satie[1], F. Aubry[1], B. Jégou[1], R. Le Grand[3], B.F. Keele[4], K.A. Crandall[2], N. Dejucq-Rainsford[1]
[1]INSERM, IRSET-INSERM U 1085, Rennes, France, [2]Computational Biology Institute, George Washington University, Ashburn, United States, [3]CEA, DSV/iMETI, Division of Immuno-Virology, IDMIT, Fontenay aux Roses, France, [4]AIDS and Cancer Virus Program, Leidos Biomedical Research, Inc. Frederick National Laboratory for Cancer Research, Frederick, United States
Presenting author email: houzetl@hotmail.com

Background: Semen remains the main vehicle for HIV-1 dissemination. HIV-1 strains in semen differ from those in the blood (i.e., compartmentalized) in over 50% of infected men, and HIV-1 can persist in this body fluid despite suppressive antiretroviral therapy, indicating local viral production. In this study, we aimed to identify the tissue sources of HIV/SIV in semen and decipher the factors involved in virus compartmentalization and excretion within the male genital tract.
Methods: Five chronically infected Asian macaques were screened for viral compartmentalization in semen and testis, epididymis, vas deferens, seminal vesicle, prostate and urethra using single genome amplification of full HIV env gene and genetic analyses [phylogenies, tree-based (AI, S-M, r and rb) and Fst]. In order to investigate parameters associated with compartmentalization and excretion, the infection levels of genital organs and their expression of a range of molecules (cytokines, cell markers, antiviral/restriction factors) were assessed by quantitative PCR. Infected cells nature and localization was determined by immunohistochemistry and in situ hybridization.

Results: Compartmentalized SIV populations were identified in testis, epididymis, vas deferens, seminal vesicles and urethra from two macaques displaying compartmentalized virus in semen. We found genetic sequence similarities between viral strains present in semen and in epididymis, vas deferens or seminal vesicles from these individuals, thus highlighting the genital organs responsible for virus shedding in semen. The excretion of compartmentalized virus in semen was not associated with male organs' infection or inflammatory levels nor with the nature of infected cells within those organs.
Conclusions: This study uncovers for the first time the specific male genital organs which are source of HIV/SIV in semen. The factors involved in the compartmentalization and excretion from those organs are yet unclear and under further investigation. These data have important implications for our understanding of systemic virus shedding and persistence in semen, and provide a new basis for innovative targeted strategies to prevent and eradicate HIV in the male genital tract.

MOPEA0070

HIV cell-associated transmission in the colo-rectal mucosa *ex vivo* and its modulation by seminal plasma

J. Frouard[1], G. Matusali[1], A.-P. Satie[1], N. Rioux-Leclercq[1,2], L. Sulpice[3], C. Ravel[1,4], A. Le Tortorec[1], N. Dejucq-Rainsford[1]
[1]INSERM, IRSET-INSERM U 1085, Rennes, France, [2]Centre Hospitalier Universitaire de Pontchaillou, Laboratoire d'Anatomie et Cytologie Pathologiques, Rennes, France, [3]Centre Hospitalier Universitaire de Pontchaillou, Service de Chirurgie Hépatobiliaire et Digestive, Rennes, France, [4]Centre Hospitalier Universitaire de Pontchaillou, Laboratoire de Biologie de la Reproduction CECOS, Rennes, France
Presenting author email: julie.frouard@univ-rennes1.fr

Background: It was recently shown that intra-rectal inoculation of SIV-infected cells is more effective in initiating infection than cell free virus in macaques. To date, cell-associated (CA) transmission has been largely overlooked, especially in the colo-rectal mucosa. Since the molecular events underlying CA transmission differ from those involved in cell-free virus transmission, improving our knowledge on HIV CA transmission in human mucosa, notably the nature of the infected seminal cell types involved and the influence of seminal plasma (SP), has important implications for vaccine and microbicide development. In this context, we aimed to decipher the seminal cell types involved in CA infection of the colo-rectal mucosa, the impact of SP and the mechanisms involved.
Methods: A polarized ex vivo explant model of human colo-rectal mucosa was developed, along with an in vitro model of colonic epithelial Caco2 cells. The apical epithelium of these models was exposed to the leukocytes which are known to be infected by HIV-1 in semen (CD4 T lymphocytes and monocytes/macrophages, CFSE-labeled), in the presence or absence of 10-50% of seminal plasma (SP). The integrity of the epithelial barrier before and after exposure was evaluated by permeability measure (Dextran leaking and trans-epithelial resistance) and by junction/adhesion molecules staining. Adhesion and transmigration of leukocytes through the colonic epithelium were evaluated by fluorescence microscopy.
Results: Transmigration of both T lymphocytes and monocytes/macrophages was observed through the intact epithelium of the colon mucosa as early as 1h post-exposure, with or without SP. SP did not modify the colon mucosal barrier integrity, nor the expression pattern of the adhesion molecules E-cadherin and JAM-A. The presence of activated T lymphocytes underneath the epithelial barrier increased leukocytes transmigration, as did the pro-inflammatory cytokines TNFa and IL-1b on the apical side.
Conclusions: This is the first demonstration of active and rapid transmigration of both T lymphocytes and monocytes/macrophages across the intact colorectal barrier. Our results suggest that seminal plasma has no effect on the colorectal barrier integrity nor on the ability of leukocytes to adhere and transmigrate through this barrier.

Presenting author email: adam.burgener@umanitoba.ca

Background: Pre-exposure prophylaxis (PrEP) to prevent HIV infection has shown inconsistent results in women. We investigated whether the vaginal microbiome modulated PrEP efficacy in the CAPRISA 004 tenofovir gel trial.
Methods: Cervicovaginal lavage (CVL) samples were collected during the CAPRISA 004 trial at quarterly study visits when pelvic examinations were performed. The last HIV-seronegative CVL available from the 62 HIV seroconvertors and a randomly selected CVL sample from the 626 HIV-negative women that were assigned to either the tenofovir or placebo gel, were analyzed by mass spectrometry and 16S rRNA sequencing. Lactobacillus dominant (LD) women had vaginal Lactobacillus proteins at >50% abundance. Tenofovir concentrations in CVLs and bacterial cultures were assessed by validated mass spectrometry methods. We used an in vitro culture system to assess biodegradation of tenofovir by major bacterial species identified.
Results: Two major bacterial community state-types were identified in the 688 women profiled; one of low diversity where Lactobacillus iners and crispatus were the most common (Lactobacillus-dominant (LD), 59.2%), and the other with high ecological diversity where Gardnerella vaginalis predominated, co-dominant with Prevotella, Mobiluncus, and other anaerobic bacteria (non-Lactobacillus-dominant (non-LD), 40.8%). Women with LD had three-fold higher protection than women with non-LD; HIV incidence rates in the tenofovir and placebo gel arms were 2.7 and 6.9 per 100 women-years in LD women (Incidence rate ratio (IRR)=0.39 (95% Confidence Interval) (CI) 0.16, 0.89, P=0.013), compared to 6.4 and 7.8 per 100 women-years in non-LD women, respectively (IRR=0.82; CI: 0.37,1.77; P=0.644). Detectible mucosal tenofovir was considerably lower in non-LD women (P=0.008), despite similar adherence, and negatively correlated with G. vaginalis abundance. Bacterial cultures demonstrated that tenofovir is rapidly metabolized and depleted 64.5% by G. vaginalis in 24 hours (P< 0.001) but not L. iners or L. crispatus. Prevotella, Mobiluncus, and other anaerobic bacteria also significantly depleted tenofovir compared to abiotic controls (P=0.007).
Conclusions: Our study provides new evidence linking vaginal bacteria to PrEP efficacy in women, and proposes a putative mechanism of tenofovir depletion by bacteria which may be a factor contributing to the variable effectiveness of topical tenofovir-containing PrEP.

MOPEA0072

Human seminal plasma from HIV-1-infected patients induces migration of mucosal dendritic cells and alters integrity of intestinal epithelium

A. Ferrazzano[1], S. Dispinseri[1], M. Cavarelli[2], M.E. Mantione[3], M. Lombardi[3], U. Elmore[4], S. Nozza[5], C. Foglieni[3], C. Moog[6], G. Scarlatti[1]
[1]IRCCS San Raffaele Scientific Institute, Viral Evolution and Transmission Unit, Milan, Italy, [2]CEA, Division of Immuno-Virology, Paris, France, [3]IRC, Cardiovascular Research Area, Milan, Italy, [4]IRCCS San Raffaele Scientific Institute, Department of Gastrointestinal Surgery, Milan, Italy, [5]IRCCS San Raffaele Scientific Institute, Department of Infectious and Tropical Diseases, Milan, Italy, [6]Fédération de Médecine Translationnelle de Strasbourg, Strasbourg, France

Background: The mechanisms involved in the early stages of HIV-1 infection have not yet been elucidated. Human seminal plasma (HSP) from HIV-1 infected patients represents a source of virions rich in pro-migratory and/or pro-inflammatory factors, thus could contribute in spreading the infection and activating mucosal cells. Here we investigate the HSP capability to affect gut epithelial integrity both ex-vivo and in vitro, and characterize the migration of mucosal cells to uptake virions.
Methods: Ex-vivo and in vitro previously optimized models were applied. Ex-vivo colorectal mucosa tissue culture was apically treated with HSP from characterized HIV-1 infected, therapy naïve patients. Structural epithelial integrity and mucosal cells migration was investigated by confocal microscopy identifying molecules involved in the epithelia immunological barrier function. In vitro co-culture of polarized Caco-2/monocyte -derived Dendritic Cells (DCs) was apically treated with

HSP. Changes in the distribution of either epithelial surface antigen or junctions molecules and DCs migration were evaluated at confocal microscope. Migrated DCs were quantified by morphometry. Uptake of HIV-1 expressing mCherry was evaluated. The concentration of pro-migratory and pro-inflammatory factors in HSP was determined by ELISA.
Results: Ex-vivo experiments showed that HSP induced the migration of CD11c+/CD64- DCs but not of CD11c-/CD64+ macrophages towards the apical region of the colonic mucosa. The in vitro co-culture system demonstrated a DCs migration through the Caco-2 monolayer in response to HSP comparable to that observed with HIV-1. These effects induced by HSP were paralleled by changes in the epithelial barrier antigens in both models. The observed changes may be HIV-1-related as suggested by in vitro detection of mCherry-expressing virions in the proximity and inside $CD11c^+$ DCs.
Conclusions: These are the first results showing HSP involvement in mucosal barrier alteration and DCs migration, in relationship with penetration of HIV-1 through the colorectal epithelium. Data highlight the role of DCs in the early stages of infection. Better understanding of these mechanisms will be of importance for the development of new therapies.

MOPEA0073

A combination of broadly neutralizing antibodies prevents *in vitro* $SHIV_{162P3}$ cell-free transmission more efficiently than cell-to-cell transmission

K. Suphaphiphat[1], M. Tolazzi[2], C. Gommet[1], N. Bosquet[1], G. Scarlatti[2], R. Le Grand[1], M. Cavarelli[1]

Presenting author email: karunasinee.suphaphiphat@cea.fr

Background: HIV transmission from cell-to-cell is a common way for viral dissemination. Indeed, it has been suggested that transmission through infected cells is more efficient and more difficult to neutralize than cell-free virus. Nevertheless, most therapeutic and preventive vaccine candidates towards HIV-1 have been evaluated pre-clinically for efficacy against cell-free viral challenges. We previously reported a protective effect of a combination of three NAbs, 2G12, 2F5, and 4E10, against simian/human immunodeficiency virus (SHIV) vaginal transmission in macaques in vivo (Moog et al., 2014).
However, to date, there is no evidence that strategies that can efficiently prevent macaques exposed to cell-free SHIV, like the use of bNAbs, are also able to protect from cell associated-SHIV exposure. Here we aimed to determine in vitro the extent to which bNAbs inhibit cell-free and cell-to-cell $SHIV_{162P3}$ transmission.
Methods: We developed a cell-to-cell transmission assay and evaluated antibody-mediated virus neutralization using both TZM-bl and human PBMC as target cells and in vivo $SHIV_{162P3}$- infected spleen cells as donor cells. We used the anti CD4-binding site IgG1b12, the gp120-directed antibody 2G12, and the two gp41-directed antibodies, 2F5 and 4E10 against the two transmission route. The bNAbs were used either alone or in combinations of 3 (2G12+2F5+4E10) and 2 (2G12+4E10, 2G12+2F5, 4E10+2F5).
Results: Our results demonstrated that cell-to-cell $SHIV_{162P3}$ transmission was less sensitive to neutralizing antibodies compared to cell-free $SHIV_{162P3}$. The triple bNAb combination showed decreased potency in the TZM-bl assay than in the hPBMC assay. Moreover, inhibition of cell associated transmission was achieved only when 2G12 was present in the bNAbs combination in the TZM-bl, whereas in the hPBMC assay the double combination is more potent to neutralize the infection when 2F5 is present. In the TZM-bl assay, none of individual 2F5, 2G12 and 4E10 can inhibit cell-to-cell transmission while 2F5 can efficiently block it in the hPBMC assay. Interestingly the IgG1b12 was very efficient to inhibit cell-to cell transmission in both assays.
Conclusions: Therefore, our findings support the use of antibody combinations against cell-associated virus in future candidate therapeutic regimens.

Intestinal dendritic cells and macrophages play a different role in the early events of HIV-1 transmission

M. Cavarelli[1], A. Ferrazzano[2], N. Hantour[1], T. Schorn[2], C. Foglieni[2], A. Cosma[1], N. Bosquet[1], U. Elmore[2], G. Scarlatti[2], R. Le Grand[1]

Presenting author email: mariangela.cavarelli@cea.fr

Background: Sexual transmission of HIV is the main route for HIV acquisition. Infection frequently occurs through colorectal mucosa where mononuclear phagocytes (MP), comprising dendritic cells (DC) and macrophages (Mf), are among the first target cells.
We showed that human colonic lamina propria CD11c+DCSIGN+CD68- cells sample luminal R5 HIV in an ex vivo model, a mechanism exploited by HIV to bypass the intact epithelial barrier. However, little to nothing is known about resident DC and Mf in the lower intestinal tract, the extent to which different subsets exist, and their role in HIV acquisition.
Methods: We used multicolor flow cytometry, immunofluorescence and ex vivo explant culture of colorectal mucosa obtained from healthy human donors and Cynomolgus macaques, to define MP distribution and their susceptibility to HIV/SIV infection.
Results: CD64 allowed to differentiating colonic DC (CD11c+CD64-) and Mf (CD11c+CD64+). Three major DC subsets were identified on the basis of CD103 and the fractalkine receptor (CX3CR1) expression. The totality of colonic Mf was CX3CR1+ while about 50% expressed the M2 marker CD163. Cells were further characterized for the expression of the CD172a and CD11b.
At steady state, CD11c+CD103+ DC were detected underneath the luminal epithelium and at cript level. Following ex vivo R5 HIV-1 stimulation, both CD11c+CD64+ and CD11c+CX3CR1+ cells penetrated the intestinal epithelium, whereas an increase in CD11c+CD103+ cells migration was not observed.
Interestingly, CCR5, that we showed to drive CD11c+ cells migration toward the intestinal lumen, was preferentially expressed by the CD11c+CD64+CX3CR1+ cells, which support their involvement in active sampling of HIV and in transmission of infection in situ.
Conclusions: In conclusion we have unravel a previously underestimated complexity in the phenotype and function of the intestinal MP in human and NHP and discuss the relative contribution of different subsets of DC and Mf in the early events of HIV transmission at mucosal sites.

MOPEA0075

Virological synapses formed between HIV-1-infected $CD4^+$ T-cells and mucosal epithelium promote macrophage infection followed by reservoir formation in reconstructed urethral tissues

F. Real[1,2,3], A. Sennepin[1,2,3], Y. Ganor[1,2,3], D. Tudor[1,2,3], A. Schmitt[2,3,4], M. Bomsel[1,2,3]

Presenting author email: fernando.oliveira-real@inserm.fr

Background: During sexual intercourse HIV-1 cross epithelial barriers composing the genital mucosae, a poorly understood feature which requires an HIV-1-infected cell vectoring the entry. We have demonstrated that the adult penile urethra is an HIV-1 entry site and that, in contrast to poorly infectious cell-free virus, efficient HIV-1 penetration in the mucosa depends on infection driven by HIV-1 infected cells.
Methods: Viral synapses (VS) are the basis of HIV-1 cell-to-cell transmission and, due to their dynamic nature, require live imaging techniques to be adequately approached. Thus, we have developed immunocompetent urethral tissues reconstructed in vitro based on penile cells, and comprizing a tight epithelium overlaying a lamina propria, suitable for imaging the interaction of live CD4+T-cells, that produce infectious and fluorescent R5-tropic gag-iGFP HIV-1, and human urethral epithelial cells.
Results: We demonstrate that HIV-1 infected cells contact the epithelium, leading to virus production at the surface of urethral epithelial cells. VS are established during the first hour of interaction between infected CD4+T-cells and epithelium, resulting in virus budding that is transported across epithelium and stroma. Gp41-envelope specific IgA inhibit this contact, resulting in a reduction of HIV-1 translocation across reconstructed mucosa.
Following VS, viral transfers are detected for ≈1 hour and transcytosis of HIV-1 through mucosal epithelial cells are detected in regions where VS occurred. Efficient macrophage targeting following VS initiation results in viral production for 9 days before production halting, suggestive of macrophage reservoir formation within mucosa reconstructed in vitro. Additonally, treatment of LPS restores viral production from latency.

Conclusions: Altogether, VS formed between a donor immune cell infected with HIV-1 and a target epithelial cell in the context of reconstructed immunocompetent mucosa will potentially reveal novel aspects of HIV-1 transmission, helping to design better targeted antiviral strategies including gp41-specific IgA.

Presenting author email: nkenfou@yahoo.com

Background: Previous studies reported that girls were more at risk of in utero and perinatal mother to child transmission (MTCT) of HIV-1. We looked at the data collected in Cameroon to verify this observation. The hypothesis is that this is not true as several other factors will hinder the biologic sex effect on the MTCT of HIV-1.
Methods: We investigated biologic sex and HIV transmission among infants born to HIV infected mothers. The infants were tested by polymerase chain reaction (PCR) for HIV proviral DNA. All infants whose PCR1 was positive on two different testings were considered HIV infected. The results were analyzed using Stata software and the pearson chi 2 and Fisher exact tests.
Results: A total of 15,404 infants aged 6 weeks to 18 months were recruited (Mean age 16.7 weeks) and 34.8% were breastfed. A portion of 9.4% was infected. Generally, biologic sex was not associated to HIV transmission, but was combined to other factors. According to the type of twins´ pairs (161 twins sets) more HIV infected children were found in boy-girl twins´ sets ($p = 0.037$) and more girls were infected in this type of twins´ sets compared to girl-girl pairs ($p = 0.043$). Girls were more likely to be infected when mothers underwent treatment or prophylaxis ($p = 0.037$), and more likely to be infected in the age group of 6.1-24 weeks ($p=0.034$). Younger mother (≤25) transmitted more ($p = 0.049$). Delivery order did not impact transmission.
Conclusions: In our setting, biologic sex was associated to vertical transmission in specific conditions. More transmissions occurred in boy-girl twins´ sets, in girls when mother on ART. Many parameters may be associated to impact MTCT of HIV-1. Mechanisms underlying these associations should be further investigated. Interventions through family planning and pre natal consultation, especially for twin pregnancies should be re-enforced.

MOPEA0077

Properties of ENV derived from transmitted HIV-1 issued from transmission clusters

M. Beretta[1], A. Moreau[1], M. Bouvin-Pley[1], A. Essat[2], C. Goujard[3], M.-L.C. Baudier[4], L. Meyer[3], F. Barin[1], M. Braibant[1]
[1]INSERM Unit 966, Tours, France, [2]INSERM U1018 - CESP, Le Kremlin Bicêtre, France, [3]APHP, Le Kremlin Bicêtre, France, [4]Hôpital Saint Louis AP-HP, Paris, France

Background: Recent studies suggested that during sexual transmission of HIV-1, a single transmitted/founder (T/F) virus among numerous viral variants present in the donor is transmitted most often. The result is a genetically restricted viral population at the beginning of infection. The aim of our study was to investigate if this bottleneck event is a stochastic process or if it selects viral variants with particular biological properties that predispose them to more effectively establish new infections. To that aim, we examined the antigenic and phenotypic properties of transmitted viruses that have a common origin, derived from the same transmission cluster. Our hypothesis was that if the transmitted variants have a selective advantage, they should share some biological properties.
Methods: Between 2006 and 2013, 8 clusters of at least 3 patients infected by subtype B or CRF02-AG viruses were included in the early phase of infection in the ANRS Primo Cohort. We produced Env-pseudotyped viruses derived from the viral population infecting each patient and compared their neutralization sensitivity to a panel of broadly neutralizing antibodies targeting major epitopes of the envelope glycoprotein.
Results: We found that neutralization profiles are conserved within 7 clusters of transmission, indicating a strong antigenic conservation of the transmitted viruses. Secondly, we studied the sensitivity of pseudotyped viruses to various entry inhibitors. We observed similar sensitivities to T20 (fusion inhibitor) and Maraviroc (CCR5 inhibitor) within each cluster.
Conclusions: Together, these results support the hypothesis of a selective restriction of transmitted variants during the transmission event.

MOPEA0078

Gut-homing Δ42PD1$^+$Vδ2 T cells promote innate mucosal damage via TLR4 during acute HIV-1 infection

A. Cheung, Z. Chen
University of Hong Kong, AIDS Institute and Microbiology, Pokfulam, Hong Kong
Presenting author email: chenai@hku.hk

Background: Acute HIV-1 infection leads to vigorous innate immune responses and rapid CD4$^+$ T cell depletion in intestinal tissues. Innate immune cells underlying mucosal responses remain incompletely understood.
Methods: Δ42PD1 expression on γδ-T cells was examined in following HIV-1 infection in acute (n=57) and chronic (n=50) patient cohorts and healthy controls (n=22) in correlation with serum cytokine levels. A humanised mice model was used to determine if Δ42PD1+ γδ-T cells migrate to the gut, and tissue sections of small intestine was examined.
Results: Δ42PD1 expression was significantly up-regulated on Vδ2 subset of γδ-T cells in acute (~20%) compared to chronic HIV-1 patients (~11%) and healthy controls (~2%). Frequency of Δ42PD1$^+$Vδ2 cells and pro-inflammatory cytokines levels positively correlated in acute patients. We found that HIV-1 infection rapidly induced Δ42PD1$^+$Vδ2 cells in vitro, which also expressed high levels of gut-homing receptors CCR9/CD103, and triggered small intestinal inflammatory damages after adoptive transfer into humanized mice. The innate receptor for Δ42PD1 was discovered as TLR4/MD2 that induces pro-inflammatory cytokines by using antibody/small molecule blocking, binding affinity and co-immunoprecipitation assays. By fluorescence immunohistochemistry, co-localization of Δ42PD1$^+$Vδ2 cells and TLR4 or IL6 was evident primarily in mice small intestines. The mucosal damage was reduced when Δ42PD1-specific antibody was administered before and during adoptive transfer of HIV-induced Vδ2 cells into humanized mice.
Conclusions: In summary, this study uncovered a novel Δ42PD1/TLR4 pathway exhibited by infection-induced gut-homing Vδ2 cells that may contribute to innate immune activation and intestinal pathogenesis during acute HIV-1. Δ42PD1$^+$Vδ2 cells may serve as a new target for the investigation of diseases with gut inflammation.

MOPEA0079

In depth sampling of high-risk populations to characterize HIV transmission epidemics among young MSM using PrEP in France and Quebec

Presenting author email: achaillon@ucsd.edu

Background: The ANRS IPERGAY trial was a double-blind, randomized trial of pre-exposure prophylaxis among high-risk men conducted in France and Quebec. We reconstructed HIV transmission networks from recently infected individuals enrolled in the IPERGAY trial in combination with French and Montreal primary infection Cohorts to identify and characterize active clusters of transmission.
Methods: HIV pol sequences were generated from 31 IPERGAY participants (2012-2014). Phylogenetic and network analyses were performed to infer putative relationships between these participants and 1,352 unique HIV pol sequences from individuals enrolled in the French PRIMO ANRS Cohort (1999-2014) and 490 individuals enrolled in the Montreal PRIMO Cohort (1996-2016). We applied a logistic growth model to estimate the maximum expected size of the largest active cluster.
Results: All 31 participants from the IPERGAY trial were predominantly infected with HIV-1 subtype B (64.5%) and CRF02_AG (22.6%). At diagnosis, the median age was 34 years (IQR:27-44), the median HIV RNA and CD4 counts were 5.5 Log_{10}cp/mL (IQR:4.5-6.7) and 464 cells/mL (IQR:390-661) respectively. Fifteen individuals (48.4%) were involved in 12 clusters sampled over a median period of 2 years (IQR:0.3-7.8) including 6 dyads and 6 larger clusters ranging from 3 to 62 individuals. All clustering individuals were male and all clusters but 2 involved subtype B. All but 3 clustering sequences were identified in Paris, France while two were from Quebec. The Quebec cluster with 7 Montreal Cohort and one IPERGAY participants (surrounded in Figure) was part of a previously identified cluster with 45 MSM infected in Montreal (n= 32), Sherbrooke (n=7) and Quebec (n=6) diagnosed between 2012 and 2014.The largest cluster included 62 CRF02_AG sequences (4 IPERGAY) sampled between 2000 and 2015 with an expected maximum size of 72 by 2030. Of the 31 IPERGAY sequences, one harbored the NNRTI K103N mutation and was linked to 6 French sequences with the same mutation diagnosed between 2009 and 2012.
Conclusions: These results demonstrate high rates of HIV transmission clustering among young high-risk MSM enrolled in the IPERGAY trial. In-depth sampling of high-risk populations may help to uncover unobserved transmission intermediaries and improve prevention efforts that could be targeted to the most active clusters.

MOPEA0080

Very early treated acute HIV patients have high naïve-CD4+Tregs recovery with a decreased immune activation

A. Camiro[1], A. Cardenas-Ochoa[1], J. Sierra-Madero[1], L.E. Soto-Ramirez[1], F. Belaunzaran-Zamudio[1], D. Scott-Algara[2], R. Jaramillo-Jante[3], S. Perez-Patrigeon[1]

Presenting author email: santiago.perez@infecto.mx

Background: ARV treatment (ART) administered during acute HIV-infection presents several immunological benefits leading to a better CD4+ T cell recovery. In a prospective, observational cohort of patients with acute HIV-infection, immunologic markers and clinical characteristics were evaluated. We present here T-cell-immune-phenotypic characteristics at baseline and 2 months after ART initiation.
Methods: Patients with acute HIV-infection are being followed-up in 5 sites across Mexico. Clinical, demographic data and blood samples are collected in all patients. In a sub-set of patients, we collected fresh whole blood for flow cytometry analysis. Naïve-(Nv), central memory- (CM), effector memory (EM) and terminally differentiated- T-cells (TMRA), as well as activation markers were determined using CD3, CD4, CD8, CD45RA, CCR7, CD38 and HLA-DR markers. We used Fox-P3, CD25, CD127 and CD45RA to identify T-regs and their subsets. To assess changes over time, Wilcoxon matched-pairs signed rank test was used for each value between baseline and month 2.
Results: We included 10 patients with complete flow-cytometry data and at least 2 months of follow-up. All subjects were male infected by sexual transmission; mean age was 32 y.o. Mean CD4+ T cell count was 439 cells/uL and median viral load was 1.2 million copies/ml (23379-10x10^6 copies/ml) at the baseline. According to Fiebig criteria, patients were distributed as follows: 2 patients in Fiebig II;
4 patients in Fiebig IV and 4 patients in Fiebig V. All patients received treatment immediately. TDF+FTC+EFV were prescribed in 8 subjects (80%).
At 2 months, CD4+ T cell increased from 439 cells/uL to 609 cells/uL (p=0.1). Immune activation markers (HLA-DR, CD38) decreased from 4.55% to 2.22% (p=0.03) in T-CD4+ and from 43.25 to 8.97 (p=0.006) in T-CD8+. The proportion of T-CD4+ or T-CD8+ subsets (Nv, Cm, EM, TMRA) at 2 months did not change from baseline. Concerning T-regs, they increased from 4.8% to 7.8% (p=0.01) and this difference was mainly due to a recovery of the naïve T-regs subset (from 4.2 to 6.1, p=0.01).
Conclusions: Early total T-regs recovery driven mainly by naïve-T-reg and a decrease in immune activation markers precede the T CD4+ recovery observed in patients with acute HIV-infection treated immediately after diagnosis.

MOPEA0081

Low frequencies of HIV-infected cells in blood, colon and lymph node at the earliest stage of acute infection (Fiebig I)

Jackson Foudation Advancement of Military Medicine, Bethesda, United States, [4]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Sliver Spring, United States, [5]Vaccine and Gene therapy Institute, Port St. Lucie, United States, [6]SEARCH Thai Red Cross AIDS Research Center, Bangkok, Thailand, [7]Armed Forces Research Institute of Medical Sciences, Department of Retrovirology, Bangkok, Canada
Presenting author email: nicolas.chomont@umontreal.ca

Background: A small pool of HIV-infected cells is established early in the blood of recently infected individuals. However, little is known about the frequency of infected cells in tissues during the earliest phase of HIV infection. Here we quantified infected cells in blood, colon and lymph node from acutely infected individuals.
Methods: We measured the frequency of cells harbouring total HIV DNA in total cells obtained from the blood (n=105), colon (n=53) and lymph nodes (n=25) from recently infected Thai participants (Fiebig stages I-V) not receiving antiretroviral therapy. Samples from chronically infected Thai individuals were used as controls.
Results: Blood, colon and lymph node displayed similar frequencies of HIV-infected cells in participants from a given Fiebig stage. In contrast, lymph node from chronically infected individuals displayed slightly higher levels of infected cells compared to blood. Fiebig I individuals were unique as they displayed extremely low frequencies of infected cells in blood, colon and lymph node (median: 1.0, 0.0 and 0.9 Log10 HIV DNA copies per million cells), which were all statistically lower than any other group. Fiebig II-V participants displayed similar levels of HIV DNA as chronically infected participants in blood (2.7 vs 2.7), colon (3.0 vs 2.8) and lymph node (3.0 vs 3.2 median Log10 HIV DNA copies per million cells in Fiebig II-V vs chronic, respectively). Overall, the frequency of infected cells in blood strongly correlated with the frequencies measured in colon (p<0.0001, r=0.6) and lymph node (p<0.0001, r=0.8). Finally, HIV plasma viral load was correlated to the frequencies of infected cells in the blood (p<0.0001, r=0.4) and lymph node (p=0.001, r=0.5), but not in the colon.
Conclusions: Fiebig I individuals display lower frequencies of HIV-infected cells in blood, gut and lymph node than any other acutely infected participants. Strikingly, the frequencies of infected cells typically measured in blood and tissues from chronically infected individuals are already reached as early as Fiebig II stage. These results suggest that ART initiation at the Fiebig I stage may significantly limit the frequency of infected cells in blood and tissues.

MOPEA0082

T follicular helper cells are preserved by ART and correlate with reservoir size in early HIV infection

J.P. Thornhill[1], C. Phetsouphanh[2], C. Herrera[1], W. Stohr[3], R.W. Sanders[4], I. Bontjer[4], K. Porter[3], F. John[2], S. Fidler[1], SPARTAC Investigators
[1]Imperial College London, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]University College London, London, United Kingdom, [4]Academic Medical Center of the University of Amsterdam, Amsterdam, Netherlands
Presenting author email: thornhillj@gmail.com

Background: Evidence suggests a key role for T follicular helper cells (Tfh) in HIV antibody responses and reservoir. The impact of ART during Primary HIV infection (PHI) on Tfh is unclear. We compare early (ART-48) versus no ART (SoC) initiated in PHI, and explore the association with HIV reservoir and antibody responses.
Methods: Using longitudinal samples (baseline and week 48) from the SPARTAC RCT, 12 individuals from the ART-treated (ART-48) arm and 21 from the untreated (SoC) were studied. Expression of CXCR5, PD-1, TIGIT, Tim-3, HLA-DR, Bcl-6 and IL-21 was assessed by flow cytometry. Tfh were defined by coexpression of CXCR5 and PD-1. HIV DNA was measured by qPCR. Total, HIV specific anti-gp120 and specific anti-p24 IgG and IgA antibody responses were measured by ELISA. Mixed-effect models were used to assess the impact of ART on Tfh and CD4+CXCR5+T-cells.
Results: At baseline, using samples from all 33 individuals, expression of Tfh associated markers: PD-1 (p=0.009), TIGIT (p<0.0001), Bcl-6 (p<0.0001) & IL-21 (p=0.03) was significantly higher on CXCR5+CD4+T-cells compared to CXCR5-T-cells. There was an inverse correlation between the baseline absolute number of Tfh and both total (r=-0.4,p=0.03) and integrated HIV DNA (r=-0.5,p=0.01). In addition, a positive correlation was observed between Tfh and both CD4/CD8 (r=0.62, p<0.001) and frequency of B Cells (CD19+) (r=0.49, p=0.003).
Absolute Tfh and CXCR5+CD4+T-cell numbers at week 48 were significantly higher in ART-48 compared to SoC. Mixed effect models showed significantly increased numbers of both Tfh and CD4+CXCR5+T-cells at week 48 (p=0.001) in the ART-48 arm compared to the SoC arm.
In the ART-48 arm, expression of exhaustion (PD-1, TIM-3) and activation (HLA-DR) markers on CXCR5-CD4+T-cells decreased significantly (p<0.05 for all) between baseline and week 48; no difference was seen in the SOC arm. No difference in expression of activation and exhaustion markers was noted on CXCR5+CD4+ T-cells in either arm.
Specific-gp120 IgG/IgA ratio was higher in the SoC arm at 48 weeks compared to baseline, while specific-p24 IgG/IgA was greater in the ART-treated group.
Conclusions: These data show dynamic changes in the Tfh compartment in PHI, which correlated with reservoir size and was impacted by ART.

MOPEA0083

Evidence of fast normalization of inflammation biomarkers after ART started during acute, but not in early chronic HIV infection

F.H. Côrtes[1], H.H. Souza de Paula[1], G. Bello[1], S. Lopes Teixeira[1], A.C. Garcia Ferreira[2], S. Wagner[2], B. Grinsztejn[2], V. Gonçalves Veloso[2], M. Gonçalves Morgado[1], M. Lindenmeyer Guimarães[1]

Background: HIV-1 infection leads to chronic immune activation and systemic inflammation. We investigated the impact of early antiretroviral treatment (ART) on inflammation biomarkers and immune cells activation during acute and early chronic HIV infection.
Methods: Blood samples were obtained from HIV-uninfected (HIVneg), late chronically ART-treated HIV-infected (LcART-HIV), early chronically ART-treated HIV-infected (EcART-HIV, Fiebig VI) and acutely ART-treated HIV-infected (aART-HIV, Fiebig I-V) patients from Rio de Janeiro, Brazil.
Plasmatic levels of inflammation biomarkers (IP-10, IL-18, CRP and IL-6) were measured before the start of ART (D0) and six (M6) months after. The $CD8^+CD38^+HLA\text{-}DR^+$ T cells frequencies were evaluated by flow cytometry in D0 and M6. The Mann-Whitney test and Spearman correlation were used for statistical analyses.
Results: Among the plasmatic biomarkers analyzed, only IP-10 and IL-18 were significantly elevated at D0 in both aART-HIV and EcART-HIV infected patients. The levels of IP-10 and IL-18 reduced significantly between D0 and M6 in aART-HIV individuals, reaching values similar to HIVneg. Among the EcART-HIV patients, IP-10 levels between D0 and M6 were reduced, but remains higher than in HIVneg and no significantly reduction of IL-18 levels was observed. The $CD8^+$ T cell activation levels in aART-HIV and EcART were elevated at D0 and reduced significantly on M6, but remain higher than in HIVneg.
We found a positive correlation between IP-10 and CD8+ T cell activation in D0 in aART-HIV and EcART, this positive correlation was also found on M6 in aART-HIV patients.
Conclusions: Starting ART early during HIV infection is able to reduce systemic inflammation, but it only normalizes when ART is initiated in acute phase. T cell activation was reduced, but remains elevated in both aART-HIV and EcART-HIV patients.

IL-7 is UP-regulated in the ileal mucosa during hyperacute siv infection in Chinese rhesus macaques, triggering local chemokine expressions and immune cell migrations

A. Couedel-Courteille[1], R. Ponte[1,2], M. Rancez[1], S. Figueiredo[1], V. Fabre-Mersseman[1], J. Dutrieux[1], B. Charmeteau-de-Muylder[1], T. Guilbert[1], J.-P. Routy[2], R. Cheynier[1]

Background: The intestinal barrier, one of the first targets of HIV/SIV, is subjected to major changes during acute infection. We previously demonstrated that pharmaceutical injection of interleukin-7 (IL-7) triggers chemokine expression leading to massive T-cell homing, in particular to the intestine. We here explored mucosal IL-7 expression as part of the cytokine storm occurring during the acute phase of SIV infection in rhesus macaques.
Methods: Gut tissues were analyzed after necropsy in healthy (n=5) and acutely SIV-infected macaques (n=9). Uninfected macaques were also sacrificed following IL-7 injection (80µg/Kg, n=4). The levels of mRNA coding for IL-7 and 13 chemokines involved in lymphoid and myeloid cells homing as well as viral DNA and RNA were quantified by (RT)-qPCR. IL-7 protein was quantified in whole gut samples by ELISA. Confocal imaging after immunostaining was used to evaluate immune cell counts and distribution in large ileum sections (25 mm^2). Circulating T-cell subsets and chemokine receptors expression on these cells were followed-up over 3 weeks, by flow cytometry.
Results: Concomitant with viral detection, IL-7 expression progressively increased in the ileum of SIV-infected macaques, with a peak expression at day 10. In macaques showing enhanced ileal IL-7 mRNA/protein expression, 7 out of 13 chemokines were overexpressed in intestinal tissue. Among these, the macrophage and/or T-cell attractant chemokines CCL4, CCL25, CCL28 and CXCL8 correlated to gut IL-7 expression and were also enhanced in the ileum of IL-7-treated uninfected macaques. $CD8^+$ T-cell counts increased by day 3 in the lamina propria (LP), reaching a maximum at day 10 post-infection.
In contrast, $CD4^+$ T-cell counts were not affected in the ileum, suggesting replenishment. $CD4^+PM\text{-}2K^+$ macrophage numbers augmented at day 3 in the LP and inversely diminished in the submucosa. In the blood, absolute numbers of all T-cell subsets transiently decreased up to day 10, with a marked drop in the proportion of gut-homing $CCR9^+\beta7^+$ T-cells.
Conclusions: These findings suggest a role for IL-7 in the initiation of early mucosal immune responses to lentiviral infections. However, IL-7 triggered $CD4^+$ T-cells and macrophages localization at viral replication sites could also participate to viral spread and establishment of viral reservoirs.

Presenting author email: kgounder25@gmail.com

Background: Transmission of cytotoxic T cell escape variants, timing and frequency of CTL-mediated viral escape following acute HIV-1 infection can profoundly influence disease course but comprehensive analysis of CTL epitopes restricted by protective HLA class I alleles is lacking. We evaluated the transmission of CTL immune escape variants and immune selection over one-year following acute HIV-1 infection for epitopes restricted by the B*7 supertype and protective HLA-B*57 and HLA-B*58:01 alleles.

Methods: HIV-1 uninfected women were screened twice weekly for HIV-1 RNA by finger prick blood draw. Six females were identified possessing the HLA-B*7 supertype [HLA-B*07 (n=2), HLA-B*39:01 (n=2), HLA-B*42:01 (n=1) and HLA-B*42:02 (n=1)] while six women possessed the protective HLA-B*57:02 (n=1) and HLA-B*58:01 (n=5) class I alleles. Plasma samples were available at baseline (Fiebig I-III) and at 2-6 subsequent time points thereafter over one year of infection. Deep sequencing of gag was performed using the Illumina MiSeq platform. Amplicons were molecularly bar-coded, pooled and sequenced resulting in >250-fold coverage. A subset of limiting-dilution full-length HIV-1 genome amplicons were also sequenced by PacBio at ~1000-fold coverage. Sequence analysis was performed using Geneious v8.1.8 (Biomatters Ltd).
Results: In transmitted/founder viruses, the four known Gag CTL epitopes presented by HLA-B*57/B*58:01 were wild type in two of the six participants, with the remaining four participants showing evidence of CTL-mediated pre-adaptation in at least one epitope. By one-year post infection, de novo CTL-mediated selection was observed in all 6 subjects, but never in all 4 epitopes. 5 of 6 participants experienced escape within the immunodominant TW10 epitope. Of the five known Gag epitopes presented by the HLA-B*7 supertype, all six participants showed evidence of a CTL variant in at least 3 epitopes within the transmitted virus sequence. The TL9 epitope remained wild type in 5 of 6 participants with no evidence of CTL escape up to one-year post infection. Transmitted escape variants remained virtually unchanged throughout the follow up period except in one participant who showed evidence of slow reversion in the HLA-B*57/58 ISW9 epitope.
Conclusions: Deep sequencing reveals extensive transmission of pre-adapted CTL variants and slow immune selection within immunodominant epitopes restricted by protective HLA class I alleles.

NKp30 and its ligands: emerging players in HIV-2-infected patients

O. Lucar[1], M. Sadjo Diallo[1], C. Bayard[1], A. Samri[1], P. Debré[1], F. Brun-Vézinet[2], S. Matheron[3], R. Cheynier[4], V. Vieillard[1], for the ANRS CO5 IMMUNOVIR-2 Study Group
[1]Centre d'Immunologie et des Maladies Infectieuses-INSERM U 1135, Paris, France, [2]Assistance Publique - Hôpitaux de Paris, Laboratoire de Virologie, Hôpital Bichat, Paris, France, [3]Assistance Publique - Hôpitaux de Paris, Service des Maladies Infectieuses et Tropicales, Hôpital Bichat, Paris, France, [4]INS, Paris, France
Presenting author email: olivier.lucar@gmail.com

Background: HIV-2 infection progresses more slowly to AIDS, and subjects survive longer than those with HIV-1 infection. It is well established that natural killer (NK) cells are the critical antiviral effectors of the innate immune system. They distinguish their targets from healthy cells via a panel of activating and inhibitory receptors that recognize ligands specifically induced on "stressed" cells. It has been reported that their activities (cytokine production and cytotoxic functions) prevent HIV-1 transmission and viral replication. Due to the scarcity of data in HIV-2 infection, knowledge about the differentiation and function of NK cells is critical to better understand their role in the evolution of the disease.
Methods: Twenty-two untreated HIV-2-infected patients (19 controllers and 3 progressors), included in the ANRS HIV-2 cohort, were compared to LTNP or controllers HIV-1 patients from the ANRS ALT cohort, and healthy controls. Extensive phenotypic and polyfunctional NK cell assays were performed by flow cytometry. Cytolytic function and expression of ligands for NK cell receptors were assessed on CEM T cells infected with HIV-2 or HIV-1 strains.
Results: HIV-2+ patients displayed altered NK cells, highlighted by a profound down-modulation of the activating NKp30 receptor ($p<0.0001$), as compared to HIV-1 patients and healthy controls. NKp30 expression was positively correlated with both NKG2A and Siglec7 ($r=0.65$ and $r=0.60$, respectively), and negatively with HLA-DR and CD57 ($r=0.68$ and $r=0.60$, respectively), suggesting a major impact on NK cell differentiation. $NKp30^{low}$ phenotype was also associated with reduced NK-cell polyfunctionality, even toward stimulation with HIV-2-infected target cells. To determine the mechanism leading to NK-cell dysfunction in HIV-2, expression of cellular ligands for major NK-cell receptors was analyzed. As previously observed for HIV-1, NKp44L was specifically upregulated on bystander non-infected cells in HIV-2, whereas NKG2D ligands were slightly more expressed on both bystander and infected target cells. Importantly, a higher frequency of HIV-2-target cells (up to 70%) expressed NKp30 ligands, as compared to uninfected and HIV-1-infected cells.
Conclusions: Taken together, these data suggest that constitutive expression of NKp30 ligands on HIV-2-infected cells could provoke decreased NKp30 expression by NK cells, eventually leading to their functional impairment.

MOPEA0087

Prevalence and risk factors associated with HIV/viral hepatitis B and C co-infections among people who inject drugs in Mozambique, 2013-2014

C.A. Semá Baltazar[1], M. Boothe[2], I. Sathane[3], E. Fazito[4], R. Horth[5], N. Bhatt[6]
[1]Instituto Nacional de Saude, Health Surveillance Department, Maputo, Mozambique, [2]University of California, San Francisco, Global Health Sciences, Maputo, Mozambique, [3]University of California, San Francisco, Global Programs for Research and Training, Maputo, Mozambique, [4]The Joint United Nations Program on HIV/AIDS, Maputo, Mozambique, [5]University of California, San Francisco, San Francisco, United States, [6]Instituto Nacional de Saude, Centro de Investigação em Saúde da Polana Caniço, Maputo, Mozambique
Presenting author email: cynthiasema@yahoo.com

Background: While the high burden of HIV in the general population of Mozambique is well documented, no data exist on HIV, Hepatitis B (HBV) and C (HCV) virus among People Who Inject Drugs (PWID). The first Integrated Bio-Behavioral Surveillance (IBBS) Survey among PWID took place in 2013-2014 to address this gap in knowledge. The present analysis assesses the prevalence of HBV and HCV infection among PWID and describes associated risk factors.
Methods: Using respondent-driven sampling, PWID aged 18 years and older were recruited in Maputo and Nampula/Nacala, two large urban centers of Mozambique. Rapid screening of HIV, HBV (HBsAg) and HCV was performed on site. We pooled data from both sites to conduct unadjusted bivariate analysis using chi-square where HIV/HBV and HIV/HCV coinfections were separate outcomes.
Results: Among the 492 eligible PWID, 94% were male and median age was 32 years. The prevalence of HIV/HBV and HIV/HCV co-infections among survey participants was 4.0% and 19.6%, respectively. Figure 1 illustrates the burden of disease among participants. HIV/HBV co-infection was independently statistically associated ($p<0.01$) with older age, prior history of needle sharing and drug injection in the last month. HIV/HCV co-infection was independently statistically associated with older age, prior history of needle sharing, drug injection in the last month, needle sharing in the last month and history of arrest. There was no association of sexual risk behaviors with either HIV/HBV or HIV/HCV co-infections.
Conclusions: There is a high burden of HBV and HCV among HIV-infected PWID in two urban areas in Mozambique. Our results highlight the need for targeted harm reduction interventions that include needle exchange programs and integrated services for diagnosis and treatment of HIV,HBV and HCV in Mozambique to address these epidemics among PWID. Efforts should be made to assess the feasibility of introducing HBV vaccination in this high-risk population.

Background: HIV/HBV co-infected patients exhibit increased liver dysfunction and fibrosis, but the mechanisms contributing to this differential pathology remain poorly understood, and an animal model of HIV/HBV co-infection is needed. Rhesus macaques are regularly utilized as models for HIV infection, but no endogenous HBV strain has been discovered in this species. We hypothesized that the block to HBV replication in rhesus hepatocytes is due to failure to gain cell entry. To test this hypothesis, we expressed the HBV receptor -- human NTCP (hNTCP) -- on rhesus hepatocytes both in vitro and in vivo. We show for the first time that macaques expressing hNTCP can be infected with HBV, paving the way for a physiologically relevant animal model of HIV/HBV co-infection.
Methods: We generated helper-dependent adenovirus (HDAd serotype 5) and adeno-associated virus (AAV serotype 8) vectors expressing hNTCP and transduced freshly isolated rhesus and baboon primary hepatocytes (PH) in vitro. We then challenged these PH with HBV and monitored in vitro infections by supernatant HBsAg/HBeAg ELISA, HBV DNA qPCR, and electron microscopy. For in vivo studies, macaques were injected with HDAd and AAV vectors expressing hNTCP and challenged with HBV. We monitored in vivo HBV infections by HBV DNA and alanine transaminase concentrations in the serum, HBV DNA and RNA levels in isolated hepatocytes, anti-HBV humoral and cellular immunity, and expression of HBcAg in the liver.
Results: Rhesus and baboon PH expressing hNTCP supported high levels of HBV infection, evidenced by increasing supernatant concentrations of both HBsAg and HBeAg. In addition, covalently-closed circular DNA (cccDNA) qPCR and electron microscopy revealed the formation of cccDNA and the release of Dane particles, respectively. These results indicate that all stages of HBV replication are present in rhesus hepatocytes. Expression of hNTCP in vivo facilitated HBV infection, evidenced by detection of serum HBV DNA, HBV DNA/RNA in isolated hepatocytes, anti-HBV humoral and cellular immunity, and HBcAg expression in the liver.
Conclusions: We have built a physiologically relevant HBV infection model using rhesus macaques. Given the long history of HIV research in this species, our new data portend the future use of rhesus macaques in HIV/HBV co-infection research.

Presenting author email: mbangiwat@gmail.com

Background: Mother to child transmission (MTCT) of hepatitis B virus (HBV) is a major health problem, as infections acquired in early childhood are more likely to lead to chronic infections. High rates of HBV MTCT have been reported in HBV surface antigen (HBsAg) and HBV e antigen (HBeAg) positive mothers despite universal HBV vaccination of infants. Higher rates of HBV transmission (8-12%) have also been reported among infants born to mothers with high HBV viral loads. We determined the prevalence of HBsAg and of HBeAg, and compared HBV viral loads, in HIV-negative and -positive pregnant women in Botswana.
Methods: We enrolled and followed 443 HIV-infected and 451 HIV-uninfected mothers in a prospective observational study in Botswana (Tshipidy cohort). A total of 752 maternal plasma samples collected at delivery from this cohort were available for screening for HBV infection using Murex HBsAg ELISA. HBsAg-positive samples were screened for HBeAg using the Monolisa™ HBe Ag-Ab PLUS ELISA, and HBV viral loads were determined using the COBAS® AmpliPrep COBAS® Taqman®. HBV genotyping was conducted by amplifying a 410bp fragment of HBsAg which was sequenced using Big-Dye sequencing chemistry. Sequences were edited and compared to reference sequences to determine the HBV genotypes.
Results: Of the 752 pregnant women, 368 were HIV-negative and 384 were HIV-positive. Overall, 16 (2.1%; 95%CI 1.08 - 3.12%) were HBsAg-positive. Among HIV-positive women, 12 were HBsAg-positive (3.1%; 95%CI 1.37 - 4.83%) and in HIV-negative women, 4 were HBsAg-positive (1.1%; 95% CI 0.03 - 2.17%) p=0.04. Of the 16 HBsAg-positive samples, 13 were tested for HBeAg and 3 were positive and were all from HIV-negative women. HBV viral loads were higher among HIV-negative women than HIV-positive women, (452 IU/mL [Q1,Q3: 166, 2250] vs >1.7 x 10^8 IU/mL, p= 0.02). Of the 8 samples successfully genotyped, 6 were genotype D and 2 were genotype A.
Conclusions: HBV seroprevalence was higher among HIV-positive pregnant women compared to HIV-negative pregnant women. However, HIV-negative HBV positive pregnant women were all seropositive for HBeAg and had higher HBV viral loads than HIV-positive women. The impact of higher HBV viral loads and HBeAg seropositivity among HIV-negative women warrants further investigation.

Presenting author email: phearavin@gmail.com

Background: The knowledge of hepatitis C virus (HCV) burden in Cambodia is essential for evidence informed policy development and for the mobilization of resources, including improving access to HCV cure with direct acting antivirals. The objectives of this study were to assess the prevalence and genetic diversity of HCV and to identify associated risk factors with hepatitis C mono-infection or with HCV/HIV co-infection.
Methods: Between March and April 2016, we conducted a cross-sectional survey on HCV in four geographical areas in Cambodia: Phnom Penh, Battambang, Siem Reap and Preah Sihanouk province. Subjects were randomly selected among HIV-uninfected pregnant women attending public antenatal care clinics and among HIV-infected subjects who were followed-up in the national HIV program. HCV Ab testing was done with the HCV Bio-Rad enzyme-linked immunosorbent assay (ELISA). All HCV Ab-positive subjects were tested for HCV RNA viral load (VL) with the Omunis PUMA HCV kit. HCV genotyping was performed in the NS5B region.
Results: A total of 935 participants were enrolled, including 510 (54.6%) pregnant women and 425 (45.4%) HIV-infected individuals, with median age of 27 years (IQR, 24-31) and 42 years (IQR, 37-49), respectively. Overall, HCV Ab prevalence was 3.6% (34/935) and significantly higher in HIV-infected individuals, compared to pregnant women (6.8% vs 0.9%) (p< 0.001). Of the 34 anti-HCV-positive individuals, 24 (70.6%) showed detectable HCV RNA VL results, leading to an overall prevalence of active HCV infection of 2.6%. Active HCV infection rate was higher in HIV-infected subjects than in pregnant women (23/425, 5.4% vs 1/510, 0.2%) (p< 0.001). HCV RNA median was 6.29 $\log_{10}$ IU/mL (range, 2.47-7.08). Predominant HCV genotypes were 1b (55%), 6 (40%), and 2 (5%). In multivariate analysis after adjustment on HIV status and provinces, HCV infection was significantly associated with older age (OR:4.54, 95%CI: 1.62-12.72, p=0.004), having a family member positive for HCV (OR:3.49, 95%CI: 1.47-8.25, p=0.004), reporting a history of testing for hepatitis infection (OR:2.53, 95%CI: 1.14-5.58, p=0.021), and having received intravenous medication in the last past 5 years (OR:8.26, 95%CI: 1.10-61.99, p=0.040).
Conclusions: In Cambodia, active HCV infection is common among HIV-infected subjects, and is associated with history of intravenous medication.

Presenting author email: ngomuakeem@yahoo.fr

Background: Up to 50% of individuals with HIV-associated cryptococcal meningitis (CM) experience paradoxical clinical deterioration, known as cryptococcosis-associated immune reconstitution inflammatory syndrome (C-IRIS), weeks after initiation of combination antiretroviral therapy (cART). The immunological mechanisms underlying C-IRIS are incompletely understood and no reliable biomarkers to predict C-IRIS exist.
We investigated whether C-IRIS could be predicted by plasma or cerebrospinal fluid (CSF) levels of cytokines and, for those that did, we examined aspects of related T cell function.
Methods: CM individuals that experienced C-IRIS upon cART initiation (n=27) were compared to CD4 T-cell count-matched patients without C-IRIS in a 1:1 ratio. Plasma and CSF cytokine levels were quantified using a high-sensitivity Luminex kit. IL-7 receptor (CD127) expression on various T cell subsets was measured by flow cytometry. All parameters were measured from samples obtained at baseline following antifungal therapy and immediately prior to cART initiation; and at the time of the C-IRIS event post-cART initiation for the C-IRIS group.
Results: Of 17 cytokines analyzed, plasma levels of IL-7 and IL-5 pre-cART were higher in C-IRIS patients compared to controls after Bonferroni correction (both p< 0.001). In a multivariate Cox proportional hazard-regression analysis, high IL-7 (HR=9.30 [95% CI, 1.96-44.0]; p=0.005) and IL-5 (HR=5.76 [95% CI, 0.77-43.0]; p=0.088) were predictive of C-IRIS. Median cytokine levels were up to 100-fold higher in CSF compared to plasma except for IL-7, but no differences were noted between those with and without C-IRIS. Pre-cART, we observed lower percentages of $CD127^+CD27^+$ $CD8^+$ T cells in C-IRIS patients (median=3.32%, [IQR] 1.87-4.42%) compared to non-C-IRIS (5.88% [2.57-7.89%) (p=0.053) (Mann-Whitney); but no differences in the $CD4^+$ T cell compartment. At the time of the C-IRIS event, there was a significant increase in both $CD127^+CD27^+$ $CD8^+$ and $CD4^+$ T cells compared to baseline (both p<0.05, Wilcoxon signed ranks).
Conclusions: High plasma IL-7 levels and decreased percentage of IL-7 receptor expressing memory $CD8^+$ T cells in patients who develop C-IRIS suggests that dysfunction in the IL-7/IL-7-receptor signaling pathway is associated with the immunopathogenesis of C-IRIS. Further studies to investigate the specific involvement of this pathway in the pathogenesis of C-IRIS are warranted.

Background: Minor resistant variants of HIV-1 could influence the virological response to treatments using non-nucleoside reverse transcriptase inhibitors but data on minor rilpivirine-resistant variants are scarce. Next-generation sequencing (NGS) can detect and quantified minor variants (less than 20% of a virus quasispecies).
The objective of the study was to identify patients harbouring minority variants that have rilpivirine-resistance mutations and to assess the impact of this resistance on the virological response.
Methods: The 541 HIV-1-infected patients studied were from 24 French virology laboratories (members of the ANRS HIV-1 resistance group). They started their first line regimen (rilpivirine, tenofovir and emtricitabine) between 2012 and 2015. NGS was performed retrospectively on the GS FLX platform (Roche) using the XL+ kit to obtain long reads (724 base pairs) of the reverse transcriptase gene. The sensitivity threshold for detecting minor variants was < 1%.
Results: The median patient age was 36 years and 79% were men. The mean virus load at treatment initiation was 4.5 log copies/mL and the mean CD4 cell count was 494 cells/mm^3. Virological success was achieved in 90.6% of patients after a median follow up of 24 months. Virological failure occurred in 16 patients (3.3%) while 30 patients were lost to follow-up. Baseline NGS found resistance-associated mutations (IAS list) that accounted for 1-5% of variants in 17.2% of samples, for 5-20% in 5.7% of samples, and for >20% in 29% of samples. We identified 35 patients who harbored rilpivirine-resistant variants (7%) before treatment initiation. Also, 15 samples contained variants resistant to tenofovir and/or emtricitabine. Thus, the regimens of 12% of patients contained fewer than 3 active drugs according to the ANRS algorithm (threshold: 1%). The frequencies of variants resistant to rilpivirine in patients whose antiretroviral treatment failed (6.2%) and in patients with virological success (7%) were similar.
Conclusions: NGS identified rilpivirine-resistant variants in 7% of patients with a 1% sensitivity threshold. We found that minor resistant variants had no impact on the virological response of our 541 treatment-naive patients to a rilpivirine-based regimen.

Primary HIV-1 drug resistance by massive parallel sequencing among treatment naïve HIV-infected blood donors

R. Pessôa[1], S.S. Sanabani[2]

Presenting author email: rodrigo_pessoa1@hotmail.com

Background: Drug resistance mutations (DRMs) in human immunodeficiency virus (HIV) is one of the main reasons for treatment failure. Sanger sequencing is currently the routinely used assay to perform genotyping analysis of therapy resistant variants in HIV-1 protease (PR) and reverse transcriptase (RT). However, this assay has the capacity to detect only mutant variants present at levels above 20% in the viral quasispecies. This drawback was tackled by the introduction of the massive parallel sequencing (MPS) approach, which allows generation of thousands of sequences from the viral population. Here, we used both the Sanger and massive parallel sequencing data to simultaneously detect DRM associated with the inhibitors of the PR, nucleoside reverse transcriptase (NTRI) and non-nucleoside reverse transcriptase (NNTRI) in plasma specimens of 18 drug naïve blood donors.
Methods: The viral nucleic acid were extracted, amplified and successfully sequenced by Illumina paired-end protocol. The conventional Sanger data of the HIV-1 PR and RT nucleotide sequences of the same samples were obtained from the database.
Results: Analysis of DRMs of the 18 plasma samples demonstrated that 4 Sanger and 18 MiSeq samples possessed one or more major resistance mutations based on the list of 2015 IAS-USA. The sensitivity and specificity of the MPS was 100% in detecting DRMs identified by Sanger sequencing. NRTI resistance mutations were only detected in all 18 (100%) samples sequenced by MPS. On the other hand, NNRTI resistance mutations were observed in 4 samples (22.2%) and 17 samples (94.4%) sequenced by Sanger and MPS, respectively. The F77L and M230I were the most common NTRI and NNTRI resistance mutations detected in 88.9% and 77.8% of samples sequenced by MPS, respectively. Minority variants with major DRMs to a lower limit of 1% were detected by MPS in all subjects. No variants with major DRMs were identified in the PR gene either by Sanger or MPS assays.
Conclusions: The majority of HIV variants with DRMs that became undetectable by Sanger sequencing were detected by MPS. The significance of these variants and how they will influence the future therapeutic decisions remains to be determined.

Presenting author email: shaow@mail.nih.gov

Background: Next generation sequencing technologies are widely used to study the genetics of HIV-1 populations. Although software is available for processing large scale sequence data, no pipelines include an automated analysis of HIV-1 drug resistance mutations. Therefore, we developed a pipeline that constructs high quality consensus sequences from reads with identical primer IDs as reported previously (Jabara CB, et. al. PNAS, 108: 20166) and reports drug resistance mutation profiles for each consensus by interacting with the Stanford HIV database (https://hivdb.stanford.edu/hivdb/by-sequences/).
Methods: We developed a pipeline that, after binning sequence reads generated by paired-end Illumina Miseq technology according to their common primer IDs, applies a super-majority rule which requires ≥80% agreement at each nucleotide position in order to detect and eliminate PCR-based errors. Consensus sequences are subsequently generated from each group of primer IDs and are automatically processed in the Stanford HIV database. The pipeline is written in Perl.
Results: Our new bioinformatics pipeline produces high quality consensus sequences that have error rates equivalent to the gold-standard single-genome sequencing assay and generates an automated excel spreadsheet that reports each HIV-1 genome that contains drug-resistant mutations. The final report produced from the pipeline includes the frequencies of each HIV-1 drug resistance mutation in the total dataset, the frequencies of linked drug resistance mutations, and the characterization of the genetic backbones on which linked mutations occur.
Conclusions: Our new pipeline allows for the rapid profiling of drug resistance mutations in targeted, HIV-1 next-generation sequencing datasets and is a reliable and easy tool for highly sensitive HIV-1 genotyping.

Presenting author email: barbaraweiser2@gmail.com

Background: Emergence of CXCR4(X4)-tropic HIV-1 strains in infected individuals often heralds CD4 cell depletion and accelerated disease progression, as demonstrated during the pre-HAART and early HAART eras. To investigate whether long-term ART mitigates the deleterious effect of X4 strains, we examined the relationship of HIV-1 tropism to CD4 count and mortality due to AIDS in 529 women followed for 18 years in the Women's Interagency HIV Study (WIHS).
Methods: Participants in the Bronx and Brooklyn WIHS sites were interviewed, examined, and had lab studies performed semiannually (1994-2012). We determined tropism of plasma-derived HIV-1 at 1-3 visits per subject using a heteroduplex tracking assay.
Results: X4 strains were detected, either exclusively or in a mixture with R5 strains, in 39% of participants. We compared CD4 counts over time in subjects with X4's to those with CCR5(R5) strains only, controlling for HIV-1 load. Although CD4 counts rose in both groups, the X4 group displayed significantly diminished counts throughout the entire follow-up period compared to those with R5 strains only (P=0.026).
To examine mortality in relation to tropism, we categorized subjects according to reported visits on HAART after initiation: 1) ≤3 visits on HAART, 74% of whom reported no HAART; 2) < 70% of visits on HAART; 3) >70% of visits on HAART; 4) Viral suppression for ≥3 years on HAART.
Analyses controlled for CD4 count and viral load. AIDS mortality rates in each category for subjects with X4 strains vs those with R5 strains only, respectively, were as follows: Group 1) 63% vs 18% (P< 0.0001); Group 2) 23% vs 21% (NS); Group 3) 6% vs 12% (NS); Group 4) 0 vs 2.5% (NS). Logistic Regression revealed that complete HIV-1 suppression for 10 visits, or 25% of visits after initiation of HAART (for those with fewer than 10 visits), was sufficient to mitigate the deleterious effect of X4 strains on mortality.
Conclusions: In a women's cohort studied for 18 years, long-term HAART mitigated the potency of X4 strains on AIDS mortality. The reduction in mortality, however, was correlated with duration of HAART and viral suppression, supporting HIV-1 suppression as a crucial treatment goal.

Presenting author email: giulia.marchetti@unimi.it

Background: HIV infection is associated with dyslipidemia marked by low levels of high-density lipoprotein (HDL), low-density lipoprotein, total cholesterol and increase of triglycerides. To maximise lipid rafts and virus budding, HIV Nef protein downregulates ATP cassette binding transporter A1 (ABCA1), reducing cholesterol efflux from macrophages and the generation of nascent HDL.. To analyse the correlation between HDLs level, HIV viremia and CD4/CD8 ratio in a group of ART-naive HIV-positive patients and to evaluate its role in HIV replication and disease progression.
Methods: We included ART-naïve HIV-infected people in the ICONA Foundation cohort. We considered persons for whom ≥2 viral load (VL) measurements prior to ART initiation were available. The viral set point (VLset) was defined as the mean of the first two VL and the date of the 2nd value chosen as the index date for this cross-sectional analysis. We then included people without statin therapy and with a value of HDL over 3 months of the index date. We performed correlation unadjusted and gender/age, HCV status, BMI and AIDS diagnosis adjusted linear regression analyses. VLset and CD4/CD8 ratio were fitted in the $\log_{10}$ scale, HDL distribution in the raw scale.
Results: We included 2,596 individuals; median age was 36 (range: 18-81). Thirty-nine (1.5%) were aviremic (VLset ≤50 copies/mL), 20% female, 12% PWID and 48% MSM. We observed a negative correlation between HDL and VLset (R^2=0.03, from fitting a linear regression model -3.2 mg/dl per $\log_{10}$ higher VL, p<0.0001), and a positive correlation between HDL and CD4/CD8 ratio (R^2=0.02, +8.9 mg/dl per $\log_{10}$ higher ratio, p<0.0001). There was a dose-response relationship between HDL levels and VLset strata independent of age, gender and CD4/CD8 ratio which was no longer significant after controlling for other factors such as HCV status and BMI. In contrast, greater values of CD4/CD8 ratio were independently associated with higher HDL levels.
Conclusions: Our data show that HDL level is associated with VLset (negative correlation) and CD4/CD8 ratio (positive correlation), suggesting that the change in lipid metabolism caused by HIV is an important step in its life cycle and should confirm the close relationship between HIV infection and CVD.

Association between inflammatory/coagulation biomarkers and mortality in HIV-infected adults with high CD4 counts in Côte d'Ivoire, West Africa (TEMPRANO ANRS 12136)

R. Affi[1], D. Gabillard[2], R. Moh[3], J.-B. Ntakpe[4], A. Badje[4], G.M. Kouame[4], C. Danel[2], H. Ahibo[1], A. Inwolley[1], J. Sibli[1], S.P. Eholie[3], X. Anglaret[2], L. Weiss[5], Temprano ANRS 12136 Study Group
[1]CHU de Treichville, CeDReS, Abidjan, Cote D'Ivoire, [2]University of Bordeaux, Inserm 1219, Bordeaux, France, [3]Université Felix Houphouet Boigny, Departement de Dermatologie et Maladies Infectieuses, Abidjan, Cote D'Ivoire, [4]PACCI/site ANRS de Côte d'Ivoire, Abidjan, Cote D'Ivoire, [5]AP/HP, Hôpital Européen Georges Pompidou, Université Paris-Descartes, Sorbonne Paris Cité, and Institut Pasteur, Unité Cytokines & Inflammation, Paris, France
Presenting author email: miyossai@yahoo.fr

Background: Several inflammatory and coagulation biomarkers have been previously associated with clinical outcomes in untreated or treated HIV-infected patients in high-income countries. We analyzed the association between ten biomarkers and mortality in HIV-infected adults who participated in a trial of early antiretroviral therapy (ART) and 6-month IPT in Côte d'Ivoire, West Africa.
Methods: In the Temprano trial (ANRS 12136), HIV-infected adults were randomly assigned to immediate ART or deferred ART. The trial follow-up (TFU) was 30 months. Participants who completed the TFU were invited to participate in a post-trial phase (PTP). The PTP endpoint was all-cause death. Serum/plasma samples were collected and frozen at baseline. We used these samples to measure IL-6, IL-1RA, sVCAM-1, sCD14, sCD163, IP-10, D-dimer, hsCRP, fibrinogen, and albumin in patients assigned to deferred-ART. We used Cox proportional models to analyse the association between all-cause mortality and each marker from inclusion in Temprano (March 2008) to the end of the PTP phase (January 2015). Markers significantly associated with death in univariate analysis were included in a step-by-step ascending multivariate analysis. Analyses were adjusted for sex, HIV-RNA, total HIV-DNA, CD4 count, and IPT. Marker concentrations were treated as categorical (< vs. ≥ 3rd quartile).
Results: 1,023 patients (77% women, mean baseline CD4 count 459/mm^3) were randomized to deferred ART and followed for 4,657 patient-years (median 4.8, IQR 3.3-5.8 years). A total of 49 deaths were observed. In univariate analysis, the hazard ratio of death was 2.16 (95%CI 1.21-3.85) for IL-6, 1.09 (0.56-2.15) for IL-1RA, 2.83 (1.58-5.05) for sVCAM-1, 3.96 (2.16-7.27) for sCD14, 2.02 (1.13-3.60) for sCD163, 2.70 (1.49-4.87) for IP-10, 1.84 (1.01-3.34) for D-dimer, 1.50 (0.79-2.83) for hsCRP, 1.15 (0.62-2.14) for fibrinogen, and 0.74 (0.33-1.66) for albumin. In multivariate analysis, sVCAM-1 and sCD14 remained independently associated with mortality (adjusted HR [aHR] sVCAM-1=2.07 [95%CI 1.06-4.03, p=0.03]; aHR sCD14=3.26 [95%CI 1.74-6.13, p< 0.001]).
Conclusions: In these West African adults with high CD4 counts, sVCAM-1, an endothelial activation marker, and sCD14, a marker of monocyte activation, were independent predictors of all-cause mortality. While the latter association was previously reported, to our knowledge this is the first report of the association between sVCAM-1 and mortality.

[1]University of Bordeaux, Inserm 1219, Bordeaux, France, [2]PACCI/site ANRS de Côte d'Ivoire, Abidjan, Cote D'Ivoire, [3]Université Felix Houphouet Boigny, Departement de Dermatologie et Maladies Infectieuses, Abidjan, Cote D'Ivoire, [4]CHU de Treichville, CeDReS, Abidjan, Cote D'Ivoire, [5]CHU Necker, Virology, Université Paris Descartes, Paris, France
Presenting author email: rmoh73@gmail.com

Background: In sub-Saharan Africa, high HIV-1-DNA levels in PBMCs have been previously associated with a higher risk of severe morbidity and a faster decline in CD4 count. Here we report the association between HIV-1-DNA and mortality in HIV-infected adults who participated in a trial of early antiretroviral therapy (ART) in West Africa.
Methods: In the Temprano ANRS 12136 trial, untreated HIV-infected adults with < 800/mm^3 and no WHO criteria for starting ART were randomly assigned to start ART immediately or defer ART until WHO criteria were met. The trial follow-up (TFU) was 30 months. Participants who completed the TFU were invited to participate in a post-trial phase (PTP). The PTP endpoint was all-cause death. PBMCs were frozen at -80°C at baseline. HIV-1-DNA in PBMCs was measured using a real time PCR method (Biocentric, Bandol, France). We used a multivariate Cox proportional model to analyse the association between all-cause mortality, PBMC HIV-1-DNA (≥3 vs. < 3 $\log_{10}$copies/million PBMCs) and plasma HIV-1-RNA (≥5 vs. < 5 $\log_{10}$copies/ml) from inclusion in Temprano (March 2008) to the end of the PTP phase (January 2015) in patients assigned to deferred-ART. The multivariate analysis included baseline HIV-1-RNA, baseline HIV-1-DNA, sex, baseline CD4 count, time-updated ART status, and isoniazid preventive therapy status (received/not received).
Results: 1,023 patients (77% women) were randomized to deferred ART and followed for 4,657 patient-years (median 4.8 years, IQR 3.3-5.8). At baseline, median CD4 count was 459/mm^3 [IQR 362-567], median plasma HIV-1-RNA 4.6 $\log_{10}$copies/ml [IQR 4.0-5.2], and median HIV-1-DNA 3.0 $\log_{10}$ copies/million PBMCs [IQR 2.5-3.3]. During follow-up, 49 participants died. In univariate analysis, the hazard ratio [HR] of death was 2.97 (95%CI, 1.58-5.60) for patients with HIV-1-DNA ≥3 $\log_{10}$ copies/million PBMCs vs. others, and 2.08 (95%CI, 1.19-3.64) for patients with HIV-1-RNA ≥5 log10copies/ml vs. others. In multivariate analysis, PBMC HIV-1-DNA ≥3 remained strongly associated with the risk of mortality (adjusted HR=2.55, 95%CI 1.26-5.15, p=0.009) while the association between plasma HIV-1-RNA and mortality was not significant (adjusted HR=1.37, 95%CI 0.74-2.54, p=0.32).
Conclusions: In these sub-Saharan African adults with high CD4 counts, HIV-1-DNA level ≥ 3 $\log_{10}$ copies/million PBMCs was a strong independent predictor of death.

Background: Guidelines regarding ART initiation in HIV infection have varied over time, with 2015 recommendation by the World Health Organization to initiate ART at the time of diagnosis regardless of CD4 T cell counts.
Herein, we investigated the influence of sociodemographic and clinical factors in addition to time trends on early ART initiation among participants of the Montreal Primary HIV Infection Study.
Methods: The Montreal Primary HIV Infection Study is a prospective cohort established in three community medical centres and two university medical centres. Recently diagnosed HIV-infected adults were categorized as receiving early (vs. delayed) ART if ART was begun within 180 days of the baseline visit. Associations between early ART initiation and sociodemographic, socioeconomic and behavioral information were examined. Independent associations of factors linked with early ART initiation were determined using multivariate binary logistic regression analysis.
Results: A total of 348 participants had a documented date of HIV acquisition of <180 days. The median (IQR) age of participants was 35 (28; 42) years and the majority were male (96%), having paid employment (63%), men who have sex with men (MSM) (78%) and 1-4 sexual partners in the last three months (70%). Participants presented with a median (IQR) HIV plasma viral load of 4.6 (3.7; 5.3) $\log_{10}$ copies/mL, CD4 count of 510 (387; 660) cells/µL and were recruited in community medical centres (52%) or university medical centres (48%). Early ART initiation was observed in 47% of the participants and the trend followed a V-shaped curve with peaks in 1996-97 (89%) and 2013-15 (88%) with a dip in 2007-09 (22%). Multivariate analyses showed that having paid employment (aOR: 2.43; 95% CI: 1.19, 4.95), lower CD4 count (aOR per 50 cell increase: 0.93; 95% CI: 0.87, 0.99) and care at university medical centres (aOR: 2.03; 95% CI: 1.06-3.90) were independently associated with early ART initiation.
Conclusions: Early ART initiation during primary HIV infection was associated with poorer biologic prognostic factors and calendar time mirroring evolution of treatment guidelines. In addition, despite universal access to care in Canada, sociodemographic factors such as no employment may be a barrier in accessing early ART.

Background: French guidelines recommend universal treatment of HIV infection, since primary infection (PHI) and regardless of CD4 cell count. However many patients are still diagnosed during chronic infection. To determine the consequences of delayed diagnosis, we compared long-term immunovirological and inflammatory outcomes according to whether patients were treated since PHI (immediate ART - iART, N=77) or not (differed ART - dART, >12 months after PHI, N=73).
Methods: We selected patients from the ANRS French PRIMO Cohort treated for >3 years, with a sustained HIV-RNA <50cp/mL and available frozen samples. CD4 and CD8 cell counts and plasma HIV-RNA were measured locally; total cellular HIV-DNA, plasma usHIV-RNA and inflammation markers (IL-6, IL-1α, TNFα, MCP-1, IP-10, sCD14, sCD163, IL-10, LAP and iFABP; FlowCytoMix or ELISA assay) were measured centrally. We compared between iART and dART patients inflammation markers levels at PHI, before ART initiation, at 36 months of ART and at the last follow-up visit on ART. We modelled CD4 count, CD4/CD8 ratio and HIV-DNA dynamics with mixed models.
Results: Patients were mostly Caucasian men (79%), median age 37 years. ART was initiated within a median time of 1 and 29 months after PHI in the iART and dART groups, respectively, mostly with protease inhibitor-containing regimen (82%). At PHI, median CD4 and HIV-RNA levels were 414 cells/mm3 and 5.5 log10cp/mL in the iART group and 539 and 4.6 in the dART group. In both groups, IP-10, MCP-1, sCD163, IL-6 levels decreased on ART while TNFα and sCD14 levels remained stable. IL-1α levels remained higher in the dART vs. iART group at 36 months of ART. At the last follow-up visit on ART (iART: 91.0 months, dART: 73.5 months), no difference in inflammation markers and usHIV-RNA levels were observed between groups. Modelling showed a sustained lower HIV-DNA level in the iART vs. dART group (between -0.3 and -0.6 log10cp/106PBMC). On the other hand, the benefit in CD4 and CD4:CD8 ratio observed with iART gradually diminished overtime and no longer differed after 45 months on ART between the groups.
Conclusions: These results strongly argue for an immediate ART initiation during PHI, to optimize long-term viral reservoir level.

MOPEB0245

Prevalence of non-B subtypes and trends in transmission of primary drug resistance in patients with primary HIV-1 infection during the last 10 years (2005-2015) in Marseille university hospitals, Southeastern France

C. Tamalet[1], T. Dieng[2], I. Poizot-Martin[3], H. Tissot-Dupont[4], H. Chaudet[2], I. Ravaux[5], P. Colson[1]
[1]IHU Méditerranée Infection, Virology, Marseille, France, [2]IHU Méditerranée Infection, Statistics, Marseille, France, [3]University Hospital Ste Marguerite, Haematology and Clinical Immunology, Marseille, France, [4]IHU Méditerranée Infection, Infectious Diseases Clinics, Marseille, France, [5]IHU Méditerranée Infection, Maladies Infectieuses, Marseille, France
Presenting author email: isabelle.ravaux@ap-hm.fr

Background: Transmitted HIV-1 drug resistance (TDR) remains a public health problem and requires a sentinel national surveillance at the country-scale. In addition, non-B HIV-1 subtypes are increasing in developed countries. We assessed the prevalence of transmitted drug resistance (TDR) and the frequency of non-B subtypes in patients with acute HIV-1 infection in Marseille university hospitals, Southeastern France, during the period 2005-2015
Methods: Between 2005 and 2015 (10 years), all patients with a genotypic test performed at the time of primary HIV-1 infection (PHI) in Marseille University hospitals were enrolled. HIV-resistance-associated mutations (RAMs) to reverse transcriptase and protease inhibitors were characterized using both the 2009 WHO list of mutations and the French ANRS Algorithm V.26. Subtypes were determined by phylogenetic analysis of the reverse transcriptase gene.
Results: 115 patients diagnosed with PHI were analyzed. According to the ANRS algorithm v.26, the prevalence of protease, nucleoside/nucleotide reverse transcriptase, 1st generation nonnucleoside reverse transcriptase inhibitor and ETV/RPV-associated RAMs were 27%, 5.2%, 7.8% and 5.2%, respectively. Among resistant viruses the proportion of those resistant to 2-3 classes was 15.3%. Men having sex with men (MSM) were more frequently infected with resistant viruses than were other transmission groups (26% vs 7%, p=0.011). RAMs frequency did not differ in patients infected with B compared with non-B subtypes. Non-B subtypes were identified in 31% of patients. Non-B strains were diverse and included 4 subtypes (3 A; 1 C; 5 F; 1 J; and 4 circulating recombinant forms (CRFs) including 23 CRF_AG; 1 CRF06_cpx; 1 CRF30; 1 D/K). The proportion of non-B subtypes increased significantly over time in particular during the 2011-2013 period vs the 2005-2011 period (p= 0.03, Kendall's rank correlation tau). Of note, CRF02_AG largely predominated in the 2005-2013 period, whereas rare recombinant D/K, CRF06-cpx and CRF30_0206 emerged only recently (2014-2015).
Conclusions: These data highlight two tendencies in southeastern France: (1) the spread of resistant HIV strains among MSM; (2) the recent increase of rare CRF/cpx of HIV. This should be taken into account when implementing suitable prevention strategies particularly in MSM and in starting combined antiretroviral therapy in this setting.

Presenting author email: ccicala@niaid.nih.gov

Background: The α4β7 integrin is one of the major gut-homing receptors involved in the migration of a variety of lymphocytes, including CD4+ T cells, into the gut associated lymphoid tissue (GALT). α4β7 expressing lymphocytes are involved in the pathogenesis of a number of human diseases that involve GALT, including graft-versus-host disease, and inflammatory bowel diseases such as Crohn's disease and ulcerative colitis. More recently, a role for α4β7-expressing cells has been described in the non-human primate (NHP) model of SIV infection in which, during the early stages of disease, the GALT is a major target of infection. Of note, in a NHP model, SIV-infected macaques, when treated with a combination of antiretroviral therapy (ART) and an anti-α4β7 mAb, were able to maintain low to undetectable viral loads and normal CD4+ T-cell counts in plasma and gastro-intestinal tissues for over 2 years, even after all treatments were withdrawn.
Methods: We compared $\alpha_4\beta_7$ integrin levels on $CD4^+$ T cells in blood of study participants who remained HIV uninfected versus those that acquired HIV infection in the CAPRISA 004 tenofovir vaginal gel study conducted in South Africa.
Results: We found that increased frequencies of α4β7 CD4+ T cells in blood are associated with an increased likelihood of acquiring infection and a more rapid disease course following infection. We also find that at the earliest stages of HIV infection, CD4+ T cells expressing α4β7 are rapidly depleted, particularly from the gut, and are not restored by early initiation of ART.
Conclusions: This is the first study to link pre-HIV α4β7 expression with HIV susceptibility and clinical outcomes in humans. These results further substantiate the central role of α4β7 in HIV transmission and pathogenesis.

Long-term non-progressors and factors associated to immunological progression among HIV-2-infected individual in West Africa

B.K. Tchounga[1,2], D.K. Ekouévi[1,2,3], The IeDEA West Africa Study Group
[1]University of Bordeaux, ISPED, Centre INSERM U1219, Bordeaux, France, [2]PACCI Research Center / ANRS Research Unit in Côte d'Ivoire, HIV-2 Infection, Abidjan, Cote D'Ivoire, [3]Université de Lomé, Département des Sciences Fondamentales et Santé Publique, Lomé, Togo
Presenting author email: boris.tchounga@yahoo.fr

Background: The low pathogenicity of HIV-2 infection leads to consider the majority of these patients as long term non progressors (LTNP) which are therefore out of the scope of therapeutic guidelines. Despite the long asymptomatic phase of the infection, all HIV-2 infected patients may progress to AIDS and to death in ab-

sence of holistic care. There is limited data on the prevalence of LTNP and the time to immunologic progression among people living with HIV-2 in West Africa. This study aimed at estimating the prevalence of LTNP among HIV-2 infected patients followed in the HIV-2 cohort of the IeDEA West Africa collaboration (WADA-HIV-2).
Methods: A cross-sectional survey was conducted from February to December 2014 in Burkina Faso and Côte d'Ivoire, within the WADA-HIV-2 cohort. All HIV-2-infected patients, aged 18 years and above, attending the HIV clinic for a follow-up visit were invited to participate. A dedicated questionnaire was used to collect clinical and biological characteristics of patients. We defined LTNP in this study as ART-naïve patients with CD4 count >500 cells/mm^3 at HIV diagnosis and who maintained high CD4 count (>500 cells/mm^3) during at least five years. We defined progression as the fact of having at least one measure of CD4 count < 500 cells/mm^3. We performed survival analysis to estimate the probability of staying LTNP over the time.
Results: Among the 631 patients who participated in the study, the median age was 49 (IQR [42-55]) years, 381 (60.6%) were women, 470 (77.9%) were receiving ART and 18 were identified as LTNP. The prevalence of LTNP was estimated to 2.8% (95%CI [1.6-4.2]). All LTNP had undectable plasma HIV-2 viral load at the time of screening, 6 (33.3%) of them had CD4 count >750 cells/mm^3. Initial CD4 count >750 cells/mm^3 was the only factor associated with long term non progression among HIV-2 patients (aOR=5.8; 95%CI [3.2-10.8]; p=0.003). The probability of staying LTNP was declining over the time, 20% after 5 years to 10% after 10 years.
Conclusions: The low proportion of HIV-2 long term non progressors sheet light on the necessity to revisit the therapeutic guidelines, specifically toward universal treatment.

Gender differences, impact of violence exposure on drug use, and HIV risk behaviors among young adult African Americans in Washington DC

F. Saadatmand[1], R. Harrison[2], J. Bronson[3], D. Crouse[3]
[1]Howard University, Pediatrics, Washington, United States, [2]2M Research sevices, Washington, United States, [3]Howard University, Washington, United States
Presenting author email: frough.saadatmand@howard.edu

Background: This presentation provides baseline preliminary analysis of data collected in a longitudinal study from 440 African Americans young adults ages 18-25 living in Washington. One component of the study is designed to test the effects of social and environmental stressors, such as exposure to violence, on alcohol, tobacco and other drug (ATOD) use, and on sexual risk behaviors that may render African American young adults more vulnerable to contracting HIV/AIDS. The objective here is to understand how exposure to violence impacts ATOD use and HIV risk behaviors, and to determine if the strengths of the associations vary based on violence type and gender.
Methods: We conducted a factor analysis of the exposure to violence scale items to identify domains or types of violence. We then conducted a series of regression analyses to measure how various violence types affect the dependent variables representing ATOD use, and knowledge and perception of HIV risk factors.
Results: Women and men differed in the types of violence to which they were likely to have been exposed. Women were significantly more likely to have been exposed to personal violence and attacks, which explained 65.8 percent of the total variance explained in the model for behaviors that obviate a need to worry about HIV. Exposure to drug sales or physical violence explained 70.1 percent of the total variance explained in women's knowledge of HIV transmission risks. Exposure to gun use or seeing violent deaths explained 76.5 percent of the total variance explained in women's attitudes towards condom practices, and 79.9 percent of the total variance in their perceptions of condom users. Among men, exposure to gun use or seeing violent deaths explained a much smaller 38.2 percent of the total variance explained in attitudes towards condom practices, and exposure to childhood sexual abuse explained 36.5 percent of the total variation explained in worrying about contracting HIV.
Conclusions: The results suggest that a large percentage of young African American adults are exposed to violence, that violence has a strong impact on ATOD use and HIV risks behaviors, and that African American women and men are exposed to different kinds of violence.

MOPEB0249

Social behavioural determinants of early HIV infection in young South African women

L. McCloskey[1], I. Eloff[2]
[1]Indiana University, Applied Health Sciences, Bloomington, United States, [2]University of Pretoria, Educational Psychology, Pretoria, South Africa
Presenting author email: lmcclosk@indiana.edu

Background: New incidents of HIV are high among Black South African women 15 to 24 years. We adopt a lifecourse approach we test whether early adverse life circumstances such as parental HIV, orphanhood, physical and sexual abuse and extreme poverty in childhood predict sexual behaviors (e.g., early sexual debut) which place women at risk for HIV exposure.
Our hypotheses are that (1) childhood history predicts sexual experiences, gender-based violence and partner characteristics; (2) that partner characteristics such as age difference and antisocial behaviour will be associated with HIV infection.
Methods: Findings derive from a 2016 case-control interview study of 869 women outpatients (M age = 23) who reside in informal settlements surrounding Pretoria in Gauteng, South Africa. Women outpatients were recruited in waiting rooms from hospitals and clinics and interviewed for one hour in SeSotho, Setswana, isiXhosa and English. Their HIV status was confirmed through medical records (HIV+=450; HIV-=419). The interview included mainly standardized instruments. Approval was granted from five different ethics review boards. Data entry was completed in December 2016 and SPSS used as the statistical program.
Results: Findings reveal that there is a strong intergenerational risk for HIV, with 65% of HIV+ patients recounting HIV+ relatives in contrast to controls (25%). Parental death from any cause predicted HIV status. Sexual behaviors were inconsistently related to HIV and HIV+ women were no more likely to have multiple sexual partners.
The most significant proximal risk indicator for early onset HIV was a long-term union before the age of 19, typically with a man at least four years older; risk was heightened if he was violent or drank to excess. Departure from secondary school was associated with long-term unions at an early age.
Conclusions: To avert the rise in new incidence among girls in South Africa immediate interventions are needed for teenage girls who recall child abuse or whose mothers are absent or deceased. Furthermore, efforts must be intensified to retain girls in school and discourage early live-in relationships.

Diagnostic and Monitoring

Provider initiated testing and counseling uptake in Wum District hospital (Nord-West Cameroon): a hospital-based cross sectional study

D.G. Reine Charlye[1,2], C. Ditah[3]
[1]Cabinet Medicl Bordeau Douala, Recherche Clinique, Douala, Cameroon, [2]Alternative Action, Douala, Cameroon, [3]MSF, Minnesota, United States
Presenting author email: dombureine@yahoo.fr

Background: An estimated 1.6% of Cameroonian adults are HIV positive, of which 85.6% have never done an HIV test. To achieve the UNAIDS goal of 90-90-90, the Cameroon Ministry of Health mandated that all clients who have never done an HIV test and clients whose last HIV test was negative and dates more than three months should be systematically proposed an HIV test at all medical visits. However, there is no data on the acceptability of this test by the population in Cameroon.
Our main goal was to determine the proportion of patients who finally get to do the HIV test after recommendation and counseling.
Methods: We carried out a cross sectional descriptive study over a three months period in the outpatient consultation clinic of the Wum District hospital. During this time, HIV testing was recommended to clients who had never had an HIV test, or whose prior negative test had been more than three weeks earlier. For those who consented, rapid (Determine) and confirmation (BISPOT) tests were administered and results reported to the prescribing physician. Data were entered into a spreadsheet and analyzed using SPSS.
Results: About 50% of persons consulting at the Wum district hospital still do not know their HIV status. Despite routine recommendation and counseling for testing, only about half of the persons who received counseling did not do the test, figure 1.
Conclusions: Acceptability of testing for HIV despite routine recommendation and counseling is a barrier to achieving the 90-90-90 goals in this setting. We recommend that a large-scale study be carried out to determine the reasons why persons decline getting tested for HIV.

MOPEB0251

Performance of alere HIV combo test in established and acute HIV infection

S. Sirivichayakul[1], T. Pankam[2], S. Pattanachaiwit[2], K. Phancharoen[2], N. Barisri[2], S. Areeyolwattana[2], P. Phanuphak[2]
[1]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [2]Thai Red Cross AIDS Research Centre, Pathumwan, Thailand
Presenting author email: sunee.s@chula.ac.th

Background: Rapid anti-HIV test is highly preferred for busy laboratories and mobile VCT settings. Most of the commercially available rapid tests are 3rd Generation kits. We evaluated the performance of Alere HIV Combo (AlereCOMBO), the newly available 4th Generation anti-HIV test.
Methods: Three sets of an overall 250 stored plasma samples [(1) HIV positive, N = 100 as defined by positive Abbott Architect 4th generation Ag/Ab test (Test 1) and confirmed by both immunochromatography (Determine) (Test 2) and gel particle agglutination (Test 3); (2) HIV negative, N = 100 as screened by Test 1; (3) acute HIV infection, N=50 as defined by positive Test 1 but negative both Test 2 and 3 whereas HIVRNA by Aptima was positive] from the Anonymous Clinic of the Thai Red Cross AIDS Research Centre were used to evaluate AlereCOMBO. Sample/cut-off (S/CO) ratio of the test and the viral load (VL) of each sample were used for analysis.
Results: AlereCOMBO correctly detected all the confirmed positive and negative samples gaining 100% sensitivity and specificity. The overall sensitivity and specificity of the entire 250 samples were 91.3% and 100% respectively. Of particular interest was on the 50 acute HIV infection samples, AlereCOMBO could detect 37/50 (74%): 5 anti-HIV positive only (R1), 26 p24 antigen positive only (R2), and 6 both p24 Ag and anti-HIV positive (R3). S/CO ratios of R1/R2/R3 were 21.55/148.38/72.97 respectively as compared to 7.57 for the non-reactive (NR) acute HIV samples**.** R2 and R3 had significantly higher S/CO than NR or R1 ($p<0.001$).. The corresponding $\log_{10}$ HIVRNA of NR/R1/R2/R3 were 5.55/5.64/6.74/6.30 respectively. HIVRNA in R2 and R3 were significantly higher than NR ($p<0.001$).
Conclusions: AlereCOMBO detected mainly p24 Ag in acute HIV infection as seen in 32/50 (64%) subjects, supported by the highest S/CO in the p24 Ag only group (R2), followed by the Ag+Ab group (R3). For antibody detection, AlereCOMBO could detect 11/50 (22%) more samples than the two 3rd Generation anti-HIV tests used in our testing algorithm, Therefore, AlereCOMBO is a preferred rapid test in a setting with high incidence and is more sensitive than the commonly used 3rd Generation tests.

MOPEB0252

HIV self-test: perception and intention to use in a French nationwide study

P.-E. Devez[1], O. Epaulard[2,3,4]
[1]Université Grenoble Alpes, Pharmacy Faculty, La Tronche, France, [2]Grenoble University Hospital, Infectious Diseases, Grenoble, France, [3]Institut de Biologie Structurale, UMR5075 CEA CNRS UGA, HIV and Other Persistent Viruses, Grenoble, France, [4]Université Grenoble Alpes, Fédération d'Infectiologie Multidisciplinaire de l'Arc Alpin, Grenoble, France
Presenting author email: oepaulard@chu-grenoble.fr

Background: It is considered that 28,000 undiagnosed HIV-infected people live in France. This unawareness should be reduced, as it fuels HIV transmission, and leads to late-stages of HIV infection. Since fall 2015, HIV self-test is available in French pharmacies without prescription. We aimed to explore perceptions toward this new testing tool, and whether people most at risk of HIV infection intent to use it, particularly MSM.
Methods: An anonymous online questionnaire was diffused between November 2015 and January 2016 by different means, targeting the general population and MSM population. The questionnaire explored gender, age, sexual partner gender, self-perceived HIV exposure, the use of condom in case of sexual intercourse with penetration with another partner than the usual partner (if any), the knowledge and perceptions concerning of HIV self-test, and past and planned future use.
Results: 1336 participants filled the questionnaire (male 67.1%, female 32.4%, other 0.5%; age 32.8±12 years), including 889 who completed it. 44.8% were MSM. 33.5% considered they were not exposed to HIV; 41.5% declared they did not always use or make use a condom in case of sexual intercourse with penetration with another partner than their usual partner (if any)(participants "objectively at risk"). 9.9% had already used the self-test, this proportion being higher in multivariate analysis in those with a monthly income above 1000€, and those who declared being very/rather well informed on HIV. 38.5% declared they plan to use the self-test in the forthcoming month or year, this proportion being lower in male and in MSM in multivariate analysis, and higher in those "objectively at risk". 68.4% under-estimated the delay after an HIV exposure to rule out the infection with a self-test (12 weeks). The 3 issues with self-test more frequently cited were that it does not test for other sexually transmitted infection (49.5%), that you have to pay to get tested (44.4%), and that one is alone with his/her result (41.0%).
Conclusions: HIV self-test is identified as an interesting tool by different at-risk populations, and may help reducing the proportion of undiagnosed infections. Communication should insist on the delay for reliability. A much lower price may enhance its use.

MOPEB0253

Non-reactive HIV-1 self-tests after sustained viral suppression following early antiretroviral therapy

K. Stefic[1,2], S. Novelli[3,4], N. Mahjoub[5], R. Seng[3,4], J.-M. Molina[6,7], C. Cheneau[8], F. Barin[1,2], M.-L. Chaix[5,6], L. Meyer[3,4], C. Delaugerre[5,6]
[1]Université Francois Rabelais, INSERM U966 MAVIVH, Tours, France, [2]University Hospital Center, Department of Virology, Tours, France, [3]University Paris-Sud, INSERM, U1018, Epidemiology of HIV and STI, CESP, Le Kremlin Bicêtre, France, [4]Bicêtre Hospital, AP-HP, Department of Public Health and Epidemiology, Le Kremlin Bicêtre, France, [5]Saint-Louis Hospital, AP HP, Department of Virology, Paris, France, [6]INSERM U941, Paris, France, [7]Saint-Louis Hospital, Department of Infectious Diseases, Paris, France, [8]Strasbourg University Hospital Center, HIV-infection Care Center, Strasbourg, France
Presenting author email: karl.stefic@univ-tours.fr

Background: Early antiretroviral therapy (ART) during primary HIV-1 infection (PHI) is now recommended to improve clinical outcome and prevent sexual transmission. Early ART may also impact HIV-specific serological response due to the rapid control of viral replication. Our aim was to assess the sensitivity of different HIV screening tests after a prolonged successful ART among patients treated during PHI.
Methods: Among HIV-infected patients enrolled at time of PHI in the ANRS PRIMO cohort, we selected those who received immediate ART and presented an undetectable viral load for ≥36 months afterwards. Frozen serum samples were tested using the CE-certified self-test Autotest VIH® (self-test), two point-of-care immunoassays (INSTI® HIV-1/HIV-2 Rapid Antibody Test [INSTI] and VIKIA® HIV1/2 [VIKIA]), and the 4th-generation ARCHITECT® HIV Ag/Ab Combo immunoassay (4thG ELISA).
Results: Patients (N=44) were mostly male (82%), median age was 40 years. At diagnosis, median CD4 cell count, plasma HIV-RNA and cell-associated HIV-DNA were 372/mm^3, 5.3 $\log_{10}$ copies/ml and 3.6 $\log_{10}$ copies/10^6 PBMC, respectively. ART was initiated at a median of 43 days (range 20-115) after estimated date of infection, corresponding to Fiebig stage II (5%), III (2%), IV (36%), V (21%) or

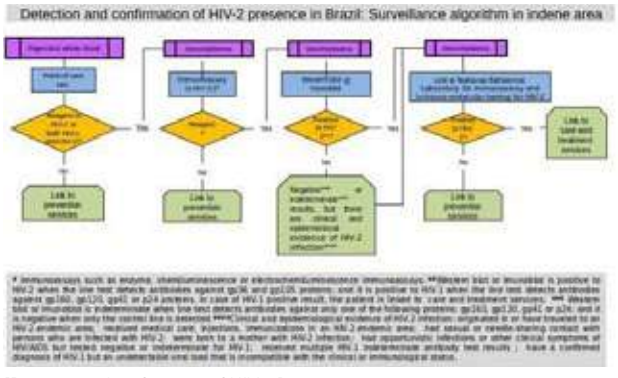
VI (36%). HIV-specific serological response was evaluated after a median of 84 months (range 36-204) of successful treatment. Non-reactivity was found to be 30% for self-test, 9% for INSTI test and 7% for VIKIA test. All participants remained positive with 4thG ELISA (median index=48 [range:1.9-491]) but 7/44 had an index value < 10. We did not find any baseline- or on-treatment immunogical or virological factor associated with non-reactivity of self-test, except the 4thG ELISA index measured at the same time which was weaker for patients with non-reactive self-test (index: 23 vs 60, p=0.003). Cell associated HIV-DNA level at time of self-test was not associated with non-reactivity; of note it remained detectable for 9 of 13 patients (69%) with negative self-test.
Conclusions: The HIV-specific antibody response is stopped and declines when ART is initiated during PHI. Several years of successful ART may lead to seronegativity of HIV self-test in 30% of patients. Particular caution should be given in case of HIV self-retesting.

MOPEB0254

Detection and confirmation of HIV-2 presence in Brazil: surveillance algorithm in indene area

D.C. Soares[1], P.C. Gaspar[1], A.F. Pires[1], N. Colaço[1], D. Costa[2], L. Ribeiro[2], O. Ferreira Junior[2], A. Benzaken[1], M. Franchini[1]
[1]Ministery of Health, IST, AIDS e Hepatites Virais, Brasília, Brazil, [2]Universidade Federal do Rio de Janeiro, Laboratório de Virologia Molecular, Instituto de Biologia, Rio de Janeiro, Brazil
Presenting author email: ana.pires@aids.gov.br

Background: Despite Brazil being an indene transmission area for HIV-2, the Brazilian Ministry of Health (MoH) established in 2010 surveillance measures for HIV-2 detection and diagnostic confirmation in view of the intense flow of people throughout Brazil and the endemic areas.
Methods: The surveillance algorithm suggests the use of point-of-care tests (POCT) in health facilities. The POCT are able to distinguish HIV-1 and HIV-2 antibodies that are present in whole blood samples (fingerstick). Whenever HIV-2 or both HIV-1 and HIV-2 are detected in the test line, a sample is submitted to immunoassay. In case of reagent result, a Western blot/Imunoblot (WB) is performed in order to detect antibodies against gp36 and gp105, HIV-2 specific proteins. If the WB is positive, a sample is sent to the National Reference Laboratory (NRL) for immunoassay and in-house molecular testing for HIV-2. If the WB is negative or indeterminate, a sample is sent to the NRL only in the event of strong epidemiological and clinical evidence of HIV-2 infection. If the HIV-2 infection is confirmed by the NRL, the patient is referred to start treatment; otherwise, the person is directed to the prevention service
Results: From 2010 to 2016, forty-three cases were investigated for HIV-2 infection. The HIV-2 infection was confirmed in two Brazilians, whose both partners were from Guinea Bissau. Other cases occurred in foreigners from Senegal, Costa do Marfim and Guinea Bissau.
Conclusions: The algorithm ensures early diagnosis, thereby minimizing transmission risk and providing opportunities for appropriate treatment. All HIV-2 confirmed cases related to epidemic countries. The MoH aims to expand the use of POCT in health facilities regardless the type of the virus.The HIV diagnosis in Brazil seeks to reach every Brazilian citizen or resident foreigner in Brazil.



[Detection and confirmation of HIV-2]

MOPEB0255

Comparison of home-based oral fluid rapid HIV self-testing vs. mail-in blood sample collection or medical/community HIV testing by young adult black, Hispanic, and white MSM: results from a randomized trial

R. Merchant[1], M. Clark[2], T. Liu[3], J. Romanoff[4], J. Rosenberger[5], J. Bauermeister[6], K. Mayer[7]
[1]Brown University/Rhode Island Hospital, Providence, United States, [2]University of Massachusetts Medical School, Worcester, United States, [3]Brown University, Department of Biostatistics, Providence, United States, [4]Rhode Island Hospital, Providence, United States, [5]Pennsylvania State University, Hershey, United States, [6]University of Pennsylvania, Philadelphia, United States, [7]Fenway Health, Boston, United States
Presenting author email: rmerchant@lifespan.org

Background: A primary goal for home-based oral fluid rapid HIV self-testing is to encourage people at higher risk for HIV infection and those with reduced access to traditional medical/community testing facilities to be tested for HIV, such as young white and ethnic minority men-who-have-sex-with-men (YMSM). We aimed to determine if black, Hispanic and white YMSM were more likely to complete home-based oral fluid rapid HIV self-testing than either mail-in blood sample collection or medical facility/community organization-based HIV testing.
Methods: This randomized trial included 125 black, 150 Hispanic, and 150 white HIV-uninfected 18-24-year-old YMSM recruited through eight social media platforms across the US. Within each race/ethnicity stratum, participants were randomly assigned to use a free home-based oral fluid rapid HIV self-test (n=142), use a free mail-in blood sample collection HIV test (n=142), or be tested at a medical facility/community organization of their choice (n=141). Test completion, time to test completion, and legitimate referrals of other YMSM to use the same HIV test were compared by study arm using summary statistics with 95% CIs.
Results:

	Assigned HIV testing group		
	Home-based oral fluid rapid HIV self-test	Home-based mail-in blood sample collection HIV test	Medical facility or Community organization HIV test
	n=142	*n=142*	*n=141*
Completed assigned HIV test, % (95% CI)	66.2 (58.4, 74.0)	40.1 (32.1, 48.2)	56.0 (47.8, 64.2)
Days to complete assigned HIV test, median (95% CI)	14.0 (11.0, 17.0)	17.0 (15.0, 22.0)	17.0 (11.0, 26.0)
Agreed to refer, % (95% CI)	35.9 (28.0, 43.8)	19.7 (13.2, 26.3)	26.2 (19.0, 33.5)
Made at least one legitimate referral, % (95% CI)	28.9 (21.4, 36.3)	18.3 (11.9, 24.7)	22.0 (15.1, 28.8)

[Main results]

As shown in the table of the main results, completion of the assigned test and willingness to refer other YMSM to use the same assigned test were greater in the oral fluid rapid HIV self-test arm than the mail-in blood sample collection HIV test arm, but not significantly greater than the medical facility/community testing arm. Time to testing and legitimate referrals were similar across study arms. In additional analyses, there were no differences in these measured outcomes by race/ethnicity.
Conclusions: Although free home-based oral fluid rapid HIV self-testing showed moderate promise in facilitating HIV testing, it was not associated with greater HIV testing than directing these black, Hispanic, and white YMSM to medical facility/community HIV testing venues. Providing testing through multiple venues and strategies appears necessary to optimize testing for this higher HIV risk population.

Background: CheckpointLX (community-based HIV testing site) study, Lisbon MSM Cohort (Meireles et al, 2015), followed 804 MSM for a total of 893.37 person-years between April 2011 and February 2014: overall incidence of 2.80 per 100 person-years (95% CI:1.89-4.14). The median time between participant visits was 0.57 years (≈7 months) and among those who seroconverted 0.79 years

(≈9 months): showing the existence of primary infections (< 6 months) and the opportunity to target for AHI detection. This study aims to study the impact of two screening algorithms in the detection of AHI at CheckpointLX.
Methods: Between November 2016 and November 2019, MSM seeking for HIV screening are tested with Alere™ Determine HIV-1/2 Ag/Ab Combo (algorithm one, rapid Ag test) and those with AHI symptoms and non-reactive Ag are tested with Alere™ q HIV-1/2 Detect (screening algorithm two, point-of-care HIV-RNA test). All positive Ag and/or HIV-RNA confirmed cases are assessed with Alere™ Pima for CD4 count. Primary HIV infection case definition (acute or recent) according with EACS guidelines 8.1. Those with AHI are linked to care in 48 hours. Study protocol was approved by both the Ethics Committee of the Lisbon Medical Academic Centre and the National Commission for Data Protection.
Results: In the first two months of enrollment, 9 MSM with recent primary HIV infection (Ab negative to positive in the last 6 months) and 1 MSM with acute primary infection (presence of p24 or HIV-RNA in the absence of Ab) were found.
Conclusions: Preliminary data shows that at CheckpointLX recent primary HIV infection are frequent and targeted AHI screening programs enable rapid linkage to the clinical benefit of the individual and the HIV prevention benefit of the public.

MOPEB0257

Rapid oral testing improves acceptance and diagnosis of HIV in a hospital outpatient dental clinic: a case-control study in Yuxi county, China

S. Li[1], S. Su[2], L. Gao[1], Y. Cai[1], J. Fu[1], C. Guo[1], W. Lu[1], F. Cheng[3], J. Jing[3], L. Chen[1], L. Zhang[2,3,4]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS and STI Control, Yuxi, China, [2]Monash University, School of Public Health, Melbourne, Australia, [3]Tsinghua University, Research Centre for Public Health, Beijing, China, [4]Melbourne Sexual Health Centre, Melbourne, Australia
Presenting author email: shu.su@monash.edu

Background: To compare the outcomes of the routine provider-initiated HIV testing and counselling (PITC) and rapid oral HIV testing for dental clinic outpatients in a hospital.
Methods: We recruited dental outpatients into routine serum-based and rapid oral testing groups. The acceptance rate, completion rate, and result notification rate were compared between groups using descriptive statistics.
Results: A total of 758 and 816 participants were enrolled into routine and rapid oral testing groups, respectively. The percentage of participants willing to receive routine HIV testing was 28.1% (24.9-31.3%) and 96.1% (94.8-97.4%, $\chi2$=186.4, p<0.01) for the rapid testing. Among accepted participants, the percentage of who finally received HIV testing was 26.8% (20.9-32.7%) in the routine group versus 100.0% in the rapid testing group ($\chi2$=77.5, p<0.01). About 93.0% of routine testers returned for the test results in the next day, whereas all rapid testers received their test results ($\chi2$=34.6, p<0.01). These correspond to an overall completion rate of 7.0% (5.2-8.8%) and 96.1% (94.8-97.4%, p<0.01), respectively. Among the 545 patients who declined routine serum-based HIV testing, the main reasons include, an unnecessary hassle (254/545, 46.6%), having been previously tested (124/545, 22.8%) and self-perceived low risk of HIV infection (103/545, 18.9%). In contrast, only 32 individuals declined rapid oral testing, and having received a previous test is a primary reason. Three patients in the rapid testing group were later confirmed HIV-positive, yielding an HIV prevalence of 0.38%.
Conclusions: Rapid oral HIV testing is a feasible and efficient approach in a clinical setting.

MOPEB0258

Fast tracking the HIV response in Nairobi city by targeted HIV testing of key populations, Kenya, 2015

C. Ngunu-Gituathi[1], J. Omai[1], H. Kongin[2], T. Ogaro[1], S. Ochola[1]
[1]Nairobi County Government, Health, Nairobi, Kenya, [2]UNAIDS, Nairobi, Kenya
Presenting author email: ngunucarol@yahoo.com

Background: Nairobi City has the largest proportion of key populations in Kenya. The County has an estimate of 29,494 female sex workers(FSWs), 11,042 men who have sex with men(MSMs) and 6,216 people who inject drugs(IDUs).The HIV prevalence in Nairobi for FSW is 11.1%, 18.2% for MSM and 18.7% for IDUs. Program data shows that only between 11% to 21% of key populations had received a HIV test in the first quarter of 2015.We therefore carried out a HIV testing and linkage to treatment campaign with an aim of increasing the number of key populations who knew their HIV status.
Methods: Key population hot spots were mapped within the city and HIV testing services offered for free to all MSMs, FSWs and IDUs operating within those hot spots from 27th November to 7th December 2015. The target was to test 5,000 key populations and the strategies used were snowballing, moonlighting and outreaches at drop in centers (DICs) and sex dens. All KPs who tested positive were linked for free treatment services at the KP trained health facilities. Data on KPs tested was collected using standardized government HTS data registers and analyzed using MS Excel 2007.
Results: A total of 6602(132% of target) key populations were tested with 5061(77%) being FSWs, 1255(19%) MSMs and 286(4%) IDUs. Mean age was 27.3 years (range 16-57 years). Of those tested, 192(2.9%) tested HIV positive and all were successfully linked to care. The highest positivity rates were seen in Embakasi (6%),Langata (5.5%) and Dagoretti (5.5%). In addition to testing, 180,000 condoms were distributed to the key populations tested and their clients.
Conclusions: The strategies used to target the key populations worked and we were able to surpass our targets and identify HIV positives who we successfully linked to care. This activity also presented us with an opportunity for targeted condom distribution for this vulnerable group. Given the recommended guidance on testing of KPs, the city intends to carry out targeted outreaches to the key populations every quarter.

MOPEB0259

Implementing routine HIV testing in the emergency department using electronic health record modifications at University Hospital, Newark, NJ

S. Maldonado, G. Sugalski, G. Closeil, S. Swaminathan
Rutgers, New Jersey Medical School, Newark, United States
Presenting author email: swaminsh@njms.rutgers.edu

Background: The prevalence of HIV infection in Newark, NJ is >1%. Therefore, all persons presenting to care in the Emergency Room (ER) at University Hospital (UH) should be tested, yet only 9% were being tested. We implemented a routine HIV testing program in the ER using electronic health record (EHR) prompts and a patient navigator (PN) to help with connection to care (CTC).
Methods: This was a retrospective study of patients seen in select areas of the ER from April 2015 to November 2016 to see the proportion of eligible patients getting tested for HIV. The triage nurse would ask patients about HIV diagnoses or recent HIV test and an automatic order was placed if indicated unless the patient declined the test. We collected following information on HIV+ patients: age, gender, race, HIV risk factor, baseline CD4 count and HIV viral load (VL) and CTC.
Results: A total of 34,158 patients were seen in Main and Mid-Trak areas of the ER. Of these, 26,610 (78%) were eligible for HIV testing, 9,911 (37%) had the test ordered and 8,812 (89%) had the test performed. Monthly HIV testing rate increased from 9% to 75%.
Of those tested, 165 (1.9%) were found to be HIV positive (2 acute, 112 newly diagnosed, 51 previously known). The demographics of the HIV+ patients were: mean age - 48, Male 96 (58%), Race- Black 126 (76%), Hispanic 23 (14%), White 9 (6%), and Other 7 (4%). The HIV risk factors were: MSM (9%), Injection drug use (8%), heterosexual (69%) and other (20%). The Median CD4 count was 389 (range 3-1,804 cells/cu.mm) and median HIV VL was 132,352 (range < 20-2,752,888 copies/ml). 107 (65%) were either connected or are in the process of being CTC. Of the 58 not CTC, 46 (89%) were diagnosed prior to having a PN. The CTC since the PN was hired is over 70%.
Conclusions: We successfully implemented routine HIV testing in a busy ER with effective modification of the EHR and increased our monthly testing rate from 9% to 75%. However, PN navigators are essential for effective CTC especially in busy clinical settings.

Increasing testing and diagnosis for men who have sex with men using social networks for HIV self-test distribution

M. Lightfoot[1], S. Lippman[1], C. Campbell[2], M.-S. Kang-Dufour[1], E. Agnew[1], N. Moss[3]
[1]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [2]University of California San Francisco, Center for AIDS Prevention Studies, Berkeley, United States, [3]Alameda County Public Health Department, Oakland, United States
Presenting author email: marguerita.lightfoot@ucsf.edu

Background: As the HIV epidemic continues to disproportionately impact men who have sex with men (MSM) globally, novel strategies are needed to increase testing uptake. We implemented a peer network HIV self-test distribution strategy to reach African American and Latino MSM who do not regularly test for HIV. We assessed the efficacy of the program by comparing HIV-related testing outcomes to those attained through the local public health department's targeted HIV testing program.

Methods: African American and Latino MSM and Transgender women (N=31), between 18 and 45 years old were engaged and trained as peer recruiters on the basics of HIV infection, proper use of the OraQuick® In-Home HIV test (OraSure Technologies), and supporting a friend through the testing process. Each peer was given five *self-test* kits to distribute to MSM friends thought not to have tested for HIV in at least 6 months. Those receiving the self-test kits were asked to complete an online survey after completing their test. Chi-squared tests were used to compare the number of *first time* testers and new HIV *diagnoses* through the peer network testing and amongst African American and Latino MSM who tested in a geographically overlapping contemporaneous government supported traditional community-based HIV testing program.
Results: Peers distributed self-test kits to 143 social and sexual network members, of whom 110 completed the online survey. Compared to MSM who utilized the government sponsored testing programs, individuals reached through the peer-based self-testing strategy were significantly more likely to have never tested for HIV (4.0% vs. 0.5%, p<0.01) and to report a positive test result (3.7% vs 1.5%, p<0.01), though 6 people in the peer-based strategy (5.5%) declined to provide a result.
Conclusions: These findings suggest that a network-based strategy for self-test distribution is a promising intervention to increase testing uptake and reduce undiagnosed infections among African American and Latino MSM.

Use of FACSPresto™ for measurement of CD4 and haemoglobin in resource-limited settings

G. Kangogo[1], S. Kipkerich[2], N. Bowen[2], C. Ogada[2], M. Umoro[3], L. Kingwara[4], R. Mumo[4], E. Onkendi[4]
[1]National HIV Reference Laboratory (NHRL), Molecular Biology, Nairobi, Kenya, [2]National HIV Reference Laboratory, Nairobi, Kenya, [3]National Public Health Laboratories, Nairobi, Kenya, [4]National HIV Reference Laboratory (NHRL), Nairobi, Kenya
Presenting author email: geffkemboy@yahoo.com

Background: Haemoglobin and CD4 T-cell counts are important prognostic markers in HIV infection, where decline in the two is often associated with HIV disease progression.
As a result, accurate and reliable data in monitoring CD4 and haemoglobin (Hb) levels is of critical importance to patient management. Conventionally, BD FACSCalibur and the Mindray hematology analyser are some of the equipment used in measuring CD4 and Hb respectively. However, with up to 50% of HIV patients still in need of life-saving ARV medications, alternative CD4 testing platforms are warranted. FACSPresto™ machine is a point of care testing (POCT) device for both CD4 cell count and haemoglobin. In Kenya, medical devices need to be verified before use in health care facilities. Verification of the BD FACSPresto™ machine was carried out at the National HIV Reference Laboratory (NHRL).
Methods: A total of 103 consenting patients were enrolled. Fresh whole blood (matched capillary and venous) samples from HIV positive patients were collected from Mbagathi Hospital clinical laboratory by trained staff. Laboratory testing for CD4 and haemoglobin levels was done on BD FACSCalibur, BD FACSPresto (Becton Dickinson, East Rutherford, NJ, USA) and Mindray Haematology Analyzer BC-5380 following manufacturer's instructions.
Laboratory analysis entailed the absolute and percent CD4 counts, and total haemoglobin concentration in the whole blood from HIV-infected patients. Statistical analysis entailed calculation of Pearson´s correlation and Bland Altman analysis for mean bias.
Results: The mean CD4 absolute count from the Presto was 805.89 compared to 889.49 from Calibur. Correlation at 0.93 was near perfect and the results were substantially equivalent. The mean difference between the reference method (Facscalibur) and test method (Facspresto) absolute CD4 counts was 76.3 which is within the 28% acceptance criteria.
Average Hb reading from venous sample was 12.65 compared to 12.56 from capillary sample. Correlation at 0.94 was near perfect. The mean difference between venous and capillary Hb reading was 0.091 and was not statistically significant.
Conclusions: The results obtained from the BD FACSPresto™ machine were comparable to the two reference equipments.
BD FACSPresto™ can utilize both venous and capillary blood thus it can be used as a point of care device.

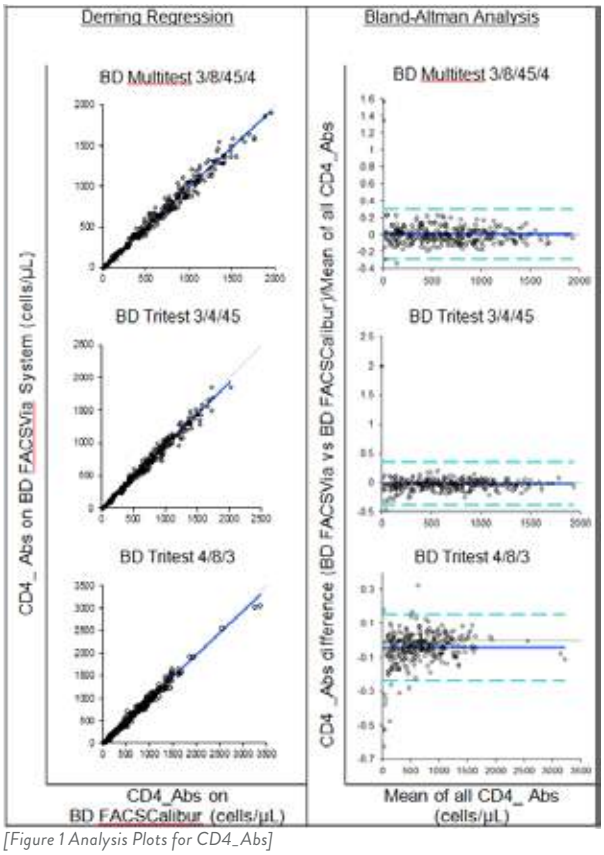
Multicenter evaluation of CD4 T-cell counts on the new BD FACSVia™ system using BD Tritest™ and BD Multitest™ reagents

Y. Zeng[1], R. Sukhadia[2], R. Hsen[2], R. McLean[2], C. Mutschmann[3], D. Taufmann[3], S. Tessmer[3], D. Sauer[3], F. Oreizy[1], A. Chen[1], A. Keya[1], S. Meyerovich[1], M. Saleminik[1], F. Mosqueda[1], A. Lin[1], K. Judge[1], M. O'Gorman[2]
[1]BD Life Sciences, San Jose, United States, [2]Children's Hospital Los Angeles, Los Angeles, United States, [3]SYNLAB Umweltinstitut, GmbH, Berlin, Germany
Presenting author email: yang_zeng@bd.com

Background: $CD3^+CD4^+$ T-lymphocyte count remains one of the most important laboratory indicators in HIV/AIDS diagnosis/staging, treatment initiation, monitoring of regimen effectiveness and patient risk management, for example, using a CD4 cell count at or below 350 to initiate treatment for HIV patients (WHO 2016 guidelines). To meet global health needs, BD has developed a simple-to-use, affordable flow cytometer, the BD FACSVia™ System.* It features novel designs that provide workflow efficiency and high throughput in clinical laboratories. We evaluated CD4 absolute counts (CD4_Abs) on the BD FACSVia System vs the predicate BD FACSCalibur instrument at three study centers using BD Tritest™ (CD3/CD4/CD45 and CD4/CD8/CD3), BD Multitest™ (CD3/CD8/CD45/CD4) reagents.
Methods: De-identified venous blood specimens from HIV+ patients (n = 204), immune reconstitution patients (n = 51) and normal donors (n = 50) were enrolled in the study. Each specimen was stained using the two BD Tritest and the BD Multitest reagents in BD Trucount™ tubes, followed by acquisition on the BD FACSVia System and BD FACSCalibur instrument. CD4_Abs results were compared between the two systems using Deming regression and bias analysis. A two-by-two contingency table was used to assess agreement about a CD4 clinical cutoff, at 200 cells/µL and 350 cells/µL.
Results:

Reagent	Deming regression on CD4_Abs			Bland-Altman analysis on CD4_Abs	Percent agreement about CD4 clinical cutoff (95% LCI, 95% UCI)	
	Slope (95% CI)	Intercept	R^2	Bias% with 95% Limits of agreement	Cutoff ≤ 200 cells/µL	Cutoff ≤ 350 cells/µL
BD Multitest 3/8/45/4	0.99 (0.98, 1.00)	2.70	0.99	0.9% (-28.8%, 30.7%)	N** = 55, 98.6 (96.5, 99.5)	N = 80, 98.3 (96.0, 99.3)
BD Tritest 3/4/45	0.97 (0.95, 0.98)	1.19	0.99	-1.8% (-38.7%, 35.1%)	N = 50, 98.3 (96.1, 99.3)	N = 78, 99.7 (98.1, 99.9)
BD Tritest 4/8/3	0.98 (0.96, 1.00)	-5.89	0.99	-4.3% (-23.8%, 15.2%)	N = 52, 99.7 (98.1, 99.9)	N = 78, 98.7 (96.6, 99.5)
**note: N is the number of samples at or below cutoff as measured on the BD FACSCalibur instrument						

[Table 1 Analysis results for CD4 absolute count]



[Figure 1 Analysis Plots for CD4_Abs]

Conclusions: The BD FACSVia System demonstrated equivalent results in the accessed range of CD4 T-cell absolute count, as well as around CD4 clinical cutoff compared to the BD FACSCalibur instrument. Since CD4 count remains an important parameter in the management of HIV patients, the BD FACSVia System provides an easy-to-use, affordable solution to clinical laboratories.
*This product was CE Marked (EU IVD Directive 98/79/EC).

Outcomes of routine viral load monitoring in Namibia's national antiretroviral treatment program

N. Mutenda[1], N. Taffa[2], D. Baughman[2], A. Agovi[3], M. De Klerk[2], S. Sawadogo[2], C. Roscoe[2], T. Mekonen[1], H. Kaura[4], A. Wolkon[2], G. Mutandi[2], F. Tjituka[1], D. Prybylski[2], N. Hamunime[1], S. Agolory[2]
[1]Ministry of Health and Social Services, Windhoek, Namibia, [2]Centers for Disease Control and Prevention (CDC), Windhoek, Namibia, [3]University of California, San Francisco (UCSF), Windhoek, Namibia, [4]Namibian Institute of Pathology (NIP), Windhoek, Namibia
Presenting author email: vik1@cdc.gov

Background: Namibia antiretroviral treatment (ART) guidelines recommend the use of viral load (VL) testing to monitor HIV treatment as recommended by WHO. VL testing is recommended at 6 months after ART initiation. The guidelines defines VL suppression as HIV RNA < 1000 copies/ml, and recommends switch to second-line ART following failure of VL suppression with two consecutive tests performed at 6 and 9 months. We assessed timing of VL testing and suppression rates for patients newly initiating ART.
Methods: A retrospective cohort analysis of patients initiating ART between January 2014 and March 2015 at public ART facilities in Namibia. Clinical and laboratory records were matched from two non-interfaced, client-based electronic systems used for patient management and laboratory services. Matching was performed using probabilistic record linkage (Link Plus v3.0 software) using patient surname, first name, and date of birth. VL results were described by age, sex, baseline CD4 cell count.
Results: Out of 8366 adult and pediatric patients with matched laboratory and clinical records, 2536 (30%) received a first VL test within 6-9 months of ART initiation. VL suppression was achieved among 97.3% adults (95% CI: 96.6-97.9) and 92.4% children (95% CI: 86.7-95.8). An additional 3528 (42%) patients received a first VL test >9 months after ART initiation and lower suppression rates were observed for both adults (94.0%, 95% CI: 93.2-94.8) and children (81.1%, 95% CI: 75.6-85.6), p=< 0.05. Out of the 315 who failed to suppress the first VL test, only 26 (8.3%) follow-up VL tests were performed 3-6 months later, of which 15 (57.7%; 95% CI: 38.9-74.5) achieved suppression. Clients who failed initial VL suppression had lower baseline median CD4 cell counts (148 vs. 292, p <0.01), compared to those achieving suppression.
Conclusions: Though suppression at 6-9 months was high among patients who had VL testing after ART initiation, overall there was low compliance to timely VL monitoring. VL suppression declined for patients not monitored within the recommended interval after starting ART, especially in children. Improved recording and compliance to routine VL monitoring guidelines in Namibia is urgently needed to better detect early treatment failure and minimize development of ART resistance.

MOPEB0264

A pilot evaluation of whole blood finger-prick sampling for rapid and convenient point-of-care HIV viral load measurement: the UNICORN study

S. Fidler[1], J. Thornhill[1], J. Meyerowitz[2], H. Lewis[1], K. Kuldanek[1], D. Muir[1], A. Bonnissent[3], G. Timson[3], J. Frater[2], Collaborative HIV Eradication of Reservoirs UK BRC (CHERUB)
[1]Imperial College, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Cepheid Inc, Sunnyvale, United States
Presenting author email: john.frater@ndm.ox.ac.uk

Background: Antiretroviral therapy treatment interruption (TI) is the only test for HIV remission or cure in the absence of a validated laboratory biomarker. Clinical studies incorporating TI within their protocols require frequent plasma viral load (pVL) monitoring - up to every 2-3 days - to identify rebound viraemia and inform recommencement of ART. Such regular blood draws are a substantial inconvenience to participants and may impact recruitment. We present the first study of a simple whole blood finger-prick pVL analysis using an off-label protocol for GeneXpert Cepheid cartridges.
Methods: The UNICORN study is an analysis using two point-of-care (PoC) assays of 40 HIV+ve participants, 20 with detectable viraemia and 20 with undetectable pVL (<20 copies/ml). Using 100µl finger-prick whole blood samples, the Cepheid GeneXpert HIV Viral Load and HIV Qual cartridges were compared with formal laboratory pVL assessment from plasma (TaqMan, Roche). Samples were diluted and tested with and without a three minute spin using a benchtop microcentrifuge in the clinic room. Results were available within 90 minutes.
Results: At the 50% recruitment stage, for those participants with undetectable viraemia (< 20 RNA copies/ml) by TaqMan Roche, only 63.6% were ‚undetectable' using the GeneXpert VL assay and 33.3% ‚not detected' using the Qual assay, likely reflecting detection of cellular HIV nucleic acid. However, after a 3 minute spin, 100% of samples were undetectable using either assay, showing full concordance with formal pVL testing.
All participants in the ‚VL detectable' group (pVL range 33-500,000 copies/ml) were identified as detectable by both assays without incorporating a spin. On comparing sensitivity including the spin, only two detectable samples (both ≤158 copies/ml by Roche) were reported as ‚not detected' by both PoC assays. After correcting for volume, values of pVL by Roche and GeneXpert post-spin were closely correlated (p=0.0006; rho=0.97).
Conclusions: Finger-prick whole blood sampling is a specific, sensitive, quick, convenient and acceptable method for screening for detectable plasma HIV viraemia using either quantitative pVL or binary qualitative PoC approaches. This method has significant potential for use in TI studies exploring HIV cure strategies, but also in resource-limited regions with minimal access to certified diagnostic laboratories.

Evaluation of the Cepheid GeneXpert HIV-1 Qualitative molecular assay in patients with early primary HIV-1 infection and on antiretroviral therapy

A. Gabassi[1], H. Delagrèverie[1,2], N. Mahjoub[1], M.-L. Néré[1], F. Simon[1], J.-M. Molina[2,3], M.-L. Chaix[1], C. Delaugerre[1,2]
[1]Hôpital Saint-Louis, Laboratoire de Virologie, Paris, France, [2]INSERM U941, Université Paris Diderot, Hôpital Saint Louis, Paris, France, [3]Hôpital Saint-Louis, Service des Maladies Infectieuses, Paris, France
Presenting author email: audrey.gabassi@aphp.fr

Background: The Cepheid GeneXpert HIV-1 Qual kit is a single-sample rapid molecular assay for the qualitative detection of HIV-1 in whole blood samples. It is used for the diagnosis of HIV-1 infection in newborns in the South. Our objective was to assess the performances of this assay in HIV-1-infected patients at the time of primary HIV infection (PHI) and on antiretroviral therapy (ART).
Methods: HIV-1 Qual is a qualitative endpoint RT-qPCR assay, thus potentially detecting both viral RNA and DNA from blood samples. This study was conducted in Hôpital Saint-Louis, Paris, France. We tested 59 banked frozen whole blood samples obtained from 24 PHI patients and 23 ART patients (of which 4 were followed for 72 weeks), accounting for a wide quantitative range of plasma HIV-1 RNA (Roche Cobas TaqMan HIV-1 v.2, threshold=1.3$\log_{10}$copies/ml) and of blood HIV-1 DNA (Biocentric Generic HIV-1 DNA Cell, threshold=1.3$\log_{10}$copies/10^6 cells). Negative/Positive results and threshold cycles (Ct) were recorded. Correlations were tested by the Wilcoxon signed rank-test and longitudinal changes of Ct values by Friedman´s non-parametric test.
Results: Median HIV-1 RNA was 1.8 $\log_{10}$copies/ml (range ≤1.3-7.7), including 23 samples ≤1.3 $\log_{10}$copies/ml. Median HIV-1 DNA was 2.6 $\log_{10}$copies/10^6 cells (range ≤1.3-4.21). Amplification with GeneXpert HIV-1 Qual yielded a Ct value in 47/59 samples (median Ct was 34.7, range (22.1-43.3). All tested PHI samples were assessed HIV-1 positive by HIV-1 Qual. Detection Ct was inversely correlated with viral RNA and DNA loads: R^2= 0.78 and R^2=0.60, respectively. Amongst 4 HIV-infected patients followed for 72 weeks after treatment initiation, all 4 patients originally tested HIV-positive at W0 but only two remained positive by HIV-1 Qual after 72 weeks of suppressive ART. Out of the total 12 HIV-1 blood samples which did not yield a detection Ct, 11 were aviremic samples and 1 RNA load was 2.06$\log_{10}$copies/ml. In these blood samples HIV-1 DNA load ranged from ≤1.30 (4 samples) to 2.70 $\log_{10}$copies/10^6 cells.
Conclusions: Detection Ct was correlated with HIV-1 RNA and DNA viral load and GeneXpert HIV-1 Qual assay tested positive for all viraemic blood samples ≥200 RNA copies/ml of plasma.

Performance evaluation of Xpert® HIV-1 viral load assay for rapid quantification in plasma specimens

C.R. Swathirajan[1], R. Vignesh[1,2], J. Boobalan[1], S.S. Solomon[1,3], S. Saravanan[1], P. Balakrishnan[1]
[1]YRG Centre for AIDS Research and Education, Chennai, India, [2]UniKL-Royal College of Medicine Perak, Laboratory-Based Department, Ipoh, Malaysia, [3]Johns Hopkins School of Medicine, Baltimore, United States
Presenting author email: swathi@yrgcare.org

Background: Durable control of HIV-1 replication forms the basis of antiretroviral therapy (ART) medication. Thus, accurate quantification of HIV-1 viral load has become an essential factor in monitoring the effectiveness of ART. Longer turn-around-time (TAT), batch testing and technical skills are major drawbacks of standard Real Time PCR assays. Hence, accurate and reliable assays which require very minimal technical skills and rapid TAT in quantifying HIV-1 plasma viral load are always in demand.
Methods: In this study, Xpert HIV-1 viral load assay was evaluated against Abbott Real Time PCR, m2000rt system. A total of 96 specimens that were tested by Abbott Real Time PCR as part of patient care services and the remaining specimens stored in freezer at -75 ± 5°C were utilized for this performance evaluation. Two plasma specimens were tested 5 times each, to check assay precision. Mean difference and linear relationship were calculated by Bland-Altman analysis and Pearson correlation coefficient (r), respectively. GraphPad Prism, Ver5.0 (San Diego, USA) was used to perform statistical analyses.
Results: Compared to Abbott Real Time PCR, m2000rt system, Xpert HIV-1 viral load assay showed a mean difference of 0.27 log_{10}copies/mL (95% CI, -0.41 to 0.96 log_{10} copies/mL; SD, 0.35 log_{10} copies/mL) with good correlation (Pearson r=0.81; p< 0.0001). Assay sensitivity was 96.3% in quantifying plasma specimens with viral load of ≤ 3.5 log_{10} copies/mL, while it was 100% in plasma specimens with viral load of ≤ 3.7 log_{10} copies/mL. In both the specimens tested for precision, the results were excellent with a coefficient of variation (CV) of 1.9% and 1.07%, respectively.
Conclusions: Comparable to the standard assay, shorter TAT (less than 2 hours) and ease of testing individual specimens could make Xpert HIV-1 viral load assay as an efficient alternative method for ART monitoring in clinical management of HIV disease. Rapid testing results of this assay could help in making immediate clinical decisions, which strengthens the patient care in resource-limited settings.

MOPEB0267

Risk factors for viral failure among HIV patients on antiretroviral therapy (ART) at the Infectious Diseases Institute Kampala Uganda

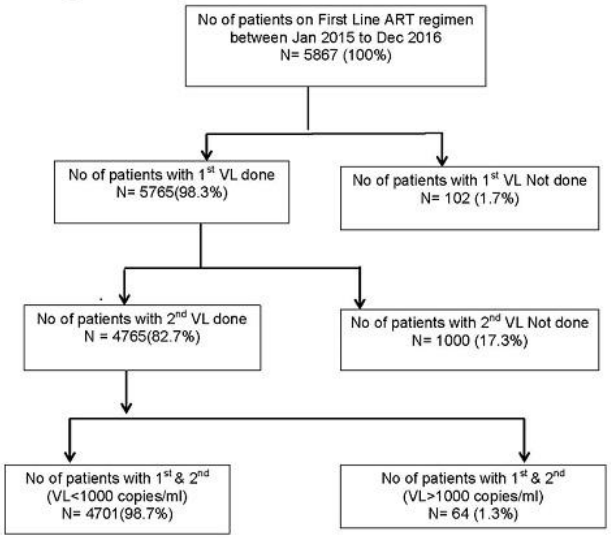
Background: Globally the UNAIDS targets that by 2020; 90% of patients on ART will have viral suppression. Despite studies assessing this objective, little is known about risk factors hindering the achievement. We assessed the risk factors for viral failure among HIV patients on ART at the Infectious Diseases Institute, Uganda.
Methods: We performed a retrospective data review of patients on first line ART between January 2015 and December 2016 who started ART before 31st December 2015.Virological failure was defined as two consecutive VL>1,000 copies/ml with in at least 6 months from ART start.We used frequencies and logistic regression to determine the characteristics associated with virological failure.
Results: 5867patients were on first line ART by 31st December 2016. Of these, 4765 (82.7%) had at least two viral loads done (Figure1). 2951 (61.9%) were female, median age 41 (IQR: 35-48) and median CD4 count 491(IQR: 358-655) cells/μL. 2831(61%) had WHO stage 3 and 4. Majority 2905 (61%) were on Efavirenz based regimen. Patients with viral failure were 64(1.3%). At multivariable analysis, being older (>45 years), being on Nevirapine and having a CD4>500 copies were protective of viral failure (OR< 1). (Table 1)

Patients characteristics	Unadjusted OR(95 CI)	P Value	Adjusted OR(95 CI)	P Value
Gender Female Male	1.00 1.04(0.62-1.72)	0.869		
Age(years) <45 >45	1.00 0.27(0.13-0.54)	<0.001	1.00 0.26(0.13-0.54)	<0.001
Baseline regimen Efavirenz Nevirapine	1.00 0.43(0.23-0.79)	0.006	1.00 0.46(0.26-0.86)	0.013
BaselineCD4(cells/μL) <500 >500	1.00 0.33(0.18-0.59)	<0. 001	1.00 0.31(0.17-0.56)	<0.001
WHO stage 1&2 3&4	1.00 0.89(0.54-1.47)	0.666		

[Table 1 Regression estimates of viral logic failure]



[Figure 1: Showing Viral loads (VL) done for patients on first line ART regimen]

Conclusions: Close monitoring for younger patients and those with lower CD4 is required to achieve better virological out comes in patients on first line ART. Further investigation is required to ascertain possible cause of viral failure among patients on Efavirenz based regimen.

MOPEB0268

No substantial sex differences in tenofovir exposure after directly-observed dosing of TDF/FTC as assessed via hair concentrations

C. Koss[1], A. Liu[2], P. Bacchetti[3], S. MaWhinney[4], C. McHugh[4], K. Kuncze[1], A. Louie[1], S. Seifert[4], H. Horng[1], M. Gandhi[1], P. Anderson[5]
[1]University of California, San Francisco, Department of Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States, [3]University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]University of Colorado Denver, Aurora, United States, [5]University of Colorado Denver, Department of Pharmaceutical Sciences, Aurora, United States
Presenting author email: peter.anderson@ucdenver.edu

Background: Pre-exposure prophylaxis (PrEP) with tenofovir (TFV) disoproxil fumarate (TDF)/ emtricitabine (FTC) is highly efficacious, although several studies in sub-Saharan Africa demonstrated lower effectiveness in women than men. This difference was attributed to poor adherence, although relatively lower TFV levels in vaginal versus rectal mucosa could have contributed. Hair concentrations reflect cumulative adherence and exposure, both of which can impact PrEP effectiveness. We sought to evaluate whether TFV hair concentrations differ between men and women receiving directly observed dosing of TDF/FTC.
Methods: We compared TFV hair concentrations in low-risk, HIV-uninfected volunteers on directly observed TDF/FTC in Denver and San Francisco (DOT-DBS, NCT02022657). Participants were randomized to two of the following 12-week dosing regimens: 100%, 67%, or 33% of daily dosing. Hair samples were collected at dosing weeks 4, 8, and 12 and every 3 weeks during a 12-week washout. TFV concentrations in the proximal 1.5 centimeters of hair (representing 6 weeks of exposure) were analyzed using a validated liquid chromatography/tandem mass spectrometry (LC-MS/MS) assay. Linear regression models with random-person effects modeled TFV hair concentrations in terms of sex, doses taken over the prior 6 weeks, and number of days since last dose.
Results: Hair was collected from 46 individuals (52% female): median age 29 years; 57% white, 15% African American; 28% Hispanic ethnicity. Female participants had similar TFV hair concentrations to males (fold-difference 0.95, 95% CI 0.78-1.15, p=0.6). The estimated fold-difference in TFV levels for female versus male participants did not appreciably change when age (0.96, CI 0.79-1.17), weight (0.90, CI 0.73-1.12), or race (0.97, CI 0.79-1.18) were added to the model.
Conclusions: Under directly-observed dosing, TFV hair concentrations in women were similar to those in men. This observation remained constant regardless of race, age and weight. As pharmacokinetic metrics are increasingly used to monitor PrEP, these findings provide guidance for assessing adherence-response relationships via hair concentrations in men and women.

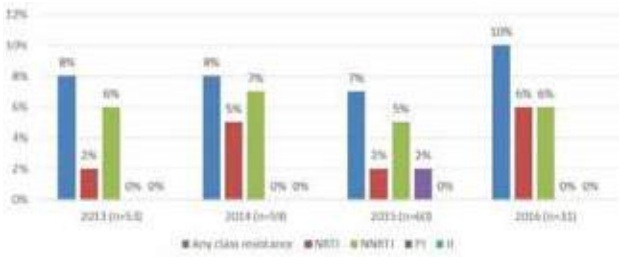
Transmitted drug resistance in treatment-naïve HIV-Infected VCT clients in southern Taiwan, 2013-2016

H.-C. Tsai, I.-T. Chen, S.S.-J. Lee, Y.-S. Chen
Kaohsiung Veterans General Hospital, Infectious Diseases, Kaohsiung, Taiwan, Province of China
Presenting author email: hctsai1011@yahoo.com.tw

Background: The use of antiretroviral therapy has reduced the mortality and morbidity of patients with HIV/AIDS. However, Transmission of drug-resistant (TDR) strains poses a challenge for the control of the HIV-1 epidemic. The aim of this study was to monitor the prevalence of TDR in Taiwan, where free highly active antiretroviral therapy (HAART) was provided since 1997.
Methods: A prospective study on TDR was conducted in antiretroviral treatment-naïve HIV-1-infected voluntary counseling and testing (VCT) clients from 2013 to 2016 in southern Taiwan. Genotypic drug resistance was determined by ViroSeq™ system, CCR-5 tropism and integrase strand-transfer inhibitor (INSTI) resistance were determined by the in house population sequencing.
Results: From 2013 to 2016, a total of 18615 clients received a VCT. The positive rate for HIV-1 infection was 2.5%. Sequences were obtained from 184 individuals, of whom 96.7% were infected by MSM, and 3.3% were infected by heterosexually. Ten percent (19/183) of the patient had hepatitis B and 33.3% (61/183) had syphilis infection. Subtype B HIV-1 strains were found in 96.1% of the individuals, and subtype CRF01_AE in 3.9%. Fifteen patients (8.4%, 15/178) were found to harbor NRTI/NNRTI/PI resistance. CCR-5 coreceptor usage was found in 71.4% (130/182) of the patients. No one had INSTI resistance, But 17 patients had INSTI polymorphic substitution. Those who had INSTI polymorphic substitutions were more likely have higher HIV viral load (p=0.039) and CCR-5 coreceptor usage (p=0.043).



[HIV drug resistance in 2013-2016]

Conclusions: Although the implementation of early treatment in HIV infected patients, the rate of TDR to PI and INSTI were low in these 4 years. Further monitor trend of TDR in our community is needed with the increase use of integrase strand-transfer inhibitor in the future.

MOPEB0270

Usefulness of proviral HIV-1 DNA resistance testing in virologically suppressed HIV-infected patients candidate for maintenance therapy

A. Rodallec[1], L. Le Guen[1], A. Leplat[1], C. Luco[1], N. Hall[2], C. Bernaud[2], S. Bouchez[2], E. André-Garnier[1], V. Ferré[1], F. Raffi[2], C. Allavena[2]

Presenting author email: audrey.rodallec@chu-nantes.fr

Background: Switch of antiretroviral therapy (ART) in virologically suppressed patients is frequent, to prevent toxicities or for simplification or convenience reasons. Pretherapeutic genotypic resistance testing (GRT) on plasma RNA can be lacking in these patients before switching because of a long period since ART introcuction. For patients with history of virological failure resistance information provided by GRT on proviral DNA is less informative than the cumulative history of standard plasma RNA genotypic results. In patients virologically controlled with no history of virological failure few data are available on the concordance of current proviral DNA GRT and pre-therapeutic plasma RNA GRT.
Methods: Monocentric, cross sectional study including virologically suppressed patients on ART with no history of virological failure. Proviral DNA GRT was compared with pre-ART plasma RNA genotype. Mutations described in the V.24 ANRS algorithm were considered as resistance-associated mutations (RAMs), and the others as polymorphism mutations (PMs).
Results: Sixty nine pair-wised sequences from plasma RNA and blood DNA compartments 47 months apart were compared. A stop codon was evidenced in 23% of proviral DNA sequences. These strains were considered as defective and non-replicative. There was a high concordance rate between plasma RNA and non-defective proviral DNA both on protease (88%) and reverse transcriptase (76%) genes. Presence of RAMs only in DNA but not in pretherapeutic RNA was evidenced in 8 % on protease and 19% on reverse transcriptase sequences. When considering RAMs to nucleoside reverse transcriptase inhibitors, all mutations detected on RNA were also detected on provirus DNA. In 5 cases, RAMs were detected only on proviral DNA (M41I, E44K, V75A, K219Q, K219R). Concerning non-nucleoside reverse transcriptase inhibitors, 2 minor mutations (K101R and V179I) were detected only on RNA, while 2 others (V106I and M230V/I) were detected only on proviral DNA. In all other cases, mutations were present both on RNA and provirus DNA. The phylogenetic analysis showed that the DNA and RNA sequences were linked with a bootstrap score >99% for each patient.
Conclusions: Proviral DNA GRT might be an informative tool before switching ART in virologically suppressed patients, especially when pretherapeutic GRT is lacking, but interpretation should be restricted to non-defective viruses.

Presenting author email: esocias@cfenet.ubc.ca

Background: Transmitted drug resistance (TDR) may compromise response to antiretroviral treatment (ART) among HIV-positive individuals. However, there is limited data on TDR among people who use illicit drugs (PWUD). We sought to characterize TDR patterns among HIV-positive PWUD in Vancouver between 1996 and 2015.
Methods: Data was drawn from ACCESS, a community-recruited longitudinal cohort of HIV-positive PWUD in Vancouver, Canada, linked to comprehensive ART dispensation and clinical monitoring records. TDR was defined according to the WHO 2009 list for surveillance of drug resistance mutations. We estimated the prevalence and correlates of TDR among ART-naïve PWUD and evaluated trends over time.
Results: Among 573 ART-naïve PWUD (65% male, 95% with a history of injection drug use, 18% recent seroconverters), the overall prevalence of TDR was 9.8% (95%CI 7.3-12.2). TDR-associated mutations were more common for non-nucleoside reverse transcriptase inhibitors (NNRTI, 5.4%, 95%CI 3.5-7.3), followed by nucleoside reverse transcriptase inhibitors (NRTI, 3.0%, 95%CI 1.5-4.4), and protease inhibitors (PI, 1.9%, 95%CI 0.7-3.1). TDR prevalence was significantly lower among PWUD with recent HIV seroconversion (AOR = 0.39, 95% CI 0.15-0.87). We observed an increasing trend of TDR over the study period, from 8.5% (95%CI 3.4-13.8) in 1996-1999 to 21.1% (95% CI 10.9-31.3%) in 2010-2015 (p=0.003), mainly driven by resistance to NNRTI.
Conclusions: Between 1996 and 2015, the prevalence of TDR increased significantly among PWUD in this setting, mainly driven by increases in NNRTI-mutation K103N. These results suggest that ART-naïve PWUD may be an important source of TDR. Lower rates of TDR among recent seroconverters may be partially explained by limited exposure to ART among PWUD in the earlier years, when most seroconversions were documented. Our findings support current recommendations for baseline resistance testing to guide ART selection, as well as for early initiation of ART to limit the spread of TDR.

Presenting author email: a_nanfack@yahoo.fr

Background: The main obstacle to successful antiretroviral therapy (ART) is the emergence of HIV drug resistance mutations (HIVDRM); the detection of HIVDRM relies on genotyping assays, however their use is limited in resource-constrained settings (RCS). Hence the need to develop an affordable and reliable point-of-care resistance testing assay for RCS is warranted.
Methods: ART naïve HIV-1 infected patients from Cameroon were subjected to a multivariate HIVDR analysis using Amplification Refractory Mutation System (ARMS)-PCR (a PCR-based point mutation assay), Standard sequencing (Sanger) and longitudinal Next-Generation Sequencing (NGS, MiSeq Illumina), to determine their mutation profiles for K103N, Y181C, K65R, M184V and T215Y/F. Subtyping was performed using phylogenetic methods (MEGA5.2 and FigTree).
Results: We processed 29 ART-naïve HIV-1 infected patients and generated pol sequences with the prevalent subtypes CRF02_AG (73%), F2 (14%), D (3%), A1G (3%), CRF11_cpx (3%) and CRF37_cpx (3%), confirming the predominance of CRF02_AG and the increasing rate of F2 in Cameroon. Pol sequences further served to identify HIVDRM and to validate ARMS-PCR. We compared three resistance testing methods for 29 patients, 5 mutation sites each (145 patient/mutation data sets). Using standard sequencing, the overall prevalence of HIVDR mutations was 4.8% (7/145) and included all studied mutations except K65R. Comparing ARMS-PCR with Sanger sequencing as reference, we obtained a sensitivity of 100% (7/7) and a specificity of >97% (135/138), caused by three false positive calls with ARMS-PCR. With NGS as reference, we observed one additional mismatch made up by minority variants (7%) that might not be clinically relevant. Longitudinal NGS analyses revealed changes in HIVDRM in four subjects that could not be attributed to treatment or superinfection.
Conclusions: The high sensitivity and specificity of the cost-effective ARMS-PCR method suggest it as a potential point-of-care assay to monitor transmitted HIVDRM in RCS. ARMS-PCR assay can guide the choice of more successful ART regimens; therefore, help improve ART programs in RCS. Longitudinal changes in HIVDRM should be considered even in the absence of treatment.

RNA and DNA sanger sequencing versus ultra-deep sequencing for HIV-1 drug resistance testing in treatment-naive patients

E.K. Alidjinou[1], J. Deldalle[1], C. Hallaert[1], O. Robineau[2], F. Ajana[2], D. Hober[1], L. Bocket[1]
[1]*Université Lille 2, CHU Lille, Virology Laboratory, Lille, France,* [2]*Université Lille 2, CH Dron, Infectious Diseases Department, Tourcoing, France*
Presenting author email: enagnonkazali.alidjinou@univ-lille2.fr

Background: HIV-1 drug resistance testing is recommended in patients at entry into care. Sanger sequencing on plasma RNA is the standard method used in clinical laboratories, but is limited by the non-detection of resistance associated mutations (RAMs) with prevalence below 20%. We compared RNA and DNA Sanger sequencing (RSS and DSS) to RNA ultra-deep sequencing (UDS) for RAMs detection in HIV-1 reverse transcriptase (RT), protease (PR), and integrase (IN) genes.
Methods: Sanger sequencing was performed on RNA and DNA, following recommendations of the French Agency for AIDS Research (ANRS). UDS was performed on RNA using the HIV-1 Drug Resistance Assay - v3.0 (Roche) on the 454 GS Junior sequencer. The IAS-USA list (2015) was used to identify RAMs in the different HIV-1 genes. ANRS, Rega and Stanford algorithms were used for drug resistance interpretation.
Results: The study included 54 ART-naive patients. The median age was 38.5 years old and patients were mainly male (87%). The number of patients with a least one major RAM was 3, 5, 5, 10 and 20 when using RSS, DSS, UDS 20%, UDS 5% and UDS 1% respectively. The highest number of major mutations was observed in the RT gene. UDS allowed detection in 2 patients of N155H mutation in the integrase gene, while no major mutation was found with RSS and DSS. Numerous minor mutations were detected in patients, especially in the PR gene. A very good agreement in RAMs detection was observed between RSS, DSS and UDS 20%, and drug resistance interpretation overall yielded high rates of susceptibility to antiretrovirals. Significant differences were observed between algorithms. ANRS algorithm was clearly the most stringent tool regarding PR inhibitors, while Stanford algorithm interpretations highly impacted IN inhibitors. Patients received mainly PR inhibitors and IN inhibitors based ART, and no impact of the minority RAMs detected by UDS was found on the virological outcome, six months after treatment initiation.
Conclusions: DSS does not clearly improve the detection of RAMs in ART-naive patients, as compared to RSS. UDS allows detection of minority RAMs; however their impact on the different drug classes and the clinically relevant threshold require further investigation.

MOPEB0274

Atypical mutations for RAL resistant clinical isolates, and associated integrase strand transfer inhibitor susceptibility with public algorithms

M. Underwood[1], R. Wang[1], K. Remlinger[2], Y. Zhao[2], C. Vavro[1], J. Horton[3]
[1]*ViiV Health Care, Clinical Virology and Immunology, Research Triangle Park, United States,* [2]*Glaxo Smith Kline, Research Triangle Park, United States,* [3]*Parexel International, Durham, United States*
Presenting author email: mark.r.underwood@viivhealthcare.com

Background: We previously evaluated INSTI resistance for 705 RAL-resistant isolates (RAL fold change in IC50 (FC) >1.5, Monogram biological cutoff). IN resistance substitutions H51Y, L74I/M, E92Q/V, T97A, G118R, E138A/K/T, G140A/C/S, Y143C/H/R, S147G, Q148H/K/R, V151I, S153F/Y, N155H, G163K/R, G193E, and R263K were originally available. We evaluated full-length integrase sequences for 48 of 85 isolates without RAL resistance mutations Y143C/H/R, Q148H/K/R, and N155H. We searched for additional substitutions associated with higher INSTI resistance, and compared FCs with predicted susceptibilities using publically available interpretation algorithms.
Methods: IN substitutions were enumerated by IAS 2015 **major** and minor mutations: **T66I, E92Q, F121Y, S147G, Y143C/H/R, Q148H/K/R, N155H,** T66A/K, L74M, E92G, T97A, E138A/K, G140A/S, R263K or non-IAS substitutions at positions V151I, E157Q, G163E, G193E, and V260I. Atypical substitutions are standard font. Comparison of HIV-1 genotypic resistance interpretation algorithms (HIVdb, REGA, ANRS), was performed using Stanford HIV Drug Resistance Database web tool HIValg, version 7.0.1, using the option to normalize algorithm interpretations to Susceptible (S), Intermediate (I), Resistant (R).
Results: For each 48 full length sample, all IN substitutions observed were summarized at each position with n= number of sequences with any listed substitution at that position; counts for atypical substitutions are also given: T66A/**I**/N/R (n=5; 2 with N/R), L74I/M (n=20; 6 with I), E92L/**Q**/V (n=7; L=1,V=1), T97A (n=33), F121**Y** (n=1), E138D/K (n=4; D=2,K=2), Y143A/G/S (n=13; G=7,A=1,S=2,A/S=3), V151I (n=8), N155S (n=2), E157Q (n=5), G163E/K/R/T (n=9), G193E/N/R (n=8), and V260I (n=1). Comparison of FC data with predictions from resistance databases ANRS, HIVDB, and REGA showed a substantial number of isolates with apparent higher FC than would be algorithm predicted.

Algorithm - Prediction	DTG FC Med. (Range) [#pts]	EVG FC Med. (Range) [#pts]	RAL FC Med. (Range) [#pts]
ANRS - S	1.0 (0.2 - 4.3) [48]	9.2 (1.2 - 71) [21]	4.45 (1.1 - 64) [25]
ANRS - I	NA [0]	NA [0]	NA [0]
ANRS - R	NA [0]	55 (6.1 - 144.7) [27]	100.2 (2.0 - 170.6) [23]
HIVDB - S	1.0 (0.2 - 4.3) [43]	7.8 (1.2 - 43) [15]	1.6 (1.1 - 14) [4]
HIVDB - I	1.4 (1.0 - 3.9) [5]	37.5 (3.2 - 131.9) [22]	8.7 (1.4 - 131.5) [29]
HIVDB - R	NA [0]	76 (11 - 144.7) [11]	100.7 (29 - 170.6) [15]
REGA - S	1.0 (0.2 - 4.3) [38]	17 (1.2 - 132.7) [37]	4.2 (1.1 - 137.3) [24]
REGA - I	1.0 (0.3 - 3.0) [9]	40 (40 -40) [1]	58.5 (1.7 - 170.6) [22]
REGA - R	3.9 (3.9 - 3.9) [1]	76.5 (11 - 144.7) [10]	13 (13-13) [2]

[Resistance Database Predictions]

Conclusions: Higher FCs were observed for EVG and RAL than expected in predicted Intermediate and Susceptible categories. This may be associated with a relatively high frequency of T97A (33 of 48) and atypical substitutions at positions previously associated with INSTI resistance.

HIV drug resistance among adults initiating antiretroviral therapy in Namibia

N. Mutenda[1], N. Taffa[2], S. Sawadogo[2], T. Nakanyala[1], C. Yang[3], C. Roscoe[2], A. Wolkon[2], M. De Klerk[2], G. Mutandi[2], S.V. Patel[3], D. Lowrance[4], N. Pentikainen[5], D. Prybylski[2], S. Agolory[2], E. Raizes[3], N. Hamunime[6], N.T. Wordofa[2]
[1]Ministry of Health and Social Services, Windhoek, Namibia, [2]Centers for Disease Control and Prevention (CDC), Windhoek, Namibia, [3]Centers for Disease Control and Prevention (CDC), Atlanta, United States, [4]Centers for Disease Control and Prevention (CDC), Dar es Salaam, Tanzania, United Republic of, [5]Namibian Institute of Pathology (NIP), Windhoek, Namibia, [6]Ministry of Health and Social Services (MOHSS), Windhoek, Namibia

Background: Knowledge of pre-treatment HIV drug resistance (PDR) can assist countries to monitor effectiveness of first-line antiretroviral therapy (ART) and minimize spread of HIV drug resistance (HIVDR). We present preliminary results from the first national PDR survey among adults initiating ART in public health facilities in Namibia.
Methods: Twenty-three clinics were randomly selected from among 74 ART clinics. Adults (≥18 years) initiating treatment were consecutively enrolled based on 2014 WHO PDR survey methodology. Consenting patients self-reported prior ART exposure and provided finger-prick dried blood spots (DBS) for HIVDR testing. HIVDR testing was performed at the CDC-Atlanta laboratory using ATCC HIV-1 genotyping kits. HIVDR mutations (DRMs) from quality-assured sequences were determined using the Stanford HIVDR interpretation algorithm. Significant DRMs (SDRMs) were defined as those predicted to cause low-, intermediate-, and high-level of resistance to drugs used in Namibia and recommended by WHO, including (NNRTIs [NVP & EFV], NRTIs, and PIs (DRV/r, LPV/r & ATV/r) for first-line ART.
Results: Overall, 509 patients were enrolled (67.8% females and 32.2% males) and 83 (16.3%) indicated prior ART exposure (15.2% males; 16.8% females). Samples from 387 DBS (76.0%) were successfully genotyped; DRMs were identified in 34.3% (95% CI: 29.8%-39.2%) and SDRMs in 13.0% (95% CI: 10.0%-16.8%). SDRM rates were 93.9%, 24.5% and 12.2% to NNRTIs, PIs, and NRTIs, respectively.
The most prevalent DRMs were K103N/S (9.0%), T74S (8.8%), E138A/D/E/G/K/N/Q (7.5%), and K20I/M (3.4%). Patients with prior ART exposure were more likely to have PDR than those without (30.4% v 9.2%; OR=4.3; 95% CI: 2.3-8.3). Viral load (VL) data were available for 116 survey patients on ART for 9-12 months since survey enrollment.
The viral suppression rate (VL <1000 copies/ml) was lower among patients with ART exposure (76.2%; 95% CI: 54.9%-89.4%), compared to those without (97.8%; 95% CI: 92.6%-99.4%).
Conclusions: Our unweighted results showed a moderately high level of PDR among adults initiating ART. Patients with prior ART exposure had more PDR and a lower probability of VL suppression after treatment. Alternative, non-NNRTI-based, first-line regimens need to be considered for patients reporting previous ART exposure to maximize the benefit of first-line treatment and minimize risk of HIVDR in Namibia.

MOPEB0276

HIV multi-class resistance in patients failing to first and second-line ART in resources limited setting, Mali

Background: Antiretroviral treatment (ART) has been widely implemented in resources constraint setting. Second-line ART has become more and more available but the biological monitoring is still limited. In order to achieve the goal of the three 90 of UNAIDS it will be interesting to know the resistance profile of the patients failing to ART. The objective of this study is to determine the prevalence of HIV multi-class resistance viruses and their impact the virological outcome.
Methods: All patients with virological failure on first or second-line ART in our routine genotyping system were included. The pol gene was sequenced by using viroseq or in house ANRS method.
Results: We identified 342 patients with genotypes available: 273 (79.9%) and 69 (20.1%) were on first and second-line ART, respectively. The median viral load (VL) was 69,740 copies/mm^3 and median CD4 was 276 cells/mm^3 at failure. The main first-line regimen was TDF/3TC/EFV and second-line was AZT/3TC/LPVr. Among the 342 patients, 21 (6%) had a wild-type virus and 321 (94%) with multi-class resistant virus. The prevalence of resistance mutations was: M41L (37%), A67G/N (42%), M184V (100%), T215F/Y (68%), K219E/Q (37%) and Q151M (16%) for the nucleoside. For non-nucleoside: K103N (32%), K101E/H/P (11%), Y181C/I/V (37%) and H221Y (21%). For PI: L76V (42%), V82A/F/T/S (21%) and I84V (37%). Patients were resistant to NRTIs in 83%, NNRTIs in 94% and PIs in 42%. Among the second-line ART failures, 19% were resistant to darunavir. After 6 and 12 months of ART, 63% and 76% of patients had suppressed HIV RNA less than 40 copies/ml.
Conclusions: Our results show a high level of resistance after first and second-line ART failure in Mali. Thus, resistance genotypic testing is crucial for patient failing to ART in resources limited setting to achieve the goal of the three 90.

Transmission of a primary integrase inhibitor resistance mutation identified in a Bronx, NY ambulatory clinic

T. Kanter[1,2], R. Kagan[3], H. Batterman[3], A. Omara[1], A. Menon[1,2], E. Gonzalez[1,2], M. Singh[1,2], C. Zeana[1,2], P. Kelly[1,2], M. Cavallo[4,5], M. Purswani[4,5]
[1]Bronx Lebanon Hospital, Department of Internal Medicine, Bronx, United States, [2]Bronx Lebanon Hospital Center, Division of Infectious Diseases, Bronx, United States, [3]Quest Infectious Diseases, Inc., San Juan Capistrano, United States, [4]Bronx Lebanon Hospital Center, Department of Pediatrics, Bronx, United States, [5]Bronx Lebanon Hospital Center, Division of Pediatric Infectious Diseases, Bronx, United States
Presenting author email: msingh1@bronxleb.org

Background: Primary integrase inhibitor (INI) resistance transmission is rare. However, INIs are now recommended as a first-line therapy for HIV infection. This report describes an antiretroviral -naïve individual who acquired an integrase mutation at primary infection.
Methods: Retrospective chart review of a patient followed by primary care providers at a clinic in the Bronx, NY. Clinical history and results of resistance testing were obtained through chart abstraction.
Results: A 17-year-old man reported to have a negative HIV test in February 2013. He and his male sexual partner tested negative for HIV with the expressed intention of having sex without use of a condom. In July 2013, after his partner screened HIV positive, the patient presented with disseminated lymphadenopathy and had a reactive 4th generation HIV screening test. His viral load (VL) was 100,234 copies/mL and CD4 count was 237 cells/µL. Resistance testing performed in August 2013 identified the reverse transcriptase (RT) mutation D67N and protease (PR) mutations M36M/I, D60E, I62V and A71T. No phenotypic resistance was reported. Integrase resistance testing was not performed. Further testing in December 2013 reported the same mutations, except M36M/I, and low levels of phenotypic resistance to unboosted atazanavir (fold-change [FC] 2.4) and nelfinavir (FC 3.9). Darunavir/ritonavir/tenofovir/emtricitabine was initiated in January 2014; however, complicated psychosocial issues led to incomplete adherence. In May 2015 the patient restarted the same regimen, when his VL and CD4 were 125,164 copies/mL and 258 cells/µL, respectively. Subsequent adherence was sporadic and, although his VL initially did not decline, by November 2015 the VL and CD4 were 744 copies/mL and 334 cells/µL, respectively. Genotypic testing at that time reported the M184M/V NRTI mutation and integrase mutations E92K and R263K, despite never having been prescribed an INI. R263K is a rare non-polymorphic mutation selected in patients receiving raltegravir (RAL) and dolutegravir (DTG). It reduces RAL, DTG, and EVG (elvitegravir) susceptibility by 2-4 fold.
Conclusions: This is the first report of integrase mutation R263K transmission in an antiretroviral-naïve patient with concurrent RT and PR resistance mutations. Since INIs are now recommended as first line therapy, baseline INI resistance testing should be considered in high-risk demographic settings.

Trends in HIV resistance to integrase inhibitors in Newark, New Jersey, USA

M. Brown[1,2], L. Sriramulu[1,2], T. Johnson[1,2], M.E. Szabela[1,2], J. Slim[1,2]
[1]*Saint Michael's Medical Center, Infectious Disease, Newark, United States,* [2]*New York Medical College, Medical Education, Valhalla, United States*
Presenting author email: drmsbrown@yahoo.com

Background: Integrase strand transfer inhibitors (INSTIs) are a relatively new and growing class of antiretroviral (ARV) drugs active against human immunodeficiency virus (HIV). Raltegravir (RAL) was the first INSTI approved in October 2007 followed by elvitegravir (EVG) as part of a fixed drug combination in August 2012. Most recently dolutegravir (DTG) was FDA-approved in August 2013 and has a high genetic barrier to resistance. DTG resistance has not been reported in clinical trials in those naïve to INSTIs.
The aim of our study was to identify the incidence of INSTIs resistance in our community and determine the likelihood of developing treatment-emergent INSTI resistance.
Methods: A retrospective chart review from October 1st, 2013 and October 31st, 2015 was performed in HIV-positive patients on INSTIs attending an outpatient HIV clinic in Newark, New Jersey. Four hundred and thirty-four patients were enrolled and clinical plus demographic data were obtained. Failure of ARV therapy was defined as a confirmed detectable viral load (VL) (VL >200 copies/ml) in patients previously controlled (defined as VL <20 copies/ml). Genotypic resistance testing was performed to determine the frequency of major mutations associated with the various ARVs.
Results: There were 253 male patients (58.3%). Two hundred and fifty-one patients (n=251, 57.8%) were on EVG for a total of 15,687.5 patient-week weeks. Fifty-eight (13.4%) were on RAL for 10,266 patient-week weeks and 125 patients (28.8%) on DTG for 2,750 patient-week weeks. Of the total 433 patients, only 13 developed resistance while on therapy. Eight patients were receiving EVG while 5 patients were on RAL. However, none receiving DTG developed resistance. Of these 13 patients, 5 (38.5%) had dual or triple class resistance.
Conclusions: The use of INSTI-based therapy has steadily increased as these agents have been proven safe and efficacious in the treatment of HIV. Resistance to first generation INSTIs RAL and EVG was rarely encountered, and DTG resistance was not identified in our patient population. However, this may be due to DTG's recent introduction. We propose that additional real world data is needed to determine how best to use INSTIs in efforts to preserve their utility.

MOPEB0279

The clinical utility of Cystatin C in assessing renal function among HIV-positive patients on antiretroviral therapy at Mildmay Uganda

E. Wekiya[1], J. Nakiyingi[2], J. Sanya[2], J. Nakaweesi[2], E. Mutebi[3], D. Nakanjako[3], Y. Karamagi[2], E. Namitala[2], G. Mujuzi[2], B. Mukasa[2], M. Matovu[4]
[1]*Mildmay Uganda, Medical Services, Kampala, Uganda,* [2]*Mildmay Uganda, Kampala, Uganda,* [3]*Makerere University, College of Health Sciences, Kampala, Uganda,* [4]*Makerere University College of Health Sciences, Clinical Epidemiology Unit, Kampala, Uganda*
Presenting author email: enock.wekia@mildmay.or.ug

Background: In clinical practice, measurement of glomerular filtration (GFR) rates is the gold standard for assessing renal function. Extra renal factors affecting creatinine concentration, the most widely used molecule in GFR estimation limit its efficiency. Use of exogenous substances e.g. inulin to measure GFR is not possible due to cost and complexity. Cystatin C has been proposed as a potential renal function marker but its use in HIV-Positive patients has not been well evaluated. The study was carried out to assess the clinical utility of Cystatin C based prediction equation in determining renal function among HIV-positive infected individuals.
Methods: A cross sectional study was carried out on 914 HIV-positive adults (≥18 years) on ART attending Mildmay Uganda for care and treatment between January to March 2015. Serum Cystatin C was measured by a quantitative sandwich enzyme immunoassay using the particle enhanced immunoturbidimetric assay. Creatinine was analyzed using enzymatic Creatinine PAP method. Using the results of the eGFR by creatinine as reference method, the sensitivity, specificity and positive/negative predictive values and likelihood ratios of Cystatin C were calculated.
Results: Of the 914 participants 626 (68.5%) were females and 288 (31.5%) were males. Median age in the study was 38.4years (IQR 31 - 45). Median weight was 61.5 (IQR 52 - 70). Mean Cystatin C (mg/L) concentration was 0.8mg/L. Means and standard deviation of the main blood chemistries were Serum Creatinine 77(31.8), Serum Cystatin C 0.8(.02), Potassium 4.4(0.6), Sodium 140(7.9), and Urea 3.1(1.6). The sensitivity of Cystatin C was 15.1% (95% CI= 8.4, 24) with specificity 99.3% (95% CI=98- 99.7). Positive and negative predictive values were 70.0% (95% CI 45.7-88.1) and 91.2% (95% CI 98.11-92.94) respectively. Positive likelihood ratio was 18.81 and negative likelihood ratio was 0.85. Cystatin C had diagnostic accuracy of 90.7 and area under curve was 0.768.
Conclusions: Cystatin C exhibited a high specificity and a high positive likelihood ratio in diagnosis of kidney disease among HIV-positive patients.

Management of cryptococcal meningitis in sub-Saharan Africa: still a long way to go

J. Gonzalez Perez[1], M. Muddu[2], J. Kwatampora[3], C. Nattembo[2], T. Tarumbiswa[4], J. Ssali[2], P. Iutung Amor[2]
[1]*AIDS Healthcare Foundation, Kigali, Rwanda,* [2]*AIDS Healthcare Foundation, Kampala, Uganda,* [3]*AIDS Healthcare Foundation, Nairobi, Kenya,* [4]*AIDS Healthcare Foundation, Maseru, Lesotho*
Presenting author email: juan.perez@aidshealth.org

Background: Cryptococcal Meningitis (CM) is one of the leading causes of mortality in HIV patients. Current WHO recommendations include screening with cryptococcal antigen (CrAg) test if CD4 baseline below 100 cells and initiation of treatment in symptomatic patients with CrAg positive when no immediate access to lumbar puncture (LP). Many African countries have adopted this approach but there is little evidence on how it is implemented. Here we analyze program data from facilities supported by the AIDS Healthcare Foundation (AHF) in Uganda, Kenya and Lesotho.
Methods: Data from HIV positive patients enrolled in facilities where CrAg test was available between January 2013 and July 2016 were included in the study. Six months retention in care after a positive CrAg test was calculated using Kaplan-Meier survival methods. Cox proportional hazards model was used to identify predictors of attrition in patients with CM.
Results: Twenty two health facilities met the inclusion criteria and 3985 clients had a CrAg test done during the study period. 222 of those tests were positive (5.6%). Out of those positive with complete data (74%), 45% were women, median age was 33 years and median CD4 was 45 cells. Overall 6 months retention after the CrAg positive result was 79%. 96 patients (58%) had symptoms suggestive of CM at the time of the CrAg result and 22% of them had an LP done. Out of those with positive CrAg in Cerebrospinal fluid (CSF) 53% received Amphotericin B as part of the antifungal treatment. Among the clinical suspects with CrAg positive where LP was not done, 12% received Amphotericin B and 80% received a regimen containing just Fluconazole (9% received the one recommended by WHO).
Conclusions: We identified several gaps in the implementation of WHO recommendations for diagnosis and management of CM, especially the low percentage of diagnosis confirmed with LP and patients treated with Amphotericin B. It is also concerning that just a small percentage of patients treated only with Fluconazole received the regimen recommended by WHO. National programs need to make an effort to increase access to LP and Amphotericin B and ensure clinicians are updated in the new protocols.

Presenting author email: amex_etu@yahoo.com

Background: Hepatitis C virus (HCV) antigen and antibody combination assays have been launched as a cost-effective alternative to nucleic acid testing (NAT) for early diagnosis by reducing the window period. This study evaluated the clinical performance of HCV antigen/antibody combination assays during window period using HCV seroconversion panels followed by NAT for ELISA reactive samples.
Methods: The performance of the Monolisa HCV antigen-antibody Ultra (Monolisa, Bio-Rad) and the Murex Ag/Ab test (Murex, Abbott) were compared by using two sets of serially diluted commercial HCV seroconversion panels [Genotypes (Gt) 1a & 2b]. Moreover, both assays were used to screen HCV co-infection in filter dried serum spots (DSS) of newly diagnosed HIV-cases (n=1683). All samples positive for both tests were evaluated in the quantitative RT-PCR (qRT-PCR) developed to amplify the 5´ non-coding region of HCV genome.
Results: For lower dilutions of HCV seroconversion panels, the Murex detected HCV infection 9 (Gt 1a) and 2 (Gt 2b) days earlier than the Monolisa. However,

Murex showed fluctuating and lower OD values below the cut-off for higher dilutions until days 28 (Gt 1a) and 135 (Gt 2b) compared with the Monolisa which showed a progressive increase in the OD value for all dilutions in each panel. Accordingly, 219/1683 (12.9%) and 193/1683 (11.4%) DSS samples were found positive in the Murex and Monolisa, respectively. Further testing of ELISA reactive samples by qRT-PCR revealed 167 NAT positive results. Of these, 74 (44.3%) were also positive for both, the Murex and Monolisa. Moreover, 10/167 (5.9%) of samples positive in the HCV RNA assay were only positive in the Monolisa while 5/167 (2.9%) were only positive in the Murex ELISA.
Conclusions: The Monolisa provides more reliable results for the detection of HCV infections in all dilutions compared to the Murex indicating its potential use for HCV screening in DSS. However, with its reactivity at earlier days of HCV infection, the Murex may serve as an additional diagnostic tool in HIV/HCV co-infected patients to narrow the window period. Moreover, the application of NAT on ELISA positive samples can be used to confirm early infections and to distinguish between active/chronic and resolved HCV infections.

Detecting mild HIV-associated neurocognitive disorders in multi-ethnic Malaysia

T. Mukherjee[1], R. Sakthivel[2], H. Yen Fong[2], M. McStea[2], S. Faridah Omar[2,3], C. Ai Virn[3], R. Rajasuriar[2,4,5], A. Kamarulzaman[2,3], L.A. Cysique[6]
[1]Yale University, Internal Medicine, New Haven, United States, [2]University of Malaya, Center of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia, [3]University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia, [4]University of Malaya, Department of Pharmacy, Kuala Lumpur, Malaysia, [5]University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [6]University of New South Wales, Neuroscience Research Australia, New South Wales, Australia
Presenting author email: lcysique@unsw.edu.au

Background: The Montreal Cognitive Assessment (MoCA) is commonly used to screen for HIV-associated neurocognitive disorder (HAND), primarily in Western countries, however, studies have found medium to adequate sensitivity for mild forms of HAND. Outside these regions, the validity of the MoCA is uncertain, especially when using the recommended cut-off score (≤ 26).
This study determines the optimal sensitivity of the MoCA to cognitive impairment in HIV-positive individuals on cART with viral suppression, and community-based controls in Malaysia.
Methods: A cross-sectional study of 350 HIV-positive (median CD4=106 cells/μL) from an infectious disease clinic at University of Malaya Medical Center, and 286 HIV-negative persons was completed between September 2014 and July 2016. All participants completed the MoCA and Lawton Instrumental Activities of Daily Living (IADL) to assess cognitive impairment and functional decline. The MoCA was scored according to the recommended cut-off, and regression based normative formula accounting for demographic variables and first order interactions were developed for the total score. The formulas were applied to the HIV-positive group, and impairment was defined using the Global Deficit Score (GDS) method. The Frascati criteria were used to determine HAND.
Results: The mean age was 44.3 ± 11.7 years, 72.7% were male, 42.6% had completed less than 12 years of education, and 24.3%, 65.3%, 9.9% were of Malay, Chinese and Indian ethnicity. When using a MoCA cut-off value of ≤ 26, the rate of impairment was 59.4% (HIV-negative) and 64.3% (HIV-positive). After establishing norms based on demographic characteristics, 40 (14.1%) HIV-negative and 78 (23.4)% HIV-positive persons were considered impaired. Of the 78, 65 (83.3%) and 13 (16.7%) were classified with asymptomatic neurocognitive impairment (ANI), and mild neurocognitive disorder (MND), respectively. HIV-associated dementia (HAD) was not detected in this population.
Conclusions: Normative corrections are needed when using the MoCA to detect cognitive impairment in Malaysian populations. Without normative corrections, there is not only poor sensitivity to HAND in the HIV-positive sample, but also considerable overestimation of cognitive impairment in healthy populations. When using norms, the MoCA is sensitive to mild HAND, similar to previous studies in different regions of the world. Criterion validity against more extensive neuropsychological testing is required.

Dolutegravir use during pregnancy and birth outcomes: data from the Antiretroviral Pregnancy Registry (APR)

V. Vannappagari[1,2], J. Albano[3], L. Ragone[1], A. Scheuerle[4], H. Tilson[2], T. Cook[5], Y. Xue[6], M. Bowen[7], N. Vielot[2], H. Garges[8]
[1]ViiV Healthcare, Epidemiology and Real World Evidence, Research Triangle Park, United States, [2]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, United States, [3]INC Research, Real World & Late Phase, Raleigh, United States, [4]University of Texas, Department of Pediatrics, Dallas, United States, [5]INC Research, Real World & Late Phase, Wilmington, United States, [6]INC Research, Biometrics, Raleigh, United States, [7]INC Research, Biometrics, Wilmington, United States, [8]ViiV Healthcare, Global Medical Sciences, Research Triangle Park, United States
Presenting author email: vani.x.vannappagari@viivhealthcare.com

Background: There are no well-controlled studies evaluating safety of dolutegravir (DTG) in pregnant women. The Antiretroviral Pregnancy Registry (APR) is an ongoing international, voluntary, prospective exposure-registration cohort study, that monitors for early warning signal of major teratogenic effects of antiretroviral (ARV) therapy and collects data on pregnancy and neonatal outcomes.
Methods: Using APR data on prospectively reported pregnancies, this analysis describes maternal demographic and clinical characteristics, pregnancy outcomes and frequency of birth defects among neonates with prenatal exposure to DTG.
Results: As of 31 January 2016, 61 pregnancies with exposure to DTG were prospectively reported to the APR with initial DTG exposure occurring among 32 pregnancies during 1st trimester, 7 pregnancies during 2nd trimester and 22 pregnancies during 3rd trimester. At enrolment, 23 (37.7%) women had a CD4 count ≥ 500 cells/μL, 19 (31.1%) had a CD4 count of 200-499 cells/μL, 16 (26.2%) had a CD4 count of < 200 cells/μL and unknown for 3 (4.9%).
Of 61 pregnancies, 51 (83.6%) resulted in live births (22 with 1st trimester and 29 with 2nd/3rd trimester DTG exposure), 3 (4.9%) resulted in induced abortions (all with 1st trimester DTG exposure), and 7 (11.5%) resulted in spontaneous abortions (all with 1st trimester DTG exposure). There were no stillbirths reported. Two of 51 live births (3.9%) reported birth defects - a bilateral polydactyly, post-axial to both hands with 1st trimester DTG exposure; and one Hypoglossia Hypodactylia Syndrome with 3rd trimester exposure to DTG.
Five of 51 live births reported non-defect adverse outcomes: 2 Preterm (<37 weeks of gestation), 1 low birth weight (LBW<2500 grams), 1 Preterm + LBW, and 1 Preterm + Very LBW (<1500 grams).
Conclusions: This analysis of birth defects includes the largest number of prenatal exposures to DTG to date. While limited in sample size to reach definitive conclusions, APR data do not demonstrate an increased risk of congenital anomalies with DTG use above the population expected rate of defects (2.72 - 4.17/ 100 live births from MACDP and TBDR respectively). Continued monitoring of prenatal DTG exposure and outcomes is needed. Clinicians are urged to continue reporting ARV exposures to the APR.

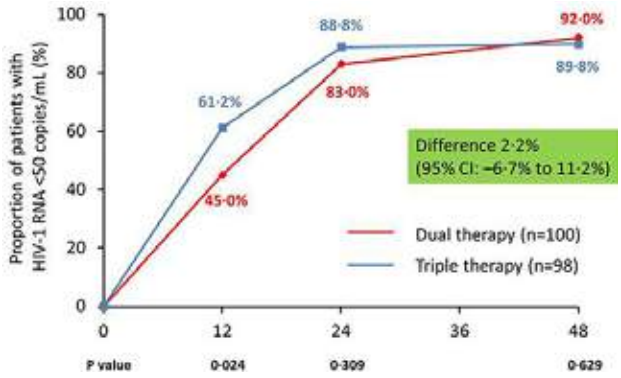
MOPEB0284

Simplified dual therapy (LPV/r plus 3TC) for ART-naïve patients is a viable alternative in resource-limited settings in China: 48-week results from a randomized, open-label, non-inferiority trial

W. Cai, H. He, L. Li, F. Hu, Y. Lan, X. Tang
Guangzhou Eighth People's Hospital, Guangzhou, China
Presenting author email: llheliza@126.com

Background: The evidence supporting dual therapy as a viable HIV treatment strategy for ART-naïve HIV-infected patients is increasing, driven by improvements in toxicity, costs and future options. However, there are very few reports from China where triple-therapy containing efavirenz (EFV) is recommended as the first-line regimen.
We evaluated the efficacy and safety of dual-therapy [lopinavir and ritonavir (LPV/r) plus lamivudine (3TC)] in Chinese ART-naïve HIV-infected patients, as compared to triple-therapy containing tenofovir (TDF), 3TC plus EFV.
Methods: This was a randomized, controlled, open-label, non-inferiority trial conducted in China. ART-naïve HIV-1-infected patients were randomized 1:1 to receive a dual-therapy regimen of LPV/r plus 3TC or a triple-therapy regimen of TDF, 3TC plus EFV. All patients were followed-up for 48 weeks after receiving ART. The primary endpoint was the proportion of patients with plasma HIV-1 RNA <50copies/mL at week 48, assessed with the US FDA snapshot algorithm.
Results: 274 patients were screened, of which 198 were found eligible and randomized into the dual-therapy group (DT group, n=100) or triple-therapy group (TT

group,n=98). 92 patients(92%) in the DT group and 88(89.8%) in the TT group achieved plasma HIV-1 RNA< 50copies/mL at week 48(difference 2.2%, 95%CI-6.7% to 11.2%,p=0.629).



[Proportion of patients with HIV-1 RNA <50copies/mL]

Among patients with baseline HIV-1 RNA100,000copies/mL,13 of 14 achieved primary endpoint in the DT group, as compared to 9 of 9(100%) in the TT group(p=1.000). No virological resistance was found in both groups. Mean changes in CD4 count from baseline through 48 weeks were similar in both groups (+203.2cells/mm^3 in the DT group vs. +174.8cells/mm^3 in the TT group,p=0.114). The safety profile was similar between the two groups. The majority of adverse events were mild and only one serious adverse event occurred in the DT group, which was unrelated to the study drugs.

Conclusions: Dual-therapy of LPV/r plus 3TC is effective, safe and comparable to the first-line triple-therapy regimen containing TDF,3TC plus EFV in China, even in patients with high baseline viremia.

MOPEB0285

Cost-effectiveness of the introduction of dolutegravir in first or second-line ART regimens in sub-Saharan Africa

A. Phillips[1], F. Venter[2], T. Apollo[3], A. Calmy[4], A. Pozniak[5], A. De Luca[6], A. Hill[5], P. Ehrenkranz[7], V. Cambiano[1], M. Wainberg[8], J. Lundgren[9], D. Pillay[10], M. Vitoria[11], N. Ford[11], L. Nelson[12], S. Bertagnolio[11], M. Doherty[11], P. Revill[13], Working group on cost effectiveness of dolutegravir introduction in sub-Saharan Africa

[1]UCL, London, United Kingdom, [2]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]University of Geneva, Geneva, Switzerland, [5]Chelsea & Westminster Hospital, London, United Kingdom, [6]University of Siena, Siena, Italy, [7]Bill & Melinda Gates Foundation, Seattle, United States, [8]Montreal Jewish General Hospital, Montreal, Canada, [9]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [10]Africa Health Research Organisation, Durban, South Africa, [11]World Health Organisation, Geneva, Switzerland, [12]Office of the US Global AIDS Co-ordinator, Washington, United States, [13]University of York, York, United Kingdom
Presenting author email: andrew.phillips@ucl.ac.uk

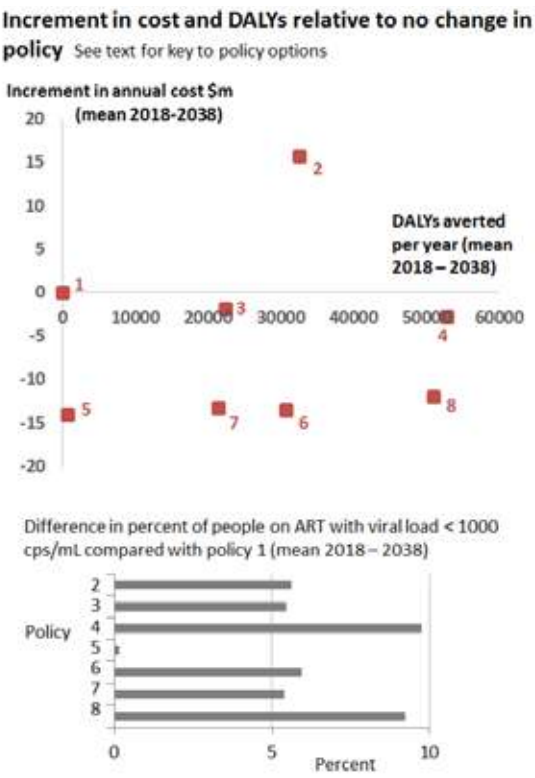
Background: While current ART regimens are highly successful there is potential for improvement in cost effective regimen choice with the introduction of the integrase inhibitor dolutegravir, which has a higher barrier to resistance, appears to be associated with reduced toxicity, although potential issues over pregnancy, people with TB and IRIS remain. .

Methods: We synthesized existing evidence in the framework of a dynamic, individual-based model and estimated the cost effectiveness of various policies involving use of dolutegravir-based regimens in the context of sub-Saharan Africa starting in 2018. Policy options considered were:

1. No change;
2. Increase rate of switch to 2nd-line (atazanavir-based);
3. All ART initiators: dolutegravir-based 1st-line;
4. All on first line ART: move from efavirenz to dolutegravir;
5. Transition of 2nd-line regimen to dolutegravir-based rather than atazanavir-based;
6. Transition of 2nd-line regimen to dolutegravir-based rather than atazanavir-based, plus an increase in rate of switch to 2nd line;
7. Dolutegravir 1st-line regimen for all new ART initiators, no switching to 2nd- line in those on dolutegravir, replacing atazanavir with dolutegravir in those on 2nd line already;
8. Dolutegravir-based regimen for all on 1st-line, no switching to 2nd-line in those on dolutegravir, replacing atazanavir with dolutegravir in those on 2nd-line already.

Dolutegravir cost $44, efavirenz $38, atazanavir $213; health systems perspective, 20 year time horizon, 3% discount rate.

Results: The figure shows the predicted increment in cost and DALYs averted for the alternative policies in the context of a country of population 10 million adults.



[Figure]

Dolutegravir introduction is predicted to lead to substantial DALY benefits, and a large reduction in costs if atazanavir is replaced in 2nd-line.

Conclusions: Dolutegravir introduction will likely bring health benefits and may well be cost saving, with various options for its use. However we should proceed with caution and current studies and possible future trials of dolutegravir are important to inform future use of the drug.

MOPEB0286

Patient reported outcomes (PROs) in HIV-infected adults enrolled in the NEAT001/ANRS143 trial comparing first-line ART regimens with darunavir/ritonavir (DRV/r) in combination with tenofovir DF/emtricitabine (TDF/FTC) or raltegravir (RAL)

Presenting author email: melanie.huet@chu-nantes.fr

Background: There are few data comparing patient reported outcomes (PROs) in HIV-infected individuals receiving first-line antiretroviral therapy (ART) with either a standard PI/r-based triple combination or a dual combination. We present results from a substudy of the NEAT001/ANRS143 trial.

Methods: The randomised trial demonstrated non-inferiority of first-line DRV/r 800/100mg once daily plus RAL400mg twice daily compared with DRV/r plus TDF/FTC 245/200mg once daily. Changes in PROs were assessed at 4, 12, 24, 48 and 96 weeks from baseline. PROs recorded were as follows: the EuroQoL 5

domains questionnaire (EQ-5D) and Visual Analogue Scale (VAS), the Centre for Epidemiologic Studies Depression scale (CES-d), and the HIV Treatment Satisfaction Questionnaire (HIVTSQ). Major Depressive Disorder (MDD) was defined as CES-d≥16. General estimating equations were used to model change over time in PROs form baseline. Cohen's d measuring effect size was calculated to compare arms in change from baseline for EQ5D.

Results: Of the 805 participants, 797 (99%) contributed to the substudy: 683/797 (86%) at baseline, 611 (77%) at W96, and 526 (66%) at both visits. Baseline PROs data were similar for the two treatment groups for all the variables. Participants reported health improvements over time (mean increase in VAS score of 7.98 by W96 (95%CI 6.5-9.4; p<0.001)). There were no statistically significant differences between the arms on EQ-5D during the study (VAS p=0.77, Cohen's d<0.2 for all EQ-5D domains). In addition, there was no significant difference between treatment groups on CES-d p=0.87, or odds of MDD during follow-up, adjusted for baseline MDD (OR=0.98, 95%CI 0.82-1.18). Satisfaction with treatment was lower in the RAL+DRV/r arm (Table 1) (median score: 53 RAL/r+DRV/r vs 55 TDF/FTC+DRV/r (p=0.001)).

Treatment Satisfaction Question at Week 96	RAL + DRV/r (% very satisfied)	TDF/FTC + DRV/r (% very satisfied)	X ² p-value
HIV well controlled	250/268 (93%)	277/287 (97%)	0.08
Satisfied with extent of unwanted side effects	234/267 (88%)	250/287 (87%)	0.85
Satisfaction with how demanding treatment is	180/267 (67%)	220/286 (77%)	0.01
Convenience	209/268 (78%)	249/287 (87%)	0.007
Flexibility of treatment	176/271 (65%)	217/285 (76%)	0.004
Satisfaction with understanding of HIV	232/266 (87%)	252/287 (88%)	0.84
Extent with which treatment fits into lifestyle	203/264 (77%)	250/287 (87%)	0.002
Recommendation to a friend	230/266 (86%)	267/288 (93%)	0.02
Continuation of treatment	230/266 (86%)	252/286 (88%)	0.56

[Table 1: HIVTSQ results]

Conclusions: PROs improved in both arms after starting ART, but with no statistically significant difference between arms. The lower level of convenience, flexibility and lifestyle suitability of RAL+DRV/r, may be explained by twice-daily drug administration.

MOPEB0287

Dolutegravir-lamivudine as initial therapy in HIV-infected, ARV naive patients: 96 week results of the PADDLE trial

M.I. Figueroa[1], M.J. Rolón[1], P. Patterson[1], A. Gun[2], P. Cahn[1], O. Sued[1]
[1]Fundacion Huesped, Clinical Research, Buenos Aires, Argentina, [2]Fundacion Huesped, Laboratory Research, Buenos Aires, Argentina
Presenting author email: maria.figueroa@huesped.org.ar

Background: Based on the results of the GARDEL trial, we designed a proof of concept study to evaluate the antiviral efficacy, safety and tolerability of a dual therapy regimen with Dolutegravir (DTG) 50m mg QD plus Lamivudine (3TC) 300 mg QD as initial HAART among ARV-naïve patients. Week 48 analysis was presented at AIDS 2016 (90% (18/20) reached the primary end point of a pVL <50 copies/mL. Week 96 results are reported here.

Methods: Pilot study including 20 HIV-infected ARV-naïve adults. Eligible participants had no IAS-USA defined NRTI resistance, HIV-1 RNA <100.000 copies/mL at screening and negative HBsAg. Viral load (pVL) was measured at baseline, on days 2, 4, 7, 10, 14, 21, 28 and on weeks 6, 8, 12, and thereafter every 12 months up to 96 weeks. Primary endpoint was the proportion of patients with HIV-1 RNA <50 copies/mL in an ITT-exposed analysis at 48 weeks and week 96(FDA-snapshot algorithm).

Results: Eighteen patients completed 48 weeks and were included in the extension phase. Fifteen patients completed week 96, 100% maintained plasma HIV-1 RNA below 50 copies/mL. Three patients are virologically suppressed at week 84. Their week 96 results will be reported at the conference. Mean CD4+ increase between baseline and week 96 was 271 cell/mm^3, without change between 48 and 96 weeks. No new virologic failures, no new AIDS defining illnesses, or SAEs (related/possibly related to study drugs) were observed. No Treatment discontinuations were reported through the extension phase. Two grade 3 laboratory abnormalities were reported (high cholesterol, and proteinuria) but considered unrelated to study drug.

Conclusions: In this pilot study, dual therapy with DTG+3TC has demonstrated efficacy, safety, tolerability and durability through 96 weeks of treatment. This strategy is being explored in a large randomized trial.

MOPEB0288

Adults with renal impairment switching from tenofovir disoproxil fumarate to tenofovir alafenamide have improved renal and bone safety through 144 weeks

D. Podzamczer[1], J.R. Arribas[2], A. Clarke[3], L. Cotte[4], T. Mudrikova[5], E. Negredo[6], W.J. Short[7], S. Jiang[8], A. Cheng[8], M. Das[8]
[1]Hospital Universitari de Bellvitge, Infectious Diseases Service, Barcelona, Spain, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom, [4]Hôpital de la Croix Rousse, Rhône, France, [5]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands, [6]Hospital Universitario Germans Trias i Pujol, Barcelona, Spain, [7]University of Pennsylvania, Philadelphia, United States, [8]Gil, Foster City, United States

Background: Elvitegravir, cobicistat, emtricitabine, and TAF (E/C/F/TAF) was associated with high efficacy and improved bone and renal safety in HIV-1 infected adults with mild to moderate renal impairment at Weeks (W) 48 and 96. We now report long-term (W144) efficacy and safety outcomes.

Methods: Virologically suppressed adults with stable renal impairment (eGFR$_{CG}$ 30 to 69 mL/min) switched from TDF- and non-TDF-containing regimens to open-label E/C/F/TAF. We report efficacy (HIV-1 RNA <50 c/mL FDA snapshot algorithm), renal and bone safety endpoints overall, and stratified by pre-switch TDF use.

Results: Of 242 participants switched to E/C/F/TAF [mean age 58 years (range: 24 - 82), 18% Black, 39% HTN, and 14% DM], 65% were on TDF pre-switch. At W144, virologic suppression was 83.1% (90% CI 77.7%, 87.7%). We observed significant improvements in median eGFR$_{CG}$ overall and by pre-switch TDF use, while those not on TDF pre-switch had no change (Table). No new participants discontinued study drug for renal adverse events after W96. There were no cases of proximal renal tubulopathy or Fanconi syndrome through W144. Participants had significant improvements in total proteinuria, albuminuria, and tubular proteinuria, with particularly marked improvements in pre-switch TDF takers (p<0.001 for all) (Table). Clinically significant proteinuria (UPCR >200 mg/g) and albuminuria (UACR ≥30 mg/g) at baseline resolved for 69% and 47% of all participants, respectively. Both hip and spine BMD increased significantly overall and more markedly for pre-switch TDF takers (p<0.001 for both); spine BMD increased significantly in non-TDF takers (p=0.030).

Conclusions: Through W144, HIV-infected adults with mild and moderate renal impairment who switched to E/C/F/TAF had high rates of virologic suppression, stable renal function, and significant improvements in proteinuria and BMD, with benefits particularly marked for pre-switch TDF users. These long-term data support switching from TDF-containing regimens to E/C/F/TAF in those with mild to moderate renal impairment.

MOPEB0289

Switching from TDF to TAF improves bone and renal safety independent of age, sex, race, or 3rd agent: results from pooled analysis (N=3816) of virologically suppressed HIV-1-infected adults

J. Rockstroh[1], C. Orkin[2], Y. Yazdanpanah[3], G. Di Perri[4], P.E. Sax[5], J.R. Arribas[6], K. Brinkman[7], D.A. Wohl[8], A. Cheng[9], L. Zhong[9], S. McCallister[9], M. Das[9]
[1]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany, [2]Royal London Hospital, Barts Health NHS Trust, London, United Kingdom, [3]Groupe Hospitalier Bichat Claude Bernard, Paris, France, [4]Comprensorio Amedeo Di Savoia, Turin, Italy, [5]Brigham and Women's Hospital, Boston, United States, [6]Hospital Universitario La Paz, Madrid, Spain, [7]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands, [8]University of North Carolina School of Medicine, Chapel Hill, United States, [9]Gil, Foster City, United States

Background: Five randomized trials evaluating switching from a tenofovir disoproxil fumarate (TDF)-containing regimen to a tenofovir alafenamide (TAF) regimen demonstrated improved bone and renal safety.

Methods: We pooled data at Week (W) 48 from five trials of HIV-infected, virologically suppressed individuals who switched from a TDF-containing to a TAF-containing regimen to assess outcomes in subgroups at risk of bone and renal complications: age, sex, race, baseline eGFR, and 3rd agent prior to switch (PI, integrase, or NNRTI).
Results: Of 3816 participants, 2205 (58%) switched to TAF and 1611 (42%) remained on TDF. 48 weeks after switching to TAF, there were statistically significant improvements in hip and spine BMD, eGFR, and total and tubular proteinuria overall and in all subgroups (Table 1). Of note, greater magnitude benefits were seen in those at greater bone and renal risk. Significant improvements in mean BMD % change were seen after switching to TAF vs TDF in women (hip: +1.4% vs +0.1%, spine: +2.3% vs -0.4%) and adults ≥50 years (hip: +1.1% vs -0.3%, spine: +1.9% vs -0.1%). Those on TAF with baseline eGFR < 90 mL/min had greater improvements in median eGFR (+6.2 vs +1.0 mL/min), significant median % declines in total (UPCR: -30.2% vs +14.8%, UACR: -25.1% vs +22.4%) and tubular proteinuria (RBP:Cr: -45.4% vs +43.7%; B2M:Cr: -62.6% vs +45.3%) compared with increases with TDF. Black participants who switched to TAF had improvements in both bone (hip: +1.2% vs +0.1%, spine: +1.9% vs -0.3%) and renal (UPCR: -15.6% vs +8.5%) safety. Improvements in bone and renal safety were independent of 3rd agent.
Conclusions: For >2200 individuals who switched to TAF, those at greater bone and renal risk had more benefit. These data support switching from TDF to TAF, in particular in TDF-treated individuals at high risk for low BMD or renal disease.

Subgroup		Treatment	Mean % change in BMD: Spine	Mean % change in BMD: Hip	Median eGFR$_{CG}$* change (mL/min)	Mean % change in renal biomarkers: UPCR	UACR	RBP: Cr	β2M: Cr

Limited impact of first-line drug resistance mutations among patients receiving second-line therapy in Uganda

M. Nanfuka[1], W. Zhang[2], S. Okoboi[1], J. Birungi[1], P. Kaleebu[3], S. Tibengana[1], J. Zhu[2], B. Afolabi[2], D. Moore[4]
[1]The AIDS Support Organisation, Research, Kampala, Uganda, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Medical Research Council, Research, Kampala, Uganda, [4]University of British Columbia, Vancouver, Canada
Presenting author email: nanfukam@tasouganda.org

Background: Most ART programs in low-income countries in Africa still have limited access to routine viral load (VL) testing. Concerns have arisen that delayed detection of treatment failure among patients in these settings may lead to sub-optimal response to second-line therapy due to accumulated drug resistance mutations (DRMs) on first-line ART.
Methods: Beginning in June 2012 we followed participants who had been on NNRTI-based first line ART for ≥4 years and had a measured VL ≥1000 copies/mL at enrollment. Participants were switched to protease inhibitor- (PI) based regimens and followed every six months until September 2016. We collected clinical and behavioural data by an interviewer administered questionnaire and measured VL at study exit. We conducted DRM testing on VL samples ≥1000 copies/mL collected at enrollment and study exit. We compared factors associated with virologic failure(VF) using Wilcoxon Rank Sum, Chi-square and Fisher's Exact Test.
Results: We enrolled 137(64.3% female) participants who had VL > 1000 copies/mL with a median age of 44 years(Q1-Q3= 4-7) and median duration on ART of 6 years(Q1-Q3=38-48). In a median of 2.8years(Q1-Q3=2.6-3.2) of follow-up, 7 (5%) died, 5(3.6%) voluntarily withdrew and 2 (1.5%) became lost-to-follow-up. Of 116 participants with a VL result at study exit, 20 (17.2%) had VL> 1000copies. Virologic failure was associated with a lower BMI both at baseline and 36 months (p=0.007) and (p=0.009) respectively and sub-optimal adherence (P=0.028). Of 105 patients with drug resistance data at enrollment, 103 (98%) had at least one drug resistance mutations, Participants with thymidine analogue mutations (TAMS) at enrollment were less likely to develop virologic failure on PI-based therapy (11% vs. 36%; p=0.007).
Of 18 patients with drug resistance testing at study exit 14(77%) had mutations, with M184V being most common (11/4 or 78%). A total of 4 participants developed PI resistance mutations and 1 had K65R.
Conclusions: Even in the presence of multiple DRMs at enrollment, virologic failure at nearly 3 years of follow-up on PI-based ART was infrequent. Sub-optimal adherence to ART was associated with virologic failure, but no DRMs found at enrollment were positively associated with failure.

MOPEB0291

Efficacy and safety of switching from RPV/FTC/TDF or EFV/FTC/TDF to RPV/FTC/TAF in Black adults

J.-M. Molina[1], E. DeJesus[2], B. Rijnders[3], F.A. Post[4], B. Vandercam[5], M. Stoeckle[6], A. Thalme[7], C. Orkin[8], Y.-P. Liu[9], D. SenGupta[9], H. Cao[9]
[1]Hôpital Saint-Louis, Paris, France, [2]Orlando Immunology Center, Orlando, United States, [3]Erasmus MC, Dept. Internal Medicine, Rotterdam, Netherlands, [4]King's College Hospital NHS Foundation Trust, London, United Kingdom, [5]Cliniques Universitaires St-Luc, Bruxelles, Belgium, [6]Universitätsspital Basel, Medizinische Poliklinik, Basel, Switzerland, [7]Karolinska Universitetssjukhuset, Stockholm, Sweden, [8]Royal London Hospital, Barts Health NHS Trust, London, United Kingdom, [9]Gil, Foster City, United States
Presenting author email: chloe.orkin@bartshealth.nhs.uk

Background: Black adults are disproportionately affected by HIV and chronic kidney disease. We report the efficacy and safety of switching from either emtricitabine/tenofovir disoproxil fumarate plus rilpivirine (RPV/FTC/TDF) or efavirenz (EFV/FTC/TDF) [TDF group] to the single-tablet regimen rilpivirine/emtricitabine/tenofovir alafenamide (RPV/FTC/TAF) in Black individuals.
Methods: We conducted a post-hoc subgroup analysis in Black adults using the Week (W) 48 efficacy and safety data pooled from 2 phase 3, double-blinded, randomized, active-controlled studies in virologically suppressed HIV-infected participants. Viral suppression (HIV-1 RNA <50 copies/mL) rates by FDA snapshot analysis at W48 were compared, and percent change in bone and renal measurements are reported.
Results: Of 1505 treated participants, 357 self-identified as Black (RPV/FTC/TAF n=183, TDF n=174). Baseline characteristics among Blacks were generally balanced between treatment groups; the median (range) age was 47 (21-76) years, 5% had diabetes and 34% hypertension. At W48, rates of virologic success were 87.4% RPV/FTC/TAF vs. 91.3% TDF (difference -3.9%, 95% CI -10.5% to 2.7%; p=0.30); the lower rate of success was primarily driven by study drug discontinuation (10.9% RPV/FTC/TAF vs. 6.5% TDF) due to reasons other than AEs, rather than by virologic failure. There was no emergent resistance with RPV/FTC/TAF. Lumbar spine and total hip BMD increased with RPV/FTC/TAF and minimally declined with TDF; differences in BMD change were statistically significant at W48 (p<0.001, Table 1). Assessment of renal safety using estimated glomerular filtration rate (eGFR) and protein:creatinine and albumin:creatinine ratios favored RPV/FTC/TAF, with similar trends observed for renal tubular biomarkers (Table 1). Switching to RPV/FTC/TAF from either EFV/FTC/TDF or RPV/FTC/TDF had minimal impact on fasting total cholesterol to HDL ratios.
Conclusions: Virologically suppressed Black adults who switched to RPV/FTC/TAF experienced improvements in proteinuria, albuminuria and BMD while maintaining high rates of viral suppression through Week 48.

	Blacks: RPV/FTC/TAF (n=183)	Blacks: TDF group (n=174)	P-value

MOPEB0292

Efficacy and safety of tenofovir alafenamide vs tenofovir disoproxil fumarate in HIV-infected virologically suppressed older adults: 96-week subgroup analysis of a randomized switch study

Y. Yazdanpanah[1], F. Raffi[2], J. Reynes[3], M. Johnson[4], C. Orkin[5], N. Clumeck[6], B. Conway[7], A. Lazzarin[8], F. Maggiolo[9], M. Rhee[10]
[1]Groupe Hospitalier Bichat-Claude Bernard, Paris, France, [2]C.H.U. de Nantes, Nantes, France, [3]C.H.U. Gui De Chauliac, Montpellier, France, [4]Royal Free London NHS Foundation Trust, London, United Kingdom, [5]Royal London Hospital, Barts Health NHS Trust, London, United Kingdom, [6]C.H.U. St-Pierre, Bruxelles, Belgium, [7]Vancouver ID Research and Care Centre Society, Vancouver, Canada, [8]Osp, Milano, Italy, [9]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [10]Gil, Foster City, United States

Background: As the HIV-infected population ages and has increasing prevalence of co-morbidities, efficacy and safety of antiretrovirals in older participants is of heightened importance. Tenofovir alafenamide (TAF) has a potential to benefit older individuals, as it has previously demonstrated an improved renal and bone safety profile compared to tenofovir disoproxil fumarate (TDF).
Methods: We conducted a 96-week subgroup analysis in those ≥50 years old for efficacy (pre-specified) and safety (post-hoc) from a randomized, double blind, active-controlled study in virologically suppressed HIV-infected participants on ARV regimens composed of emtricitabine/TDF (FTC/TDF) plus third agent, who either switched to FTC/TAF or remained on FTC/TDF, while maintaining their third agent.
Results: Of 663 treated, 294 were ≥ 50 years (FTC/TAF n=150, FTC/TDF n=144). Baseline viral load, CD4 counts, renal laboratory parameters, and bone mineral density (BMD) were similar between the two arms within those ≥ and < 50 years, respectively. For participants ≥50 years, virologic success by FDA snapshot algorithm at Week 96 was FTC/TAF 92% vs. FTC/TDF 92%; for those < 50 years, it was 86% vs 87%. Few participants discontinued study drug due to adverse events in either subgroups (≥50 years, FTC/TAF 3.3% vs. FTC/TDF 2.1%; < 50 years, 1.6% vs. 0.5%). The assessment of renal and bone safety using estimated glomerular filtration rate (eGFR), renal biomarkers, and BMD had significant differences between the two arms that consistently favored FTC/TAF over FTC/TDF (Table 1). No cases of Fanconi syndrome or proximal renal tubulopathy were reported with FTC/TAF (vs one participant ≥50 years in FTC/TDF group).
Conclusions: At 96 weeks, virologically suppressed adults ≥50 years who switched to FTC/TAF had comparable efficacy and improved bone and renal safety to those remaining on FTC/TDF. These findings of improved safety with TAF relative to TDF in older individuals are of particular importance as the population living with HIV ages and experiences more renal and bone-related comorbidities.

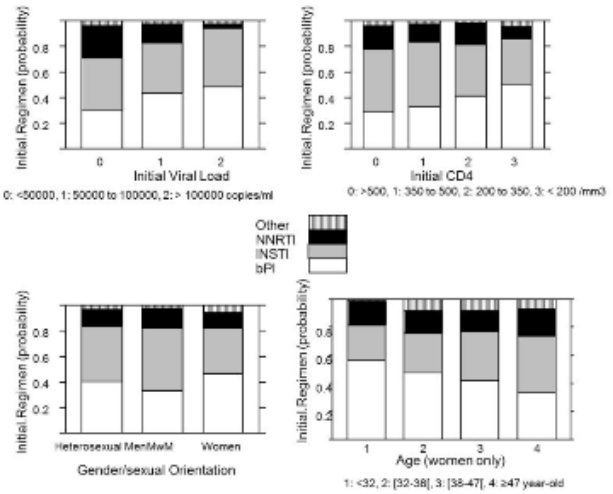
Presenting author email: cuzin.l@chu-toulouse.fr*

Background: To describe the evolution of initial ART regimens between 2005 and 2015 and the patients´ characteristics related with the choice of the regimen in 2015.
Methods: Patients starting ART between 2005 and 2015 were selected from a large prospective French cohort. Regimens were classified as three nucleos(t)ide reverse transcriptase inhibitors (NRTI); 2 NRTIs with a boosted protease inhibitor (bPI), with a non-nucleoside reverse transcriptase inhibitor (NNRTI), or with an INSTI; or other. A multinomial logit model was fitted to analyze characteristics related with the choice of the regimen in 2015.
Results: We analysed 15 897 patients, median age 38 years (stable across the study period), 63% men in 2005 to 73.8% in 2015 (p< 0.001). CD4⁺ cell count at initiation increased, from a median of 232 in 2005 to 390/mm³ in 2015 (p< 0.001) with no change in initial median viral load (VL) (4.7 log_{10}.copies/ml). Proportion of patients starting with: a bPI decreased from 60% before 2014 to 38.1% in 2015; a NNRTI decreased from 30% in the past years to 17.8% in 2015; an INSTI increased to 39.4% in 2015. In 2015, patients with an initial VL greater than 5 log.copies/ml were less prone to receive NNRTI (β=-2.46, SE=0.33) or INSTI regimens (β=-0.37, SE=0.15) than bPI, patients with initial CD4⁺ T cell count below 200/mm³ were less prone to receive NNRTI (β=-1.26, SE=0.25) or INSTI (β=-0.85, SE=0.18) than bPI, and women were less prone to receive an NNRTI (β=-0.23, SE=0.24) or an INSTI regimen (β=-0.33, SE=0.18) than a bPI, although for women age was also related with initial ART choice. The figure shows the probability of the initial regimen according to these factors and to age for women.



[Probability of initial regimen]

Conclusions: Choosing a first ART regimen in France is evolving. Forthcoming data in some patients' specific populations may lead to greater modifications.

MOPEB0294

A fixed dose combination of elvitegravir, cobicistat, emtricitabine, tenofovir disoproxil fumarate for the initial treatment of HIV-2 infection: 48 week results from Senegal, West Africa

S. Ba[1], D.N. Raugi[2], R.A. Smith[2], F. Sall[1], K. Faye[1], S.E. Hawes[3], P.S. Sow[1], M. Seydi[1], G.S. Gottlieb[2,4], University of Washington-Dakar HIV-2 Study Group
*[1]SMIT, CHNU Fann, UCAD, Dakar, Senegal, [2]University of Washington, Medicine/AID, Seattle, United States, [3]University of Washington, Epidemiology, Seattle, United States, [4]University of Washington, Global Health, Seattle, United States
Presenting author email: gottlieb@u.washington.edu*

Background: There is an urgent need for safe and effective ART for HIV-2 infection. HIV-2 treatment is complicated by intrinsic resistance to many FDA-approved HIV-1 drugs, and multidrug-resistance is common in individuals failing ART. There are limited options for 1st- and 2nd-line ART for HIV-2 in resource-limited settings. An increasing body of data suggests that integrase inhibitor-based regimens may be of utility for the treatment of HIV-2. We have undertaken the first clinical trial of a once-daily fixed-dose combination pill containing elvitegravir/cobicistat/emtricitabine/tenofovir disoproxil fumarate (E/C/F/TDF) to assess the effectiveness of this regimen in HIV-2-infected individuals in Senegal, West Africa.
Methods: HIV-2-infected, ART-naïve adults with WHO stage 3/4 disease or CD4 counts below 750 cells/mm³ were eligible for this open-label trial (NCT02180438), with planned enrollment of 30 subjects and follow-up for 48 weeks. We analyzed: HIV-2 viral load, CD4 counts, adverse events, mortality and loss to follow-up.
Results: We screened 35 subjects and 30 subjects started ART with E/C/F/TDF. 26 subjects have achieved at least 48 weeks of follow-up. The majority were female (80%), with a median age of 49 years at enrollment. There were no deaths, 1 loss to follow up/withdrawal and no new AIDS-associated clinical events. Median baseline CD4 count was 422 cells/mm³ (IQR: 317-530) and increased to 507 cells/mm³

(IQR: 413-604) at week 48. 25 subjects had baseline HIV-2 viral loads (VL) of fewer than 50 copies/ml of plasma, including 15 subjects who had viral loads below the limit of detection (10 copies/ml). In those with detectable HIV-2 VL, the median was 41 copies/ml (IQR: 22-57). Using a mITT analysis (FDA snapshot method), 24 of 25 (96%) had viral suppression at 48 weeks. E/C/F/TDF was generally well tolerated; there were three grade 3-4 adverse events, none were deemed study related. Adherence was good by self-report and pill count.
Conclusions: Long-term outcomes of HIV-2 infected patients on ART in West Africa are suboptimal and new therapeutic options are needed. Initial data suggest that E/C/F/TDF, a once-daily single-tablet regimen, is safe, effective, and well-tolerated in this population. Our findings support the use of integrase inhibitor-based regimens for HIV-2 treatment.

MOPEB0295

Comparison of 2 versus 3 fully-active drugs regimen in long-term virological success after first-line NNRTI failure. The key question: is three a crowd?

E. Loiza[1,2], N. Porteiro[1,2], V. Mingrone[1,2], E. Cordova[2]
[1]Hospital Francisco J. Muñiz, HIV Outpatient Care, Buenos Aires, Argentina, [2]IDEAA Foundation, HIV Outpatient Care, Buenos Aires, Argentina
Presenting author email: elianaloiza@yahoo.com.ar

Background: After virological failure HIV treatment guidelines recommend that a new ARV regimen should contain at least two, and preferably three, fully active drugs. Nevertheless, there are increasing data showing that an active boosted PI (PI/r) plus one active NRTI may effectively reduce viral load in some patients. The aim of our study was to evaluate in a real-life setting the long-term virological outcome of a PI/r-based therapy containing 2 or more active drugs after a first-line NNRTI treatment.
Methods: Retrospective study. HIV-1 infected patients who had virological failure to a first-line NNRTI regimen that started a PI/r-based regimen after genotyping test (TRUGENE HIV-1 Genotyping Assay) were included from the Outpatient Care Unit Muñiz Hospital cohort (MHOBA), Buenos Aires, Argentina (2002-2014). Number of active drugs was defined using the REGA genotypic sensitivity score (GSS): GSS 2.5: two active drugs; GSS ≥3: three or more active drugs. Sustained virological suppression was defined as HIV viral load (VL) < 50 copies/ml at week 96. Patients with PI resistance were excluded.
Results: A total of 164 patients were included. Male: 66%. Median age: 40 years. Median baseline CD4+ T-cell count: 210 cells/mL; baseline VL: 10.496 copies/ml. Fifteen percent of the patients had previous PI/r exposure and switched to a NNRTI-based therapy due to toxicity. Based on GSS, 30.4% of the patients started a PI/r plus 1 active drug (GSS 2.5) and 69.6% started a PI/r plus ≥2 active drugs (GSS ≥3). No significant differences were observed in both groups except for higher baseline HIV-VL in the GSS 2.5 group (p=0.03). The proportion of VL< 50 copies/ml at week 96 was: GSS 2.5 group: 48%; GSS ≥3 group: 49%; (p=0). No differences were observed between both groups stratifying by gender, age, VL, CD4+ T-cell < 200 cells/mL, and PI-experience.
Conclusions: After first-line NNRTI virological failure, a 2 fully-active drug regimen including a PI/r was as effective as a 3 or more fully-active drug regimen at week 96. The use of fewer active drugs in this setting could reduce toxicities and costs without affecting the long-term virological efficacy.

MOPEB0296

Prevalence of viral suppression in persons living with HIV on antiretroviral treatment in 30 facilities in Botswana

E. Raizes[1], J. Theu[2], S. Matambo[3], L. Block[1], T. Marukutira[3,4], W. Abrams[3], V. Novitsky[5], A. Miller[1], S. Lockman[5], S. Moyo[6], S. El-Halabi[2], L. Mills[3,7]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]Botswana Ministry of Health, Gabarone, Botswana, [3]Centers for Disease Control Botswana, Gabarone, Botswana, [4]Monash University, Melbourne, Australia, [5]Harvard T H Chan School of Public Health, Boston, United States, [6]Botswana-Harvard AIDS Institute, Gabarone, Botswana, [7]Centers for Disease Control Rwanda, Kigali, Rwanda
Presenting author email: eraizes@cdc.gov

Background: Viral suppression (VS) is the third component of the UNAIDS 90-90-90 targets for HIV epidemic control. The Botswana Combination Prevention Project (BCPP) offers a unique opportunity to evaluate rates of VS in Botswana. The baseline household survey (BHS) component of BCPP found that 96.5% of HIV-infected persons on ART in 30 BCPP communities had VS defined as a viral load (VL) HIV-1 RNA ≤ 400 copies/ml. This report provides additional information on rates of VS from clinics providing ART in BCPP communities.
Methods: Data on VL testing and other clinical and demographic information are routinely captured in national electronic medical record systems for all persons currently on antiretroviral therapy (ART). Botswana national guidelines call for VL testing 3 and 6 months after ART initiation and every 6 months thereafter. We used clinical and VL data from patients receiving ART in 30 communities taking part in the ongoing community-randomized BCPP. Using the most recent VL, rates of VS were determined for all persons living with HIV (PLHIV) currently on ART in one of these 30 community clinics, with at least one VL reported between January 13, 2016 and January 12, 2017.
Results: Of the 21,920 PLHIV designated as currently on ART for ≥ 6months, 18,856 (86.0%) had a VL recorded in the prior 12 months with 18,194 (96.5%) having VS. Assuming that PLHIV with missing VL are not suppressed, then overall 83.0% of PLHIV on ART for ≥ 6 months were found to have VS.
Conclusions: Analysis of program data from 30 community clinics participating in BCPP reveals very high levels of VS consistent with prior reports of rates of VS derived from the BHS. However, PLHIV with missing VL data may be less likely to have VS and therefore there is uncertainty as to whether the 3rd 90 (90% of persons on ART with VS) has been achieved in these communities. Factors associated with high rates of VS noted in two different modalities of evaluation, a household survey and a clinic record review within these 30 communities, along with the impact of missing data should be further explored.

MOPEB0297

Real-world comparative 48-week outcomes of switching to 2 nucleoside reverse transcriptase inhibitors and an integrase inhibitor

Ustianowski[11]
[1]Royal Sussex County Hospital, Brighton, United Kingdom, [2]University College London, London, United Kingdom, [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [4]Chelsea and Westminster Hospital, London, United Kingdom, [5]Western General Hospital, Edinburgh, United Kingdom, [6]Royal Free London NHS Foundation Trust, London, United Kingdom, [7]London Northwest Healthcare NHS Trust, London, United Kingdom, [8]Lewisham and Greenwich NHS Trust, London, United Kingdom, [9]King's College Hospital NHS Foundation Trust, London, United Kingdom, [10]Heart of England NHS Foundation Trust, Birmingham, United Kingdom, [11]North Manchester Genral Hospital, Manchester, United Kingdom, [12]Homerton University Hospital, London, United Kingdom

Background: Switching to integrase inhibitor (INI) based ART can reduce toxicities and drug interactions. There is a lack of comparative data between the three current INIs to guide use.
Methods: Multicentre retrospective evaluation of patients on ART with HIV VL< 50c/mL switching to a dual-NRTI backbone with the INIs dolutegravir (DTG), cobicistat-boosted elvitegravir (EVG) or raltegravir (RAL) in the UK and Ireland from 1/1/15-31/8/15. The main outcome was 48-week viral suppression (VL< 50c/mL): (i) those without 48-week VL excluded (M=E; S=I); (ii) those without 48-week VL considered as VL>50c/mL (M=F; S=I); (iii) those without 48-week VL or who switched from INI considered as VL>50c/mL (M=F; S=F; NRTI changes ignored).
Results: 12 centres provided data on 359 individuals. 105 (29%) switched to RAL; 218 (61%) DTG; and 36 (10%) EVG. At switch, there were no significant differences in gender (male: RAL-70%, DTG-75%, EVG-72%), median age (46, 47, 48 years), white ethnicity (61%, 65%, 64%) or main HIV risk being sex between men (58%, 61%, 53%). There were differences in percent with CD4< 200 cells/µl (0%, 6%, 3%; P=0.03). 64%, 60% and 44% switched from PI/r-based ART respectively (p=0.0048).
At 48 weeks, comparable proportions achieved VL< 50 c/mL (table, M=E; S=I); however when considering INI switch and missing VL as failure significant differences were observed.
By 48 weeks, 25/105 (24%) discontinued RAL, 27/218 (12%) DTG and 8/36 (22%) EVG (P=0.023). VL was detectable at switch in 2/25 (8%) taking RAL, 1/27 (4%) DTG and 0/8 (0%) EVG. No genotypes or resistance development was reported for anyone discontinuing initial INI. Side effects/toxicity was the most common indication for stopping INI (37/60, 62%). Switch for simplification was common for RAL (9/25, 36%).

Outcome	RAL (n=105)	DTG (n=218)	EVG (n=36)	P (b)
M=E, S=I	69/73 (95%)	159/162 (98%)	26/28 (93%)	0.19
M=F, S=I	69/105 (66%)	159/218 (73%)	26/36 (72%)	0,40
M=F, S=F	51/105 (49%)	140/218 (64%)	23/36 (64%)	0.023
(a) on initial INI with VL<50 (b) chi-squared test				

[Viral load outcomes (VL<50c/mL) at 48 weeks]

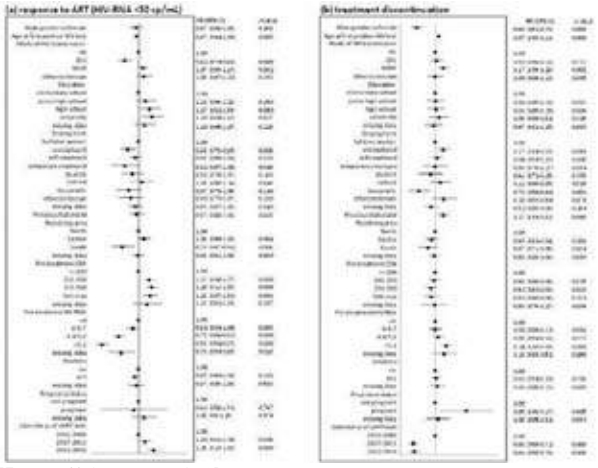
Conclusions: Those switching to INI+2NRTI had high rates of viral suppression, with discontinuations driven mainly by side effects/toxicity. Twice daily dosing of RAL seemed to prompt a small number to switch again for convenience.

MOPEB0298

Impact of social determinants on antiretroviral therapy access and outcomes entering the era of universal treatment for HIV-infected people

A. Saracino[1], M. Zaccarelli[2], P. Lorenzini[2], A. Bandera[3], G. Marchetti[4], F. Castelli[5], A. Gori[3], E. Girardi[6], A. d'Arminio Monforte[4]
[1]University of Bari, Clinic of Infectious Diseases, Bari, Italy, [2]National Institute for Infectious Diseases ,Lazzaro Spallanzani' IRCCS, Clinical Department, Rome, Italy, [3]'San Gerardo' Hospital - University of Milano-Bicocca, Clinic of Infectious Diseases, Monza, Italy, [4]San Paolo Hospital, University of Milan, Clinic of Infectious Diseases, Milan, Italy, [5]University of Brescia and Spedali Civili General Hospital, University Division of Infectious and Tropical Diseases, Brescia, Italy, [6]National Institute for Infectious Diseases ,L. Spallanzani', IRCCS, Department of Epidemiology, Rome, Italy
Presenting author email: annalisa.saracino@uniba.it

Background: Social determinants are known to be a driving force of health inequalities, even in high income countries. Aim of our study was to determine if these factors can limit ART access, outcome and retention in care of people living with HIV (PLHIV).
Methods: All ART naïve PLHIV of Italian nationality enrolled in the Icona Cohort from 2002 to 2016 were included. The association of socio-demographic characteristics (age, sex, risk factor, education, occupational status and residency area) with time to ART initiation from 1st-positive anti-HIV test, 1-year probability of HIV-RNA <50 cp/mL, and 1-year risk of 1st-ART regimen discontinuation were evaluated by Cox regression, Kaplan Meier and log-rank test. Three study periods were compared: 2002-2006; 2007-2011; 2012-2016.
Results: A total of 8,023 PLHIV (82% males, median age at first positive anti-HIV test 36 years, IQR: 29-44) were included, of whom 6,214 (77.5%) started ART during the study period. Females, pts aged >50 years, unemployed vs employed, and people with lower educational levels presented the lowest CD4 count at ART initiation. The overall median time to ART initiation was 0.6 years (IQR 0.1-3.7), with a significant decrease over time [2002-2006=3.3 yrs (0.2-9.4); 2007-2011=1.0 yrs (0.1-3.9); 2012-2016=0.2 yrs (0.1-2.1), p<0.001]. By multivariate analysis, females (p<0.01), IDUs (p<0.001), retired patients (p<0.001) and housewives (p=0.18) presented a longer time to ART initiation, while older people (per 10 yrs increase) (p<0.001), subjects with higher educational levels (p<0.001), unemployed (p=0.02) and students (p<0.001) were more likely to initiate ART. Factors associated with
(a) virological response to ART (HIV-RNA < 50 cp/mL) and with
(b) treatment discontinuation for any cause are shown in Figure 1.



[Figure 1. Multivariate analysis]

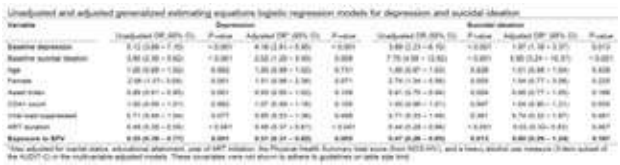
Conclusions: Despite median time to ART start decreased dramatically from 2002 to 2016, socio-demographic factors still contribute to disparities in ART initiation, outcome and durability.

MOPEB0299

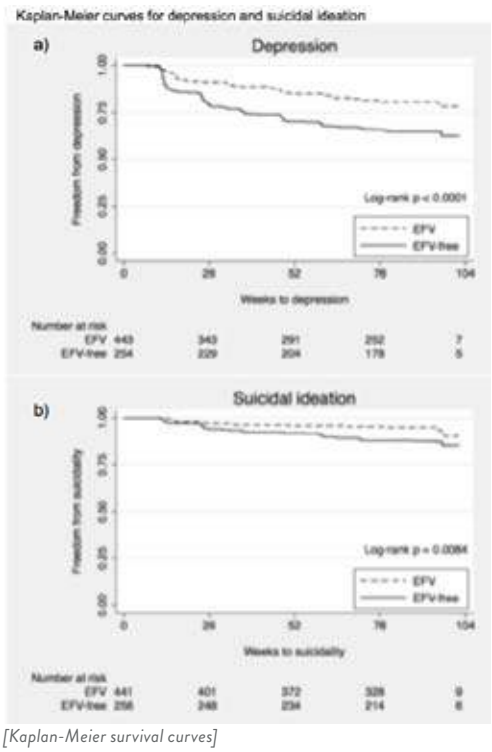
Efavirenz use and risk of depression and suicidal ideation in HIV-infected adults receiving antiretroviral therapy in Southwestern Uganda

J. Chang[1,2], A. Tsai[2,3,4], J. Haberer[2,5], Y. Boum[4,6], J. Martin[7], P. Hunt[8], D. Bangsberg[4,9,10], M. Siedner[2,4,11]
[1]Duke University School of Medicine, Durham, United States, [2]Massachusetts General Hospital, Center for Global Health, Boston, United States, [3]Massachusetts General Hospital, Department of Psychiatry, Boston, United States, [4]Mbarara University of Science and Technology, Mbarara, Uganda, [5]Massachusetts General Hospital, Department of Medicine, Boston, United States, [6]Epicentre Mbarara, Mbarara, Uganda, [7]University of Californi, Department of Epidemiology and Biostatistics, San Francisco, United States, [8]University of California, Department of Medicine, San Francisco, United States, [9]Oregon Health & Science University, Portland, United States, [10]Ragon Institute, Boston, United States, [11]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States
Presenting author email: jonathan.chang@duke.edu

Background: There is conflicting evidence on the morbid neuropsychiatric effects of efavirenz and limited data in sub-Saharan Africa, where efavirenz remains commonly used.
Methods: We analyzed data from 704 participants in the Uganda AIDS Rural Treatment Outcomes Study, a cohort of adults in southwestern Uganda observed every 3-4 months from 2005-2015. The primary exposure was efavirenz use, defined as a prescription including efavirenz for seven consecutive days and >60/90 days prior to a visit. Outcomes of interest were: 1) depression, defined by a score >1.75 on the Hopkins Symptom Checklist; and 2) self-reported suicidal ideations (SI). We fitted generalized estimating equations (GEE) logistic regression models and graphed Kaplan-Meier curves to examine the association between efavirenz and risk of depression and SI, accounting for baseline depression and SI, demographics, CD4 count, viral suppression, ART duration, year of ART initiation, quality of life, and heavy alcohol use.
Results: There were no differences at ART initiation in depression or SI among those receiving efavirenz versus other regimens (P>0.5). In multivariable-adjusted models, use of efavirenz was paradoxically associated with a lower risk of depression (GEE AOR 0.51; 95% CI, 0.31-0.82) and was not associated with SI (GEE AOR 0.60; 95% CI, 0.29-1.24). Results were robust to exclusion of baseline suicidal and depressed patients.



[GEE logistic regression models]



[Kaplan-Meier survival curves]

Conclusions: We did not identify an association between efavirenz use and an increased risk of depression or SI in southwestern Uganda. Future analyses should assess for the possibility of time-varying confounding to corroborate this finding and to support efavirenz as a first-line agent in the region.

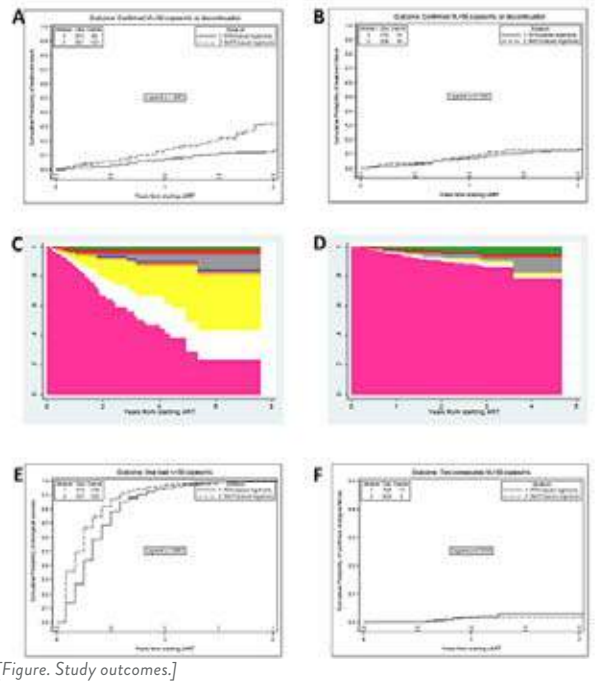
MOPEB0300

Durability of rilpivirine- and integrase inhibitor-based first-line regimens in HIV-infected patients starting antiretroviral therapy with a viral load < 100,000 copies/mL: data from the ICONA Foundation Study

N. Gianotti[1], F. Maggiolo[2], A. Cozzi-Lepri[3], A. Antinori[4], S. Nozza[1], G. Lapadula[5], A. De Luca[6], C. Mussini[7], A. d'Arminio Monforte[8], ICONA Foundation Study Group
[1]San Raffaele Scientific Institute, Infectious Diseases, Milano, Italy, [2]ASST Papa Giovanni XXIII, Infectious Diseases, Bergamo, Italy, [3]University College London, London, United Kingdom, [4]National Institute for Infectious Diseases, Infectious Diseases, Roma, Italy, [5]Ospedale San Gerardo ASST Monza Brianza, Infectious Diseases, Monza, Italy, [6]Siena University Hospital, Infectious Diseases, Siena, Italy, [7]Azienda Ospedaliero Universitaria Policlinico di Modena, Infectious Diseases, Modena, Italy, [8]Clinic of Infectious Diseases, S. Paolo Hospital, University of Milan, Milano, Italy
Presenting author email: nicola.gianotti@hsr.it

Background: Aim of the study was to compare the durability of rilpivirine (RPV) and integrase inhibitor (InSTI)-based first-line regimens in HIVinfected patients starting antiretroviral therapy (ART) with < 100,000 HIV-RNA copies/mL.
Methods: Patients enrolled in ICONA Cohort who started ART since January 2012 with HIV-RNA < 100,000 copies/mL, RPV or one InSTI, ≥1 follow-up visit thereafter, were included in this analysis.
Primary endpoint: cumulative probability of treatment failure (TF=confirmed virological failure >50 copies/mL or discontinuation of ≥1 drug in the regimen), as assessed by Kaplan-Meier method and log-rank test; independent associations were investigated by Cox regression.
Results: 1476 patients, 18% females, 4% in stage C, 10% with a CD4+ nadir < 200/µL, included in the analysis. 815 and 661 started RPV and InSTI (38% elvitegravir/cobicistat, 42% dolutegravir, 21% raltegravir), 96% and 73% with tenofovir/emtricitabine, respectively.
Over a median (Q1-Q3) follow-up of 17 (7-28) and 8 (2-15) months in the RPV and in the InSTI group, the cumulative probability of TF was higher in the InSTI group (p< .0001, Figure, panel A), but there was no difference when considering only patients who started a single table regimen (STR, Figure panel B).

Figure. A) cumulative probability of treatment failure in the overall population; B) cumulative probability of treatment failure in patients who received a single tablet regimen; C) cumulative probability of discontinuation of an integrase inhibitor-based regimen according to reason(*); D) cumulative probability of discontinuation of a rilpivirine-based regimen according to reason(*); E) cumulative probability of attaining <50 HIV-RNA copies/mL; F) cumulative probability of virological failure (two consecutive HIV-RNA values >50 copies/mL).
*(Green = failure; Red = Intolerance; Grey = Toxicity; Orange = Non-Adherence; Yellow =Simplification; White = Other reason; Pink= Never stopped)



[Figure. Study outcomes.]

The main reason for discontinuation in the InSTI group was treatment simplification (43/114=38%). After adjusting for age, gender, nation of birth, mode of HIV transmission, hepatitis coinfection, stage C, tenofovir/emricitabine vs. abacavir/lamivudine as backbone, baseline CD4+ count and HIV-RNA and year of starting ART, risk of TF was independently associated with treatment with InSTI (AHR [95%CI]=2.41 [1.75-3.31]; p< .001).
Conclusions: In patients starting ART with < 100,000 HIV-RNA copies/mL, the risk of TF was lower in patients starting a RPV-based treatment compared to those initiating InSTIs, but there was no longer a difference when restricting to STR regimens. A STR seems to be a key factor for the durability of initial antiretroviral treatment.

MOPEB0301

Similar reduction of blood HIV-1 DNA reservoir with raltegravir and efavirenz in HIV-infected patients co-infected with tuberculosis

Background: Faster viremia control is obtained on integrase inhibitor (INI)-based compared to non-nucleoside reverse transcriptase inhibitor (NNRTI)-based regimens. The respective effects of INI and NNRTI on HIV DNA reservoir are unknown. We studied the evolution of HIV-1 DNA quantification over the first year of treatment with efavirenz or raltegravir-based regimens.
Methods: The ANRS REFLATE I phase 2 study was a non-comparative, open-label, randomized trial including antiretroviral-naive patients with HIV-1 infection and tuberculosis to receive raltegravir 400mg (RAL400), raltegravir 800mg (RAL800) or efavirenz (EFV) with tenofovir and lamivudine. Total HIV-1 DNA load in TCD4+ cells was quantified using Biocentric Generic HIV DNA Cell kit in blood samples obtained at week 0 (W0), week 24 (W24) and week 48 (W48). HIV-1 DNA levels and changes over time in the 3 treatment groups were compared with a linear mixed model including random effects on intercept and slope.
Results: Blood samples (including at least W0 baseline sample) were available for 126 participants (RAL400, n=40; RAL800, n=41; EFV, n=45), mostly men (71.4%) and a median (IQR) age of 36 (30-44) years. Baseline median (IQR) plasma HIV-1 RNA was 4.9 (4.4-5.5) $\log_{10}$copies/ml and median CD4+ count was 140 (61-305) cells/mm^3. Treatment led to plasma HIV-1 RNA < 50copies/ml in RAL400 (79% at W24 and 91% at W48), RAL800 (89% and 85%) and EFV (76% and 90%) arms. Respective median TCD4+ increases from inclusion to W24 and to W48 were 195 (76-370) and 214 (161-372) in the RAL400 arm, 134 (76-233) and 222 (108-395) in the RAL800 arm, and 170 (88-268) and 216 (87-328) in the EFV arm. Median (IQR) HIV-1 DNA ($\log_{10}$copies/10^6 CD3+CD4+ cells) at inclusion was 4.7 (4.2-5.1) in the RAL400 arm, 4.6 (4.2-5) in the RAL800 arm and 4.9 (4.4-5.1) in the EFV arm (Kruskall-Wallis p=0.28). Estimated HIV-1 DNA decreases ($\log_{10}$copies/10^{6}CD3+CD4+ cells) per one year were -0.91 in the RAL400 arm, -0.90 in the RAL800 arm and -0.93 in the EFV arm (p=0.98).
Conclusions: In AIDS patients with tuberculosis, HIV-1 DNA decrease in blood was estimated as 1 $\log_{10}$ copies/10^{6}CD3+CD4+ cells over 1 year, with either dose of raltegravir and efavirenz in combination with TDF/3TC.

Presenting author email: kara.mcgee@duke.edu

Background: Prompt diagnosis and treatment of Acute HIV Infection (AHI) may have important clinical and public health benefits. This study sought to determine if integrase inhibitor (InSTI)-based antiretroviral treatment (ART) initiated during AHI suppresses HIV replication more rapidly than efavirenz-based ART.
Methods: This is a prospective, multicenter, single arm, 48-week open-label study of co-formulated elvitegravir (EVG), cobicistat (COBI), emtricitabine (FTC), and tenofovir disoproxil fumarate (TDF) initiated within 30 days of AHI diagnosis. The primary endpoint is the proportion of participants with HIV RNA < 200 copies/mL (c/mL) by week 24 and < 50 c/mL at week 48. We compared the time to viral suppression in this study population to that of a previously studied cohort of patients treated within 30 days of AHI with co-formulated FTC/TDF/Efavirenz (EFV) using the Wilcoxon-Mann-Whitney test.
Results: Between September 2012 and April 2015, 33 participants with AHI started InSTI-based ART. Their median age was 26 years (range 18-54), 64% were black, and most (76%) were MSM. Three participants discontinued early, leaving 30 study participants for analysis. In a previous study, 90 acutely infected participants were treated with EFV-based ART between January 2005 and December 2011, and 89 remained on ART and included in time to suppression analysis. Demographic data was similar in both groups, as was time to ART initiation, median pre-treatment CD4 count and peak HIV RNA. Of those treated with InSTI-based ART, 29/30 (97%) achieved HIV RNA < 200 copies by week 24, and 26/30 (87%) to <50 copies/mL by week 48, compared to 92% at week 24 and 80% at week 48 of participants treated with EFV-based ART. The median time from ART initiation to viral suppression was significantly more rapid for InSTI-based ART patients (HIV RNA <200 copies/mL at 26 days (range 7-132) and <50 copies/mL at 54 days (range 12-251) compared to EFV-based ART [65 days (range 7-523) and 105 days (range 14-523)] respectively (p<0.0001).
Conclusions: Once daily InSTI-based ART with EVG/COBI/FTC/TDF in acute HIV infection achieves rapid HIV suppression, potentially limiting infectivity during a period of high infectiousness. These results support the use of integrase inhibitor-based treatment for AHI.

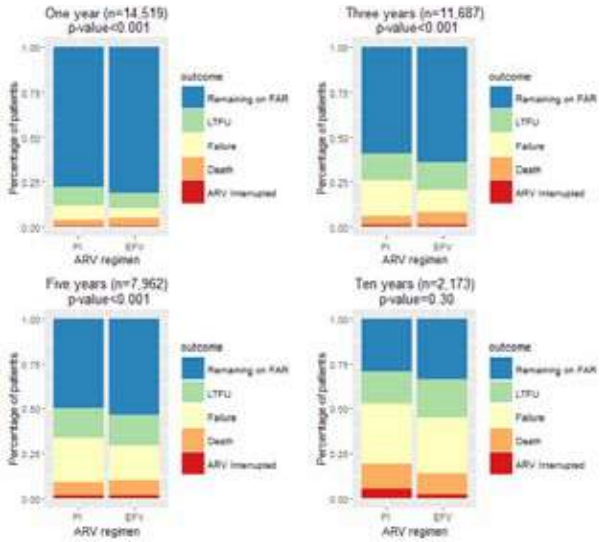
Presenting author email: yanink.caro@infecto.mx

Background: Efavirenz (EFV) and boosted Protease Inhibitors (PI) are preferred options for the third component of first-line antiretroviral regimens (FAR) in Latin America. Clinical trials and meta-analyses have shown comparable short-term efficacy between both. Long-term follow-up could provide additional information on clinical outcomes, especially considering expected long-term use and increasing life-expectancies of people living with HIV (PLWH). We assessed the durability and long-term outcomes of patients receiving EFV or PI as the third component of FAR in our region.
Methods: ART-naïve PLWH ≥18 years old, enrolled in CCASAnet, and starting EFV- or PI-based FAR (Lopinavir/ritonavir or Atazanavir/ritonavir) between 2000-2016 were included. Outcomes were: Time on FAR and events ending FAR (i.e., virologic failure(VF), treatment interruptions >180 days (TI), death, and/or loss to follow-up (LTFU)). Events were compared between groups at 1, 3, 5, and 10 years of follow-up. Kaplan-Meier estimators for median times were generated and stratified by baseline CD4 (> or ≤200 cells/μL).
Results: We included 14,519 patients: 12,898 (89%) started EFV and 1,621 (11%) a PI. Median time on EFV was 5.2(IQR: 5.0-5.4) and on PI was 4.1 (IQR: 3.6-4.5) years; p-value <0.001. There were differences in median time on FAR among patients starting ART with >200 cells/μL (5.52 years for EFV vs. 3.77 years for PI; p-value <0.01). Differences between outcomes were found at 1, 3 and 5 years of follow-up (Figure 1).
Including the first event during all the follow-up there were 6,474 (50%) first-line-ending events in the EFV group: 854 (13%) deaths, 3,185 (49%) LTFU, 2,235 (34%) VF and 200 (3%) TI. In the PI group, we observed 843 (52%) first-line-ending events: 84 (10%) deaths, 364 (43%) LTFU, 372 (44%) VF and 23 (3%) TI (p-value <0.001).



[Figure 1. Distribution of outcomes by FAR at first, third, fifth and tenth year of follow-up]

Conclusions: In this ART-naïve cohort, duration of FAR was longer with EFV than PI. These differences were observed only in those with >200 CD4 cells/μL and were explained mostly by differences in rates of VF.

Presenting author email: pulidof@gmail.com

Background: We aim to assess the impact of initiating ART on patients' Health-Related Quality of life (HRQoL) from the perspective of clinicians, community representatives and patients.
Methods: Qualitative research with 2 focus groups (FG) with clinicians (n=9/n=8), 2 in-depth interviews with NGO's representatives and 9 with patients from CoRIS. We selected patients who had recently started ART. A specific script containing main themes was used for each profile. FG and interviews were registered, transcribed, codified and a content analysis was performed.

Results: ART initiation is reported as a turning point where HIV+ patients consider themselves as "sick persons". Before ART initiation, patients' fears of side effects, largely lipodystrophy and other visible signs because of HIV stigmatization. Patients also report anxiety related to ART and the impact on their professional life. Upon ART initiation, there is no consensus regarding the timing or who should be responsible for taking the decision to initiate ART. Clinicians consider themselves as the most qualified to make this decision, while NGOs favor empowering patients, and among patients, there are not agreement. The choice of ART is not entirely up to the clinicians, but is based on hospital guidelines, varying by Spanish Autonomous Communities, and cost of ART is key in the decision-making process. Of available ARTs, the choice of treatment by clinicians is driven by patients' lifestyles, resistance tests and drugs interactions. Once ART is initiated, side effects are uncommon but have important implications on patients' HRQoL. Psychological implications of treatment are linked to the anxiety of involuntary disclosure of HIV status. Patients often hide their pills and worry about being seen collecting the medication at the hospital pharmacy. Patients relate their ART with the feeling of being ill and often report non-adherence to ART as "escaping" from the disease. Clinicians, patients and NGOs agree that nonadherence often occurs when patients find it difficult to maintain a routine.
Conclusions: ART has important social cost as psychological charge of feeling sick and anxiety derived from be discovered with HIV. These feelings have important implications on adherence and thus, on virological failure that may increase treatment costs for the Health National System.

MOPEB0305

Faster immune-virological response following initiation of first line NNRTI- and INI-based antiretroviral therapy compared to boosted PI-containing regimens: a real life cohort study (2010-2015)

L. Gazzola, F. Bai, A. Tavelli, T. Bini, G. Marchetti, A. d'Arminio Monforte
University of Milan, Department of Health Science, S. Paolo Hospital, Clinic of Infectious Diseases, Milan, Italy
Presenting author email: francesca.bai@unimi.it

Background: We aimed to evaluate viro-immunological response in untreated HIV-positive patients starting a boosted-PI-, NNRTI- or INI-based cART.
Methods: Cohort study on antiretroviral-naive patients starting a triple boosted-PI-, NNRTI- or INI-based cART (01/01/2010-31/12/2015). Time to virological success (VS:confirmed HIV-RNA< 40 copies/mL) and time to immunological response (IS1, increase of >100/mmc CD4+ from baseline; IS2, increase to >500/mmc CD4+ in patients starting≤350/mmc; IS3, increase to ≥1 CD4/CD8 in patients starting with ratio< 1) were evaluated (Kaplan-Meier,Cox analyses, intention-to-treat).
Results: We enrolled 427 patients:

	PI-based cART (N 180)	NNRTI-based cART (N 159)	INSTI-based cART (N 88)	p values
Age, median (IQR)	38 (33-45)	37 (30-42)	44 (35-51)	0.0001
Female, %	18.7	13.3	18.4	0.4
Caucasian, %	76.3	86	85.2	0.15
MSM, %	53.8	68.3	58.9	0.11
CD4+ nadir(cells/mmc), median (IQR)	277 (143-381)	385 (285-439)	385 (179-417)	0.0001
Baseline Log10 HIV-RNA copies/mL, median (IQR)	4.8 (4.1-5.3)	4.2 (3.7-4.7)	4.7 (4.1-5.2)	0.552
Antiretroviral backbone, %	TDF/FTC 90.2; ABC/3TC 5.8; ZDV/3TC 4.0	TDF/FTC 94.4; ABC/3TC 5.0; ZDV/3TC 0.6	TDF/FTC 75.6; ABC/3TC 24.4; -	-
Antiretroviral third drug, %	DRV/r 60.7; ATV/r 29.5; LPV/r 9.8	EFV 52.2; RPV 45.3; NVP 2.5	RAL 28.4; EVG/cobi 40.9 DGT 30.7	-

[Demographic and immuno-virological characteristics]

After a mean follow-up of 5.9 months (95%CI 5.2-6.6), the 6-month probability of VS was 61.8% (95%CI 54.4-69.2) for boosted-PI, 79.9% (95%CI 73.5-86.3) for NNRTI and 72.6% (95%CI 61.8-83.4) for INI (p=0.0002). A higher probability of VS with NNRTI and INI was confirmed after adjustment for baseline HIV-RNA and CD4+; the other predictive factor of VS was lower HIV-RNA. The 12-month probability of IS1 was 75.7% (95%CI 69.1-82.3) for boosted-PI, 82.6% (95%CI 76.6-88.6) for NNRTI and 81.3% (95%CI 68.5-94.3) for INI (p=0.03); no difference in IS2-IS3. Predictors of IS1 were: NNRTI, younger age, lower CD4+ and higher HIV-RNA. Higher CD4+ was the strongest predictor of long-term immunological reconstitution (IS2-IS3), younger patients showed an increased probability of IS2.

[Probability of VS/IS by Cox analyses]

Conclusions: In this observational setting patients given first-line NNRTI or INI, compared to boosted-PI, displayed a faster virologic response. In NNRTI the earlier virologic suppression seems to drive a rapid immunological recovery, suggesting T-cells redistribution from lymphoid compartment. Conversely, adequate immune reconstitution is predicted by higher baseline CD4+, independently by cART regimen, confirming the role of an early cART initiation.

MOPEB0306

Can WHO guidelines use observational data? An empirical comparison of three methods for adjusting observational data and a meta-analysis of randomized controlled trials (RCT)

G. Rutherford, M.L. Lindegren
University of Calfornia, San Francisco, Epidemiology and Biostatistics, San Francisco, United States
Presenting author email: george.rutherford@ucsf.edu

Background: RCTs provide the strongest evidence for efficacy of an intervention. Observational studies can inform clinical guidelines when RCT data are lacking. Using data from IeDEA and a meta-analysis of RCTs, we compared how closely three different strategies for adjusting observational data approximated RCT results approximated RCT results.
Methods: We compared two initial regimens, TDF+XTC+EFV with all other two-drug NRTI combinations + EFV. We calculated RR and 95% CI for 96-week all-cause mortality and 48-week retention in care on initial regimen in ART-naïve HIV-infected adults ≥16 years old IeDEA participants in six regions using three separate adjustment techniques: (1) propensity scores for receiving TDF+XTC+EFV based on sex, age, country and baseline CD4 count with each individual matched to one individual receiving 2NRTIs + EFV with a similar propensity score (within 0.001); (2) a multivariable regression model controlling for the same variables as the propensity score; and (3) a meta-analysis by IeDEA region using a random effects model. We compared these estimates to those from a systematic review of seven RCTs.
Results: For the propensity score-matched analysis and the multivariable regression model we evaluated 19,470 IeDEA participants. For the regional meta-analysis, we evaluated 58,232 for retention and 47,985 for mortality. For mortality, all three methods overlapped with the 95% CI of the RCT meta-analysis; propensity scoring and multivariable regression estimates produced results closer to the RCT RR than the meta-analysis by region. For retention, all three estimates overlapped the 95% CI of the RCT meta-analysis; again propensity score matching and multivariable regression produced results closer to the RCT RR.

	96-week mortality RR (95% CI)	48-week retention on initial regimen RR (95% CI)
Propensity score matched	0.99 (0.89-1.10)	1.13 (1.12-1.15)
Multivariable regression model	1.01 (0.92-1.12)	1.12 (1.11-1.14)
Meta analysis by IeDEA region	0.84 (0.61-1.16)	1.09 (1.03-1.16)
Systematic review of RCTs	1.00 (0.14-7.07)	1.14 (1.01-1.30)

[Comparison of outcomes from IeDEA ob]

Conclusions: The effectiveness of initial ART regimen estimated from IeDEA data analysed using propensity scoring and multivariable regression closely approximates efficacy as measured by meta-analysis of RCTs, but not the regional meta-analysis. Future guidelines may consider using IeDEA and other large cohort data to explore questions of effectiveness of different ART regimens overall and in specific patient subsets. We recommend propensity score matching if numbers of subjects are sufficiently large.

MOPEB0307

Demographic correlates of survival in adult HIV-infected patients initiating first-line antiretroviral therapy in Nigeria: a 7-year prospective cohort study

A. Onovo[1], E. Okechukwu[2], U. Roxo[3], K. Badiane[4], H. Kang[4]
[1]US Agency for International Development (USAID), Strategic Information and Geographic Information System, Abjua, Nigeria, [2]US Agency for International Development (USAID), Continuum of Care and Treatment, Abjua, Nigeria, [3]US Agency for International Development (USAID), Office of HIV/AIDS, Washington, United States, [4]US Agency for International Development (USAID), Office of HIV/AIDS, Abuja, Nigeria
Presenting author email: aonovo@usaid.gov

Background: USAID Nigeria through PEPFAR supports the provision of Antiretroviral Therapy (ART) to eligible HIV-infected persons in Nigeria since 2004. Universal access to ART has been the program focus. Complementary to this work is attention to survival outcomes of the ART program. This study assesses survival and associated demographic correlates among HIV-infected patients on ART in the six geographic regions of Nigeria.
Methods: A cohort of 10,278 adult patients who initiated first-line ART between January 2009 and December 2010 at 17 ART centers was followed-up for seven years. Follow-up time was calculated from the date of ART initiation to date of death or censoring. The censor date included date patient stopped ART or date of last visit. Data from patient medical records were extracted and mortality rate (per 1000 person-years [PY]) calculated. Kaplan-Meier method was used to estimate probability of survival and Cox regression applied to assess predictors of mortality by adjusted-age and sex; and lost to follow-up (LTF) accounted for using competing risk regression.
Results: The 69.1% of the cohort was female, and 3,243 were LTF. Median age at ART initiation was 33 years (IQR:28-40). Of the total 341 deaths, 60% were females, and 39% of deaths occurred within 12 months of commencing ART. The estimated mortality per 1000 PY at 12, 24, 36, 48, 60, 72 and 84 months was 2.83, 0.97, 1.18, 1.03, 0.70, 0.36 and 0.13 respectively. In Kaplan-Meier analysis, the one-year survival probability was 0.98 (95%CI, 0.96-1.00); seven-year survival probability was 0.94 (95%CI: 0.91-0.97). Males were associated with lower risk of death than females, which was similar for Cox regression (adjusted hazard ratio [AHR]: 0.72; 95%CI: 0.57-0.90,p< 0.004) and competing risk regression (ASHR: 0.87; 95%CI 0.81-0.94,p< 0.001). The hazard for age groups of 50-59 years (AHR: 1.25,p< 0.015), 60-69 years (1.69,p< 0.0001) and over 70 years (AHR: 2.11,p< 0.001) were associated with mortality.
Conclusions: In this study, mortality among HIV-infected patients on ART was highest within first year of commencement of ART and declined over time. Mortality was independently associated with female and older age groups. Findings can inform better design of differentiated care approaches for these patient populations.

MOPEB0308

Assessment of the impact of persistent low-level viremia on the subsequent risk of virologic failure in a cohort of people living with HIV after 7 years of observation in Mauritania

M. Kelly[1], Z. Fall Mlaick[2], B. Lo[3]
[1]Institut National de Recherches en Santé Publique, Nouakchott, Mauritania, [2]Institut National d'Hépato-Virologie (INHV), Nouakchott, Mauritania, [3]Université de Nouakchott, Nouakchott, Mauritania
Presenting author email: moussakelly@yahoo.fr

Background: The prognosis of people living with HIV has improved consistently in developed countries since the advent of antiretroviral therapy (ART) in 1996.
The current goal of antiretroviral therapies (ART) is to maintain HIV virologic suppression below limits of assay detection. When viral loads remain in low-level viremia (LLV), especially between 50-200 copies/mL, the best management and clinical consequences remain unknown.
Our objective was to study the long-term impact of persistent LLV on subsequent risk of virologic failure (>1000 copies/ml) in a cohort of people living with HIV in Mauritania.
Methods: We used data from an opened cohort of 605 HIV infected patients of the Ambilatoire Treatment Centre (CTA) and oriented in Nouakchott virology laboratory of the National Institute for Research in Public Health (INRSP) for biological monitoring.
We compared the cumulative incidence of subsequent virologic failure (HIV RNA >1000 copies/mL) in patients under ART for at least 12 months, following 4 persistence status (< 50, 50-199, 200-499 and 500-999 copies/mL) for 6, 9 or 12 months using Kaplan-Meier analysis. The association between subsequent virologic failure and persistence status were estimated using Cox proportional hazards model.
Results: it was about 314 women (52 %) and of 291 men (48 %). The median age was of 36 years.
The cumulative incidence of virologic failure one year after having maintained a LLV for 6 months was 19 % (95%CI: 10.5- 30.6) for 50-199 copies/mL, 27.4%(95%CI: 14.9-33.6) for 200-499 copies/mL and 45.3%(95%CI:39.2-70.3) for 500-999 copies/mL, compared to 5.7% (95%CI:4.3-7.2) when remaining undetectable. Even after adjustment for potential confounders, persistent LLV of 50-199 copies/mL for 6 months doubled the risk of virologic failure (Hazard Ratio=2.22, 95%CI:1.60-3.09) when compared to undetectable viral loads for the same duration. Similar results have been found for persistent LLV of 9 or 12 months.
Conclusions: In this cohort, all sub-categories of persistent LLV between 50-999 copies/mL were associated with an increased risk of virologic failure. The results shed new light for the management of patients with LLV, especially with regards to LLV of 50-199 copies/mL.

Presenting author email: marc-antoine.valantin@aphp.fr

Background: Patients with experience of virological failure (VF) have accumulated drugs to achieve viral suppression (VS). New drugs offer opportunity to reduce drug burden in patients suppressed a multi-cART.
Methods: ECOVIR is a prospective, single center, intervention study aiming at evaluating whether drug reduction in virologically suppressed patients, could maintain VS over 48 weeks. Patients were included with a cART ≥ 4 drugs regimen (4-DR) for ≥24 weeks, a pVL ≤ 50copies/ml for ≥12 months. Intervention based on a multidisciplinary expert advice consisted in discontinuation of genotypically less susceptible drugs (based on the ART history, cumulative drug resistance (ANRS-algorithms), intolerance and drug-drug interactions) to reach a final optimized antiretroviral treatment (OAT) with ≤ 3-DR for a Genotypic Susceptibility Score ≥2. Primary end point was maintenance of viral suppression at W24. The study was designed to show an efficacy >80% assuming a success rate of >92% with a power of 90%.
Results: From 146 individuals with cART ≥4-DR, 89 were enrolled. OAT was proposed in 82 (92%) patients, 11 patients did not switched (physician decision 9/11, patient decision 2/11) leaving 71 (80%) patients switching to OAT. Baseline characteristics (median, IQR) were: age: 57(51-63) years, CD4: 584(416-758)/mm^3, duration of treatment: 20.8(18.2-23.0) years, viral suppression: 5.4(2.8-8.1) years. Cumulative resistance profile showed full/intermediate resistance: lamivudine/emtricitabine (92%), abacavir (76%/14%), tenofovir (41%/32%), efavirenz/nevirapine (72%), rilpivirine (54%), etravirine (20%/18%), atazanavir (72%/4%), darunavir-QD (42%/6%), raltegravir (13%), dolutegravir-QD (0%/7%). Intervention led to decrease the use of NRTI (from 93% to 21%, p<0.001), PI (from 75% to 52%, p<0.001) and maraviroc (from 32% to 17%, p<0.001). Use of INI raised from 66% to 76% (p=0.020). Overall, 24% of patients switched from ≥4-DR to a 3-DR and 76% to a 2-DR. Success rate of OAT at W24 was 93.9% (95%CI: 84.4-97.6, Kaplan-Meier estimate). Four patients experienced VF (at W4, 8, 12 and 24), all with VL <600cp/ml and no emergence of resistance mutations and were subsequently resuppressed. ART monthly cost decreased from 1745.00€ to 1120€ (-36%, p<0.001).
Conclusions: Even in multi-cART treated patients with high level resistance, individualized strategies can offer 2-DR options with a significant economic impact and ensure virological success.

Presenting author email: ddsalbertorubio@hotmail.com

Background: HIV-1 infected patients with suspected or confirmed resistance to one or more families of antiretroviral drugs receive complex and expensive salvage regimens. Dual therapy with dolutegravir (DTG) plus darunavir/cobicistat (DRV/c) is especially attractive as a salvage regimen due to the absence of analogues, high genetic barrier and simplicity. The aim of this study was to evaluate the efficacy and safety of this dual therapy in pretreated HIV patients with virological failure (VF) or suppressed under other antiretroviral salvage therapy.
Methods: Retrospective study of HIV-1 infected patients on treatment with DTG-DRV/c for at least 24 weeks. We describe baseline characteristics, treatment history, and reasons for the change. Efficacy, tolerability and durability of this therapy were analyzed, as well as economic impact.
Results: We analyzed 44 patients (72.2% males), mean age 50.73 years, with a mean length of HIV infection of 18.6 years. Most of them had a nadir CD4 cell count below 200 cells/mm3 and 24 patients (54.5%) had experienced a CDC Class C event. All patients had received NRTI, 35 (79.5%) NNRTI, 41 (93.2%) protease inhibitors and 25 (56.8%) ISTI, and 18 patients had confirmed resistance to one or more families. Thirty-one patients (70.4%) received salvage regimens with more than 4 drugs or 2 families. The reasons for switching were: empiric salvage regimen in 16 patients with VF or low-grade viremia, and simplification of salvage regimen in 28 virologically suppressed patients. At 24 weeks, out of 28 patients who switched for simplification, 26 remained with undetectable viremia. Patients who started DTG-DRV/C as a salvage regimen (n=16) were all undetectable or showed an appropriate decline at 24 weeks. Mean duration of therapy is currently 13.8 months. No adverse effects have been observed. Regimen was only changed in two patients, due to potential interactions. Cost savings were a mean of 1687 euros/patient per year. Considering only simplification cases, cost savings rise to 2468 euros.
Conclusions: Dual therapy with DTG plus DRV/c seems efficacious and well-tolerated as an empiric salvage regimen or simplification of more complex therapies, sparing NRTIs and allowing a substantial reduction of the number of pills per day and cost savings.

Presenting author email: joser.arribas@salud.madrid.org

Background: Dual Therapy (DT) with 3TC+DRV/r could be as efficacious as triple therapy based on DRV/r to maintain viral suppression in selected patients.
Methods: DUAL is a multicenter, open label, randomized, 48 weeks clinical trial comparing the efficacy and safety of switching to 3TC+DRV/r in patients with HIV-RNA < 50 c/ml for > 6 months while on TDF/FTC (or ABC/3TC)+DRV/r. A subgroup analysis is presented. Multivariate linear or logistic regression were used to calculate p-values for interactions.
Results: 249 patients (75% TDF/FTC, 25% ABC/3TC) were randomized to switch to DT (n=126) or continue TT (n=123). In the primary analysis (snapshot, ITT-exposed, 48 weeks) DT was non-inferior to continuing triple therapy (TT): 89% (112/126), vs. 93% (114/123), difference -3.8; 95%CI -11% to 3.4%. There were no significant differences in efficacy when different subgroups were analyzed: time with viral load < 50 c/ml > or < 12 months; Age > or < 50 ys; CD4+ nadir > or < 200; baseline CD4+ > or < 500; HCV seropositivity; HCV replication; and baseline nucleosides (TDF/FTC or ABC/3TC).
In the whole population, switching to DT was not associated with significant changes in e-GFR and TC/HDL ratio relative to maintaining TT. At baseline, patients treated with TDF/FTC had significantly lower total-cholesterol (tC): 178 vs 202 mg/dl, LDL-cholesterol: 109 vs 122 mg/dl, triglycerides (Tg): 127 vs 146 mg/dl, but similar tC/HDL ratio: 4 vs. 4. In those patients switching from TDF/FTC, there was a non-significant trend towards higher increases in tC, LDL and Tg, without changes in Tc/HDL ratio. Changes in the estimated glomerular filtrate, or the proportion of patients with proteinuria, or pathologic uric acid or phosphate excretion between arms were not different when patients with TDF/FTC or ABC/3TC at baseline were compared.
Conclusions: Switching to 3TC+DRV/r dual therapy in patients with suppressed viral load for > 6 months maintains similar efficacy to triple therapy irrespective of the length of undetectability, age, nadir or baseline CD4+ count, HCV coinfection or baseline nucleosides. No differences were seen in changes of lipids or renal function between patients switching from TDF/FTC or ABC/3TC.

Viral and immune effects of a dose-reduction strategy in suppressed HIV+ patients

A. C. Guardo[1], A. Zarama[1], T. González[1], M.E. Bargalló[1], J.F. Rojas[2], E. Martínez[2], M. Plana[1], S. Sánchez-Palomino[1]
[1]*IDIBAPS- Hospital Clinic de Barcelona, Barcelona, Spain,* [2]*Hospital Clínic of Barcelona, Barcelona, Spain*
Presenting author email: alcrespo@clinic.ub.es

Background: Dose-reduction strategies in HIV patients with long-term virological suppression are of interest to avoid toxicity, to improve quality-of-life and to reduce cost. We aimed to comprehensively compare virological and immunological impact at 24 weeks of a reduced dose schedule (3-days a week; Mo/We/Fr) (n=30) relative to daily antiretroviral therapy (ART) (n=31) in HIV-1-infected patients. All of them treated with the fixed-dose combination efavirenz/emtricitabine/tenofovir with suppressed plasma viral load (VL) for more than 2 years.
Methods: VL (ultrasensitive RT-PCR), HIV-1 reservoir dynamics (measured as Total and Integrated DNA in CD4 T cells) and immunological profiles of activation (CD38 and HLA-DR), senescence (CD57 and CD28), apoptosis (annexin V), and the proportions of naive, Tscm and effector memory (CCR7, CD45RA, CD95 and CD27) T cells (flow cytometry) were measured at baseline, at 24 weeks, and in selected patients also at 48 weeks. Changes at 24 and 48 weeks and correlations between virological and immunological changes were assessed.
Results: From the immunological point of view no differences between arms were observed on activation, senescence or apoptosis of both CD4 and CD8 T cells during the 24-week follow-up. Only proportion of naïve CD4 T cells showed a significant decrease in the 3-days group (mean (SD); 24.6 (13.7) to 20.5 (12.9);**p=.002). VL levels and HIV-reservoir did not change in both arms during the 24-weeks follow-up. In-depth review of clinical data revealed a higher VL zenith (5.5 vs 5.0 log10 copies/ml;**p=.0048) and a tendency toward lower CD4 nadir (mean (SD); 203 (134) vs 246 (90) cells/µl) in the 3-days ART relative to daily ART. Correlations between virological and immunological parameters showed that CD4 Tscm levels in the 3-days group correlated with basal integrated DNA and in an additional sample after 48 weeks. Nevertheless, no differences were detected in the daily ART group.
Conclusions: A reduced-dose strategy with the fixed-dose combination efavirenz/emtricitabine/tenofovir did not significantly affect immunological or virological parameters. Only small differences, probably related with a bias in basal characteristics between groups, were observed. These data are reassuring and support the need of future clinical trials with longer follow-up.

Presenting author email: jean-michel.molina@aphp.fr

Background: Protease inhibitors are key antiretroviral drugs but their high price limit their availability. Reducing their dose while maintaining efficacy could yield significant cost savings and improve access. The optimum dose of darunavir (DRV) in patients without resistance-associated mutations (RAMs) has not been established.

Methods: HIV-1 infected adults with a plasma HIV RNA level < 50 cp/ml for at least 12 months, receiving a combination of 2 NRTIs + DRV 800 mg/ritonavir (r) 100 mg once daily for at least six months, with no prior virologic failure (VF) and a pre-treatment genotypic resistance test with no DRV or NRTI RAMs, were enrolled in this multicenter phase II single-arm open-label study and switched to once daily DRV 400/r with the same NRTIs. The primary study endpoint was the proportion of patients with a plasma HIV RNA level <50 cp/ml at 48 weeks without any change in the study regimen, in a modified intent-to-treat analysis.
Results: From March to October 2015, 113 patients (pts) were screened, 100 were enrolled and started the reduced DRV dosing regimen. At baseline, most patients were male (78%), with a median age of 44.3 years, a median duration of antiretroviral therapy of 43.6 months and a median CD4 T-cell count of 633 cells/mm^3. 76% received TDF/FTC and 24% ABC/3TC. Three pts with major violations of entry criteria were excluded from the analysis.
During follow-up, 1 pt withdrew consent (not considered a failure), 3 pts discontinued the study regimen, and 6 experienced VF (confirmed HIV RNA level > 50 cp/ml). The overall rate of virologic success at week 48 was 90.6% (87/96; 95% CI: 82.9-95.6). No RAM was detected in 3 amplifiable genotypes. Sixty-four pts (66%) presented a total of 213 adverse events, with only 14 (6.5%) grade 3 and 4 AEs, and a single AE (grade 2 osteoporosis) deemed to be drug-related.
Conclusions: In HIV-infected patients virologically suppressed with DRV/r (800mg/100mg) and 2 NRTIs, a reduction of the DRV dose to 400 mg/d maintained virologic efficacy. This reduced dose now deserves to be assessed in a randomized trial.

Background: ART individualization with reduction of ARV drugs to minimize toxicity is a clinical challenge in aging HIV population. Dual therapy combining integrase (INI) and non-nucleoside inhibitors (NNRTI) is an interesting approach in long-term experienced patients.
Methods: The ANRS163-ETRAL trial (NCT02212379) is a 96-week multicentre, single-arm study designed to evaluate the capacity of the dual raltegravir(RAL)/etravirine(ETR) regimen to maintain viral suppression in patients over 45 years, on a stable boosted PI-containing regimen, RAL and ETR naïve, with HIV fully susceptible to these 2 drugs. All enrolled participants switched to RAL/ETR (400/200 mg) BID. The primary endpoint was the proportion of participants maintaining plasma viral load (VL) ≤50 copies/mL up to week 48, estimated with the Kaplan-Meier method.
The study was designed to show an efficacy >90%, assuming a success rate >95%, with a power of 80% and a 5% type-one error.
Results: Overall, 170 participants were enrolled out of 219 screened in 20 sites; 5 who never took RAL/ETR were not analyzed. Baseline characteristics for the 165 analyzed participants were (median values; IQR): male (71%), age: 52 years (48-58), duration of ART: 16.8 years (11.1-19.3), viral suppression: 6.9 years (3.4-9.3), CD4: 700/mm^3 (525-904), CD4 nadir: 209/mm^3 (93-286), ART consisted in PI/r monotherapy (21%), NNRTI+PI/r (7%), 2NRTIs+PI/r (65%) as QD (73%) or BID (27%) regimen and 26.7% were on lipid lowering agents.
At W48, by ITT analysis, the rate of maintaining viral suppression was 99% (95%CI: 96-100). One patient, with previous K103N mutation, experienced virological failure at W24 (VL: 11,607 and 18,472 cp/mL) with additional NNRTI-resistance (K101E+Y181C+G190A) but no resistance to RAL, and re-suppressed on resumption of baseline ART. Seven participants discontinued the RAL/ETR regimen for AE, leading to a strategy success rate of 95% (95%CI: 91-98) and one participant discontinued with no AE. 18 SAE occurred in 17 participants of whom 4 were study drug-related. All lipid fractions and eGFR significantly improved at W48 (p<0.02).
Conclusions: RAL/ETR showed a potent and robust antiretroviral activity in virologically suppressed ageing patients, with an excellent safety profile. Longer follow-up including bone, fat tissue, and inflammation markers evaluations is on going.

HIV-1 DNA ultra-deep sequencing analysis at initiation of the dual-therapy DTG+3TC in the maintenance DOLULAM pilot study

C. Charpentier[1], B. Montes[2], N. Meftah[3], J. Reynes[4]
[1]Hôpital Bichat-Claude Bernard, Paris, France, [2]Montpellier University Hospital, Virology Lab, Montpellier, France, [3]Montpellier Universiy Hospital, COREVIH, Montpellier, France, [4]Montpellier University Hospital, Infectious Diseases, Montpellier, France
Presenting author email: charlotte.charpentier@aphp.fr

Background: DOLULAM study assessed a dual-therapy, dolutegravir+lamivudine, to maintain virological suppression in treatment-experienced patients. In this substudy, we assessed the prevalence of M184I/V mutations at time of dual-therapy initiation using historical DNA/RNA genotypes and baseline DNA genotype obtained by next-generation sequencing (NGS).
Methods: HIV-1 reverse transcriptase (RT) sequences were obtained from DNA and/or historical RNA with Sanger technology by using ANRS procedures. HIV-1 DNA RT and integrase NGS was performed using Illumina® technology (cut-off=1%). Resistance mutations were identified using the ANRS resistance algorithm.
Results: Among the 27 patients enrolled in the DOLULAM study, HIV-1 DNA sample was available at initiation of the dual-therapy in 25, and NGS was successful in 22 and 19 for RT and integrase regions, respectively. Historical HIV-1 DNA and RNA Sanger sequences were obtained in a median time before dual-therapy initiation of 2.8 years (IQR=1.0-4.0) and 9.8 years (IQR=6.6-11.0), respectively; and were available in 14 and 18 patients, respectively. Baseline DNA NGS genotypes showed that 10 (45%) and 5 (26%) patients harbored minority resistant variants (MRV) in RT and integrase, respectively.
Combining all available genotypes data, a M184I/V was observed in 16/27 patients (59%). Most M184V were detected in historical RNA genotypes (n=8/10), whereas M184I were exclusively detected in DNA genotypes (n=10, including 7 as MRV). Ten patients displayed defective viral genomes in cellular reservoirs with stop codons, all including M184I, an APOBEC G-to-A induced mutation. M184V was observed in baseline DNA NGS in 4 patients, including one as MRV.
No difference was observed in the prevalence of integrase MRV between patients pre-exposed to RAL and INI-naïve patients (p=0.62).
No impact of M184I/V on the virological outcome could be assessed, since no virological failure (2 consecutive viral load >50 c/mL) occurred during the first two years of the dual-therapy.
Conclusions: These first NGS data on HIV-1 DNA at initiation of a switch study showed: (i) a high proportion of patients harboring defective viral genomes, whose mutation M184I is a marker, (ii) a low number of patients in whom M184V remains detectable in PBMC. These elements most likely contribute to the limited impact of the M184I/V on maintenance of virological suppression.

High virological suppression rates regardless to the genotypic susceptibility score after switching to a dolutegravir-based regimen: W48 results in a prospective cohor

C. Charpentier[1], G. Peytavin[2], M. Lê[2], V. Joly[3], O. Cabras[3], M. Perrier[1], B. Phung[3], Y. Yazdanpanah[3], D. Descamps[1], R. Landman[3]
[1]Hôpital Bichat-Claude Bernard, Laboratoire de Virologie, Paris, France, [2]Hôpital Bichat-Claude Bernard, Laboratoire de Pharmacologie, Paris, France, [3]Hôpital Bichat-Claude Bernard, Service de Maladies Infectieuses et Tropicales, Paris, France
Presenting author email: charlotte.charpentier@aphp.fr

Background: To assess, in virologically-suppressed patients, based on the genotypic susceptibility score (GSS), the virological response after switching ARV-treatment to a dolutegravir (DTG)-based regimen.

Methods: A prospective observational single-center cohort enrolling all patients with a plasma viral load (pVL)< 50 c/mL initiating a DTG-based regimen between September and December 2015. pVL were performed using CobasTaqman HIV-1 V2.0 assay. GSS of the ARV regimen was calculated using the ANRS algorithm including DTG, translating the interpretations „susceptible", „possible resistance" and „resistance" into scores of 1, 0.5 and 0, respectively.
Results: Among 254 patients who switched to a DTG-based regimen, 212 (83%) had historical available genotypes. Among them, 196 (92%) have a one-year follow-up, and taking into account all historical genotypes, 27 (13%), 75 (35%) and 110 (52%) had a total GSS equal to 1 or 1.5 (group 1), 2 or 2.5 (group 2) and 3 (group 3), respectively. Median time since the last genotype was 9 (IQR=4-11), 8 (IQR=4-12) and 5 (IQR=2-8) years in groups 1, 2 and 3, respectively. History of infection differed between the groups regarding duration of prior cART or CD4 cell count nadir. Twenty patients (9.4%) discontinued DTG-based regimen in relation with occurrence of neuro-psychological adverse events (n=7), pregnancy (n=3), renal toxicity (n=2), headaches (n=1), cutaneous adverse events (n=1), virological failure (VF) (n=1), patients´ decision (n=2) and others (n=3). No VF occurred in patients of groups 1 and 2. In group 3, one patient out of 110 (0.9%) experienced a VF. It was a highly pre-treated patient who had a previous history of VF under RAL without selection of integrase mutations. Overall, 8.0% (17/212) of the patients experienced a viral blip with no difference between the three GSS groups.
Conclusions: In this observational cohort, we showed a high level of virological suppression maintenance in the first year following the switch to DTG-based regimen, regardless to the baseline GSS. These data suggesting that DTG remains potentially able to maintain viral suppression when combined with fully or incompletely active drugs in these long-term virologically-suppressed patients need to be confirmed in clinical trials.

MOPEB0317

HIV-1-infected patients under successful less-drug regimens have similar genital shedding and residual viremia than those under triple therapy

L. Hocqueloux[1], C. Gubavu[1], S. Lefeuvre[2], B. De Dieuleveult[1], J. Buret[1], C. Mille[1], C. Rouzioux[3,4], T. Prazuck[1], V. Avettand-Fènoël[3,4]

Presenting author email: laurent.hocqueloux@chr-orleans.fr

Background: There is a growing interest for less-drug regimens (LDR) to decrease side effects, toxicity and interactions of antiretrovirals. Although avoiding sexual transmission is a crucial issue in this setting only few small studies have evaluated the impact of LDR (with protease inhibitor monotherapy only) on genital shedding.
Methods: HIV-1-infected adults with plasma HIV-RNA (pVL) < 50 copies/mL receiving one among four evaluated LDR (cases) or a classic triple therapy (controls) were prospectively enrolled. Concomitant genital (i.e. sperm or cervico-vaginal lavage) and blood samples were taken to assess HIV-RNA and HIV-DNA levels using ultrasensitive assays adapted from Roche and Biocentric kits. Residual concentrations (C_{24h}) were measured in both compartments by using liquid chromatography-tandem mass spectrometry. The primary objective was to determine the proportion of patients with undetectable (versus detectable or quantifiable) HIV-RNA and/or HIV-DNA in genital secretions according to the strategies. We also looked for residual viremia.
Results: 56 patients (30 males; 26 females) were included and treated as follow: dolutegravir (DTG) monotherapy, n=14; tenofovir + emtricitabine, n=10; DTG + unboosted atazanavir (uATV), n=11; uATV + two nucleoside inhibitors, n=11; triple-therapy, n=10.
Overall, cases and controls shared similar characteristics (median): age (47), sex-ratio, CDC staging, duration with pVL < 50 copies/mL (5.8 years), duration with current strategy (0.9 year), current CD4 (701/µL) and nadir (294/µL), highest pVL, HIV-DNA in PBMC.
The LDR group had similar proportions of patients with undetectable genital HIV-RNA (88%), HIV-DNA (76%), both items (67%) and no residual viremia (34%) than the triple-therapy group (90%, 80%, 80% and 50% respectively; all p-values >0.4).
In the LDR group, no factor was predictive to find HIV-RNA and/or HIV-DNA in the genital tract whereas, in a logistic-regression analysis, a high HIV-DNA in PBMC was positively correlated (per increased quartile) with the frequency of residual viremia (OR = 2.6; 95%CI: 1.2-5.6, p=0.01). Neither the number of drugs nor C_{24h} were predictive of viral control in both compartments.
Conclusions: In our study, patients under various LDR with sustained viral suppression had similar genital shedding and residual viremia than those under a classic triple-therapy. These conclusions have to be validated in larger groups.

Presenting author email: anne-genevieve.marcelin@aphp.fr

Background: Protease inhibitor monotherapy is a potential approach to antiretroviral treatment simplification. Using 3 randomized studies: Kalesolo (LPV/r 200/50mg bid versus 1NRTI/3TC/PI or NNRTI), Dream (LPV/r 200/50mg bid versus EFV/FTC/TDF) and Monoi (DRV/r 600/100mg bid versus DRV/r + 2NRTIs), we performed a pooled-analysis. Our objective was to determine in PI monotherapy and standard tritherapy : 1) distribution of ultrasensitive viral load (USVL) at week 96 (W96); 2) virological and clinical characteristics associated with virological failure (VF) at W96 and 3) impact of baseline USVL on VF.
Methods: VF was defined as 2 consecutive measurements of HIV-1 RNA viral load>50 copies/mL and analysed in Intention-To-Treat. Patient's characteristics were defined as median and interquartile range for continuous variables and as percentages for categorical variables. A logistic model was used to investigate which variables were predictive of a VF. Fisher test was used to investigate differences in USVL at W96.
Results: Among 637 patients, 71% were male and the median age was 44.6 years (IQR 40.3-52.3), treatment duration was 4.1 years, (IQR 2.4-7.8), baseline CD4/CD8 ratio was 0.78 (IQR 0.56-1.10), baseline CD4 was 564/mm3 (IQR 422-707) and 60% presented a baseline USVL< 1 copy/mL. At W96, the proportion of USVL< 1 copy/mL was significantly different between PI monotherapy and standard tritherapy in pooled-analysis (65% versus 74%; p=0.04) with significant difference in Dream and Kalesolo but no difference in Monoi. Overall, baseline USVL< 1copy/mL and tritherapy regimen were associated with USVL< 1 copy/mL at W96 (p=0.0003 and 0.05). In PI monotherapy receiving DRV/r rather LPV/r was associated with USVL< 1 copy/mL at W96 (p=0.002). Factors associated to VF at W96 were baseline CD4/CD8 ratio< 0.6 (p<0.0001), baseline USVL>1 copy/mL (p=0.0004) and to receive PI monotherapy rather than tritherapy (p=0.04).
Conclusions: Pooled-analysis of 3 PI monotherapy trials showed better efficacy of tritherapy in terms of USVL at W96. Furthermore regarding USVL at W96, to receive LPV/r seems to be more deleterious than DRV/r. To be on PI monotherapy and to have a lower baseline CD4/CD8 ratio were associated with VF at W96. Baseline USVL impacts VF at W96 in PI monotherapy and tritherapy.

MOPEB0319

TDF-associated tubular dysfunction might not be reversible after discontinuation

Y. Mutoh, T. Nishijima, K. Teruya, Y. Kikuchi, H. Gatanaga, S. Oka
National Center for Global Health and Medicine Hospital, ACC, Shinjuku, Japan

Background: Use of TDF will phase out because of the advent of TAF in resource-rich settings. However, whether kidney tubular dysfunction (KTD) due to TDF is reversible after discontinuation of TDF is unknown.
Methods: This cross-sectional study enrolled 943 HIV-infected patients to investigate the association between KTD and duration of TDF exposure, regardless of current TDF use. Tubular function was comprehensively examined and KTD was predefined as the presence of at least two abnormalities in the following five biomarkers: urine β2-microglobulinuria, high urinary N-acetyl-beta-glucosaminidase, fractional excretion of phosphate, fractional excretion of uric acid, and non-diabetic glycosuria. Logistic regression model was used to examine the association between KTD and duration of TDF exposure.
Results: 94% of study patients were male (median age 45, median eGFR 75 ml/min/1.73m^2). 99% were on antiretroviral therapy (median CD4 575 cells/mm^3). 64% had history of TDF use and 39% was currently using TDF. 29% used TDF for >5 years. 114 (12%) patients met definition of KTD. In adjusted multivariable model, compared to patient without history of TDF exposure, patients with >5 years of TDF exposure and current TDF use (OR4.3, 95%CI2.39-7.65), >5 years of TDF

exposure and no current TDF use (OR2.4, 95%CI1.08-5.26), <5 years of TDF exposure and current TDF use (OR2.5, 95%CI1.24-4.86), <5 years of TDF exposure and no current TDF use (OR2.4, 95%CI1.23-4.66) were all significantly associated with KTD (Table).
Furthermore, in another model, longer exposure of TDF was significantly associated with KTD (per one year of exposure, OR1.1, 95%CI1.04-1.19) whereas in the same model, current TDF use was not associated with KTD.

	Adjusted OR	95% CI	*P-value*
Without history of TDF exposure	ref	ref	ref
>5 years of TDF exposure and current TDF use	4.28	2.39-7.65	<0.001
>5 years of TDF exposure and no current TDF use	2.38	1.08-5.25	0.010
<5 years of TDF exposure and current TDF use	2.46	1.24-4.86	0.031
<5 years of TDF exposure and no current TDF use	2.39	1.23-4.66	0.010
Age (per one year increment)	1.05	1.03-1.07	<0.001
Body weight (per one kg increment)	0.97	0.95-0.99	0.001
CD4 cells (per one/mm^3 increment)	1.00	1.00-1.00	0.038
eGFR (per one ml/min/1.73m^2 increment)	0.99	0.97-1.00	0.094
Hypertension	1.44	0.89-2.35	0.140

OR: odds ratio CI: confidence interval eGFR: estimated glomerular filtration rate

[Table. The association between kidney tubular dysfunction and duration of TDF exposure: multivariate analysis]

Conclusions: Regardless of current TDF use, TDF exposure is associated with KTD, and for patients with longer exposure of TDF, the association is more robust. KTD may be irreversible for patients with history of TDF exposure even after discontinuation of TDF.

MOPEB0320

Successful switch to once-daily single-tablet regimen (STR) containing elvitegravir (EVG) or dolutegravir (DTG) in virologically suppressed HIV-1-infected patients despite archived resistant quasispecies

C. Pronier[1,2], A. Maillard[1], P. Comacle[1], C. Cameli[3], J. Rohan[3], T. Jovelin[3], G. Lagathu[1], M. Dupont[4], F. Fily[4], M. Baldeyrou[5], J.-M. Chapplain[5], P. Fillatre[5], M. Revest[5], F. Souala[5], P. Tattevin[5], C. Michelet[5], C. Arvieux[3,5], V. Thibault[1,2]
[1]CHU Pontchaillou, Virology, Rennes, France, [2]Rennes 1 University, IRSET, Rennes, France, [3]COREVIH Bretagne, Rennes, France, [4]GHT Rance Emeraude, Infectious Disease, Saint-Malo, France, [5]CHU Pontchaillou, Infectious Disease, Rennes, France
Presenting author email: charlotte.pronier@chu-rennes.fr

Background: The main objective of this study was to assess switches with integrase strand-transfer inhibitor (INSTI)-based regimen STR therapy in ARV-treated patients with undetectable HIV-1 viral load (VL).
Methods: A retrospective analysis was conducted on 75 HIV-1 infected, treatment-experienced adults from 2 French centers (Rennes, Saint-Malo). The inclusion criteria were:
i) treatment-experienced,
ii) VL≤ 50 copies/mL at baseline and
iii) switch to an INSTI-based STR.
Patients were divided into two groups: previous genotypic(s) test(s) performed on plasma HIV RNA and/or cellular HIV DNA (group 1; n=51, 68%) and no historical genotypic test available (group 2; n=24, 32%). Following data were collected: demographic, treatment prior to STR, reasons for STR switch and immuno-virological data. Virological failure (VF) was defined by 2 consecutive VL >50 copies/mL. Antiretroviral susceptibility and genotypic susceptibility scores (GSS) were determined according to the ANRS v26 algorithm.
Results: Seventy-five patients were included, mostly men (n=47, 63%), median age of 52 years. EVG or DTG-based STR were prescribed in 38 and 37 patients, respectively. Patients were heavily pre-treated for a median duration of 18 years and virological success since a median of 7 years. Main reasons for switch were simplification (n= 47, 63%) and tolerability (n=26, 35%). Patients were followed-up for a median period of 13 months [range 1-84] after switching. Median CD4 count remained stable (701 vs 681 cells/mm^3) at month 12. Seven patients discontinued the new regimen due to side effects (EVG; n=3, DTG; n=2), death (hepatocellular carcinoma; DTG) and VF (EVG), one patient each.
Twenty-seven out of 50 patients (54%) in group 1 displayed virus with ≥1 drug resistance substitution on reverse-transcriptase gene (M184V; n=22, K65R; n=4, L74I/V; n=5, ≥2 TAMs; n=13) and 3 out of 14 on integrase gene (T97A).
All patients, except one, remained virologically suppressed. VF was observed at month 28 in one patient (group 1), with a baseline GSS =2 and N155H substitution selected at VF.
Conclusions: This study reflecting routine clinical practice confirms the efficacy of INSTI-based STR in virologically suppressed, ARV-experienced patients, with a low prevalence of viral failure despite archived resistant quasispecies.

Presenting author email: p.de-truchis@aphp.fr

Background: After the randomized BREATHER study demonstrating efficacy of a 5 days-a-week maintenance therapy in children/young adults, the ANRS-162-4D trial has demonstrated the feasibility of a maintenance short-cycles 4 days-on/3 days-off regimen in adults with controlled HIV infection under a PI/r or NNRTI-based antiretroviral therapy (ART). The aim of the present analysis is to assess the impact of this strategy on inflammation markers and the size of the viral reservoir.
Methods: Patients included in the ANRS162-4D trial were HIV-1 infected adults with controlled viral load (VL< 50 c/ml) for more than 1 year under ART with 2 nucleoside analogs and either a PI/r or a NNRTI. Maintenance therapy used the same regimen, taken 4 consecutive days of each week, evaluation was conducted up to 48 weeks. Success was defined as VL< 50c/ml at each visit until W48. Viral reservoir measured by total HIV-1 DNA in PBMCs, and plasma inflammation markers (CRPus, IL-6, CD14s, IP-10, MIG-1) were assessed at D0, W24, and W48. Plasma ARV drug concentrations (Ctrough) were measured at all time-points to assess adherence to the study strategy.
Results: 100 participants were enrolled in the study, aged 47 years [IQR:40-53], receiving ARV therapy since 5.1[IQR:2.9-9.3] years with VL< 50 since 4.1[IQR:2.3-6.4] years, and median CD4 count =665/mm^3 [IQR:543-829]. Current regimen included tenofovir-DF+FTC (n=89) or abacavir+3TC/x (n=11), combined with a PI/r (n=29) or a NNRTI (n=71). Overall success rate was 96% [Kaplan-Meier 95%CI: 90-98]. Residual ART concentrations showed a good adherence (>90%) to the study strategy. No significant difference was shown for total HIV-1 DNA, stable between D0 (2.4±0.7 $\log_{10}$.copies/10^{6}PBMCs), W24 (2.4±0.7 $\log_{10}$.copies/10^{6}PBMCs) and W48 (2.4±0.7 $\log_{10}$.copies/10^{6}PBMCs) (p=0.765), and for inflammation markers with stable values for CRPus, IL-6, MIG-1, IP-10. A decrease in CD14s was observed between D0 (1019±749ng/mL) and W48 (820±393ng/mL)(p=0.004).
Conclusions: Over 48 weeks, maintenance ARV therapy with 4 days a-week regimen was effective in these adults with suppressed VL under ART, resulting in a success rate of 96%. The intermittent short-cycles therapy was associated neither with increase in viral reservoir nor with increase in inflammatory markers.

Dual regimen with dolutegravir and lamivudine maintains virologic suppression even in heavily treatment experienced HIV-infected patients: 96 weeks results from maintenance DOLULAM study

J. Reynes[1,2], N. Meftah[3], E. Tuaillon[4], C. Charpentier[5], B. Montes[4]
[1]Montpellier University Hospital, Infectious Diseases, Montpellier, France, [2]IRD UMI 233/INSERM U 1175, Montpellier, France, [3]Montpellier University Hospital, COREVIH, Montpellier, France, [4]Montpellier University Hospital, Virology, Montpellier, France, [5]Hôpital Bichat-Claude Bernard, Virology, Paris, France
Presenting author email: j-reynes@chu-montpellier.fr

Background: Novel antiretroviral combinations may be needed for HIV-infected patients with long term toxicity. We aimed to assess the efficacy and safety of dual therapy with dolutegravir (DTG) and lamivudine (3TC).
Methods: DOLULAM is a prospective cohort study. Patients on a stable antiretroviral regimen with HIV RNA <50 copies/ml for >12 months, with problems of toler-

ability and without resistance to integrase inhibitors, were given the opportunity to switch to dolutegravir 50 mg plus lamivudine 300 mg once daily.
Visits and laboratory tests including plasma HIV-1 RNA levels (VL)(Roche Cobas Ampliprep / Taqman HIV-1 v.2.0.; limit of detection, 20 copies/mL) were scheduled at baseline (BL), W6, W12, W24, W36, W48, then every 12-24 weeks.
Results: We enrolled 27 patients (20 men, 7 women, median age: 59 years, plasma HIV-1 RNA zenith > 100 000 copies/ml: 56%, median nadir CD4:167/mm^3, median baseline CD4: 601/mm^3).
Before switching to dual therapy, patients had been taking antiretroviral therapy for a median of 215 (range 22-329) months and the last HAART (TDF: 48%, PI/r: 81%, RAL: 26%) for a median of 51 (13-108) months. Ten (37%) patients had a history of genotypic test prior swich with M184V mutation.
After a median of follow up of 96 weeks (2362 patients-week) no patient experienced virologic failure (defined as confirmed VL > 50 copies/ml) or severe clinical or laboratory adverse event, or was lost to follow-up. Two patients experienced one blip (52 and 66 copies/mL at week 12 and 36). Three patients wanted to discontinue DTG+3TC combination (2 at week 16 and week 24 for fatigue, one at week 18 after blip at W12 visit).
There was a small decrease from baseline in estimated glomerular filtration rate (eGFR) at first on-treatment assessment (median BL-W6 evolution: - 9 mL/min/1.73m2) but remained stable over the 96-week follow-up (median BL-W96 evolution: -6).
Conclusions: These results suggest that, in this population of heavily treatment-experienced patients without or with history of M184V mutation, dolutegravir plus lamivudine dual therapy is an attractive strategy of maintenance.

MOPEB0323

CD4/CD8 ratio in patients who switch cART therapy: triple drug regimen could be better than mono/dual?

C. Mussini[1], P. Lorenzini[2], A. Cozzi-Lepri[3], G. Marchetti[4], S. Rusconi[5], A. Gori[6], S. Nozza[7], A. Antinori[2], A. d'Arminio Monforte[4], for the Icona Foundation Study Group

Presenting author email: cristina.mussini@unimore.it

Background: A low CD4/CD8 ratio has been associated to AIDS and non-AIDS associated events. Long-term side effects have led to non-conventional NRTI-sparing regimens. Aim of the study was to evaluate if the switch to mono/dual therapy could determine a change in CD4/CD8 ratio.
Methods: naïve patients from Icona cohort who started a triple cART regimen and switched to another triple regimen or to dual- or mono-therapy and maintained it till 12 months during virological suppression. End-points: patients who at 12 months increased 1) CD4/CD8 ratio of at least 10% and 2) CD8 of at least 25% respect to baseline value. Logistic regressions were used to evaluate associated factors.

CD4/CD8 ratio at switch	0.22	0.14	0.36	<0.001	CD8 at switch (100 cells increase)	0.83	0.80	1.07	<0.001
mono/dual vs triple	0.39	0.24	0.61	<0.001	mono/dual vs triple	2.06	1.23	3.46	0.006

[Table. Multivariable logistic regression models to estimate the probability of: a) CD4/CD8 and b) CD8 increase respect to baseline value.]

Results: 905 patients included, 104 switched to mono/dual regimen (51 monoPI, 53 dual), while 801 switched to triple regimen. 76.1% males, mean age: 43 years, 9.9% migrants, 17.2% HCV positive, median time of viral suppression of 20 months (range 10-37). Patients who switched to mono/double therapy were more frequently MSM, HCV-Ab negative. At switch, there were no difference concerning duration of viral suppression and CD4, while CD4/CD8 ratio was lower in those who switched to triple therapy (0.65 vs 0.77; p< 0.013). At 12 months patients on triple regimen showed a median ratio increase +0.10(+0.01;+0.20) vs +0.05(-0.03;+0.14) (p=0.007) in triple and mono/dual respectively.
The difference was not due to CD4 increase: median increase 63 vs 99 cells/uL at 12 months (p=0.45), but to CD8 change. Indeed, at 12 months the median change was -20 cells/uL (-172;+127) in the triple and +28(-98;+166) (p=0.018) in double/mono. At multivariable (tab) pts on mono/dual therapy were independently associated with reduced probability of ratio gain and higher probability of CD8 increase at 12 months.
Conclusions: Patients who switch to a dual/mono therapy, despite viral suppression, could not completely benefit of immune-reconstitution as those who remained on a triple regimen.

MOPEB0324

Switching to rilpivirine from first-line regimens is safe and effective in resource-limited settings

S. Gatechompol[1], A. Avihingsanon[1,2], T. Apornpong[1], S.J. Kerr[1,3], K. Ruxrungtham[4]
[1]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn University, Division of Allergy and Immunology, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]Chulalongkorn University, Research and Innovation, Bangkok, Thailand
Presenting author email: sivaporn.k@hivnat.org

Background: Life-long suppressive therapy is required for HIV-infected patients. Maintaining success in the long term is facilitated by avoiding long-term toxicities and convenient regimens. There are a limited number of studies looking at switching to RPV-based regimens in resource-limited settings. This study assessed the efficacy and safety of switching from a first-line NNRTI or boosted protease inhibitor (PI)-based regimen to RPV-based regimens in virologically suppressed patients living in an Asian resource-limited setting.
Methods: From January 2011 to December 2015, we conducted a prospective cohort study in Bangkok, Thailand. Participants without history of NNRTI failure with current plasma HIV-RNA <50 copies/mL and receiving PI- or NNRTI-based regimens were switched to RPV-based regimens. The primary endpoint was the proportion of patients with plasma HIV-1 RNA level <50 copies/mL after 12 months of RPV treatment.
The secondary endpoint was safety profile, defined by changes in the kidney function and lipid results from baseline to the12-month time point.
Results: A total of 170 participants switched NNRTI or boosted PI to RPV. 7 participants stopped RPV within 3 months due to adverse event (rash, and hepatitis). Only 136 who completed 12 months of follow-up were included in this analyses. Baseline regimens were NNRTI 79 (58%) or PI-based 57(42%). The rationale for switching to RPV was due to toxic adverse-effects (63%) or simplification of cART (35%). Ninety-five (56%) participants were male with a median age of 45 (IQR 40-50) years. At 12 months, 134 (98%) participants maintained virological suppression (HIV RNA <50 copies/ml) and another 2 participants had viral loads <100 copies/mL. Significant improvements from baseline to month 12 were seen for total cholesterol (median change -18.7 (IQR -41 - 7) mg/dL; p<0.001) and triglycerides (-40.3 (IQR -73.5 - 11.5) mg/dL; p<0.001).
There was no difference in the reduction of the lipid profiles between PI- and NNRTI-pre-treated groups. And a small increase in serum creatinine 0.03 mg/dL (p<0.001) was also found.
Conclusions: RPV-based regimen is a viable switching option from other first-line therapy for maintaining virological suppression and improving the lipid profile for HIV-positive people living in a resource-limited setting.

Background: Current recommendations for the treatment of HIV infection are based on a combination of antiretroviral drugs (cART). Simplified HIV treatment maintenance regimen is strategical to ease retention of care, to improve treatment satisfaction and to reduce healthcare costs.
We aim to assess the feasibility and efficacy of dolutegravir maintenance monotherapy in patients who were virologically suppressed with conventional triple cART for at least 24 months prior to baseline by confirming that viral load is undetectable(HIV-RNA < .50 copies/ml) in peripheral blood and HIV reservoirs, including cerebrospinal fluid (CSF) and sperm.
Methods: Interventional, open label, single arm, 24-week pilot study. Eligible patients were virologically suppressed (HIV-RNA < .50 copies/ml) for at least 24 months and had no history of previous ART failure nor documented antiretroviral drugs resistance.
Primary outcome: Number of patients completing 24 weeks of dolutegravir monotherapy without experiencing virological failure defined as plasma HIV-1 RNA ≥ 200 copies/ml on two consecutive measurements or positive HIV-1 RNA level in CSF at week 24.
Results: Eight patients were enrolled, including two women. Mean age was 47 years (range 36-66 years), mean follow up since HIV diagnosis was 12 years (range 2-26 years), mean nadir CD4 count was 301/µl (range 21-555/µl) and, mean CD4 count at baseline was 800/µl (range 345-1511/µl). Three patients so-far had a lumbar puncture at baseline and at week 24. HIV-RNA in the peripheral blood and in the CSF was< 50 copies/ml in all tested samples. Results of HIV-RNA in the sperm at baseline and week 24 will be available at the end of the study. Seven patients reached week 12, all with HIV-RNA below the detection level of 20 copies/ml.
Conclusions: Treatment maintenance with dolutegravir monotherapy seems to be feasible in rigorously selected HIV-suppressed patients and presents good penetration in the CSF compartment. However closer follow-up is needed and results from larger randomized clinical trials are expected.

Presenting author email: christoph.spinner@tum.de

Background: With successful antiretroviral therapy (ART) life-expectancy of HIV-patients has substantially increased, but ART-related long-term toxicities have led to the emergence of novel treatment strategies. The combination of the integrase inhibitor dolutegravir (DTG) and the boosted protease inhibitor darunavir (DRV/r) may play a key role in this setting. However, pharmacokinetic (PK) data is sparse to date.
Methods: Prospective, randomized, non-blinded pharmacokinetic sub-study of the DUALIS study (Eudra-CT: 2015-000360-34). Virologically suppressed HIV infected patients under ART were randomized and either kept on DRV/r plus NRTI backbone or switched to DTG 50 mg qd in combination with DRV/r 800/100 mg qd. Samples for PK analysis were obtained 4 weeks after switch at a single day (before and 1, 2, 4, 8 and 12 hours after intake of DTG plus DRV/r with food) and plasma levels were determined using HPLC.
Results: A total of 10 patients (pts) (7 male, 3 female) with a median (IQR) age of 46 (37-50) years, a Body Mass Index of 24.6 (23.2-25.2), HIV RNA of 39 (19-44) cps/ml and a CD4-count of 715 (450-860) /µL were included in the sub-study. HIV RNA remained < 50 cps/mL in all patients. 9/10 pts had detectable plasma levels prior to intake (C_{trough}). Median (IQR) C_{trough} levels were 637 (483-923) ng/mL for DTG and 1245 (575-1818) ng/mL for DRV. Maximum levels measured were 3427 (2964-4048) ng/mL for DTG and 6170 (5708-8950) ng/mL for DRV (Fig_A). C_{trough} remained 4-17-fold above the protein-adjusted IC_{90} (64 ng/mL) for DTG and 1-22-fold above the protein-adjusted EC_{90} (200 ng/mL) for DRV (excluding the patient with undetectable DTG and DRV C_{trough} levels), respectively. Median (IQR) AUC_{12} DTG was 26,809 (22,441-28,459) ng·h/mL and for DRV 49920 (36,729-56,234) ng·h/mL, respectively. No drug-related adverse events (AEs) or serious AEs (SAEs) have been observed.
Conclusions: Overall drug levels showed an increase in DTG and DRV plasma levels after ART intake with C_{trough} levels for DTG and DRV above the protein-adjusted IC_{90} and EC_{90} levels, respectively, without evidence of virologic failure.
Switching to once-daily dual therapy with dolutegravir in combination with ritonavir-boosted darunavir appears to be safe and effective with regard to their pharmacokinetic profiles.

MOPEB0327

High peak plasma level of dolutegravir in patients with ABCG2 genetic variants

K. Tsuchiya[1], T. Hayashida[1], A. Hamada[2,3], S. Oki[4], S. Oka[1,5], H. Gatanaga[1,5]
[1]*National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan,* [2]*National Cancer Center Research Institute, Department of Clinical Pharmacology, Tokyo, Japan,* [3]*Kumamoto University, Department of Medical Oncology and Translational Research, Kumamoto, Japan,* [4]*National Center for Global Health and Medicine, Department of Pharmacy, Tokyo, Japan,* [5]*Kumamoto University, Center for AIDS Research, Kumamoto, Japan*

Background: The ATP-binding cassette transporter B1 (ABCB1) and the ATP-binding cassette transporter G2 (ABCG2) are both expressed in the intestines, which are efflux transporters of drugs. Dolutegravir (DTG) was recently identified to be a substrate of both ABCB1 and ABCG2. In this study, we analyzed the relations between single nucleotide polymorphisms of ABCB1 and ABCG2 genes and plasma DTG concentrations.
Methods: HIV-1-infected patients treated with DTG-containing regimens (DTG 50 mg once daily with two nucleotide/nucleoside reverse transcriptase inhibitors and/or protease inhibitors) were recruited at the AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan. Blood samples were withdrawn into heparinized tubes, and the plasma and peripheral blood mononuclear cells were separated and stored at -80°C. The Ethics Committee for Human Genome Studies at the National Center for Global Health and Medicine approved this study (NCGM-A-000243-01) and each patient provided a written informed consent. Plasma samples were obtained from HIV-1-infected patients treated with DTG-containing regimens 0.5-4 hours after DTG dosing. Plasma DTG concentrations were measured by the liquid chromatography-mass spectrometry (LC-MS) method. Genomic DNA was isolated from peripheral blood mononuclear cells. Genotyping of allelic variants of ABCB1 1236 C>T (rs1128503), 2677 G>T/A (rs2032582), 3435 C>T (rs1045642), 4036 A>G (rs3842) and ABCG2 421 C>A (rs2231142) were carried out using the TaqMan Drug Metabolism Assays.
Results: Plasma samples were collected from 42 patients and used for measurement of DTG concentrations. None of the genotypes in ABCB1 1236 C>T, 2677 G>T/A, 3435 C>T and 4036 A>G showed a correlation with plasma DTG concentration. On contrary, the mean peak plasma concentration of DTG was significantly higher in the genotypes of ABCG2 421 AA (5,002 ng/ml, n=3), compared to the genotypes of ABCG2 421 CC (2,569 ng/ml, n=22) and CA (2,479 ng/ml, n=17) (P=0.0005, one-way ANOVA).
Conclusions: The peak level of plasma DTG concentration was significantly higher in ABCG2 genetic variant holders which may be explained by low expression of efflux transporters in the intestines associated with these genetic variants.

Presenting author email: htogami@nnh.hosp.go.jp*

Background: Dolutegravir (DTG) is metabolized mainly by glucuronidation via UDP-glucuronosyltransferase 1A1 (UGT1A1). Several UGT1A1 polymorphisms have been correlated with the UGT1A1 expression level and enzymatic activity. In these polymorphisms, *6 and *28 alleles are associated with reduced levels of UGT1A1. In particular, the *28 allele accounts for most of the UGT1A1 polymorphisms in the population. On the other hand, in Asian patients, the *6 alleles are more commonly found in comparison with white patients. So we compared the effects of the two polymorphic alleles, UGT1A1*6 and *28, on plasma DTG concentrations in Japanese HIV-1 infected patients.
Methods: We recruited 179 Japanese HIV-1 infected patients (male:female=171:8) in the National Hospital Organization, Japan. Next, we measured DTG plasma trough concentrations using LC-MS, and performed UGT1A1 genetic screening (*6 and *28). This study was reviewed and approved by the Institutional Review Board of the National Hospital Organization, and each subject provided written informed consent.
Results: Among 179 patients, the frequencies of UGT1A1 genotypes were 13 patients (*6/*6, 7%),
38 patients (-/*6, 21%), 4 patients (*28/*28, 2%), 24 patients (-/*28, 13%), 8 patients (*6/*28, 4%). The trough concentrations of plasma DTG were significantly higher in patients homozygous for UGT1A1*6 (n=13, 1.44 μg/ml; p< 0.001) and compound heterozygous for UGT1A1*6/*28 (n=8, 1.23μg/ml; p=0.003) than in patients carrying the normal allele (n=92, 0.73 μg/ml). The trough concentrations of DTG in patients homozygous for UGT1A1*28 (n=4, 0.92 μg/ml), heterozygous for UGT1A1*6 and *28
(n=38, 0.86 and n=24, 0.95 μg/ml, respectively) were not significantly different from those in patients homozygous for the normal allele.
Conclusions: There were significant correlations between *6 allele and the plasma DTG concentrations. Therefore, UGT1A1*6 polymorphisms are predictive of high plasma concentrations of DTG in Asian patients. To prevent side effects of DTG, it is important to analyze UGT1A1*6 genotypes for Asian each patient.

MOPEB0329

Pharmacokinetic modelling of darunavir/ritonavir dose reduction (800/100 mg to 400/100mg once daily) containing regimen in virologically suppressed HIV-infected patients as maintenance treatment: ANRS-165 DARULIGHT sub-study

Presenting author email: gilles.peytavin@aphp.fr*

Background: Several strategies aiming at simplifying maintenance antiretroviral therapy without jeopardizing efficacy are being explored to improve long term tolerability, adherence and reduce costs.
This sub-study was conducted in the setting of the ANRS-165 Darulight trial to evaluate DRV and RTV plasma pharmacokinetic parameters in patients switching from DRV/RTV (800/100mgQD) containing regimen to DRV/RTV (400/100mg QD).
Methods: Patients enrolled in this multicenter, open-label, phase II single arm trial with plasma HIV-RNA (pVL)< 50c/mL for ≥12 months while receiving stable DRV/RTV (800/100mg QD)+2 NRTIs were offered to participate in this pharmacokinetic sub-study. Intensive 24h pharmacokinetic blood sampling was performed at D0 (before the switch) and 12 weeks after switching to DRV/RTV (400/100 mg QD) (W12). Total and unbound (DRV) and total (RTV) plasma concentrations were determined by UPLC-MS/MS. Steady-state pharmacokinetic parameters (AUC, Cmin, Cmax, $t_{1/2}$) were determined by a non-compartmental analysis. Paired Geometric Mean Ratio (GMR; IC90%) (W12/D0) was calculated (Wilcoxon test). Apparent Clearance (Cl/F) and distribution volume (Vd/F) and effect of RTV AUC were assessed by a non-linear mixed effects modelling approach, using Monolix software.
Results: Fifteen men were included and 12 full pharmacokinetic pairs (W12/D0) were available. Median age was 42 years (IQR, 41-47). Pharmacokinetic parameters are presented in Table. DRV and RTV half-lives remained unchanged. DRV and RTV Cl/F and Vd/F were determined using one-compartment model with first order absorption and linear elimination. DRV Cl/F and Vd/F were 28.4L/h (RSE (relative standard error) 22%) and 199L (RSE16%). RTV Cl/F and Vd/F were 21.3L/h (RSE7%) and 171L (RSE9%). RTV AUC did not appear to be of significant effect on Cl/F.
Conclusions: In HIV-infected patients receiving maintenance therapy with DRV/RTV (800/100mg QD)+2 NRTIs, a reduction of DRV/RTV to 400/100mg QD was associated with non-significant decreases of total DRV AUC and total/unbound DRV Cmin and a small decrease of unbound DRV AUC. Unexpectedly, RTV exposure slightly increased with the reduced DRV dosing regimen.

Exposure of darunavir (DRV), ritonavir (RTV), emtricitabine (FTC), and tenofovir (TFV) in duodenal tissue: implications for gastrointestinal (GI) immune reconstitution among HIV-infected patients undergoing antiretroviral treatment

K. Garrett[1], S. Mann[2], T. Sainz Costa[3,4], S. Serrano Villar[5,6], J.-C. Garcia[2], P. Troia-Cancio[2], X.-D. Li[2], R. Pollard[2], T. Yotter[2], A. Kashuba[1], D. Asmuth[2]
*[1]University of North Carolina, Department of Pharmacotherapy and Experimental Therapeutics, Chapel Hill, United States, [2]University of California Davis, Department of Internal Medicine, Sacramento, United States, [3]University Hospital La Paz, Department of Infectious Diseases, Madrid, Spain, [4]IdiPAZ, Madrid, Spain, [5]University Hospital Ramon y Cajal, Department of Infectious Diseases, Madrid, Spain, [6]IRYCIS, Madrid, Spain
Presenting author email: garrettk@email.unc.edu*

Background: Despite viral suppression, immune recovery in GI tissue lags behind peripheral blood, particularly in the small intestines. Whether poor antiretroviral penetration into GI tissue is a contributing factor for blunted GI immune reconstitution remains controversial.

Methods: 18 HIV+ men (pts) initiating daily DRV/RTV (800/100 mg) and FTC/tenofovir disoproxil fumarate (200/300 mg) underwent duodenal biopsy before and 1-year after starting therapy. Peripheral blood mononuclear cell (PBMC) pellets, plasma, and duodenal tissue (homogenate of snap-frozen tissue or collagenase-digested, single-cell pellets (DMC)) were analyzed by LC-MS/MS methods to quantify TFV, FTC, TFV diphosphate(-dp), and FTC triphosphate(-tp) concentrations. Published IC_{50} values were used for comparisons.
The area under the concentration time curve (AUC) was calculated in Phoenix® WinNonlin v6.4. The tissue penetration and cellular ratios (TPR/CR) were calculated as tissue/DMC AUC ÷ plasma/ PBMC AUC. Values are medians (minimum, maximum) unless stated otherwise.
Results: Median age was 40.5 (23-59) years, baseline CD4+ count and HIV RNA were 431 (93-809) cells/mm^3 and 40.5 (10-358) x10^3 copies/mL, respectively. Pts became undetectable by 3 months and CD4+ rose to 742 (124-1024) cells/mm^3 at one year. In 100% of samples, DRV and RTV tissue concentrations and TFV-dp in DMCs were >IC_{50}. In 61% of DMC samples, FTC-tp was ≥ IC_{50}. TPRs were 421 (TFV), 25.1 (RTV), 1.71 (FTC), 1.09 (DRV). CRs were 43 (TFV-dp) and 0.01 (FTC-tp). Half-lives were similar across compartments. Concentrations were higher in tissue than plasma (Table 1).
Intracellular TFV-dp and FTC-tp correlated between snap-frozen tissue and DMCs. (Spearman r=0.59 and r=0.81, respectively).
Conclusions: Active drug concentration was ≥IC_{50} in tissue for three or more agents in 100% of patients. These data provide evidence to suggest poor GI immune reconstitution may not be due to lack of local pharmacologic activity.

Predator effects of nevirapine on dolutegravir pharmacokinetics after switching

M. Grégoire[1], C. Allavena[2], E. André-Garnier[3], M. Morrier[4], E. Billaud[2], V. Reliquet[2], S. Bouchez[2], N. Hall[2], E. Dailly[1], F. Raffi[2]
[1]Nantes University Hospital, Pharmacology, Nantes, France, [2]Nantes University Hospital, Infectious Diseases, Nantes, France, [3]Nantes University Hospital, Virology, Nantes, France, [4]La Roche-sur-Yon Hospital, Infectious Diseases, La Roche-sur-Yon, France
Presenting author email: clotilde.allavena@chu-nantes.fr

Background: Co-administration of dolutegravir (DTG) 50 mg QD and nevirapine (NVP) 400 mg QD resulted in significant changes in DTG pharmacokinetics as a consequence of the enzymatic induction by NVP. Current study aimed to evaluate the duration of NVP predator effect on DTG pharmacokinetics when patients were switched from NVP to DTG.
Methods: SWAD study evaluated the efficacy, safety and satisfaction of switching from abacavir/lamivudine (600 mg/300 mg QD) + NVP (400 mg extended-release tablets QD) (ABC/3TC+NVP) to ABC/3TC/DTG (600mg/300 mg/50 mg QD). Fifty-three patients were included in this prospective, bicentric, single-arm, open-label switch study (NCT02067767). A PK substudy was conducted in 43 patients to evaluate DTG trough concentrations (C_{min}), as well as NVP residual concentrations. DTG and/or NVP plasma concentrations were measured at switch and at W1, W2, W4 and W12. Patient receiving concomitant therapy modifying DTG pharmacokinetics were excluded.
Results: At inclusion, patients were virologically suppressed for a median duration of 9.6 years and receiving an ABC/3TC+NVP regimen for a median duration of 6 years.
Mean DTG C_{min} [Standard Deviation (SD), number of subjects (n)] were 666 ng/mL [355; 35] at W1, 947 ng/mL [585; 38] at W2, 1130 ng/mL [571, 38] at W4 and 1439 ng/mL [923, 38] at W12. All patients were maintained above DTG IC90 (64 ng/mL) at all sample times. Mean NVP concentrations [SD, n] were 3435 ng/mL [1063, 35] at switch, 43 ng/mL [107, 35] at W1, 1 ng/mL [8, 38] at W2 and were undetectable at W4 and W12. NVP terminal half-life after switch was 27 hours. All patients were maintained above NVP IC90 (40 ng/mL) at switch. At W1, 27/35 patients were measured below NVP IC90 and 38/38 at W2.
At W12, all the patients maintained plasma HIV-1 RNA below 20 copies/mL.
Conclusions: After switching from ABC/3TC+NVP to ABC/3TC/DTG, DTG reached steady-state by W4/W12 when expected by D5/D10. All patients were maintained above DTG IC90 at all sample times without virological failure. Moreover, terminal half-life of NVP after switch was comparable to expected values. These PK data support switch from a NVP-based regimen to a DTG-based regimen without DTG adjustment.

MOPEB0332

A study evaluating the pharmacokinetics, safety, and tolerability of the bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) single tablet regimen (STR) in Japanese subjects

H. Zhang[1], S. West[2], A. Vu[3], R. Humeniuk[1], D. Xiao[4], H. Graham[5], H. Martin[5], J. Custodio[1]
[1]Gilead Sciences, Clinical Pharmacology, Foster City, United States, [2]Gilead Sciences, Biometrics, Foster City, United States, [3]Gilead Sciences, Clinical Operations, Foster City, United States, [4]Gilead Sciences, Bioanalytical Chemistry, Foster City, United States, [5]Gilead Sciences, Clinical Research, Foster City, United States
Presenting author email: jcustodio@gilead.com

Background: Bictegravir (BIC) is an investigational, once-daily, unboosted HIV integrase strand transfer inhibitor (INSTI) with a high barrier to resistance and potent in vitro activity against most INSTI-resistant variants. BIC, coformulated with the NRTI backbone of emtricitabine/tenofovir alafenamide (FTC/TAF), is currently in development for treatment of HIV-1 infection. This study evaluated the pharmacokinetics (PK), safety, and tolerability of BIC/FTC/TAF (B/F/TAF) in HIV-uninfected Japanese and Caucasian subjects.
Methods: Japanese subjects (n=25) were born in Japan, had not lived outside Japan >5 years, and had traceable maternal and paternal Japanese ancestry of parents and grandparents. Caucasian subjects (n=25) were not of Japanese or Asian descent. All subjects received a single, oral dose of B/F/TAF (50/200/25 mg) under fasted conditions. Intensive PK sampling was performed and statistical comparisons of the exposures of BIC, FTC, TAF, and TAF metabolite, TFV, were conducted by geometric mean ratios (GMR), associated 90% confidence intervals (CI), and no-effect boundary of 70-143%, with Japanese subjects as the test and Caucasian subjects as the reference. Safety was monitored throughout the study and follow-up.
Results: Table 1 shows the primary BIC, FTC, TAF, and TFV PK parameters (AUC_{inf}, AUC_{last}, C_{max}) and statistical comparisons. The PK of all components of B/F/TAF was similar in Japanese and Caucasian subjects and the GMR and corresponding 90% CIs of all parameters were contained within the protocol-defined no-effect boundary of 70%-143%. B/F/TAF was well tolerated and all subjects completed the study except one Caucasian subject who discontinued due to adverse events (AEs) of Grade 2 nausea and Grade 1 vomiting. No Grade 3, 4, or serious AEs and no clinically relevant laboratory abnormalities were observed.

PK Parameter		Japanese Subjects (n=25) Mean (%CV)	Caucasian Subjects (n=25) Mean (%CV)	GMR (%) (90% CI)
BIC	AUC_{inf} (ng*h/mL)	115,000 (21)	103,000 (31)	114 (100, 130)
	AUC_{last} (ng*h/mL)	114,000 (21)	102,000 (31)	115 (101, 131)
	C_{max} (ng/mL)	6,560 (18)	5,220 (21)	126 (115, 139)
FTC	AUC_{inf} (ng*h/mL)	11,200 (18)	10,600 (14)	105 (96.6, 113)
	AUC_{last} (ng*h/mL)	11,000 (19)	10,400 (14)	105 (97.0, 114)
	C_{max} (ng/mL)	2,680 (40)	2,450 (22)	103 (88.2, 121)
TAF	AUC_{inf} (ng*h/mL)	175 (52)	171 (41)	97.4 (78.6, 121)
	AUC_{last} (ng*h/mL)	170 (52)	167 (41)	95.9 (77.3, 119)
	C_{max} (ng/mL)	301 (58)	262 (42)	106 (85.4, 113)
TFV	AUC_{inf} (ng*h/mL)	325 (24)	324 (24)	100 (89.5, 113)
	AUC_{last} (ng*h/mL)	267 (24)	267 (20	99.3 (89.2, 111)
	C_{max} (ng/mL)	12.0 (30)	11.0 (24)	107 (93.4, 123)

[Table 1. B/F/TAF PK Parameter Summary]

Conclusions: Following administration of B/F/TAF, equivalent pharmacokinetics and similar safety and tolerability were observed in Japanese and Caucasians subjects supporting the use of the 50/200/25 mg dose of B/F/TAF in HIV-infected Japanese patients.

Presenting author email: thibaut.gele@aphp.fr

Background: The unbound concentration of a drug is considered the active moiety, which is available to cross cell membranes. This study aimed to characterize dolutegravir (DTG) protein binding to human serum albumin (HSA) and to plasma proteins in plasma of human and nonhuman primate (NHP, Macaca fascicularis).
Methods: DTG protein binding was measured in vitro in blank human plasma from the Blood Bank and in blank NHP plasma which were spiked with DTG to final concentrations of 800 and 1,600ng/mL. DTG HSA binding was measured using a 40g/L HSA solution prepared in pH 7.4 phosphate-buffered saline and spiked with DTG to yield 8 final concentrations from 25 to 25,000ng/mL. The influence of pH on DTG binding was studied in a 40g/L HSA solution spiked with DTG at 800 and 1,600ng/mL at pHs ranging from 7.0 to 7.8. Each experiment was run in triplicate. Bound and unbound fractions were separated by ultrafiltration (Centrifree devices). Total and unbound DTG concentrations were measured by quality controls validated assays (LC-MS/MS). A graphical Scatchard plot method was used to estimate the albumin binding characteristics.
Results: At the 800 and 1,600ng/mL DTG total concentrations, mean DTG plasma protein bindings were 99.4% (CV, 4.4%) and 99.1% (CV, 6.6%) respectively in human plasma and 98.9% (CV, 8.5%) and 98.5% (CV, 3.1%) respectively in NHP plasma. The mean binding of DTG to HSA was 89.6% (range, 83.2%-94.7%), and independent of DTG total concentration. DTG was found to bind to two classes of albumin sites: one with high affinity and one nonsaturable with low affinity. Interestingly in the pH range from 7.0 to 7.8, a 0.2U decrease in pH led to a 2% decrease in DTG albumin binding (P< 0.0001).
Conclusions: DTG binding is high mainly with HSA and is pH sensitive that could influence diffusion in some biological fluid and cells. As characterization of binding of DTG is similar in human and in NHP, the NHP model could be an adequate model for studying tissue distribution, particularly in inaccessible human tissues.

MOPEB0334

Co-administration of doravirine with an aluminum/magnesium containing antacid or pantoprazole, a proton pump inhibitor, does not have a clinically meaningful effect on doravirine pharmacokinetics

S. Khalilieh[1], K.L. Yee[1], R.I. Sanchez[1], K. Vaynshteyn[1], K. Deschamps[1], L. Fan[1], M. Martell[2], R. Pop[2], H. Jordan[3], M. Iwamoto[1]

Presenting author email: sauzanne.khalilieh@merck.com

Background: Doravirine is a novel, potent, HIV-1 non-nucleoside reverse transcriptase inhibitor currently being evaluated in Phase 3 trials for treatment of HIV-1 infection in combination with other antiretroviral therapy. As many patients with HIV-1 infection are treated with antacids or acid-reducing agents, this study was conducted to evaluate the effect of these agents on doravirine pharmacokinetics (PK).
Methods: This was an open-label, 3-period, fixed-sequence drug-interaction study in healthy adult subjects. In Period 1, a single dose (SD) of a doravirine 100mg tablet was administered. In Period 2, a SD of a doravirine 100mg tablet was co-administered with a SD of 20mL of an antacid suspension containing 1600mg of each aluminum hydroxide and magnesium hydroxide and 160mg of simethicone. In Period 3, a pantoprazole sodium 40mg delayed-release tablet was administered on Days 1-5 and a SD of a doravirine 100mg tablet was administered on Day 5. There was a washout of 10 days between each period. Blood samples to measure doravirine plasma concentrations were collected predose and through 72 hours post dose in all periods.
Results: Fourteen subjects (8 male and 6 female) were enrolled and 13 completed the study; one subject discontinued for personal reasons. Following co-administration with an aluminum/magnesium containing antacid, doravirine PK was not affected to a clinical meaningful extent. The geometric mean ratios (GMR) (90% confidence intervals) [doravirine + antacid/doravirine] for Cmax, AUC0-∞, and C24 were 0.86 (0.74,1.01), 1.01 (0.92,1.11), and 1.03 (0.94,1.12), respectively. Following co-administration with pantoprazole, there was no clinically significant effect on doravirine PK. The GMR (90% confidence intervals) [doravirine + pantoprazole/doravirine] for Cmax, AUC0-∞, and C24 were 0.88 (0.76,1.01), 0.83 (0.76,0.91), and 0.84 (0.77, 0.92), respectively. There were no serious adverse experiences (AEs) and all AEs were mild in intensity. Overall, 3 (21%) subjects reported at least one AE during the study. The most common AE was headache reported by 3 subjects.
Conclusions: Doravirine is generally well tolerated when administered alone or with an aluminum/magnesium containing antacid or with the proton pump inhibitor, pantoprazole. Coadministration of either of these agents with doravirine does not have a clinically meaningful effect on doravirine PK.

MOPEB0335

Bioequivalence of a darunavir-based single-tablet complete HIV-1 regimen compared to the separate agents

H. Crauwels[1], B. Baugh[2], E. Van Landuyt[1], S. Vanveggel[1], A. Hijzen[1], M. Opsomer[1]
[1]Janssen Pharmaceuticals NV, Beerse, Belgium, [2]Janssen Research and Development LLC, Raritan, United States
Presenting author email: hcrauwel@its.jnj.com

Background: DCFTAF is the first once-daily, single-tablet complete HIV-1 regimen containing darunavir (DRV, D 800mg), cobicistat (COBI, C 150mg), emtricitabine (FTC, F 200mg) and tenofovir alafenamide (TAF, 10mg). The efficacy and safety of DCFTAF is being investigated in two large, international, randomized Phase 3 studies AMBER (NCT02431247) and EMERALD (NCT02269917). The present study (NCT02578550) evaluated if the DCFTAF tablet is bioequivalent to combined intake of the separate agents.
Methods: This was a Phase I, open-label, randomized, 2-sequence, 2-period crossover study in healthy volunteers (n=96). In two treatment sessions, participants received a single oral dose of the DCFTAF tablet (test) or combined intake of a single oral dose of DRV (one 800-mg tablet), FTC/TAF (one 200/10-mg tablet), and COBI (one 150-mg tablet) (reference), under fed conditions (standardized regular-calorie, regular-fat breakfast), with a ≥7-day washout period in between. Bioequivalence was evaluated when taken with food in line with other DRV-based treatment regimens. Pharmacokinetic profiles were determined over 72 hours after dosing (8 hours for TAF). Plasma concentrations of DRV, COBI, FTC and TAF were determined using validated LC-MS/MS assays. Pharmacokinetic parameters were determined using non-compartmental analysis, and treatments compared using geometric mean ratios (GMR) with 90% confidence intervals (CIs). Safety and tolerability were assessed throughout.

SD = standard deviation; CI = confidence interval; C_{max} = maximum plasma concentration; t_{max} = time to C_{max}; AUC_{last} = area under the plasma concentration-time curve (AUC, calculated by linear-linear trapezoidal summation) from time of administration up to the last timepoint with a measurable concentration post-dose
AUC_{inf} = AUC from time of administration to infinity; $t_{1/2term}$ = terminal elimination half-life

[DRV, COBI, FTC and TAF pharmacokinetic parameters]

Results: No major differences were observed in the pharmacokinetic profiles for DRV, COBI, FTC and TAF between the DCFTAF complete HIV-1 regimen and the separate agents. The 90.14% CIs of the GMRs of all main pharmacokinetic parameters were within the 80.00%-125.00% bioequivalence limits for all four components (DRV, COBI, FTC and TAF) (Table). DCFTAF was generally well tolerated. No new safety issues, Grade 3/4 or serious AEs, deaths or discontinuations due to AEs occurred.
Conclusions: The DCFTAF 800/150/200/10-mg single-tablet complete HIV-1 regimen is bioequivalent to the combined administration of the separate agents DRV, FTC/TAF and COBI.

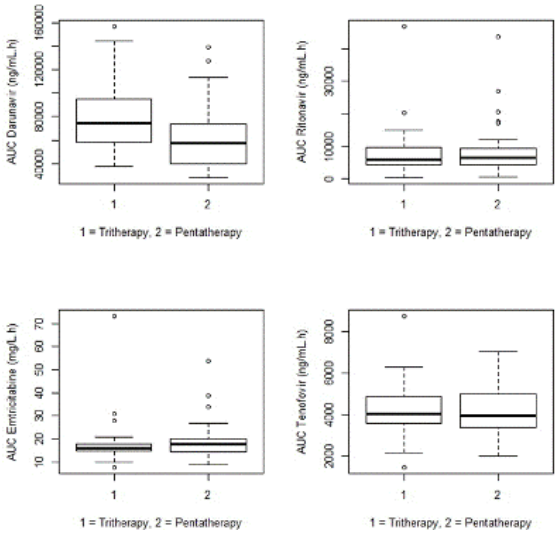
Low concentrations of darunavir once daily when coadministered with maraviroc + raltegravir, Optiprim-ANRS 147 trial

C. Pressiat[1,2], D. Hirt[1,2], J.-M. Treluyer[1,2], Y. Zheng[1,2], P. Morlat[3], A. Naqvi[4], L. Tran[5], J.-P. Viard[6,7], C. Rouzioux[7,8], L. Meyer[5], A. Chéret[7,9], Optiprim-ANRS 147 Trial
[1]Paris Centre Hospital Group, Clinical Pharmacology Department, Paris, France, [2]Paris Descartes University, EA 7323, Paris, France, [3]Saint-André Hospital, Infectious Diseases Unit, Bordeaux, France, [4]Nice Hospital, Infectious Diseases Unit, Nice, France, [5]University Paris Sud, AP-HP Hopital de Bicêtre, INSERM, CESP U1018, Le Kremlin Bicêtre, France, [6]Hôtel-Dieu Hospital, AP-HP, UF de Thérapeutique en Immuno-Infectiologie, Paris, France, [7]Paris-Descartes University, EA 7327, Paris, France, [8]Necker Hospital, AP-HP, Virology Laboratory, Paris, France, [9]Bicêtre Hospital, AP-HP, Internal Medecine, Paris, France
Presenting author email: claire.pressiat@gmail.com

Background: The OPTIPRIM-ANRS 147 trial compared intensive combination antiretroviral therapy-darunavir/ritonavir (DRV/RTV), tenofovir disoproxilfumarate/emtricitabine (TDF/FTC), raltegravir and maraviroc - started early during primary HIV-1 infection to standard tritherapy with DRV/RTV/TDF/FTC. A poorer percentage of undetectable viral load (< 50 cp/mL) was reported in the pentatherapy versus tritherapy arm from month 6 to 18. This pharmacokinetic sub-study aimed to compare antiretroviral drug concentrations in the 2 arms.
Methods: Plasma samples were collected from 50 patients at variable times from drug administration. To compare ART level between groups, for each patient a concentration just before intake (trough concentrations C_{trough}) and an exposure (area under the concentration-time curve AUC) was predicted using a maximum a posteriori probability (Bayesian estimation) from published population pharmacokinetic models. These parameters were compared between the tritherapy and pentatherapy arms using a mixed linear regression.
Results: Published models adequately described data and could be used to predict trough concentrations and exposures. No significant difference was evidenced for tenofovir, emtricitabine and ritonavir between the tritherapy and the pentatherapy arms. However, darunavir C_{trough} and AUC were significantly lower in the pentatherapy arm than in the tritherapy arm (p=0.03 and p=0.04 respectively). Due to the small number of patients enrolled in this sub-study, no pharmacodynamics relationship between viral load and AUC or $C_{through}$ could be demonstrated.



[Figure. Exposures of darunavir, ritonavir, tenofovir and emtricitabine in combination therapy and pentatherapy arm.]

Conclusions: An interaction between maraviroc and darunavir could be involved. Indeed, there are more pharmacological arguments to attribute this interaction to maraviroc than to raltegravir. We can therefore assume that this interaction had an impact on the kinetics of viral decay in the pentatherapy arm. A combined maraviroc/darunavir regimen can be an option in particular situations at the chronic stage: it would be relevant to prospectively evaluate an increased darunavir/ritonavir dosage to 600/100 mg twice daily in such situations.

MOPEB0337

Drug concentrations and HIV-1 RNA in CSF in patients switching to ritonavir-boosted atazanavir (ATV/r) plus lamivudine (3TC) dual therapy

A. Imaz[1], J. Niubó[1], A. Amara[2], S. Khoo[2], E. Ferrer[1], J.M. Tiraboschi[1], L. Acerete[1], B. Garcia[1], A. Vila[1], D. Podzamczer[1]
[1]Bellvitge University Hospital, L'Hospitalet de Llobregat, Spain, [2]University of Liverpool, Liverpool, United Kingdom
Presenting author email: aimaz@bellvitgehospital.cat

Background: Simplification to ATV/r + 3TC dual therapy in virologically suppressed patients has shown non-inferior efficacy compared to triple therapy. Since the penetration of ATV/r in CSF may be suboptimal, the aim of this study was to assess HIV-1 RNA and drug concentrations in CSF in patients who switched to ATV/r + 3TC.
Methods: Cross-sectional study including HIV-1 infected adults with suppressed plasma HIV-1 RNA and no history of resistance or failure to ATV/r and 3TC who switched from ATV/r+TDF/FTC to ATV/r+3TC. Total ATV and 3TC concentrations at the end of the dosing interval (C_{24h}) and HIV-1 RNA were measured in paired CSF and plasma samples 12 weeks after switching to ATV/r+3TC. Validated LC-MS/MS methods were used to quantify drug concentrations, and HIV-1 RNA was determined by real-time PCR.
Results: Ten patients were included, 4 male, 6 female. Median (range) age was 42.5 years (33-70), time on ART 39.5 months (11-197), time with plasma HIV-1 RNA < 40 c/mL 15.5 months (6-46), nadir CD4 count 289 cells/µL (79-580) and current CD4 count 740 cells/µL (357-1380). All had HIV-1 RNA < 40 c/mL in CSF at baseline. Twelve weeks after switching to ATV/r+3TC, 9/10 patients maintained HIV-1 RNA < 40 c/mL in both plasma and CSF. One patient with suboptimal adherence to ART had HIV-1 RNA rebound in both plasma (2658 c/mL) and CSF (1233 c/mL) although she was asymptomatic. The median CSF-to-plasma concentration ratios of ATV and 3TC were 0.013 and 0.417 respectively. Median ATV C_{24h} in CSF was 10.39 (3.71-33.45) ng/mL (in vitro ATV IC_{50} range for wild type HIV-1, 1-11 ng/mL). Median 3TC C_{24h} in CSF was 43.42 (16.20-99.33) ng/mL (in vitro 3TC IC_{50} range for wild type HIV-1, 0.68-20.6 ng/mL).
Conclusions: Twelve weeks after switching to ATV/r+3TC most patients maintained HIV-1 RNA < 40 c/mL in CSF despite CSF ATV C_{24h} close to or within the IC_{50} range in a proportion of them. The good CSF penetration of 3TC may have contributed to HIV-1 RNA suppression in this compartment. Nevertheless, a rigorous patient selection and optimal adherence is advisable to assure effective CSF viral suppression with this dual ARV simplification regimen.

MOPEB0338

The effect of fostemsavir on methadone and buprenorphine pharmacokinetics

H. Sevinsky[1], M. Magee[2], P. Ackerman[3], M. Chang[4], S. Lubin[4], E. Myers[4], W. Wu[5], C. Llamoso[3], T. Eley[5]
[1]ViiV Healthcare, Upper Providence, United States, [2]GlaxoSmithKline, Upper Merion, United States, [3]ViiV Healthcare, Wallingford, United States, [4]Bristol-Myers Squibb, Hopewell, United States, [5]Bristol-Myers Squibb, Lawrenceville, United States
Presenting author email: heather.j.sevinsky@viivhealthcare.com

Background: Fostemsavir is a prodrug of temsavir, a first-in-class attachment inhibitor that binds directly to HIV-1 gp120, preventing initial viral attachment and entry into host CD4+ T cells. This study assessed the impact of fostemsavir on the pharmacokinetics (PK) of the opioids methadone (R-, S-, and total) or buprenorphine/norbuprenorphine when coadministered.
Methods: AI438068 was a Phase 1, open-label study in subjects on methadone maintenance therapy (40 - 120 mg QD, Part 1, N=16) or buprenorphine/naloxone maintenance therapy (8/2 - 24/6 mg QD, Part 2, N=16). HIV- and HBV-positive subjects were excluded; a positive test for HCV antibodies with documentation of anti-HCV therapy was acceptable. In Part 1, subjects received methadone on Day 1 and methadone QD with fostemsavir 600 mg BID on Days 2-9. In Part 2, subjects received buprenorphine/naloxone on Day 1 and buprenorphine/naloxone QD with fostemsavir 600 mg BID on Days 2-9. Serial blood samples were collected up to 24 hours post-dose Day 1 and Day 9. Plasma concentrations were quantified by validated LC/MS/MS methods. Geometric mean ratios (GMRs) and 90% confidence intervals (CI) were derived for dose-normalized methadone (R-, S-, total), buprenorphine and norbuprenorphine PK using linear mixed-effects models. The

effect of fostemsavir was deemed clinically insignificant if the 90% CI fell within 0.70-1.43 for methadone and 0.50-2.00 for buprenorphine and norbuprenorphine. Adverse events were monitored throughout the study, including signs of withdrawal or toxicity.
Results: Methadone exposures (R-, S-, and total) increased 9-15% and buprenorphine/norbuprenorphine exposures increased 24-39% when coadministered with fostemsavir. In subjects on a stable regimen of methadone or buprenorphine/naloxone, coadministration of fostemsavir was safe and generally well tolerated with no reported symptoms of overdose or withdrawal.

Analyte	Cmax GMR (90% CI)	AUC(TAU) GMR (90% CI)	C24 GMR (90% CI)

S-methadone	1.15 (1.10, 1.19)	1.15 (1.09, 1.21)	1.10 (1.02, 1.19)
total methadone	1.15 (1.11, 1.19)	1.14 (1.09, 1.20)	1.10 (1.02, 1.18)
buprenorphine	1.24 (1.06, 1.46)	1.30 (1.17, 1.45)	1.39 (1.18, 1.63)
norbuprenorphine	1.24 (1.03, 1.51)	1.39 (1.16, 1.67)	1.36 (1.10, 1.69)

[Cmax, AUC(TAU), and C24 GMR (90% CI)]

Conclusions: Methadone and buprenorphine may be coadministered with fostemsavir without dose adjustment. Consistent with recommendations for other antiretrovirals, monitoring for clinical signs of sedation with buprenorphine may be warranted.

MOPEB0339

The effect of fostemsavir on the pharmacokinetics of a combined oral contraceptive (OC) containing ethinyl estradiol (EE) and norethindrone (NE) in healthy female subjects

M. Magee[1], H. Sevinsky[2], P. Ackerman[3], R. Adamczyk[4], A. Griffies[4], E. Myers[4], W. Wu[5], C. Llamoso[3], T. Eley[5]
[1]GlaxoSmithKline, Upper Merion, United States, [2]ViiV Healthcare, Upper Providence, United States, [3]ViiV Healthcare, Wallingford, United States, [4]Bristol-Myers Squibb, Hopewell, United States, [5]Bristol-Myers Squibb, Lawrenceville, United States
Presenting author email: mindy.2.magee@gsk.com

Background: Fostemsavir is a prodrug of temsavir, a first-in-class attachment inhibitor that binds directly to HIV-1 gp120, preventing initial viral attachment and entry into host CD4+ T cells. Women of child-bearing potential represent a significant proportion of the heavily-treatment experienced HIV-infected population; effective and convenient contraception is important. This study assessed the impact of fostemsavir on the pharmacokinetics (PK) of a combined OC containing EE and NE (Loestrin 1.5/30; 1.5 mg NE, 30 µg EE).
Methods: AI438019 was a Phase 1, open-label, single-sequence, 4-cycle, 4-treatment study in 26 healthy female subjects. Serial blood samples for PK up to 24 hours post-dose and single samples for serum progesterone were collected. Plasma concentrations were quantified by validated LC/MS/MS methods. Geometric mean ratios (GMRs) and 90% confidence intervals (CI) were derived for EE and NE PK using linear mixed-effects models. Adverse events (AEs) were monitored throughout the study.

Cycle 1	Cycle 2	Cycle 3	Cycle 4
Days 1-8	Days 1-28	Days 1-28	Days 1-21
Day 1 = 21st day of existing OC once daily (QD) (Treatment A)	Existing OC QD Days 1-21 (Treatment B)	Loestrin 1.5/30 QD Days 1-21 (Treatment C)	Loestrin 1.5/30 QD Days 1-11 Loestrin 1.5/30 QD + fostemsavir 600 mg BID Days 12 - 21 (Treatment D)
serial PK collection Day 1	serial PK collection Day 21	serial PK collection Day 10 and 21	serial PK collection Day 21
serum progesterone Day 1	serum progesterone Day 21	serum progesterone Day 11, 15 and 21	serum progesterone Day 11, 15 and 21

[Study Design]

Results: Only comparisons of EE and NE PK between Treatment D and Treatment C are presented. Fostemsavir coadministration increased EE exposures ~40%. The 90% CIs for NE Cmax and AUC(TAU) GMRs were within 0.80-1.25. Serum progesterone levels suggested fostemsavir did not negatively impact suppression of ovulation. Most study drug-related AEs were mild; 1 subject (3.8%) reported a moderate AE of headache (Treatment D).

Parameter	Treatment C Day 21 Adjusted Geometric Mean	Treatment D Day 21 Adjusted Geometric Mean	GMR (90% CI) Treatment D vs. C
EE Cmax (pg/mL)	108	150	1.39 (1.28, 1.51)
EE AUC(TAU) (pg.h/mL)	1083	1514	1.40 (1.29, 1.51)
NE Cmax (pg/mL)	23629	25582	1.08 (1.01, 1.16)
NE AUC(TAU) (pg.h/mL)	170293	184302	1.08 (1.03, 1.14)

[EE/NE Cmax and AUC(TAU)]

Conclusions: Fostemsavir, in the absence of a pharmacoenhancer, may be coadministered with combined oral contraceptives containing NE and a reduced dose of EE.

[1]Epicentre Mbarara Research Centre, Clinical Research, Mbarara, Uganda, [2]Mbarara University of Science and Technology, Mbarara, Uganda, [3]Epicentre, Clinical Research, Paris, France, [4]Mbarara Regional Referral Hospital, Mbarara, Uganda, [5]Epicentre Mbarara Research Centre, Laboratory, Mbarara, Uganda, [6]Epicentre Mbarara Research Centre, Data Managment, Mbarara, Uganda, [7]Bicetre Hospital, APHP and Inserm UMR 1184, Clinical Pharmacy, Paris, France, [8]IRD UMI 233 TransVIHMI-UM-INSERM U 1175, Montpellier, France
Presenting author email: atwine.daniel@epicentre.msf.org

Background: Despite the reported safety of high-dose Rifampicin (R) among HIV negative tuberculosis (TB) patients, no data exists among HIV-TB co-infected patients. We report the safety results from a high-dose rifampicin (20mg/kg) and efavirenz (EFV)-based ART (600 and 800mg) drug interaction study in HIV-TB co-infected patients by week-8 of TB treatment.
Methods: In a phase-2, randomized, open-label therapeutic trial (NCT01986543), newly diagnosed, XpertMTB/RIF positive and rifampicin-susceptible active pulmonary TB, HIV positive, ART-naïve, adult patients were enrolled and randomized to 3-study regimens (SR): SR_1: 8 weeks R20mg/Kg + Isoniazid(H) + pyrazinamide(Z) + ethambutol(E) and EFV600mg/J; SR_2: 8 weeks R20mg/Kg + H+Z+E and EFV800mg/J; Control regimen (CR): 8 weeks R10mg/Kg + H+Z+E and EFV600mg/J. EFV was given with tenofovir-lamivudine for all patients 2 weeks after starting anti-TB treatment(ATT). At 8 weeks, all patients were switched to standard R and EFV doses. Treatment was observed at home by a domiciliary treatment monitor. Weekly clinical assessments and bi-weekly biochemistry and full blood count monitoring was done.
Results: We enrolled 98 patients (SR_1: 33, SR_2: 32 and CR: 33), median age 33.6 years, 26.5% were females. Baseline median BMI, CD4 count and ALT were 19.5kg/m2, 142 cells/L and 19.5IU/L respectively. One and four patients were co-infected with hepatitis B and C respectively. Six patients; 2 from each arm had grade 3 or 4 increases in ALT or AST within the first 8 weeks: 1 during ATT alone vs 1 during ATT+ART for both SR1 and CR, and 2 during ATT alone vs 0 during ATT+ART for SR2. Only 4 patients (CR: 1, SR_1: 1, SR_2: 2, p = 0.780) had grade 2 neuropsychiatric AEs. No grade 3 or 4 neuropsychiatric AEs were noted. Fifteen patients, 5 from each arm had SAEs, with 2 of which resulting in death unrelated to treatment and 2 with their treatment arm changed from 20mg/kg-10mg/kg of R dose due to increase in hepatic transaminases.
Conclusions: Co-administration of a double-dose of rifampicin with efavirenz (600 or 800mg) among HIV/TB co-infected patients was well tolerated with very few severe transaminitis and no severe neuropsychiatric disorders.

MOPEB0341

Rare emergence of resistance in treatment-naive patients receiving E/C/F/TAF for 144 weeks

N. Margot, S. Cox, M. Das, S. McCallister, M. Miller, C. Callebaut
Gil, Clinical Virology, Foster City, United States
Presenting author email: christian.callebaut@gilead.com

Background: Tenofovir alafenamide (TAF) is a novel tenofovir (TFV) prodrug achieving higher levels of TFV-diphosphate in lymphocytes at a lower dose compared to tenofovir disoproxil fumarate (TDF). The single-tablet regimen (STR) elvitegravir/cobicistat/emtricitabine/TAF (E/C/F/TAF) was compared to the STR of

E/C/F/TDF in clinical studies. High proportions of patients achieved HIV-1 RNA <50 copies/mL at weeks 48, 96, and 144, and the response at week 144 (84.2% vs. 80.0% for E/C/F/TAF and E/C/F/TDF groups, respectively) favored the E/C/F/TAF group in a statistically significant manner. The final Week 144 integrated resistance analysis across two completed Phase 3 clinical studies is described.
Methods: HIV-1 genotypic testing was conducted pre-treatment using commercial population sequencing (Monogram Biosciences) to assess HIV-1 PR/RT/IN sensitivity to study drugs. For patients with HIV-1 RNA ≥400 copies/mL at time of virologic failure (VF) or early discontinuation, genotypic analysis and phenotypic antiretroviral susceptibility were evaluated.
Results: HIV-1 subtypes identified in the 1733 enrolled patients included A, A1, A2, AE, AG, B, BC, BF, C, D, F, F1, and G. Pre-existing primary resistance-associated mutations (RAMs) were observed pre-treatment in 7.4% (NRTI-RAMs), 18.1% (NNRTI-RAMs), and 3.3% (PI-RAMs) of enrolled subjects. Baseline HIV-1 subtype or NRTI- or NNRTI-RAMs did not affect E/C/F/TAF treatment response at week 144. VF resistance analyses were conducted for 28/866 (3.2%) and 30/867 (3.5%) patients in the E/C/F/TAF and E/C/F/TDF arms, respectively. Over the 3-year study, the rate of resistance emergence remained low at 1.4% in each treatment group (12/866 in E/C/F/TAF, and 12/867 in E/C/F/TDF). Resistant virus emerged in a total of 24 patients who developed primary resistance to antiretrovirals in the STRs (E/C/F/TAF: INSTI-RAMs [n=8], M184V/I [n=11], K65R/N [n=2]; E/C/F/TDF: INSTI-RAMs [n=8], M184V/I [n=9], K65R/N [n=4]). Overall, similar patterns of emergent mutations were observed in both treatment groups, with M184V/I being the most prevalent RAM (1.2% overall).
Conclusions: E/C/F/TAF achieved a high level of virologic suppression in HIV-1 treatment-naïve patients through 144 weeks of treatment. Resistance development was rare with comparable genotypic changes across the E/C/F/TAF (1.4%) and E/C/F/TDF (1.4%) treatment groups.

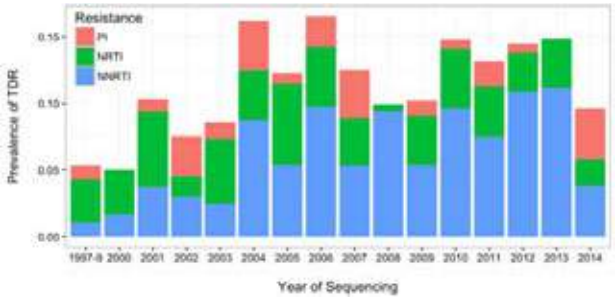
Presenting author email: levintow@email.unc.edu

Background: Transmitted drug resistance (TDR) compromises clinical management and outcomes. TDR surveillance and identification of growing transmission clusters is needed in the Southeast, the epicenter of the US HIV epidemic. We investigated prevalence and transmission dynamics of TDR in North Carolina (NC).
Methods: We analyzed surveillance drug resistance mutations (SDRM) using partial pol sequences among antiretroviral therapy (ART)-naïve patients with available genotypes presenting to two large HIV outpatient clinics from 1997-2014. We used logistic regression to compare TDR prevalence (SDRM among ART-naïve patients) by demographic and clinical factors, sequencing year, and transmission clusters. Transmission clusters were identified using maximum-likelihood trees and Bayesian methods including background pol sequences (n=15,247).
Results: 1,658 patients had a pre-ART genotype; 73% were men, 62% black, and 47% identified as MSM. Overall, ≥1 SDRM was identified in 199 patients, with an aggregate TDR prevalence of 12% (95%CI: 10-14%), increasing over time (p=0.04, Figure). Of 229 transmitted SDRM, most were NNRTI-associated mutations (58%), followed by NRTI (31%) and PI (12%). Sequences with mutations to two (n=20) and three drug classes (n=5) were uncommon. Compared to those without TDR, patients with TDR were more likely to be MSM (OR=1.39, 95%CI: 1.04-1.88), white (OR=1.42, 95%CI: 1.03-1.96), have higher CD4 counts (median 374 vs. 306 cells/mm^3, p< 0.01), and identified in a cluster (OR=1.64, 95%CI: 1.17-2.30). In our phylogenetic analysis, TDR was identified in 106 clusters. Of these clusters with TDR (range 2-26 members, 546 total sequences), 53% had K103N. In 75% of clusters, the majority of sequences shared an identical SDRM, and in 35%, all sequences had the same SDRM.



[Increasing TDR prevalence by year and drug class (N=1,658)]

Conclusions: Moderate TDR prevalence persists in NC predominantly driven by NNRTI resistance. Most TDR cases were identified in transmission clusters, signifying multiple local transmission networks and suggesting TDR circulation among ART-naïve persons. Continued TDR surveillance may help detect transmission networks for targeted prevention.

HIV-1 acquired drug-resistance during first-line regimens does not impact virological outcome after long-term second-line protease-based therapies in resource-limited countries: genotyping is not required for the reverse-transcriptase inhibitors-selection during treatment switch

C.J. Villabona Arenas[1], S. Eymard Duvernay[1], A. Aghokeng Fobang[1,2], E. Guichet[1], C. Toure Kane[3], G. Bado[4], S. Koulla Shiro[5], E. Delaporte[1], L. Ciaffi[1], M. Peeters[1]

Presenting author email: cj.villabona@gmail.com

Background: Viral load (VL) quantification is not widely available in resource-limited countries (RLCs) and diagnosis of a failing treatment may be delayed leading to the accumulation of drug resistance mutations. HIV-1 drug-resistance testing is not recommended for treatment switch and it is thus important to assess if genotyping may improve therapy optimization.
Here, we investigated the association between acquired resistance during first-line regimens and virological outcome after long-term second-line protease-based therapy in RLCs.
Methods: A total of 387 patients from the 2LADY-study (a randomized, open-label trial of three different second-line PI-based regimens in Burkina Faso, Cameroon and Senegal) were followed for 104 weeks. We model the relationship between treatment resistance data at baseline of second-line treatment initiation (genotypic susceptibility scores, resistance scores calculated for the observed mutations, number of Reverse-transcriptase inhibitors-mutations (RTIs) by drug class and duration of first-line treatment) and virological failure (three thresholds: ≥50, ≥200 or ≥1000 copies/ml) at week 104 using logistic regressions. Additional covariates included demographic (sex, age and country), biological (baseline HIV-1 VL and CD4+ count) and adherence (measured using standard questionnaires at week 4, 104, and average adherence) data.
Results: Overall, 193 (49.9%), 150 (38.8%) and 44 (11.4%) patients had respectively low/none, intermediate and high-predicted RTI-activity in their prescribed second-line regimen. The average number of mutations by RTI drug class and proportion of patients by genotypic susceptibility scores category were statistically similar irrespective of treatment outcome. No resistance, demographic or adherence data were consistently associated with successful response. VL at switch was the only consistent prognostic factor (OR>1) for virological failure after multivariate adjustment. Findings did not differ when the second-line regimens or data on the patients with incomplete adherence information were included.
Conclusions: Genotypic resistance tests are not required to guide RTIs choice for second-line PI-based regimens in RLCs and probably NRTIs may be recycled. However, VL quantification during first-line treatment is crucial to promptly detect failure and avoid a greater VL increase, which may compromise future treatment outcome. Our findings stress the need for more studies on the drug resistance mutation-selection dynamics when a drug from a new class is added to the treatment.

Presenting author email: smccluskey@partners.org

Background: Transmitted drug resistance (TDR) is increasing globally. However, correlates of TDR in sub-Saharan Africa are not well defined and could assist with risk stratifying patients initiating antiretroviral therapy (ART) in the absence of resistance testing. We sought to identify correlates of TDR and characterize its effects on mortality and loss to follow-up in Uganda.
Methods: We analyzed data from the Uganda AIDS Rural Treatment Outcomes study, a cohort of adults initiating first-line ART (2005 to 2015). We retrospectively sequenced reverse transcriptase on pre-ART specimens. We defined TDR as any WHO 2009 surveillance mutation and classified TDR level using Stanford susceptibility scores. We fit univariable logistic regression models with clinical characteristics as correlates and TDR as outcome. We then fit Cox proportional hazards models to assess whether TDR was associated with mortality and/or loss to follow-up.
Results: 643 subjects had pre-ART sequences. Median age was 34, and 69% were female. TDR was rare (N=21; 3.3%), and frequency seemed to increase over time, though trend was not significant (2.9% in 2005-2009 versus 4.4% in 2010-2013; P=0.36). Resistance to NRTIs (2.6%) was more common than NNRTIs (1.1%). Of those with TDR, 81% (17/21) had intermediate or high-level resistance to first-prescribed regimens. Female sex, no education, and each decrease in baseline $\log_{10}$ HIV RNA were significant correlates of TDR (Table). We identified a non-significant trend that TDR to first-prescribed ART regimen increased hazard of loss to follow-up (HR 2.75, 95% CI 0.85-8.84, P=0.09) but not mortality, though power was limited by low rates of TDR.
Conclusions: Female sex, no education, lower baseline viral load, and year (though non-significant) are correlates of TDR in rural Uganda. Further studies are needed to evaluate PMTCT practices as a potential factor in higher TDR risk in women. Greater vigilance is needed in the region if increasing rates of TDR are confirmed.

Variable	OR	95% CI	P value
Female	4.37	1.01-18.95	0.049
Age at ART initiation	0.95	0.90-1.01	0.107
Log10 viral load at ART initiation	0.45	0.26-0.79	0.005
CD4 at ART initiation	1.00	1.00-1.00	0.907
Year of ART initiation			
2005-2009 (reference)			
2010-2013	1.55	0.61-3.90	0.356

Surveillance of HIV-1 subtype and antiretroviral resistance in Cuban individuals failing therapy during 2009-2016

V. Kouri Cardella[1], L. Perez[1], Y. Aleman[1], Y. Martinez[1], J. Perez[2], C. Fonseca[2], Y. Pintos[1], L.M. Ortega[2], Y. Baños[1], Y. Soto[1]
[1]INS, STD Lab. Virology Department, Havana, Cuba, [2]INS, Clinical Department, Havana, Cuba
Presenting author email: vkouri@ipk.sld.cu

Background: In Cuba, more than 70% of patients are currently under antiretroviral (ARV) therapy. In the year 2009 ARV resistance and subtype surveillance was introduced in clinical practice. This work aims to investigate the level and profile of ARV resistance and subtype distribution among HIV-1 patients failing therapy.
Methods: The study compiled data of subtype and genotypic resistance analysis performed to 756 samples of HIV-1 patients taken between April 2009 and December 2016 in Cuba. HIV-1 subtype was determined with Rega Subtyping Tool v.3. Drug resistance interpretation was conducted using the resistance algorithm Rega v9.1.0. For statistical analysis, the package SPSS v.19 was used.
Results: The most prevalent HIV-1 genetic forms were subtype B (30.6%), BG recombinants (22.7%) and CRF19_cpx (19.3%). Subtype B was more prevalent in MSM (p<0.001). Subtypes A, C, F, G and H prevailed among individuals diagnosed with HIV between the years 1986-1990 (p<0.05), while BGs recombinants increased over the other subtypes after the 2000 (p≤0.0001). Interestingly, viral variant CRF19_cpx, associated with rapid progression to AIDS in Cuba, significantly increased after the year 2011(14.9% in 2009-2011 to 21.3% in 2012-2016, p=0.01). The average of acquired drug resistance to NRTI, NNRTI and PI was 51.8%, 55.1%, 24.1% respectively and increased in patients with ≥48 months of treatment. The highest drug resistance levels against NRTIs, were detected for 3TC/FTC (76.9%); against NNRTIs were for NVP (71.2%) and EFV (70.9%); against PI for NFV (33.2%). Full-class resistance (FCR) to NRTI, NNRTI, PI, and MDR was detected in 19.0%, 32.8%, 10.0%, and 6.9% of the patients, respectively. When compared the period 2009-2011 with 2012-2014, a significant declining trend of NRTI- FCR (27.0 vs 13.4%), PI-FCR (15.2% vs2.0%) and MDR (21.1% vs 5.3%) incidence was noticed (p<0.05) Worrisome, during 2016 the incidence of FCR and MDR was increased again (23.2%, 22.3% and 19.6% respectively).
Conclusions: The genetic diversity of HIV in Cuba is high and the circulation of some local recombinant forms is increasing. The high level of resistance emphasizes the need of a therapy change for first line and a further integral analysis of this situation.

MOPEB0346

No impact of PI minority resistant variants on the virological response of a first-line PI-containing regimen

[1]Hôpital Bichat-Claude Bernard, Laboratoire de Virologie, Paris, France, [2]Hôpital Bichat-Claude Bernard, Service de Maladies Infectieuses et Tropicales, Paris, France, [3]Hôpital Henri Mondor, Laboratoire de Virologie, Paris, France, [4]Université Paris Diderot, MTi (Molécules Thérapeutiques in silico), Paris, France, [5]Hôpital Pitié-Salpêtrière, Laboratoire de Virologie, Paris, France
Presenting author email: marine.perrier@aphp.fr

Background: We assessed, in a clinical cohort of HIV-1-infected patients, the impact of minority resistant variants (MRV) harboring PI-resistance mutations at baseline on the virological response to a first-line PI-based regimen.
Methods: In an observational single-center cohort, all ARV-naïve patients initiating a first-line including 2 NRTI and DRV/r or ATV/r between January 2012 and March 2015, were enrolled. A virological failure (VF) was defined as two consecutive VL >50 c/mL following VL < 50 c/mL or absence of VL < 50 c/mL after six months of ARV. Protease (PR) ultra-deep sequencing was performed at baseline using Illumina® technology (cut-off=1%). PR mutations were identified using the WHO transmitted drug resistance list and IAS-USA major PI resistance mutations list. Supervised data mining analysis was performed to identify PR mutations associated with virological outcome. PR structural modeling analysis was performed using Fold-X software.
Results: Ninety-four and 16 patients initiated a DRV/r- or an ATV/r-based regimen, respectively, were assessed. Overall, median baseline VL and CD4-cell-count were 5.61 $\log_{10}$ c/mL and 345/mm^3, respectively. Twenty-eight percent of the patients were HIV-1 subtype B, 39% CRF02_AG and 33% other "non-B" subtypes. Thirteen patients (13.8%) in the DRV/r group and three (18.8%) in the ATV/r group experienced a VF, occurring at the median time of 15.5 months. Overall, 17 (15.5%) subjects had baseline PI-MRV at the median proportion of 1.3% (IQR=1.1-1.8), mainly G73C (n=5, 4.5%), M46I
(n=3, 2.7%) and M46L (n=2, 1.8%). The proportion of patients harboring baseline PI-MRV was similar between those in virological success (14.9%) and those experiencing VF (18.8%) (p=0.71). No difference was observed in the prevalence of PI-MRV by viral subtype (p=0.56) or by PI (p=0.27). Supervised data mining analysis identified three mutations significantly more prevalent in patients experiencing VF: T4A, E21D and I72M/T (p=0.02 for all). Structural modeling analysis showed that all these mutations induced some conformational changes of some PR side-chain residues located near mutated residues.
Conclusions: These findings, including for the first time DRV, showed the limited impact of baseline PI-MRV on virological response of a first-line PI-based regimen. In addition, we identified some new positions that could be involved in HIV-1 susceptibility to PI.

Resistance profile of GSK3532795

I. Dicker[1], B. Nowicka-Sans[1], S. Zhang[1], N. Ray[2], B. Beno[2], A. Regueiro-Ren[2], S. Joshi[1], M. Cockett[1], M. Krystal[1], M. Lataillade[1]
[1]*ViiV Healthcare, Wallingford, United States*, [2]*Bristol-Myers Squibb, Wallingford, United States*
Presenting author email: ira.x.dicker@viivhealthcare.com

Background: HIV-1 maturation inhibitors (MIs) disrupt the final step in the HIV-1 protease cleavage of the Gag polyprotein between capsid (CA) and spacer peptide 1 (SP1), leading to the production of non-infectious virus. In vitro studies were conducted with the MI GSK3532795 in order to understand its resistance profile.
Methods: Selection for in vitro resistance was performed in MT-2 cells with NL_{4-3} virus or recombinants containing polymorphisms in the gag gene. Gag/pr genes from selected viruses were sequenced and recombinant viruses with the selected changes were analyzed for susceptibility to ,795 and a newer generation MI. Selected amino acids were mapped to recently described structures of the purported region of MI binding to immature Gag capsids in order to better understand the mechanism for decreased susceptibility.
In vitro results were also correlated with genotypes and phenotypes observed in the 10 day Ph2a monotherapy proof of concept study.
Results: In cell culture, GSK3532795 primarily selected for the Gag changes A364V or V362I (with additional secondary substitutions in concert with V362I). In some cases, V362I was initially selected, but later replaced by A364V. Secondary substitutions observed in vitro in the capsid C-terminal domain (CTD) included R286K, A326T, T332S/N and I333V. By themselves, these changes imparted ≤ 2-fold reductions in susceptibility; however combinations of these changes, with V362I or V370A alone, or with V362I/V370A, exhibited 1.7- to >1000-fold reduced GSK3532795 susceptibility. A next generation MI with expanded polymorphic coverage retained complete activity toward ,795 selected viruses, except for A364V. The in vitro results with GSK3532795 correlated with genotypic substitutions observed in the Ph2a proof of concept study, with certain individuals exhibiting changes at V362, A364 or V370 showing a reduced antiviral response.
Conclusions: Reduced susceptibility to GSK3532795 in vitro and in the clinic mapped to defined amino acid changes within Gag. These changes occurred in the capsid CTD region or in or nearby SP1, and potentially reduced susceptibility through destabilization of a six-helix bundle structure involved in virus maturation. With the exception of A364V, a next generation MI retained activity against the emergent changes selected by GSK3532795.

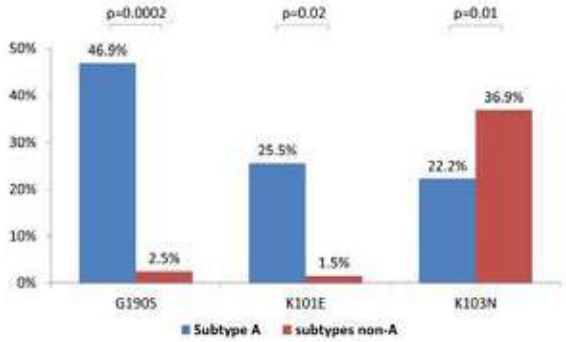
Epidemiology of HIV drug resistance in HIV patients with virologic failure in the country of Georgia

E. Karkashadze[1], N. Dvali[2], M. Karchava[1], O. Chokoshvili[1], L. Sharvadze[1], P. Gabunia[1], T. Tsertsvadze[1], N. Chkhartishvili[1]
[1]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia*, [2]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Viral Laboratory, Tbilisi, Georgia*
Presenting author email: nc@aidscenter.ge

Background: HIV drug resistance is a major threat to sustained impact of antiretroviral therapy (ART). We studied epidemiology of HIV drug resistance in the Eastern European country of Georgia.
Methods: Study included all adult patients who experienced virologic failure on first line ART and received HIV drug resistance testing between 2004-2016. HIV pol gene sequences were examined for the presence of resistance-associated mutations. Stanford HIV Sequence Database was used for interpretation of resistance data. Patient-level data were extracted from the national AIDS health information system.
Results: Of 447 patients included 75.3% were men, leading routes of transmission were injection drug use (52.8%) and heterosexual contact (40.7%), 87.8% harbored Subtype A virus, 8.3% - subtype B, 3.0% - G, other subtypes were less than 1%. The most frequent first-line regimens were Tenofovir/Emtricitabine/Efavirenz (28.9%), Zidovudine/Lamivudine/Efavirenz (26.7%) and Abacavir/ Lamivudine/Efavirenz (15.9%). The majority (85.0%) of patients with treatment failure developed at least one drug resistance mutation affecting susceptibility to ART. The most commonly detected NRTI mutations were M184V (65.3%), K65R (19.7%) and L74V (17.0%). At least three thymidine analogue mutations were detected in 6.2%.
From NNRTI mutations G190S was shown to be the most prevalent (49.4%), followed by K101E (27.0%), K103N (24.4%) and Y181C (23.3%). G190S and K101E were more common in subtype A as compared to non-A viruses (G190S - 46.9% vs. 2.5%, p=0.0002; K101E - 25.5% vs. 1.5%, p=0.02).
On the other hand, K103N was more frequent in non-A subtypes (36.9%) compared with subtype A (22.2%), p=0.01.
Conclusions: Majority of persons failing on ART had HIV drug resistance. Subtype A may have distinct NNRTI drug resistance pattern with higher prevalence of G190S and K101E mutations. Prevalence of K65R mutation remains below 20% and given the high use of Tenofovir both for treatment and prevention, efforts are needed to prevent increase in resistance to this drug.



[Distribution of the mutations by subtypes]

Presenting author email: ciwuji@yahoo.com

Background: Poor virologic outcomes on antiretroviral therapy (ART) and HIV drug resistance pose the biggest threats to the success of ART scale-up for the individual and public health. We assessed virological response and emergence of drug resistance in a cluster randomised trial of universal test and treat strategy in South Africa comparing immediate ART initiation versus CD4-guided national guidelines.
Methods: HIV-positive individuals enrolled March 2012-June 2016 on ART ≥6 months were included and data from both trial arms were combined. Participants either transferred care from the public ART programme (Transferees; N=1389 or were new ART initiators within the ANRS 12249 trial (Initiators; N=983). A 1.3kb region of the pol gene was amplified, sequenced using the Sanger method, assembled in Geneious V9.1.5 and interpreted using the Stanford Drug Resistance algorithm. Chi-Squared or Mann-Whitney tests were used for comparisons as appropriate. Logistic regression was used to estimate odd ratios (OR) and their 95% confidence intervals (CI)
Results: 96% of Initiators were on fixed-dose combination of tenofovir+emtricitabine+efavirenz vs. 16% of Transferees. 6 months viral load (VL) was available for 908 Initiators; of whom 94% (851) achieved virologic suppression [VS] (VL<400 copies/mL). Amongst Transferees, 80% had VS at their first trial clinic visit after a median ART duration of 4.0years (IQR 2.2-6.0). For both groups, the probability of VS increased with every 100 cells/mm^3 increase in CD4 at initiation [adjusted OR=1.30 (95%CI=1.07-1.58) and 1.33 (1.14-1.55) for Initiators and Transferees respectively]
Of all 2372 individuals on ART ≥6 months, 227 (9.6%) experienced virologic failure [VF] (VL>1000 copies/mL ≥6 months on ART). Of 135 (59%) for which resistance testing was possible, 119 (88%) had ≥1 drug resistance mutation at VF: M184V/I (76%); K103N/S (56%); K65R (25%). The median plasma VL at VF was similar in individuals with and without the K65R mutation [35,504 copies/mL (IQR 4961-109,278) vs. 19,699 copies/mL (3,969-80,064); p=0.96, respectively].
Conclusions: Despite good levels of VS, we observed high levels of tenofovir resistance in individuals failing the recommended first-line ART. K65R did not confer a reduced infectivity (VL). Our data suggest that drug resistance may continue to emerge and spread during a test and treat strategy.

Presenting author email: andrewrevell@hivrdi.org

Background: Optimisation of antiretroviral therapy in resource-limited settings (RLS) can be challenging without access to the newest drugs, or genotyping to help tailor therapy for the individual. Computational models have been developed to predict virological response to therapy but many require a genotype and have been developed using western data.
Here we describe the development of new models that do not require a genotype, using a large data set that includes substantial data from RLS and including, for the first time, tipranavir, maraviroc and elvitegravir.
Methods: Random forest (RF) models were trained to predict the probability of virological response (viral load < 50 copies/ml) to a new regimen following virological failure, using baseline viral load, CD4 count, treatment history, new drug regimen and time to follow-up from 52,270 treatment change episodes (TCEs), including 5,329 from RLS (4,190 from South Africa). The models were assessed during cross-validation, with an independent test set (n=3,000 including 461 from South Africa). The area under the ROC curve (AUC) was the main outcome. The predictive accuracy of the models was compared to genotyping using three rules-based interpretation systems to derive genotypic sensitivity scores (GSS).
Results: The models achieved a mean AUC of 0.83 during cross validation and 0.81 with the 3,000 TCE test set. Sensitivity was 73%, specificity 76% and overall accuracy 75%. For the South African test cases the models achieved an AUC of 0.76, sensitivity of 72%, specificity of 69% and overall accuracy of 70%. The AUC values for cases involving tipranavir, maraviroc and elvitegravir, ranged from 0.75 to 0.89. Of the 3,000 test TCEs, 634 had genotypes and the AUC for the GSS ranged between 0.55 and 0.57 - significantly inferior to the accuracy of the models ($p<0.0001$).
Conclusions: These new models, trained with our largest dataset so far, were able to predict response to HIV therapy significantly more accurately than genotyping with rules-based interpretation. They were accurate for cases from South Africa and cases involving new drugs. The models are freely available online at www.hivrdi.org/treps and have the potential to predict and avoid treatment failure by identifying potentially effective, alternative regimens.

Favorable drug-resistance background for successful use of dolutegravir in Botswana

S. Gaseitsiwe[1,2], S. Moyo[1], M. Zahralban-Steele[2], D. Maruapula[1], B. Mokaleng[1], S. El-Halabi[3], J. Theu[4], E. Raizes[5], S. Lockman[6,7], M. Essex[2,6], V. Novitsky[2,6]
[1]Botswana Harvard AIDS Institute Partnership, Laboratory, Gaborone, Botswana, [2]Harvard T H Chan School of Public Health, Immunology and Infectious Diseases, Boston, United States, [3]Botswana Ministry of Health and Wellness, Gaborone, Botswana, [4]Botswana Ministry of Health, Gaborone, Botswana, [5]Center for Disease Control (CDC), Gaborone, Botswana, [6]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [7]Harvard T H Chan School of Public Health, Immunology and Infectious Diseases, Boston, Botswana
Presenting author email: sgaseitsiwe@bhp.org.bw

Background: Botswana is the first country in sub-Saharan Africa to use dolutegravir (DTG)-based cART as the first-line regimen on the national level. This study aims to survey the background prevalence of viral mutations associated with INSTI resistance before the national scale-up of DTG in Botswana starts in June 2016.
Methods: Blood samples were collected from HIV-positive participants in the Botswana Combination Prevention Project (BCPP) residing in 15 communities. A long-range HIV genotyping protocol was applied regardless of ART history. In addition to viral RNA, proviral DNA was used as an alternative template which makes HIV genotyping possible in individuals on ART.
INSTI resistance mutations were analyzed according to the IAS-USA 2015 list with the addition of H51Y and G118R mutations described recently. All viral sequences were screened for hypermutations (HM). Mutations in sequences with adjusted HM rate and HM ratio values above the 3rd quartile of the subset of viral sequences without mutations were considered to be generated by HM, and were not counted toward drug-resistant INSTI.
Results: The majority of genotyped individuals, 413 of 665 (62.1%; 95% CI 58.3-65.8%), were receiving ART and 405 (60.9%; 95% CI 57.1-64.6%) had undetectable HIV-1 RNA £400 copies/mL. After adjustment for HM, the proportion of individuals with any INSTI mutation was low, 0.75% (95% CI 0.24-1.75%). This included H51Y (0.15%), L74M (0.30%), E138A (0.15%), and Q148H (0.15%). Without adjustment for HM, the proportion of individuals with any INSTI mutation could be inflated: 5.41% (95% CI 3.82-7.42%) due to added mutations related to HM at amino acid positions G118R (0.46%) and R263K (1.20%), and an increase at position E138A (3.55%).
Conclusions: This is the first large study surveying the prevalence of INSTI resistance mutations on a population level in Botswana. A low prevalence, below 1%, of INSTI resistance mutations in Botswana provides a strong rationale for use of DTG as the first-line regimen nationally. Adjustment for HM seems to be an important step toward proper interpretation of viral mutations associated with HIV drug resistance, particularly if proviral DNA is used for amplification. The clinical significance of INSTI resistance in HM sequences needs further investigation.

MOPEB0352

Long-acting ibalizumab susceptibility in multi-drug resistant HIV patients

S. Weinheimer[1], C. Marsolais[2], Z. Cohen[2], S. Lewis[1]
[1]TaiMed Biologics USA, Irvine, United States, [2]Theratechnologies Inc, Montreal, Canada
Presenting author email: sweinheimer@taimedbiologics.com

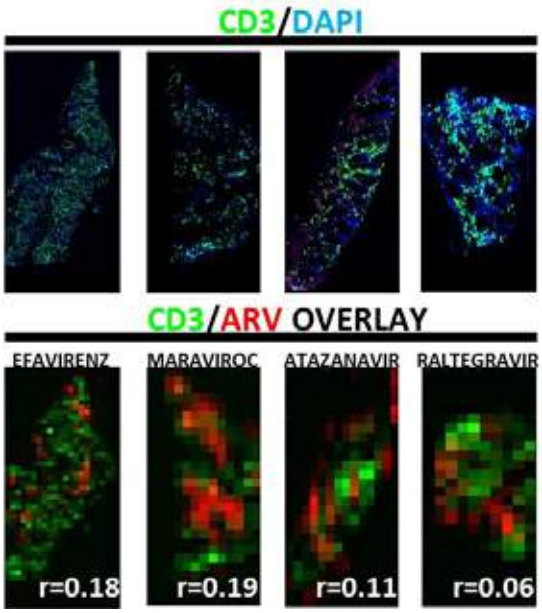
Background: Ibalizumab (IBA) is a humanized monoclonal antibody that binds CD4 domain 2 and blocks HIV-1 entry. TMB-202 was a Phase IIb clinical trial investigating the safety, efficacy and tolerability of IBA administered by intravenous (IV) infusion every 2 or 4 weeks in patients with triple-class resistant HIV-1 infections. Viral resistance testing was performed to assess the activity of IBA against multi-drug resistant (MDR) HIV.
Methods: 113 patients with MDR HIV were treated with IV IBA in combination with an optimized background regimen. Baseline resistance test results for n=105 patients were evaluated to assess the IBA susceptibility of MDR HIV and of HIV with reduced susceptibility to the approved HIV entry inhibitors enfuvirtide (ENF) and maraviroc (MVC). IBA susceptibility was determined by maximum percent inhibition (MPI) and $IC_{HALFMAX}$ Fold Change (ICHMFC) in the PhenoSense HIV Entry assay (Monogram Biosciences).
Results: There was no significant difference in IBA MPI or ICHMFC between patient HIV isolates with wild-type susceptibility to nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs), or protease inhibitors (PIs) (median MPI = 98%, 96%, and 97%, respectively; median ICHMFC = 1.1, 1.1, and 1.0, respectively) and isolates that were resistant to all NRTIs, NNRTIs, or PIs (median MPI = 99%, 99%, and 97%, respectively; median ICHMFC = 1.0, 1.0, and 0.9, respectively).
No difference in IBA susceptibility between patient HIV isolates with wild-type susceptibility to integrase inhibitors (INSTIs) (median MPI = 97%; median ICHMFC = 0.9) and those with resistance to INSTIs (median MPI = 95%; median ICHMFC = 0.9) was observed (n=17). IBA susceptibility was similar for patient isolates with wild-type susceptibility to ENF (median MPI = 96%, median ICHMFC = 1.0) and for those with reduced susceptibility to ENF (median MPI = 94%, median ICHMFC = 1.0). IBA susceptibility was similar for patient isolates with wild-type susceptibility to the coreceptor antagonist MVC (median MPI = 99%, median ICHMFC = 1.0) and for those with reduced susceptibility to MVC (median MPI = 98%, median ICHMFC = 0.8).
Conclusions: Ibalizumab is effective despite resistance to all other antiretrovirals. Ibalizumab is a potent new tool for treatment of MDR HIV.

MOPEB0353

Differential antiretroviral localization and drug transporter expression within gut-associated lymphoid tissue of HIV+ subjects: comparison to pre-clinical species

C.G. Thompson[1], H.A. Prince[2], J.K. Fallon[1], E.P. Rosen[1], C. Sykes[1], M. Mathews[3], S. Arora[2], E.S. Dellon[2], A. Peery[2], N.J. Shaheen[2], C. Gay[2], P.A. Luciw[4], R. Akkina[5], J.V. Garcia[2], P.C. Smith[1], A.D.M. Kashuba[1,2]
[1]University of North Carolina at Chapel Hill, Pharmaceutical Sciences, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, School of Public Health, Chapel Hill, United States, [4]University of California, Department of Pathology, Davis, United States, [5]Colorado State University, Department of Microbiology, Immunology, and Pathology, Fort Collins, United States
Presenting author email: thompscg@email.unc.edu

Background: Inadequate antiretroviral (ARV) exposure within gut-associated lymphoid tissue (GALT) may contribute to HIV persistence, but traditional LC-MS techniques cannot fully address this hypothesis. Mass spectrometry imaging (MSI) shows heterogeneous ARV distribution in GALT in animal models, which may be affected by drug transporters. However, application of these findings are limited without comparing these data to humans. Here, we assess ARV localization and drug transporter expression in HIV-infected subjects and make novel inter-species comparisons.
Methods: Ileum and rectum biopsies (n=10 each) were collected from five HIV-infected females receiving combination ARVs (Truvada® + raltegravir (RAL), efavirenz (EFV), atazanavir (ATV), or maraviroc (MVC)). Co-localization analysis of ARVs (measured by MSI) and T cells (measured by immunofluorescence) was performed in Matlab using Pearson correlation (r). Drug transporter protein concentration was measured from replicate biopsies by LC-MS/MS proteomics. Human data were compared to our previously generated animal data in non-human primates (n=12) and humanized mice (n=49) using ANOVA on ranks.
Results: ARV localization was heterogeneous within tissue and across therapeutic classes (Figure 1; rectum).



[Figure 1]

After correction for heme signatures, MVC and EFV showed the best ARV-T cell co-localization, which was 5-fold higher in the rectum versus ileum, and not significantly different (p>0.05) from data in primates or mice. Human drug transporter concentration was in better agreement with mice (1 to 9-fold difference) versus primates (1 to 21-fold difference), with 4-fold lower P-gp expression in primates.
Conclusions: We show that ARV distribution within biopsies is heterogeneous and may not co-localize with HIV target cells. This is consistent with animal data and may implicate ARV tissue exposure in the propagation of HIV GALT replication. Human drug transporter concentrations agreed with humanized mice better than primates, suggesting that the former may be a better animal model for developing novel ARV therapies targeted at GALT, particularly for P-gp substrates.

Can we talk about cost when choosing antiretroviral therapy? A 6 months survey with people living with HIV and prescribers in France

E. Papot[1,2], M. Doumergue[3], D. Rojas Castro[3,4], Y. Yazdanpanah[1,2], N. Kalampalikis[3], M. Préau[3], ANRS-GOTA Study Group
[1]INSERM, Paris Diderot University, Sorbonne Paris Cité, IAME UMR 1137, DeSCID Team, Paris, France, [2]Bichat-Claude Bernard University Hospital, APHP, Infectious Diseases Clinic, Paris, France, [3]Lumière Lyon 2 University, Institute of Psychology - GRePS, Bron, France, [4]AIDES, Paris, France
Presenting author email: emmanuelle.papot@inserm.fr

Background: With more efficient and better tolerated antiretroviral therapies (ART), when various regimens with similar efficacy and adverse events profile are available national and international recommendations now discuss ART cost.
The aim of this study is to evaluate the PLHIV's (People Living with HIV) and prescribers' perception of talking about ART cost in PLHIV's management.
Methods: We proposed a community-based approach to assess the knowledge, beliefs and representations of ART cost among PLHIV followed-up in a French University Clinic and among HIV-specialists providing care.
The 2 questionnaires were built on data collected during focus groups with PLHIV and HIV-specialist prescribers of this North of Paris HIV-clinic. The pilot questionnaires were discussed in a multidisciplinary team of HIV activist organisations, social psychologists and clinical researchers.
Questionnaires were proposed to PLHIV coming in the clinic for their follow-up appointment between January-April 2016, and HIV-specialist prescribers were reached through email between March-June 2016.
Results: The 129 PLHIV and 79 prescribers who answered broadly represented our cohort of more than 4,700 PLHIV and local and national HIV-specialists respectively. Among PLHIV on ART, 80% (102/128) declared they know the cost of their ART, 65% (83/128) gave a fair estimation of the cost of their current regimen when 24% (19/79) of the prescribers thought that most of their patients precisely know it; 75% (97/129) PLHIV thought their prescribers should know ART cost.
Finally, 56% (72/129) of the PLHIV declared they could consider asking their HIV-specialist to switch to a less expensive ART regimen if effectiveness and side-effects would be the same.
Though: 67% (86/129) would not change if the number of pills or the dosing frequency would increase, 37% (48/129) if pills were bigger, while 64% expressed fear of more adverse events occurrence when switching (17% of prescribers thought PLHIV felt bad about switches).
Conclusions: PLHIV knowing ART cost seems unexpected by HIV-specialists; openly discussing the issue between them appears interesting. Our multidisciplinary research group works on guidelines for shared decision-making in ART regimen choice using these results. Their pilot implementation will be monitored in terms of medical, psycho-social and economic outcomes, with constant feedback from PLHIV and HIV-associations.

Factors associated with recruitment to antiretroviral therapy trials in a large London clinic

L. Haddow[1], R. Matthews[1], J. Stockton[2], N. Brima[1], A. Severn[1], S. Tariq[1]
[1]University College London, Research Department of Infection and Population Health, London, United Kingdom, [2]University College London, Epidemiology and Public Health, London, United Kingdom
Presenting author email: lewis.haddow@ucl.ac.uk

Background: Some demographic groups are likely to be under-represented in antiretroviral therapy (ART) trials. We aimed to determine whether gender, ethnicity, or other factors were associated with non-participation in randomised controlled trials (RCTs) at a large HIV clinic in the UK.
Methods: Age, sex, ethnicity, country of birth, mode of transmission and home postcode were obtained from clinic databases on adult patients with >1 clinic visit at least 1 year apart in 2012-2016. Participation in ART trials running during the study period was ascertained from recruitment logs. Distance from clinic and socioeconomic indices were determined from postcodes. Associations between RCT participation and demographic variables were estimated using logistic regression.
Results: Of 5371 patients, mean age was 45.6 years (standard deviation [SD] 10.6). 947 (18%) were women. Of men, 3862 (87%) were men who have sex with men (MSM). The largest ethnic groups were white UK-born (1711, 32%), white non-UK-born (1841, 34%) and black African (950, 18%). Mean duration of clinic attendance was 11.5 (7.8) years, median distance from clinic was 6.2 km (interquartile range [IQR] 3.8-11.1), and median Index of Multiple Deprivation was in the third-lowest national decile (IQR 2nd- to 5th-lowest deciles). One hundred and fifty-four patients (2.9%) had participated in a RCT. RCT participation was positively associated with longer duration of clinic attendance (OR 1.45 per decade,

95% CI 1.20-1.76, p<0.001) and older age (OR 1.33 per decade, 95% CI 1.14-1.54, p<0.001). Associations with broad ethnicity and gender categories are shown in the table.

Ethnic category	Gender / orientation	Odds ratio (95% confidence interval)	p
White, UK-born	MSM	Reference category	
	Heterosexual men	0.74 (0.23-2.42)	0.62
	Women	0.32 (0.04-2.34)	0.26
White, non-UK-born	MSM	0.86 (0.59-1.26)	0.44
	Heterosexual men	0.93 (0.28-3.02)	0.90
	Women	0.44 (0.11-1.81)	0.25
Black or other minority ethnic group	MSM	0.52 (0.29-0.94)	0.029
	Heterosexual men	0.49 (0.22-1.07)	0.074
	Women	0.41 (0.22-0.77)	0.006

[Gender, ethnic factors and trial participation]

Conclusions: Women, those of black or minority ethnicity, younger patients and newer clinic attendees were less likely to participate in ART trials. We cannot ascertain if this is due to clinician- or patient-led factors. Ongoing qualitative work will explore research participation among HIV+ women. Meanwhile, efforts should be made to involve under-represented patient groups in trials.

Use of herbal drugs by PLHAs: data from cross-sectional survey done at National AIDS Research Institute, Pune, India

A. Kadam, R. Bagul, V. Chinchkar, N. Gurav, M. Ghate, R. Gangakhedkar
National AIDS Research Institute, Pune, India
Presenting author email: akadam@nariindia.org

Background: Proportion of people living with HIV and AIDS (PLHAs) on antiretroviral therapy (ART) and PLHAs not on ART using Herbal drugs is not known in India. In this cross sectional survey we analyzed the frequency and reasons for use of herbal drugs,source of information about herbal drugs and reasons for not informing the use of herbal drugs to health care providers.
Methods: We screened 794 PLHAs on ART and 600 PLHAs who were not on ART attending our clinics in Pune for use of herbal drugs. PLHAs reporting use of herbal drugs were interviewed with a semi-structured questionnaire after taking written informed consent during September 2015 to November 2015.
Results: Use of Herbal drugs was reported by 11.3% (90/794) PLHAs on ART and 9.04% (56/600) PLHAs who were not on ART. Female to male ratio was 1.1:1 and median age was 43 years in both the groups. Herbal drugs were used to improve immunity and CD4 count in 45% of PLHAs on ART and 40% PLHAs not on ART. Herbal drugs were also used for co-morbid conditions like hemorrhoids, gastritis, hair fall, weight loss. Use of more than one herbal drug formulation was more common among PLHAs on ART (55.5%) rather than PLHAs not on ART (29%).
"Triphala churna "was the most common ingredient (n=45) in branded herbal drug formulations PLHAs used followed by herbal powder (n=36) and liquid (n=24) with unknown ingredients packed and dispensed in unlabeled paper envelopes and bottles.
28.8% PLHAs on ART and 25% PLHAs not on ART had not informed the use of herbal drugs to health care provider since nobody asked them about use of herbal drugs
Internet and local news papers were the source of Information for 57% of PLHA using herbal drugs rather than qualified Ayurvedic professionals (12%).
Conclusions: Herbal drugs are considered safe hence are neither taken under expert guidance nor the use is informed to health care providers. Immunomodulatory activities of herbal drugs need to be evaluated in clinical trials to generate evidence based results. There is a need to create awareness regarding use of herbal drugs among PLHAs as well as health care providers.

Presenting author email: eaconu.ihvar@gmail.com

Background: Nigeria bears a major brunt of global HIV and TB burden with a prevalence of 4.1% and ratio of 323/100000 cases (National HIV sero prevalence survey 2010 and first National TB prevalence survey 2012). WHO recommends IPT as an effective TB prevention strategy to reduce the burden of TB among PLHIV (WHO 1998). A 12 month retrospective CCCRN ART program data revealed the rate of IPT uptake was low at 3.1%. The goal of this initiative was to increase rate of IPT uptake at CCCRN PEPFAR supported ART Clinics in SE Nigeria to reduce the burden of TB.
Methods: Capacity to implement IPT was evaluated at 49 PEPFAR supported treatment sites in three southeastern states in Nigeria. Criteria for evaluation included - Availability of clinician to evaluate for active TB; Access to TB Microscopy and Chest X-ray ;Capacity to prescribe and manage INH stock. A root cause analysis was conducted to identify reasons for low uptake. Interventions were identified and prioritized. A 3 day facility based IPT training for clinic providers was conducted; reporting tools were provided;' stick on ,reminder notes with the clinical screening algorithm were provided at strategic facility points. The primary outcome was defined as proportion of newly enrolled HIV patients who received IPT over a 12 month period from October 2014 to September 2015 and measured quarterly
Results: 40 sites (82 %) were eligible for IPT implementation. During study period, 5,045 newly diagnosed HIV positive clients were enrolled and 4,623 were found to be eligible for IPT. Patients receiving IPT increased from 3.1% in the first quarter to 24% in the last quarter. Most cited barrier to IPT uptake was isoniazid stock out and inadequate human resource at facilities to implement multiple parallel health initiatives.
Conclusions: Simple interventions can be used to scale up IPT in resource limited settings. To further strengthen IPT uptake, efforts should be dedicated towards retention of trained staff, positive reinforcement towards increased staff productivity and task shifting of non-essential duties from skilled staff to trained lay workers.

Sequential Vacc-4x/GM-CSF and romidepsin during combination antiretroviral therapy (cART): Vacc-4x/GM-CSF induced immune effects and changes in HIV reservoirs

G. Tapia[1], J.F. Højen[2], M. Ökvist[3], R. Olesen[2], S. Leth[2], S.K. Nissen[2], J.D. VanBelzen[4], U. O'Doherty[4], A. Mørk[3], K. Krogsgaard[5], O.S. Søgaard[2], M. Tolstrup[2], G. Pantaleo[1], M. Sommerfelt[3]
[1]Lausanne University Hospital, Lausanne, Switzerland, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Bionor Pharma AS, Oslo, Norway, [4]University of Pennsylvania, Philadelphia, United States, [5]KLIFO, Glostrup, Denmark
Presenting author email: giuseppe.pantaleo@chuv.ch

Background: The REDUC clinical study (NCT02092116) Part B investigated Vacc-4x/GM-CSF therapeutic vaccination prior to HIV latency reversal using romidepsin. Main findings showed statistically significant reductions from baseline in total DNA (39.7%; n=17, p=0.012) and in the inducible replication competent HIV reservoir (38%; n=6, p=0.019). Reductions in integrated DNA were not statistically significant (19%; n=15, p=0.123). Plasma HIV RNA remained undetectable throughout romidepsin treatment in 9/17 participants. Here we evaluated functional T-cell responses following Vacc-4x/GM-CSF immunotherapy in relation to virological outcomes on HIV reservoir measurements.
Methods: This single center study conducted in Aarhus, Denmark, enrolled participants (n=20) with CD4>500 cells/mm^3 on cART. Eligible participants received six Vacc-4x (1.2mg) intradermal (i.d) immunizations using rhuGM-CSF (60µg) i.d as local adjuvant at week (wk) 0,1,2,3,11,12 followed by 3 weekly intravenous infusions of romidepsin (5mg/m^2) at weeks 15,16 and 17. Immune responses were determined by IFN-γ ELISPOT and T-cell proliferation to p24 15-mer peptides at weeks 0, 15,

17 and 25. Participants showing a ≥2 fold increase in T-cell proliferation from baseline were defined as ‚responders'. Intracellular cytokine staining and viral inhibition were also determined.
Results: Participants (14/16; 87.5%) had robust ELISPOT responses at baseline. We observed the frequency of participants with positive CD8+ T-cell proliferation assay responses increased from 8/16(50%) at baseline to 11/15(73%) post-vaccination (wk15), a slight decrease during romidepsin (6/14(43%)) before recovering at wk25 (9/15(60%). These modest changes were not statistically significant. Positive CD8+ T-cell proliferation assay responses post-vaccination showed significant changes from baseline in total HIV DNA post-vaccination (wk15; p=0.00585) and after latency reversal (wk23; p=0.00506), and a change in CA-RNA post-vaccination (wk15; p=0.0152) unlike those with negative assay responses. The proportion of participants that showed increased CD8+ T-cell proliferation compared to baseline was 6/15(40%). These ‚responders' showed a statistically significant reduction in CA-RNA post vaccination from baseline (wk15; p=0.0277). There was a trend towards increased viral inhibitory capacity post-vaccination (wk15;p=0.08) and an increase in dual-functional (IFN-γ/TNF-α) CD8+ T-cells to HIV^{Gag} from baseline to post-romidepsin (p=0.039).
Conclusions: This study provides the first data supporting a relevance for including immune-based therapies in HIV ‚shock and kill' approaches to reduce HIV reservoirs during ART.

Presenting author email: ari.bitnun@sickkids.ca

Background: EPIC4 is a multicenter Canadian study investigating the impact of early initiation of combination antiretroviral therapy (cART) on HIV reservoirs and HIV-specific immune responses in perinatally infected children. Preliminary results on predictors of HIV reservoir size are described.
Methods: Cross-sectional analysis of children enrolled in EPIC4 with sustained virologic suppression (SVS) after initiation of their first cART regimen; children with intermittent virologic blips were included if SVS was subsequently achieved without cART regimen change. HIV reservoir size estimated by measuring viral load in cell culture supernatants following stimulation of CD4+ T-cells with a synthetic prostratin analog. HIV serologic responses were quantified using the Architect HIV-1/2 Ag/Ab combination screening test, expressed as signal-to-cutoff value (S/CO).
Results: Twenty-nine children with median age 10.7 years (range 4.2-18.4 years) were included; 62% were female. Median age at cART initiation was 1.3 years (range 1 day-16 yrs), age at SVS was 2.4 years (range 89 days-17.6 years), and duration of SVS was 6.5 years (91 days-14.5 years). Median reservoir size (copies/10^6 CD4 T-cells) was significantly lower for children initiated on cART prior to 6 months of age (n=10) compared to those started later (n=19) (median 3.4 copies/10^6 CD4 T-cells [IQR 0, 48.1] vs. 67.4 copies/10^6 CD4 T-cells [IQR 30.3, 287.3]; p=0.02). Five children had no detectable virus, three of whom initiated cART within 72 hours of birth. Reservoir size correlated directly with age at cART initiation (Spearman correlation, p<0.01) and age at virologic suppression (p=0.04) and inversely with proportion of life on cART (p=0.02); all correlations were more robust in analysis restricted to those without virologic blips (n=23; p<0.01). The magnitude of HIV serologic response (n=20) correlated directly with age at cART initiation and age at virologic suppression and inversely with proportion of life on cART and proportion of life with SVS (all p<0.001).
Conclusions: In perinatally HIV-infected children, earlier initiation of cART is associated with reduced HIV reservoir size in peripheral blood as estimated by the prostratin stimulation assay. Other potential predictors of reservoir size include age and duration of SVS, and magnitude of HIV-specific humoral immune response.

MOPEB0360

HIV-1 viral outgrowth during ART and rebound viremia during an analytical treatment interruption originate from genetically different proviruses

A. Winckelmann[1,2], V. Morcilla[2], W. Shao[3,4], M.H. Schleimann[1], S. Leth[1], P.W. Denton[1,5,6], L. Østergaard[1,5], O.S. Søgaard[1,5], M. Tolstrup[1,5], S. Palmer[2]
[1]Aarhus University Hospital, Dept. of Infectious Diseases, Aarhus, Denmark, [2]The Westmead Institute, The University of Sydney, Centre for Virus Research, Westmead, Australia, [3]Leidos Biomedical Research, Inc, Advanced Biomedical Computing Center, Frederick, United States, [4]HIV Dynamics and Replication Program, National Cancer Institute, Frederick, United States, [5]Institute of Clinical Medicine, Aarhus University, Aarhus, Denmark, [6]Aarhus Institute of Advanced Studies, Aarhus, Denmark
Presenting author email: anniw@clin.au.dk

Background: Integrated HIV-1 proviruses are a barrier to cure and cause viral rebound when antiretroviral therapy (ART) is interrupted. Most of the integrated HIV-1 DNA is known to be defective, however it remains unclear which intact HIV-1 proviruses have the capacity to produce infectious virions. Here we investigate the phylogenetic relationship between circulating proviruses, stimulated outgrowth viruses and rebound viremia.
Methods: In a clinical trial, 17 participants on suppressive ART were treated with six doses of the therapeutic HIV gag peptide vaccine Vacc-4x (Bionor Pharma) over 12 weeks, then three doses of romidepsin over three weeks followed by an analytical treatment interruption (ATI). Viral outgrowth assay (VOA) was performed at baseline, after the immunization phase and at follow-up. Four of the participants with a positive VOA were selected for sequencing analysis. CD4+ T cells were obtained from baseline, once during and after the immunization phase, twice during romidepsin therapy and at follow-up (total of six time points).
We performed single-genome/proviral sequencing of a 2.1 kb region spanning the p24-RT region on HIV-1 DNA and cell-associated (CA) RNA from peripheral CD4+ T cells, VOA supernatants and plasma HIV-1 RNA from the treatment interruption.
Results: One participant had a viral diversity of 0.1% and was excluded from phylogenetic analysis. In the remaining three participants we observed no instances of intermingling between stimulated outgrowth viruses and rebound viremia. In one participant we identified a viral outgrowth sequence from baseline that was identical to an expansion of 14 identical proviruses sampled from four time points as well as one CA RNA sequence sampled during romidepsin therapy. In another participant, we found an ATI plasma HIV-1 RNA sequence that was identical to an expansion of 36 identical proviruses sampled from all six time points. Notably this expansion was not identified in any of HIV-1 CA RNA sequences.
Conclusions: These results emphasize that expansions of identical proviruses may have the capacity to produce virions and are activated by romidepsin to produce cell-associated RNA. Furthermore, there was no overlap between the viral outgrowth and ATI sequences representing replication-competent virus, suggesting that activation of replication-competent provirus is a unique, random event.

Pharmacokinetics and pharmacodynamics of disulfiram on inducing latent HIV-1 transcription in a phase 2b trial

S. Lee[1], J. Elliott[2], J. McMahon[2], W. Hartogenesis[1], N. Bumpus[3], J. Lifson[4], R. Corelick[4], P. Bacchetti[1], S. Deeks[1], S. Lewin[5], R. Savic[6]
[1]University of California San Francisco, Medicine, San Francisco, United States, [2]Alfred Hospital and Monash University, Department of Infectious Diseases, Monash, Australia, [3]Johns Hopkins University, Pharmacology and Molecular Sciences, Baltimore, United States, [4]Frederick National Laboratory for Cancer Research, AIDS and Cancer Virus Program, Frederick, United States, [5]The University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [6]University of California San Francisco, Bioengineering and Therapeutic Sciences, San Francisco, United States
Presenting author email: sulggi.lee@ucsf.edu

Background: Disulfiram was well tolerated and activated viral transcription (cell-associated unspliced [CA-US] and plasma HIV RNA) in a phase 2 dose-escalation trial in HIV-infected individuals on suppressive antiretroviral therapy (ART). Here, we investigated whether exposure to disulfiram and its metabolites predicted these changes in HIV transcription.
Methods: The participants in a dose-escalation study of disulfiram at 500 mg (N=10), 1000 mg (N=10), and 2000 mg (N=10), given daily for 3 consecutive days were enrolled in the sub-study. Disulfiram and four metabolites were measured by ultra-performance liquid chromatography-tandem mass spectrometry on dosing days 1-3 as well as days 4, 8, and 31. Changes in CA-US HIV RNA in CD4+ T cells and plasma HIV RNA were quantified by PCR. Data were analyzed using the non-linear mixed effects approach in NONMEM. Pharmacokinetics of the metabolites were linked to the pharmacodynamics endpoints using an indirect response model.

Results: Disulfiram and four metabolites were simultaneously described using a seven-compartment PK model. The pharmacokinetics of disulfiram was not dose-proportional; its metabolites demonstrated non-linear elimination. The cumulative area under the curve (AUC_{total}) for disulfiram given at 500, 1000, and 2000 mg were 3,420, 8,942, and 23,834 mg*hr/L, respectively. Higher PK exposure was associated with greater increases in CA-US HIV RNA (Emax=134%, AUC_{50}=844 mcg*hr/L, P< 10^{-5}). There was no identifiable exposure-response for plasma HIV RNA, except for a suggestive association at day 31 (5.0-fold increase in plasma HIV RNA per fold-increase in AUC_{total}, P=0.050). We also observed that participants with higher pre-disulfiram plasma HIV RNA had higher post-disulfiram plasma HIV RNA, and that participants in the lowest dose (500 mg) cohort had higher median baseline plasma HIV RNA.
Conclusions: Despite considerable inter-individual variability in PK, there were statistically significant increases in CA-US HIV RNA with increasing exposure to disulfiram. A similar trend was seen with plasma HIV RNA at day 31, but higher observed responses in participants with greater baseline plasma HIV RNA may have confounded the overall interpretation. Given the toxicity of other latency reversing agents (LRAs) currently being tested in HIV cure trials, these results provide rationale for further development of disulfiram as a safe and potentially effective LRA.

Presenting author email: amelie.guihot@aphp.fr

Background: Immune checkpoint-blocking antibodies can reverse T cell anergy, boost immune responses against tumors, and has become the new standard of care for second-line treatment of advanced non-small cell lung cancer (NSCLC). The question of whether anti-PD-1 could be a tool for HIV-cure is still pending. Here we report for the first time the clinical experience in 12 HIV-infected patients treated with the anti-PD-1 antibody nivolumab, and the detailed immunovirological evolution in one patient with lung cancer.
Methods: Twelve HIV-infected patients (10 male, 1 female, 1 transgender) received nivolumab as a second line therapy for NSCLC (n=11) or melanoma (n=1). Ultrasensitive plasma viral load (US-VL), HIV-cell associated DNA, phenotypic and functional T cell analysis, intracellular-cytokine-staining assay against 15-mer HIV peptides, and plasma IL-6 levels were quantified at all time points (D0, D14, D30, D60, D120) in one patient.
Results: In the 12 patients, best tumoral response was partial response (n=3), stability (n=5), or progression (n=4). All plasma HIV viral load were undetectable at D0, and no viral rebound was further observed. CD4 and CD8 cell counts were slightly modified upon nivolumab in only 5/12 patients (median 338 and 674/mm^3 at D0; 351 and 525/mm^3 after 3 or 4 nivolumab injections). In one patient, US-VL was undetectable and stable, but a slight 2-fold increase in HIV-cell associated DNA levels was observed (116 at D0 vs 213 copies/10^6 PBMC at D30). IL-6 plasma levels peaked at D14 (539 pg/mL) and returned to normal beyond D60. PD-1 and LAG3 expression on total CD4 and CD8 T cells decreased at D30. PD-1 expression remained low at D120 whereas LAG3 expression returned to D0 level. HIV-specific IFNg+CD8+ cells increased from 0.1% at D0 to 0.4% at D30. Finally, the total transitional-memory (CD8+CCR7-CD27+CD45RA-, TM) CD8 population increased (+64%) while the RA-re-expressing effector-memory cells decreased (-41%) at D120.
Conclusions: Our data suggest that nivolumab is well tolerated in HIV-infected patients, is successful at enhancing the capacities of HIV-specific CD8 TM cells to proliferate and to secrete cytokines, expanding the PD-1low T cell subset, with no or little impact on HIV replication or reservoirs.

MOPEB0363

Implementation of routine multivitamin supplementation decreases mortality and improves treatment outcomes for Tanzanian HIV-infected adults enrolled in care

C. Sudfeld[1], A. Buchanan[2], N. Ulenga[1,3], D. Spiegelman[1], E. Mtisi[3], E. Hertzmark[1], A. Muya[3], D. Sando[1], E. Mungure[1], M. Mizinduko[4], W. Fawzi[1]
[1]Harvard T H Chan School of Public Health, Boston, United States, [2]University of Rhode Island, Kingston, United States, [3]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [4]Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of
Presenting author email: csudfeld@hsph.harvard.edu

Background: Randomized trials indicate that multivitamin supplementation may be an effective intervention to reduce mortality and slow HIV progression. The objective of this study was to evaluate implementation of routine multivitamin supplementation on mortality and health outcomes within a large HIV care and treatment program in Tanzania.
Methods: The urban Dar es Salaam HIV care and treatment program provided adult patients with multivitamin supplements (containing vitamins B-complex, C, and E) as routine care during 2004-2012; however, stockouts and other implementation issues did not afford universal coverage. We present a prospective cohort study of the 67,707 adult program participants during this period and use multivariate Cox proportional hazard models to assess the time-varying association of multivitamin supplement provision with mortality and HIV progression outcomes.
Results: The study cohort was seen at 1,731,385 clinic visits and contributed 170,855 person-years of follow-up time. Multivitamins were provided at 86% of all ART-naïve clinic visits and at 55% of all ART clinic visits. Among 48,207 ART-naïve adults, provision of multivitamins significantly reduced the risk of mortality (adjusted hazard ratio (aHR): 0.67; 95% CI: 0.58-0.78), incident tuberculosis (TB) (aHR: 0.78; 0.72-0.85), and reaching ART eligibility criteria (aHR: 0.75; 95% CI: 0.70-0.80) after adjustment for possible confounding. Similarly among 46,977 ART-experienced patients, multivitamin provision reduced the risk of mortality (HR: 0.87; 95% CI: 0.82-0.93), incident TB (aHR: 0.86; 95% CI: 0.80-0.92), and immunologic failure (aHR: 0.76; 0.73-0.78). There was no indication multivitamin provision increased the risk of hepatotoxicity.
Conclusions: In the context of a large urban adult HIV treatment program in Tanzania, implementation of routine pre-ART and ART-adjunct multivitamin supplementation was a simple, effective, and safe intervention to improve survival, reduce incidence of TB, and improve treatment outcomes.

MOPEB0364

Impact of serum-derived bovine immunoglobulin (SBI) on vitamin D metabolite levels in subjects with HIV enteropathy measured by a novel sensitive method using mass spectrometry

D. Wan[1], J. Yang[1], S. Mann[2], J.C. Garci[2], P. Troia-Cancio[3], T. Yotter[3], R.B. Pollard[3], B.D. Hammock[1], D.M. Asmuth[3]
[1]University of California Davis, Department of Entomology, Davis, United States, [2]University of California Davis School of Medicine, Internal Medicine/Gastrointestinal Diseases, Sacramento, United States, [3]University of California Davis School of Medicine, Internal Medicine/Infectious Diseases, Sacramento, United States
Presenting author email: dasmuth@ucdavis.edu

Background: The mechanism(s) for vitamin D (VitD) deficiency and the optimal metabolites that should be measured are controversial. SBI is an oral medical food the neutralizes bacterial antigen in gastrointestinal (GI) tract, improves mucosal immunity, and reduces systemic inflammation in patients with HIV enteropathy. We measured VitD metabolites by a novel methodology in patients receiving SBI to explore correlations with immune reconstitution and inflammation.
Methods: Eight virologically-suppressed patients on multiple stable regimens with HIV enteropathy received SBI 500 mg orally twice daily for eight-weeks with a 4-week washout period. We validated a novel derivatization reagent (PyrNO) to abrogate isomeric endogenous-species interferences for mass spectrometry according to FDA guidance using DEQAS reference samples. 1,25-vitaminD3 (the active metabolite), 25-vitD3, C3-epi-25 vitD3, 25 vitD2, C3-epi-25 vitD2, and 24,25 vitD3 were measured at weeks 0, 7 and 12 from plasma. GI immune reconstitution was measured from duodenal biopsies and plasma biomarkers for inflammation and microbial translocation were measured by ELISA. Values are reported as medians (range)(Wilcoxon signed-rank p-value). Correlations between parameters were calculated by dividing the timepoint in question by the baseline value and performing Pearson correlations.
Results: Resolution of GI symptoms, duodenal immune reconstitution, and improved systemic inflammation/microbial translocation have been previously published. Levels increased from baseline to week 7 and continued to rise to week 12. 25VitD3 went from 12.45 (10.8-32.5) to 23.99 (16.7-39.9) (p=0.055) and

1,25VitD3 went from 0.026 (0.012-0.052) to 0.034 (0.021-0.078) at week 12 (p=0.039). Correlations between increased duodenal CD4 density and 25VitD3 (R^2=0.54, p=0.04) and 1,25VitD3 (R^2=0.74, p=0.006) were observed at week-7. We also observed correlations between decreased MCP-1, a biomarker of monocyte activation and 25VitD3 (R^2=0.77, p=0.004) and 1,25VitD3 (R^2=0.82, p=0.002) and between decreased BPI, a biomarker of gram-negative microbial translocation, 25VitD3 (R^2=0.89, p=0.0004) and 1,25VitD3 (R^2=0.93, p=0.0001), all at the week 0-7 timepoints.
Conclusions: In this small exploratory cohort, VitD metabolites improved during treatment with SBI due either to improved absorption or the impact of SBI on inflammatory pathways that impacted improved immune reconstitution, reduced systemic inflammation and/or microbial translocation. This novel PyroNO method for measuring the most relevant metabolites of VitD in HIV patients can be used in future research into the association between VitD and immune reconstitution.

Prevention of HIV Transmission from Mother to Child and in Other Populations

MOPEC0595

High rates of mother to child HIV transmission among pregnant and breastfeeding women with delayed HAART initiation in Kenya

I. Mutisya[1], L. Ng'ang'a[1], C. Muriithi[2], A. Njoroge[2], A. Katana[1], M. Muchiri[2], I. Waithera[2], J. Motoku[2], K. M. De Cock[1]
[1]Centre for Disease Control and Prevention, Nairobi, Kenya, [2]Eastern Deanery AIDS Relief Program, Nairobi, Kenya
Presenting author email: yry1@cdc.gov

Background: Despite rapid scale up of highly active antiretroviral therapy (HAART) among pregnant and breastfeeding women, mother to child HIV transmission (MTCT) remains high in Kenya at 7% at 6 weeks and 17% at 18 months. The study evaluated MTCT rates among women receiving routine prevention of mother to child HIV transmission (PMTCT) services at Eastern Deanery AIDS Relief Program (EDARP) sites in Nairobi, Kenya.
Methods: A retrospective chart review of mother-infant pairs enrolled in all 14 EDARP sites for PMTCT between January 2013 and January 2015 was done. HIV-infected women who received HAART (defined as 2NRTI +1NNRTI or PI) were included. Five percent of charts with incomplete information were excluded. Quantitative data were analyzed using STATA. Timing of HAART initiation, maternal viral suppression, and 6 week and 18 month MTCT rates were obtained using descriptive statistics. We controlled for confounding factors for MTCT and obtained odds ratios at bivariate and multivariate analyses.
Results: We reviewed 1,440 mother-infant pair charts. Median maternal age was 29 years (IQR 25-34 years). Timing of maternal HAART was: 55% pre-pregnancy, 17% at 1st and 2nd trimester, 8% in 3rd trimester and 20% postpartum. There were 395 maternal viral load (VL) results: 82% < 1000 copies/ml and 18% >1000 copies/ml. Uptake of infant ARV prophylaxis was 94%. MTCT rates were 2.7% at 6 weeks and 4.5% at 18 months. HAART initiated in third trimester or post -delivery was associated with higher MTCT rates compared to pre- pregnancy or 1st or 2nd trimester, adjusted odds ratio (AOR) 3.2 (95% CI, 1.6 -6.3), p-value=0.001. Lack of, or undocumented infant ARV prophylaxis was independently associated with higher MTCT rate, AOR 3.4 (95% CI, 1.6-7.3) p= 0.001. MTCT rates were higher among women with a VL > 1000 copies/ml, crude Odds Ratio 4.5 (95% CI, 0.6 -32.5) p= 0.135; VL sample size was underpowered to detect a statistically significant difference.
Conclusions: High MTCT rates are associated with delayed HAART initiation for PMTCT and lack of infant prophylaxis. To achieve virtual elimination of MTCT efforts should be made to improve case identification and early initiation of HAART in the pre-partum or intrapartum period

MOPEC0596

Male partner HIV testing is associated with maternal HIV retesting in pregnancy: a prospective cohort study

A. Osoti[1], J. Kinuthia[2], D. Krakowiak[3], J. Mark[3], B. Betz[3], V. Asila[4], S. Parikh[5], M. Gone[6], M. Sharma[3], C. Farquhar[7]
[1]University of Nairobi/University of Washington, OB/GYN and Epidemiology, Nairobi, Kenya, [2]Kenyatta National Hospital, University of Nairobi, Research and Programs, Obstetrics and Gynecology, Nairobi, Kenya, [3]University of Washington, Epidemiology, Seattle, United States, [4]Kenyatta National Hospital, Research and Programs, Obstetrics and Gynecology, Nairobi, Kenya, [5]University of Washington, Computer Science, Seattle, United States, [6]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [7]University of Washington, Global Health, Medicine, Epidemiology, Seattle, United States
Presenting author email: alfosoti@yahoo.com

Background: World Health Organization recommends maternal HIV retesting in pregnancy for timely identification of HIV-negative women who seroconvert so as to offer interventions that minimize risk of mother-to-child HIV transmission. We evaluated whether couple-based male partner HIV testing, an elimination of mother-to-child HIV transmission (EMTCT) strategy, increased maternal HIV retesting
Methods: This was a prospective cohort study nested within a randomized controlled trial comparing effectiveness of home-based versus clinic-based couple education and HIV testing on maternal and perinatal outcomes in Nyanza, Kenya. Eligible HIV negative women in stable relationships were enrolled antenatally and followed until 6 weeks postpartum from September 2013 to June 2014. Using facility records and study data, we defined association between male partner HIV testing and maternal HIV retesting and determined if the association was modified by the venue of male partner testing or the woman's awareness of male partner testing before pregnancy. Odds ratios (OR) for associations were obtained using logistic regression. Adjusted OR were estimated in a multivariable regression model adjusting for potential confounders. In stratified analyses, we assessed modification of the association between male partner HIV testing and maternal HIV retesting.
Results: Among 408 HIV negative women, 103 (25%) underwent couple-based male partner HIV testing. Baseline characteristics were similar between women who tested alone and those who tested with partners. The majority of women were young, with median age 24 years, in second trimester (median 20, IQR 17-25 weeks), and during follow-up most (81%) delivered in government institutions. Overall, 311 (76%) of women were retested for HIV. Maternal retesting was higher if women tested with their male partners (n=94 of 103, 91%) compared to testing alone (n=217 of 305, 71%). In the crude analysis, male partner testing was associated with four-fold greater odds in maternal HIV retesting OR 4.24; 95% Confidence interval (CI) [2.05-8.77]; P <0.001). This association persisted in adjusted analysis (OR 4.95; 95% CI [2.29-10.72]; p<0.001), and did not vary by either venue (p=0.734) or pre-pregnancy knowledge (p=0.483) of male partner testing
Conclusions: Couple-based male partner HIV testing during pregnancy is associated with increased maternal HIV retesting and may contribute to accelerated progress towards EMTCT

MOPEC0597

Effects of PMTCT-interventions and feeding-options on the HIV vertical transmission in Yaoundé-Cameroon: targeting areas for improved implementation

C.L. Mekue Mouafo[1,2], C. Nkenfou[1,3], J. Fokam[1], M.N. Ngoufack[1], V. Colizzi[4], J. Thèze[5], A. Ndjolo[1], B. Dambaya[1]
[1]Chantal BIYA International Reference Center, Yaoundé, Cameroon, [2]University of Dschang, Dschang, Cameroon, [3]University of Yaounde 1, Yaoundé, Cameroon, [4]University of Tor Vergata, Rome, Italy, [5]Institut Pasteur, Paris, France
Presenting author email: josephfokam@gmail.com

Background: The advent of antiretrovirals has significantly contributed in eliminating mother to child transmission of HIV (eMTCT) in high-priority countries, with a rate from 12.10% in 2010 to 5.6% in 2015 MTCT in Cameroon. Though countries are transitioning to option B+, there are settings where prophylaxis is still applied, thus indicating the need to evaluate the extent to which such PMTCT-intervention might contribute in eMTCT. Our study aimed at assessing the effect of different PMTCT-interventions and feeding options on eMTCT.
Methods: A cross-sectional study was conducted among 218 HIV+ mothers and their infants at the Chantal BIYA International Reference Centre for research on HIV/AIDS prevention and management (CIRCB) in Yaoundé-Cameroon from January 2013 to September 2015. A standard questionnaire was used to collect data on the maternal PMTCT-regimen; and early infant diagnosis of HIV was performed using the roche PCR amplicor kit version 1.5. Statistical analysis were performed using Mann Whitney U test, with p< 0.05 considered significant.
Results: The overall rate of MTCT was 19.9% (42/218), with a statistically significance between the four groups (triple antiretroviral therapy [ART] (9%) vs.

biprophylaxis (11%) vs. monoprophylaxis (19%) and ARV-naïve (37% for) group (p<0.0002). Specifically, the group of mothers exposed to triple ART or monoprophylaxis exhibit significant reduction in MTCT compared to ARV-naive mothers (p<0.0001 or p=0.04 respectively). According to feeding options, infants exposed to mixed feeding had the highest rate of MTCT (43%) compared to those on exclusive breastfeeding (20.1%) or formula feeding (12.5%), p=0.005.
Conclusions: The present finding underscores the necessity of scaling-up option B+, including at primary healthcare levels in all PMTCT high-priority countries. Similarly, efforts to limit the practice of mixed feeding would be of great relevance in eMTCT. Thus, strategies supporting the wide implementation of these policies would greatly contribute to the virtual eMTCT and an AIDS-free generation in children.

Presenting author email: andreas.haas@ispm.unibe.ch

Background: In Malawi, HIV-infected pregnant and breastfeeding women receive antiretroviral therapy (ART) according to Option B+ and HIV-exposed children are enrolled in the national HIV program. We examined retention and risk of HIV mother-to-child transmission among HIV-exposed children enrolled in Malawi's HIV program.
Methods: We abstracted data from routine patient records at 21 health facilities, and included HIV-exposed children enrolled into care between September 2011 and June 2014. We used competing risks models to estimate the probability of retention, loss to follow-up, discharge, ART initiation, and death, and used pooled logistic regression and inverse probability of censoring weighting to estimate the mother-to-child transmission risk at the end of breastfeeding.
Results: More than 80% of 11,285 children were born to women who initiated ART during pregnancy. By the time children were 30 months old, 57.9% were lost to follow-up; 36.5% were discharged HIV-free (Figure 1). Loss to follow-up was highest among children who enrolled late, who did not receive nevirapine prophylaxis, or whose mothers were not on ART. We projected that 5.3% (95%-confidence interval 4.7-5.9) of the children who enrolled were HIV-infected by the age of 30 months, but only 2.6% (95%- confidence interval 2.3-2.9) were diagnosed (Figure 2).
Conclusions: Mother-to-child transmission rates were low, but due to poor retention, less than half of the projected total number of HIV-infected children were diagnosed. We recommend implementation of infant defaulter tracing and HIV testing of children in immunization centers and out-patient clinics to ensure that all HIV-positive children have access to early ART.

Presenting author email: jade.ghosn@aphp.fr

Background: Few "real life" data on raltegravir use during pregnancy are available.
Methods: Data on women receiving raltegravir during pregnancy between 2008 and 2014 in ten selected clinical centers across France were collected retrospectively. The primary objective was to describe the proportion of women who received raltegravir anytime during pregnancy and achieved an HIV-RNA < 50 copies/ml at delivery. Secondary objectives were to describe demographic and immune-virological characteristics, timing of raltegravir initiation during pregnancy and pregnancy outcome.
Results: Ninety-four women were included: median age was 33 years, 80/94 originated from Sub Saharan Africa, 15/94 did not have a regular health insurance coverage, 16/94 were antiretroviral treatment (ART) naïve (HIV diagnosis at a median of 30 weeks of gestation)and 78/94 were already on ART before pregnancy (40% of them had an HIV-RNA <50 copies/ml). In those with an HIV-RNA >50 copies/ml before pregnancy, median HIV-RNA was 9823 copies/ml (range 63 - 638388). 33/94 were already on a raltegravir-based ART before pregnancy, and raltegravir was initiated during the second trimester in 11/94 (2 switch for intolerance of boosted-protease inhibitor and 9 intensification because HIV-RNA was >50 copies/ml) and during the third trimester in 50/94 (34 intensification and 16 ART initiation in naïve late-comers pregnant women). Raltegravir was well tolerated during pregnancy with no discontinuation due to adverse event. Overall, at the time of delivery, HIV-RNA was <50 copies/ml in 70% and <400 copies/ml in 84% of women. Interestingly, at delivery, HIV-RNA was <50 copies/ml in 82%, 54.5% and 56% of cases when raltegravir was started before pregnancy, during the second or during the third trimester of pregnancy, respectively. Median term was 38 weeks of gestation (20% before 37 weeks), with vaginal delivery in 49% and C-section in 51% of cases. Median newborns' weight was 3.1 kg, no defect was reported and all were HIV-negative at Month 6.
Conclusions: Raltegravir appears safe and efficacious in this "real-life" study, with the achievement of an undetectable HIV-RNA at delivery in 70% of pregnant women overall: 82% when started before pregnancy and 56% when started during the third trimester. No defect was reported in newborns and all were HIV-negative.

MOPEC0600

Viral suppression at delivery among pregnant women newly initiated on antiretroviral therapy (ART) during pregnancy: PMTCT Option B+ in Malawi

M.B. Chagomerana[1,2], W.C. Miller[3], I.F. Hoffman[1,4], B.C. Mthiko[1], J. Phulusa[1], M. John[1], A. Jumbe[1], M.C. Hosseinipour[1,4]
[1]UNC Project Malawi, Lilongwe, Malawi, [2]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [3]Ohio State University, Division of Epidemiology, College of Public Health, Columbus, United States, [4]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States
Presenting author email: mchagomerana@unclilongwe.org

Background: Effective ART for PMTCT reduces HIV viral load in pregnant women to minimize vertical transmission during pregnancy, labor or delivery. In PMTCT Option B+ programs, HIV-infected pregnant women who are not on ART are started on ART during pregnancy and continued for life. As women may present late in their pregnancy for first antenatal care, whether women achieve viral suppression by delivery and how suppression varies with time on ART is unclear.
Methods: We conducted a prospective cohort study of HIV-infected pregnant women initiating ART for the first time under PMTCT Option B+ program at Bwaila Hospital in Lilongwe, Malawi from June 2015 to November 2016. We used multivariable Poisson models with robust variance estimators to estimate risk ratios (RR) and 95% confidence intervals (CI) of the association between duration of ART and both viral load (VL) ≥1000 copies/ml and VL ≥40 copies/ml at delivery.
Results: Among 300 women enrolled, the median gestation age at first antenatal visit was 22 weeks (Interquartile rage (IQR): 18.2 - 26). The median duration of ART prior to delivery was 17 weeks (IQR: 13 - 21). Of the 253 women (84%) who had viral load test at the time of delivery, 40 (16%) and 78 (31%) had VL ≥1000 copies/ml and VL ≥40 copies/ml respectively.
Compared to women who were on ART ≤12 weeks at the time of delivery, women who were on ART 13 - 20 weeks (RR = 0.52; 95% CI: 0.36 - 0.74) or 21 - 35 weeks (RR = 0.26; 95% CI: 0.14 - 0.48) were less likely to have VL ≥40 copies/ml.

	Viral load at delivery			
Duration of ART	≥1000 copies/ml (N=40)	<1000 copies/ml (N=213)	Unadjusted RR (95% CI)	Adjusted RR † (95% CI)
≤ 12 weeks	15 (37.5)	42 (19.7)	1.00	1.00
13 - 20 weeks	19 (47.5)	106 (49.8)	0.58 (0.32, 1.05)	0.67 (0.37, 1.22)
21 - 35 weeks	6 (15.0)	65 (30.5)	0.32 (0.13, 0.78)	0.36 (0.15, 0.90)
	≥40 copies/ml (N=78)	<40 copies/ml (N=175		
≤ 12 weeks	32 (41.0)	25 (14.3)	1.00	1.00
13 - 20 weeks	35 (44.9)	90 (51.4)	0.49 (0.35, 0.72)	0.52 (0.36, 0.74)
21 - 35 weeks	11 (14.1)	60 (34.3)	0.28 (0.15, 0.50)	0.26 (0.14, 0.48)
†Adjusted for age, BMI, baseline CD4 cell count, baseline viral load, education, marital status, parity, and HIV WHO clinical stage				

[ART duration at delivery and viral suppression]

Conclusions: Women with longer duration of ART during pregnancy had lower risk of non-suppressed viral load at delivery. Countries implementing PMTCT Option B+ should encourage early ANC attendance in pregnancy to facilitate prompt ART initiation for HIV-positive women.

MOPEC0601

Prevalence of antiretroviral therapy (ART) treatment failure among HIV-infected pregnant women at first antenatal care: PMTCT Option B+ in Malawi

M.B. Chagomerana[1,2], W.C. Miller[3], I.F. Hoffman[1,4], B.C. Mthiko[1], J. Phulusa[1], M. John[1], A. Jumbe[1], M.C. Hosseinipour[1,4]
[1]UNC Project Malawi, Lilongwe, Malawi, [2]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [3]Ohio State University, Division of Epidemiology, College of Public Health, Columbus, United States, [4]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States
Presenting author email: mchagomerana@unclilongwe.org

Background: ART treatment failure can lead to the development of HIV drug resistant (HDR) strain. For HIV-infected pregnant women, the HDR strain can be transmitted to the child, resulting in impaired ART efficacy in both mother and child. In Malawi´s PMTCT Option B+ program, HIV-infected pregnant women who are already on ART are continued on therapy without testing for treatment failure at the first antenatal care (ANC). As women are not tested for treatment failure, the prevalence of treatment failure among women who are already on ART at first ANC is unknown.
Methods: We conducted a cross-sectional study of HIV-infected pregnant women who were on ART at the first ANC under PMTCT Option B+ program at Bwaila Hospital in Lilongwe, Malawi from June 2015 to December 2016. We used logistic regression models to investigate predictors of ART treatment failure.
Results: A total of 434 women were tested for ART treatment failure and their median age was 30.8 years (interquartile range: 26.9 - 34.2). Of the women tested 402 (93%) were married, 343 (82%) were in HIV-WHO stage 1, and 353 (82%) attended first ANC during the 2nd trimester. The overall prevalence of ART treatment failure was 7.1% (95% confidence interval (CI): 5.1 - 10.0). Compared to women with none or primary education, women with secondary or tertiary education had an indication of reduced odds of having developed treatment failure, odds ratio (OR) = 0.67, 95% CI: 0.27 - 1.70. For women who knew their partners' HIV status, women with HIV-infected partners had an indication of reduced odds of having developed treatment failure (OR = 0.45, 95% CI: 0.10 - 2.03) compared to those with HIV-uninfected partners.
Conclusions: A notable number of pregnant women who were already on ART at first ANC had ART treatment failure. Countries implementing PMTCT Option B+ but have limited resources for HIV-RNA screening at first ANC should develop mechanisms that will identify women at risk of having developed ART treatment failure to prompt switch to an alternative and effective ART regimen during pregnancy.

MOPEC0602

Level and predictors of receiving essential mother-infant PMTCT services in Tanzania: maternal ART adherence, infant ARV prophylaxis and early diagnosis

G. Antelman[1], G. Mbita[2], T. Machalo[2], A. Maijo[2], P. Njau[3], J. van ,t Pad Bosch[2], R. van de Ven[2], G. Woelk[4]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Strategic Information and Evaluation, Dar es Salaam, Tanzania, United Republic of, [2]Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of, [3]Ministry of Health, Community Development, Gender, Elderly and Children, PMTCT Unit, Dar es Salaam, Tanzania, United Republic of, [4]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States
Presenting author email: ga_zzz@yahoo.com

Background: Full PMTCT service adherence, including maternal ART, HIV-exposed infant (HEI) nevirapine (NVP) dosing, and early infant diagnosis (EID), is not routinely measured in Tanzania's PMTCT program. This secondary cohort analysis from 27 PMTCT clinics describes the level and predictors of full PMTCT adherence.
Methods: The Supporting Attendance for Facility Delivery and Infant Health study recruited HIV-positive pregnant women, administering interviews at enrollment and 12-weeks postpartum, with medical-record-abstraction of outcomes. Mother-infant PMTCT adherence--defined as maternal ARV adherence (zero self-reported missed ARV doses in past seven days and not missing two consecutive days of ARV dosing in past six months) HEI NVP birth/6-week dosing, and EID--is described among 584 women-infant pairs. Generalized-estimating-equation regression methods were used to predict PMTCT adherence, adjusting for age, education and site cluster. Hypothesized predictors included known/new HIV-positive, phone access/contact with health providers, ART/MTCT knowledge, facility delivery and clinic volume.
Results: Among HEI overall, 75% received the full NVP regimen; and 70% received both NVP and EID. Maternal ART adherence was 83%, and predicted receipt of HEI services. Eighty-one percent of ART-adherent mothers' HEI received NVP and EID compared to only 51% of non-adherent mothers (p<0.0001). Overall, 67% of mother-infant pairs were PMTCT adherent.
Factors reducing PMTCT adherence were pre-ART status compared to women on ART before pregnancy (known-positive, pre-ART: adjusted odds ratio [AOR] 0.28, p<0.0001; newly diagnosed HIV-positive, pre-ART: AOR 0.25, p<0.0001); and loss of mobile phone access (AOR 0.48, p=0.006) compared to maintaining access from baseline to follow-up. Factors positively associated with PMTCT adherence included knowing that ARVs reduce MTCT risk (AOR 3.18, p<0.0001), delivering in a facility (AOR 2.90, p<0.0001), having phone contact with a health provider (AOR 2.33, p<0.0001), and attending a low-volume ANC facility compared to a high-volume ANC (AOR 5.28, p<0.0001; <90 new patients/quarter vs. >=200).
Conclusions: Increased client-provider interaction may improve PMTCT adherence through promoting ART/PMTCT knowledge and access to facility delivery. Special attention should be focused on newly diagnosed and newly ART-initiated. Facilitating provider-client communication using mobile phones may enhance effectiveness of PMTCT service models. Further investigation is needed to understand why lower volume ANC clinics are associated with better adherence.

MOPEC0603

Risk factors for loss to follow-up before delivery: identifying those most in need of retention interventions

G. Antelman[1], L. Mutasingwa[1], G. Mbita[1], C. Makoko[1], J. van ,t Pad Bosch[1], R. van de Ven[1], P. Njau[2]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, PMTCT Unit, Dar es Salaam, Tanzania, United Republic of
Presenting author email: roland@pediads.org

Background: Cohort monitoring of prevention of mother-to-child HIV transmission (PMTCT) retention under Option B+ often begins at ART initiation, rendering vulnerable newly-diagnosed pregnant women who delay or refuse ART uncounted. Understanding factors linked to early non-retention among all HIV-positive pregnant women (PW) can improve retention interventions.
Methods: A retrospective cohort study using medical record abstraction of 917 HIV-positive pregnant women receiving any PMTCT services from January 2012 to June 2015 was conducted at 12 clinics in four regions of Tanzania. Data sources included ANC/HIV clinic registers and HIV medical charts which documented testing status, ART initiation or pre-ART status, pregnancy/delivery, and clinic attendance history. The outcome of interest was early PMTCT retention, defined as having a documented antenatal entry visit and a documented delivery.
Results: Overall, early PMTCT PW retention was 70% (95% CI: 67,73), and did not differ before or after the introduction of Option B+ in October 2013 (p=.66). PMTCT PW retention among ART-initiated was 85% (CI:82,87), compared to only 22% (CI:17,28) among PW who did not initiate ART during pregnancy. High PMTCT PW retention (93%) was observed among women who started ART before pregnancy, while only 76% of those starting ART during pregnancy were retained (p<0.0001). Among known-positive PW whose partners tested, 94% were retained to delivery compared to 78% whose partners did not test (p<0.04). After introduction of Option B+, 19% of newly-diagnosed PW were lost prior to ART initiation, which represented 48% of all non-retained PW.
Conclusions: Option B+ policies have not resulted in universal ART initiation among PW in Tanzania. One-in-five PW delay or refuse initiation of ART, contributing to sub-optimal early PMTCT-PW retention and accounting for nearly half of PW lost prior to delivery. The high proportion of PW lost during pregnancy who never started ART necessitates programs to adapt service delivery models to better prepare PW for ART initiation, and develop specific interventions that actively counsel, support and track newly-diagnosed PW who initiate ART, delay/refuse ART, or who do not report their partner has tested for HIV.

MOPEC0604

Systematic HIV-testing in delivery rooms is crucial, even when mothers are tested during pregnancy: a pilot program through 8 624 consecutive deliveries in Burundi, East Africa

H. Leroy[1,2], B. Ninyibutse[3], S. Manyundo-Risase[3], A. Mambaleo[3], J. Biziragusenyuka[4], C. Arvieux[1]
[1]University of Rennes, Infectious Diseases, Rennes, France, [2]Reseau Louis Guilloux, Rennes, France, [3]Hopital Prince Regent Charles, Bujumbura, Burundi, [4]ESTHER-Burundi, Bujumbura, Burundi
Presenting author email: cedric.arvieux@chu-rennes.fr

Background: Burundi associates high HIV prevalence (1,3% in 15-49 years old, 2012) and limited resources. Since april 2012, systematic HIV-testing has been proposed for all women in the delivery room of Bujumbura´s main hospital. If a woman is diagnosed HIV-positive, she is proposed immediate lamivudine/tenofovir/efavirenz intake and a free 72H hospitalization. More than 98% of women are tested.
Methods: As free HIV testing during pregnancy is recommended by national guidelines, more and more women know their status before delivery. To know if systematic HIV-testing in delivery rooms is necessary, we describe the women who have been tested and their previous tests results.
Results: From June 2014 to November 2016, 7570 women were tested for HIV during delivery : the median age was 26 years, 75% were married. It is the first pregnancy for 32%, the median number of children is 2 per woman. Only 48 women (0,6%) have never been tested for HIV, 37% have been tested one time, 56% two, 5% three, with an average of 1,7 tests. The median duration between the test in delivery room and the previous one is 75 days (IC25,75 [47;112]). 37 first tests and 34 confirmation tests were positive, and the prevalence of newly positive tested women is 0,45%. Among these 34 positive women, 19 have previously been tested HIV negative (56%), 17 during this pregnancy. The 15 other positive assert no prior HIV-test, which represents a HIV-seroprevalence of 31% within the group of women with no prior test. 55% of women know the HIV negative status of their partner, 0,5% the HIV positive one. Among the newly positive women, only 3 knew the HIV status of their partner who are all HIV-negative.
Conclusions: Systematic testing in delivery rooms is feasible and useful to decrease mother-to-child-transmission as a third of women who say having never been tested are positive. Despite a good rate of HIV testing during pregnancy, a majority of women tested newly positive in delivery room have been infected during the current pregnancy, and very few are aware of their partner HIV-status. Further efforts are needed to test men during their partner's pregnancy.

Mourier, AP-HP, Colombes, France
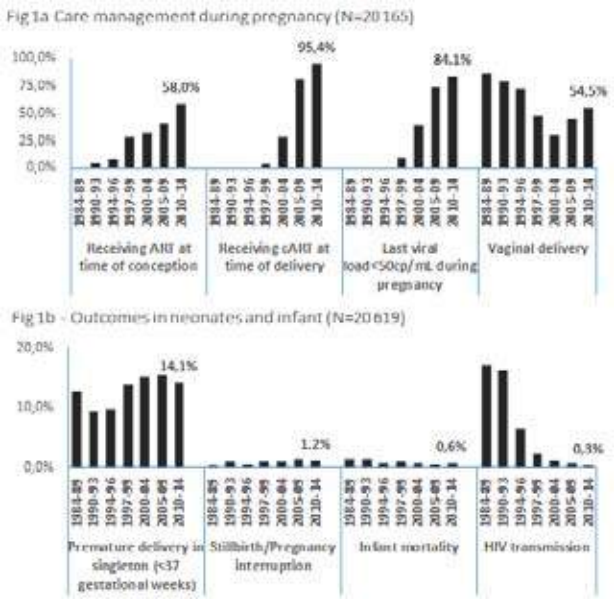
Presenting author email: laurent.mandelbrot@aphp.fr

Background: We aimed to describe trends over 30 years of the strategies of prevention of perinatal HIV transmission, and of neonatal and infant outcomes in France.
Methods: The ANRS-EPF-CO1/CO11 cohort prospectively enrolls pregnant HIV-infected women in 90 centers throughout France. Children are followed until 2 years old, and more if infected.
Results: Between 1984 and 2014, 20 619 mother-infant pairs with delivery ≥ 22 gestational weeks were included. Since 1997, the proportion of undetectable viral load (VL) near delivery increased in parallel with early exposure to combined antiretroviral therapy (cART) (Fig 1a). Elective cesarean section peaked in 2000 to sharply decrease since 2013, with a majority of vaginal deliveries. Among the 4967 women who delivered in 2010-14, 58% were already treated at time of conception, 95% received cART during pregnancy, and 84% had a VL < 50 cp/mLnear delivery. Premature delivery in singletons increased from 10% before 1996 to around 15% after 2000, with a non-significant lower rate in 2010-14 (14%) (Fig 1b). Stillbirths and pregnancy terminations increased from 0.8% in 1997-2004 to 1.3% in 2005-14 (p=0.009). Infant mortality did not significantly differ over these two periods (0.8% and 0.6% p=0.24). The transmission rate continuously decreased through 0.3% [95% confidence interval: 0.2-0.5] in 2010-14.
Conclusions: The use of early and highly effective cART tends to eradicate perinatal HIV transmission in France. The short and long term monitoring must be maintained for other adverse perinatal outcomes.



[Fig. 1 Trends of PTME outcomes - ANRS EPF 1984-2014]

MOPEC0606

Sexual risk behaviors and alcohol use among HIV-infected and -uninfected pregnant and postpartum women in Cape Town, South Africa

D. Joseph Davey[1,2,3], E. Farley[3], Y. Gomba[3], L.-G. Bekker[4], J.D. Klausner[2], P. Gorbach[1], T. Coates[2], L. Myer[3]
[1]University of Californa, Fielding School of Public Health, Department of Epidemiology, Los Angeles, United States, [2]University of California, David Geffen School of Medicine, Los Angeles, United States, [3]University of Cape Town, School of Public Health and Family Medicine, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [4]Desmond Tutu HIV Foundation, Cape Town, South Africa
Presenting author email: dvoradavey@gmail.com

Background: HIV prevention efforts have focused separately on reducing HIV acquisition risk and perinatal HIV transmission among pregnant and breastfeeding women. However, there is limited knowledge of behavioral risk in HIV-infected (HIV+) and -uninfected (HIV-) pregnant and postpartum women.
Methods: We conducted a mixed method study among pregnant and postpartum women. We investigated demographic, substance use and sex behaviors through interviewer-administered questionnaires as well as in-depth interviews (n=25) to evaluate and contextualize factors associated with sexual risk behaviors and alcohol use.
Results: We surveyed 226 HIV- and 151 HIV+ women (52% pregnant; mean age, 29y). Sexual risk behaviors and alcohol use differed significantly by serostatus. Overall 46% of HIV+ women and 42% of HIV- women were married/cohabiting with the father of the index pregnancy/child (FOC). 1 HIV- woman reported having a HIV+ partner, and 35% didn't know; 21% of HIV+ women reported being in serodiscordant relationships with the FOC, and 38% didn't know. 51% of HIV- and 45% of HIV+ women who didn't know the FOC's status reported condomless sex at last sex. HIV- women reported more condomless sex (21% vs. 45% of HIV+ women at last sex), sex partners (16% vs. 14% of HIV+ women), and anal sex, but less alcohol use during pregnancy. One-third of pregnant women reported alcohol use during pregnancy (32% HIV+; 27% HIV-) of whom 66% HIV+ and 57% HIV- women reported ≥6 drinks on ≥1 occasion. Results from in-depth interviews demonstrated common themes including: lack of control over decisions in sex and condom use, high prevalence of substance use during pregnancy, beliefs around condom use during pregnancy (e.g. sex is good for baby) and fear of discussing HIV testing/disclosure with partner(s) (Table 1).

Theme	Select results from in-depth interviews (n=25)	Select ultivariate regression results
Heavy alcohol use during pregnancy	"When you are drunk, you don't think that if I have sex with this person I can get HIV."	Alcohol use during pregnancy was associated with increased odds of reporting =>1 partner (aOR=3.06;95%CI=1.10-8.49) and serodiscordant FOC (aOR=2.39; 95% CI=1.29-4.45) adjusted for age
Condomless sex during pregnancy/ postpartum period	"I once suggested we use a condom, he got angry and asked why I am saying we should use a condom....he asked if I have a disease."	Condomless sex was associated with: pregnancy vs. postpartum period (aOR=3.24; 95% CI=2.03-5.17) & serodiscordant vs. seroconcordant FOC (aOR=3.16; 95% CI=1.39-7.19) adjusted for age
Lack of knowledge of partner's serostatus	"When you go to test, they say they are also (HIV) negative because you tested negative"	HIV+ mothers (vs. HIV- mothers) had increased odds of not knowing their FOC's serostatus (aOR=3.27, 95% CI=2.09, 5.14) adjusted for education and age

[Table 1]

Conclusions: We identified significant HIV transmission and acquisition risk during pregnancy and postpartum periods including alcohol use, multiple partners, condomless sex, serodiscordance and lack of knowledge of partner's serostatus. Primary and secondary prevention of sexual HIV transmission in pregnant and postpartum women is a neglected but important area for reducing horizontal and vertical HIV transmission.

MOPEC0607

Maternal humoral immune correlates of mother to child transmission of HIV-1 in the setting of peripartum antiretrovirals

C. Mutucumarana[1,2,3], J. Eudailey[1], E. McGuire[1], N. Vandergrift[1], G. Tegha[4], C. Chasela[5], S. Ellington[6], C. van der Horst[7], A. Kourtis[6], S. Permar[1], G. Fouda[1]
[1]Duke University, Duke Human Vaccine Institute, Durham, United States, [2]Duke University School of Medicine, School of Medicine, Durham, United States, [3]Doris Duke Charitable Foundation, New York, United States, [4]University of North Carolina, UNC Project, Lilongwe, Malawi, [5]University of Witwatersrand, Division of Epidemiology and Biostatistics, Parktown, South Africa, [6]Centers for Disease Control and Prevention, Division of Reproductive Health, Atlanta, United States, [7]University of North Carolina School of Medicine, Division of Infectious Diseases, Chapel Hill, United States
Presenting author email: cpm24@duke.edu

Background: More than 150,000 annual pediatric HIV-1 infections occur due to mother to child transmission (MTCT) despite the availability of antiretrovirals (ARVs). In the pre-ARV era U.S. Women and Infants Transmission study (WITS), we previously reported that maternal HIV envelope-specific anti-V3 IgG, CD4 binding site antibodies, and tier 1 virus neutralization predicted reduced HIV-1 MTCT. As the majority of pediatric HIV infections occur in clade C HIV-infected populations with increased access to ARVs, we studied a Malawian HIV-infected pregnant women cohort from the Breastfeeding, Antiretrovirals, and Nutrition (BAN) study. We sought to determine if immune factors in the setting of ARVs predict reduced MTCT and help eliminate pediatric HIV-1.
Methods: Plasma from a subset of BAN clade C HIV-infected Malawian mothers (n=88, 45 transmitting and 43 non-transmitting) and their infants were studied. Women and infants received ARVs at delivery, and the majority of peripartum MTCT was during pregnancy (91%). Binding antibody multiplex assays, HIV-1 neutralization assays, and soluble CD4 blocking ELISAs measured plasma IgG against multiclade HIV Env antigens, neutralizing capacity, and CD4 binding site antibodies, respectively.
A multivariable logistic regression model analyzed the association of maternal and infant immune responses with peripartum MTCT risk.
Results: No significant association was detected between maternal anti-clade C V3 IgG (OR 0.57, p=0.42) or tier 1 neutralization (OR 1.37, p=0.70) and MTCT. Surprisingly, plasma blocking of the CD4 binding site (OR 1.06, p=0.03) and maternal anti-clade C V1V2 IgG (OR 1.62, p=0.04) were associated with increased MTCT independent of maternal viral load. Maternal anti-V1V2 IgG transfer efficiency to infants was not associated with transmission (OR 1.00, p=0.67).
Conclusions: This study revealed an association between high maternal CD4 binding site antibodies and anti-V1V2 IgG and transmission. Distinct humoral immune correlates of MTCT in the BAN and previous studies could be due to differences between transmission mode, virus clade, or maternal antiretroviral use. The association between specific maternal antibody responses and in utero transmission, distinct from potentially protective maternal IgG in the WITS cohort, underlines the importance of investigating additional cohorts with well-defined transmission modes to understand the role of maternal antibodies during HIV-1 MTCT.

MOPEC0608

Reducing paediatric HIV transmission in Northern Namibia

P. Kalimugogo[1], N. Hamunime[2], A. Zegeye[3], P. McQuide[1], J. Mdala[1], S. Ndhlovu[4], T. Gwande[4], R. Mulang[4], T. Lazarus[4], A. Kudumo[4]
[1]IntraHealth International, Windhoek, Namibia, [2]Ministry of Health and Social Services, Windhoek, Namibia, [3]USAID, Windhoek, Namibia, [4]USAID HIV Clinical Services Technical Assistance Project, Windhoek, Namibia
Presenting author email: pkalimugogo@intrahealth.org

Background: USAID's HIV Clinical Services Technical Assistance Project (UTAP), led by IntraHealth International, supports Namibia's Ministry of Health and Social Services in HIV high-burden districts in Northern Namibia by increasing capacity to provide high-quality HIV prevention, care, and treatment services. With expanded prevention of mother-to-child transmission (PMTCT) of HIV and accessibility of HIV testing for children, UTAP observed an increase in HIV-exposed children testing HIV-positive. UTAP conducted a case study of HIV-positive children to identify missed opportunities to reduce HIV-positivity in HIV-exposed children.
Methods: The study analyzed cases of HIV-exposed and HIV-positive children from July-September 2016 in eight districts. Quantitative data were derived from patient care booklets and clinic reports. Qualitative analysis was obtained through interviews with parents/guardians.
Results: UTAP traced 63 (80%) of 79 infants and children testing HIV-positive. Children ranged from five months to eight years old, and were tested using age-appropriate HIV testing algorithm. Further review revealed 22 of the 63 were later confirmed HIV-negative using the DNA/PCR test. The remaining 41 children were

confirmed HIV-positive; 33 (80%) were born to known HIV-positive women. Six were born to women who tested HIV-negative during the antenatal period but did not undergo HIV testing during the breastfeeding period. Recently expanded provider-initiated HIV testing and counseling (in clinics and hospitals) identified 26 (63%) HIV-positive children. Fourteen children (34%) received inadequate Nevirapine prophylaxis.
Noteworthy characteristics of mothers included: HIV-positive and defaulted or refused to take HIV treatment; HIV-negative during antenatal period; did not attend antenatal care; and/or had a home delivery. During this same period 6,839 pregnant, labor and delivery women were tested in these same districts; 17.5% were known or new HIV-positive.
Conclusions: Delivering a full package of PMTCT services and strengthening adherence and retention of pregnant and breastfeeding women who are on ART are needed. A concerning number of women seroconverted in breastfeeding period (15%) highlighting the importance of continued HIV prevention interventions for HIV-negative women during postnatal and breastfeeding periods. Universal treatment for pregnant and breastfeeding women works best when adherence and retention of known HIV-positive pregnant and breastfeeding women are improved and HIV-exposed children receive comprehensive, integrated HIV services.

MOPEC0609

Pregnancy and neonatal outcomes following prenatal exposure to dolutegravir

C. Thorne[1], G. Favarato[1], H. Peters[1], T. Soriano-Arandes[2], M. Floridia[3], A. Colbers[4], T. Goetghebuer[5], L. Ragone[6], D. Burger[4], A. Pozniak[7], C. Giaquinto[8], K. Aebi-Popp[9], V. Vannappagari[6], European Pregnancy and Paediatric Cohort Collaboration (EPPICC)

Presenting author email: claire.thorne@ucl.ac.uk

Background: Dolutegravir (DTG) is an integrase strand inhibitor approved for the treatment of HIV in adults and adolescents since 2013. There is minimal information on use of DTG in pregnant women. Our aim was to assess maternal and fetal outcomes following DTG use during pregnancy in real-world European settings.
Methods: A retrospective analysis of individual patient data prospectively collected in observational studies of pregnant women living with HIV and their infants within the European Pregnancy and Paediatric HIV Cohort Collaboration was conducted. All women with any prenatal exposure to DTG and reported to studies by September 2016 were included.
Results: A total of 81 pregnancies in 81 women were identified. Median maternal age at conception was 33.1 years (interquartile range [IQR], 26.7-37.1 years), and 44/81 (54.3%) born in sub-Saharan Africa. Most (62/74, 83.8%, 7 unknown acquisition) women had heterosexual acquisition of HIV, 9 women were vertically infected and 3 had injecting drug use acquisition. Most women had been diagnosed with HIV before conception (70/75, 6 unknown), 48 conceived whilst on any ART and 28 conceived on a DTG-based regimen. There were two twin pregnancies (all live births). Pregnancy outcomes were known for 64 pregnancies (1 moved to another country before delivery, 16 continuing): 61 ended in live births (29 with 1st trimester DTG exposure), 1 in stillbirth (without 1st trimester DTG exposure), 1 in termination (with 1st trimester DTG exposure) and 1 in spontaneous abortion (with 1st trimester DTG exposure). Birth outcomes for the 63 delivered liveborn infants (including 2 twin pairs) and 1 stillborn infant (62 pregnancies) are in the Table. The congenital abnormalities with 1st trimester DTG exposure were: patent foramen ovale; bilateral hexadactyly of hands (familial) and hypospadias (both in 1 child); in 2nd trimester: ankyloglossia.

	1st trimester earliest DTG exposure	2nd / 3rd trimester earliest DTG exposure
First prenatal CD4 count (median, IQR)#	525 cells/mm3 (323-660)	338 cells/mm3 (218-591)
Preterm delivery (<37 weeks)*	2/27 (7.4%)	9/33 (27.3%)
Low birth weight (<2500g)*	8/25 (32.0%)	13/33 (39.4%)
Very low birth weight (<1500g)*	0/25 (0.0%)	0/33 (0.0%)
Congenital abnormality (livebirths)	2/29 (6.9%) (2 missing)	1/32 (3.1%) (0 missing)
# available for 58 of 62 pregnancies	* calculated for the 60 singleton deliveries (59 livebirths, 1 stillbirth) only	

[Characteristics by trimester of DTG exposure]

Conclusions: Although this is the largest study to date, small numbers preclude firm conclusions regarding safety of DTG in pregnancy and further prospective monitoring is required.

MOPEC0610

Prevention of mother to child transmission of HIV: postpartum adherence to Option B+ until 18 months in Western Uganda

S. Theuring[1], S. Decker[1], E. Rempis[1], A. Schnack[1], V. Braun[1], J. Rubaihayo[2], P. Busingye[3], N. Tumwesigye[4], G. Harms[1]
[1]Charité-Universitätsmedizin, Institute of Tropical Medicine and International Health, Berlin, Germany, [2]Mountains of the Moon University, Public Health Department, Fort Portal, Uganda, [3]Virika Hospital, Fort Portal, Uganda, [4]Makerere University, School of Public Health, Kampala, Uganda
Presenting author email: stefanie.theuring@charite.de

Background: Since 2012, the WHO has recommended Option B+ for the prevention of mother-to-child transmission of HIV. This approach entails the initiation of lifelong antiretroviral therapy in all HIV-positive pregnant women, also implying protection during breastfeeding for 12 months or longer. Research on long-term adherence to Option B+ throughout breastfeeding is scarce to date. Therefore, we conducted a prospective observational cohort study in Uganda to assess adherence to Option B+ until 18 months postpartum.
Methods: We recruited 67 HIV-positive, Option B+ enrolled women six weeks after giving birth in Fort Portal, Western Uganda and scheduled them for study follow-up after six, twelve and 18 months. Two adherence measures, self-reported drug intake of the previous month and rate of drug refill visits, were combined to define adherence, and were assessed together with feeding information and infants´ HIV status at all study visits. Risk factors for postpartum adherence were analyzed.
Results: At six months postpartum, 51% of the enrolled women were considered to be adherent, and 91% of the babies had been exclusively breastfed for 6 months. Until twelve and 18 months postpartum, adherence for the respective follow-up interval decreased to 19% and 20.5% respectively. No woman was completely adherent until 18 months. At the same time, 76.5% of the women breastfed for 12 months or beyond. Longer breastfeeding duration was not linked with higher adherence. Risk factors for postpartum adherence to Option B+ were older age of the mother ($p< 0.01$), higher travel costs ($p=0.02$), and higher number of previous deliveries ($p=0.04$). We found no case of vertical transmission in our cohort.
Conclusions: Our results imply that postpartum long-term adherence is a challenge in Option B+ implementation, while at the same time, prolonged breastfeeding until 12 months or beyond is widely applied. This needs to be taken into serious account by healthcare providers, because poor postpartum adherence might eventually cause a setback in prevention of vertical transmission during the breastfeeding period. HIV-positive mothers require intense support for postpartum adherence to Option B+. Effectiveness in terms of low transmission despite suboptimal adherence needs to be verified in further research.

MOPEC0611

Serological and nutritional outcome of infants born to HIV-positive mothers undergoing option B + therapy in Guédiawaye

J.B.N. Diouf
Centre Hospitalier Roi Baudouin Guédiawaye, Dakar, Senegal
Presenting author email: jeanniokhor@yahoo.fr

Background: As part of its Plan to eliminate mother-to-child transmission of HIV, Senegal has adopted since 2012 WHO´s B + option, which consists of systematic triple therapy for HIV-positive pregnant women associated with breastfeeding and antiretroviral (ARV) prophylaxis for their infants. Our study aims to analyze the risks of mother-to-child transmission of HIV and the nutritional outcome of infants undergoing B + option.
Methods: We conducted a descriptive, retrospective study at the Roi Baudouin hospital in Guédiawaye from 1 September 2012 to 30 April 2015. All infants whose mothers were on triple therapy, undergoing protected breastfeeding, ARV prophylaxis and serological test at 14th months were included in the study.
Results: Out of the 126 infants undergoing PMTCT program, 42 or 33.33% of infants following the B + guidelines were included in the study. The age of mothers ranged from 15 to 42 years, with an average age of 31 years. The majority of mothers (88.1%) carried type 1 virus and 11.9% carried type 2 virus; 20 couples (47.62%) were sero-concordant, 14 were serodifferent, while the serological status was unknown or not investigated in 8 fathers (19.05%). A significant difference between fathers´ serological profile and the sharing status ($p < 0.05$) was found. The majority of infants (88.1%) were born at term via vaginal delivery (95.2%), with an average birth weight of 2880 grams. In relation to prophylaxis, the majority of infants

received prophylactic monotherapy, 27 (64.28%) received Nevirapine, 4 (9.52%) received Zidovudine, while 11 (26.19%) received triple combination of Zidovudine + Lamivudine + Nevirapine. The exclusive breastfeeding was effective in 80.9% of infants and weaning began at 12 months in 80.9% of infants. In relation to nutritional status, at 6 months 12% and 7.1% of infants had moderate acute malnutrition and severe acute malnutrition respectively. At 12 months, 19.1% of infants had moderate acute malnutrition. Retroviral serology was negative in all the 42 infants at 14 months.
Conclusions: B + option is an effective strategy to reduce the MTCT rate. However, early malnutrition in children requires nutritional support for breastfeeding mothers as well as a good psychosocial Support.

MOPEC0612

Improvement in viral suppression among women up to one-year post-partum after implementation of universal ART in the SEARCH test-and-treat trial

L. Brown[1], D. Kwarisiima[2,3], F. Mwangwa[2], J. Ayieko[4], A. Owaraganise[2], T. Ruel[5], E. Bukusi[4], E. Charlebois[6], T. Liegler[1], T. Clark[1], M. Petersen[7], D. Havlir[1], C. R. Cohen[8]
[1]University of California, Division of HIV, Infectious Diseases & Global Medicine, San Francisco, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Makerere University, Kampala, Uganda, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]University of California, Division of Pediatric Infectious Diseases, Department of Pediatrics, San Francisco, United States, [6]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [7]University of California, School of Public Health, Biostatistics, Berkeley, United States, [8]University of California, Department of Obstetrics, Gynecology & Reproductive Services, San Francisco, United States
Presenting author email: fmwangwa@idrc-uganda.org

Background: The WHO's "Option B+" strategy calls for lifelong ART for pregnant women; however, a substantial proportion of women on ART at delivery are lost from care during the post-partum period. Post-partum women may be more likely to remain in care and on ART when universal test-and-treat is implemented at a population level. We evaluated viral suppression among HIV-infected women who were up to one-year post-partum living in communities with universal ART as part of the SEARCH (NCT01864603) test-and-treat trial.
Methods: Women age 15-49 years who were residents of 16 SEARCH intervention communities in Uganda & Kenya were tested for HIV at baseline and annually through engagement in hybrid mobile testing between 2013-2016, which reached 93%, 94%, and 87% at baseline, one year (FUY1), and two years (FUY2). Among HIV-infected women who reported a live birth within the previous 12 months at testing, the proportion with viral suppression (HIV RNA< 500 copies/ml) was calculated at baseline, FUY1, and FUY2; a missing viral load (VL) was considered non-suppressed. Predictors of non-suppression at FUY1 and FUY2 were assessed using logistic regression. Multivariate models included age, region, marital status, education, number of previous pregnancies, and years since HIV diagnosis
Results: Among HIV-infected women who reported a live birth in the previous 12 months 72% (443/609) at FUY1 and 76% (384/503) at FUY2 were virally suppressed in comparison to 35% (335/944) at baseline prior to the SEARCH intervention. Younger women (15-24 years) were more likely to have detectable VL at FUY1 than women ≥24 years (aOR 1.78; 95% CI 1.06-2.97). Women diagnosed with HIV within the previous year were more likely to have detectable VL at both FUY1 (aOR 2.45; 1.48-4.05) and FUY2 (aOR 1.89; 1.24-2.87) compared to HIV+ women with an earlier diagnosis. Among women with detectable VL, 94% had HIV RNA >1000 copies/mL.
Conclusions: Among post-partum women seen at annual hybrid mobile campaigns, the proportion virally suppressed doubled after two years of community-wide universal ART. Young women and those recently diagnosed are at highest risk for viremia that may result in poorer maternal health outcomes and ongoing transmission in the post-partum period.

MOPEC0613

Experiences and perceptions of community-based mentor mothers (cMM) supporting HIV-positive pregnant/postpartum women on lifelong antiretroviral therapy in Southwestern Kenya

A. Helova[1], L.L. Abuogi[2], M. Onono[3], E.A. Bukusi[3], I. Wanga[3], G.O. Odhiambo[3], E. Akama[3], W.Z. Nalwa[4], T.A. Odeny[3,5], P. Musoke[1], J.M. Turan[1]
[1]University of Alabama at Birmingham School of Public Health, Health Care Organization and Policy, Birmingham, United States, [2]University of Colorado Denver, Department of Pediatrics, Aurora, United States, [3]Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya, [4]Kenya Ministry of Health, Migori County Referral Hospital, Nairobi, Kenya, [5]University of Washington, Department of Epidemiology, Seattle, United States
Presenting author email: ahelova@uab.edu

Background: Community-based mentor mothers (cMM) are HIV-positive mothers providing peer support to HIV-positive pregnant/postpartum women in the community with the aim to enhance lifelong antiretroviral therapy (ART) adherence and retention in care.
Methods: To explore the perceptions of cMMs on their role in supporting HIV-positive pregnant/postpartum women, we completed 24 in-depth interviews with cMMs from ten communities in Kenya between April-May 2016. Transcripts were coded with Dedoose software using a coding framework based on the literature, interview guides, and emerging themes from transcripts, and fine-coded using an inductive approach. Main themes were explored in longitudinal questionnaire data collected by cMMs during their home visits for 159 women and their infants at 6-weeks postpartum.
Results: cMMs expressed high acceptability of their work in the community and health facilities, and emphasized their positive impact on HIV-positive women and their infants. They described provision of health education; making linkages to HIV care, prevention of mother-to-child transmission (PMTCT) and maternal and child health (MCH) services. The cMMs reported serving as role models and confidantes, supporting acceptance of HIV status, providing encouragement about the potential of having an HIV-negative child; assisting with partner disclosure/communication, and providing tangible support (development of birth plans, picking up medications). Additionally, cMMs described personal benefit through self-empowerment and increased income. Reported challenges included possible inadvertent disclosure of clients' HIV status, transportation, and cultural barriers/myths. Positive impact of home visits described by cMMs was reflected in questionnaire data. At 6-weeks postpartum, 96% of women visited at home self-reported 100% adherence to ART as well as increase in disclosure to male partner to 96% from 84%; all infants were on preventive HIV regimen and 99% were properly adhering, 94% of infants had been tested for HIV, 89% were delivered at the hospital, and 99% were exclusively breastfed and immunized.
Conclusions: Kenya, similar to other countries, is in a need of innovative approaches to overcome challenges associated with the scale-up of lifelong ART services. This study suggests that a cMM strategy may play an important role in enhancing PMTCT as well as MCH in Kenya and may have positive effects on the cMMs themselves.

MOPEC0614

Preliminary results of prevention of mother to child transmission of hepatitis B virus through treatment of mothers and vaccination of newborns at Ouagadougou, Burkina Faso

A.N. Guingane[1], N. Meda[2], R. Sombié[3], I. Guiraud[4], A. Bougouma[3]
[1]Centre Hospitalier Universitaire Yalgado Ouédraogo, Médecine, Ouagadougou, Burkina Faso, [2]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [3]Centre Hospitalier Universitaire Yalgado Ouédraogo, Ouagadougou, Burkina Faso, [4]Research Institute of Health Sciences, Ouagadougou, Burkina Faso
Presenting author email: aliceguingane@yahoo.fr

Background: Vaccination practices alone are not enough to control the HBV epidemic. Treatment of women in the third trimester of pregnancy with tenofovir, if the maternal DNA level of hepatitis B virus is >106 IU / ml, has also been confirmed as an effective strategy but very little evaluated in sub- Saharan Africa. The objective of this study was to assess the effectiveness of these two strategies in Ouagadougou.
Methods: The data collection took place from 01/09/2014 to 01/09/2015 during a prospective study with regular monitoring of pregnant women and their newborns. Pregnant women were infected with hepatitis B with or without HIV / HCV co-infection and were followed for their infection at Yalgado Ouedraogo University Hospital. Women at high risk of transmission (DNA >106 IU / ml) were all on treatment and vaccination in the first 24 hours of life was offered to all newborns. The effectiveness of the strategy was evaluated at 7 months of life by the assays of Ag HBs and Ac anti HBs in all newborns.

Results: A total of 266 pregnant HBs positive HBs were followed. Co-infections HBV / HIV and HBV / HCV were found in six patients (2.26%) and two patients (0.75%), respectively. During our study 190 babies were born alive including one twin pregnancy. There were 5 (2.63%) deaths born or miscarriages. The perinatal mortality rate was 1.58% or 3 cases. Ten women had a viral load greater than 10^6 IU / ml, and all were put on treatment in the third trimester of pregnancy. Among the 190 children, 96 or 50.52% had their serological status at 7 months and 92 of them, 95.84% were HBs Ag-negative compared with 4 positive (4.16%). The mothers of these infected infants had in 3 cases a viral load greater than 10^6 IU / ml and 2 of them were Ag HBe positive. In all infants the anti-HBs antibody assay was positive and protective.
Conclusions: In the prevention of mother-to-child transmission of hepatitis B virus, the combination of these two strategies gives us a success rate of 95.84% even in the absence of immunoglobulins.

MOPEC0615

Barriers and facilitators for men obtaining HIV voluntary counseling and testing during prenatal care in Brazil

N. Yeganeh[1], M. Simon[2], D. Mindry[3], K. Nielsen-Saines[1], M.C. Chavez[2], B. Santos[2], M. Melo[2], P. Gorbach[4]
[1]David Geffen School of Medicine at UCLA, Pediatrics, Los Angeles, United States, [2]Hospital Conceicao, Infectologia, Porto Alegre, Brazil, [3]UCLA Center for Culture and Health, Department of Psychiatry and Behavioral Sciences, Los Angeles, United States, [4]Fielding School of Public Health at UCLA, Epidemiology, Los Angeles, United States
Presenting author email: nyeganeh@mednet.ucla.edu

Background: Providing HIV voluntary counseling and testing (VCT) to men who attend their partner´s prenatal care is an intervention with potential to reduce HIV transmission to women and infants during the vulnerable period of pregnancy. Little is known about the acceptability of this intervention in global settings outside of Africa.
Methods: We conducted in-depth qualitative interviews to evaluate potential barriers and facilitators to male prenatal care attendance for HIV VCT with 20 men who did and 15 men who did not attend prenatal care with their partners in Porto Alegre, Brazil. Men were recruited at the labor and delivery unit via a scripted invitation while visiting their newborn infant. Interviews lasted from 35-55 minutes and were conducted by a trained local resident. All interviews were transcribed verbatim, translated, and then analyzed using thematic coding in Atlas.ti.
Results: If offered HIV testing during prenatal care, all men in both groups stated they would accept this intervention. Yet, individual, relationship and systemic factors were identified that affect these Brazilian men´s decision to attend prenatal care, informing our final conceptual model. The men interviewed had a general understanding of the value of prevention of mother to child HIV transmission. They also described open and communicative relationships with their significant others and displayed a high level of enthusiasm towards optimizing the health of their expanding family. The major barriers to attending prenatal care included perceived stigma against HIV infected individuals, men's lack of involvement in planning the pregnancy as well as inconvenient scheduling of prenatal care, due to conflicting work schedules.
Conclusions: Brazilian men displayed high levels of HIV-related knowledge as well as open communication about HIV testing; especially when compared to findings from African studies. Future efforts should reorient prenatal care towards providing care to the entire family with a clear focus on protecting the infant from preventable diseases.

MOPEC0616

Late diagnosis of HIV and shorter duration of antiretroviral drug exposure in HIV-infected mothers in PMTCT program, Mandalay, Myanmar

K.W.Y. Kyaw[1], N.T.T. Kyaw[2], T.K. Aung[3], J. Moe[3], K.H. Phyo[3], A.A. Mon[3], T. Htun[4], H.N. Oo[5], A.M. Kumar[6]

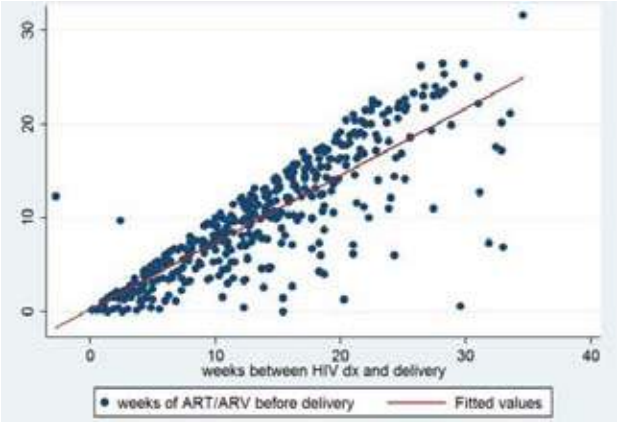
Presenting author email: thurainhtun@theunionmyanmar.org

Background: Longer duration of antiretroviral treatment (ART) before delivery is critical to reduce viraemia during pregnancy, delivery and postpartum breastfeeding and reduce the chances of mother to child transmission (MTCT). We aimed to determine the duration of ART/ antiretroviral drugs (ARV) received by HIV-positive pregnant mother and factors associated with unfavourable outcomes (non-initiation or late ART; duration of ART/ARV ≤12 week) in prevention of MTCT (PMTCT) program in Mandalay, Myanmar.
Methods: This is a retrospective cohort study on routinely collected data.
Results: Of 671 ART naïve HIV-positive mothers newly enrolled in PMTCT program between March 2011 and November 2016, 570 (85%) have delivered as of November 2016. Only 80% of them (461/570) got ART/ARV before delivery in which 60% has ≤12 week duration of ART before delivery. The median (Interquartile range, IQR) duration of ART/ARV before delivery was 9 week (4-15). The median (IQR) time to initiate ART/ARV since diagnosis and since enrolment to PMTCT program were 3 week (1-6) and 1 week (0-3). Figure shows positive correlation (r 0.72, P< 0.001) between earlier diagnosis of HIV before delivery and longer duration of ART before delivery.



[Figure. Plot of weeks of ART/ARV before delivery]

HIV-infected mothers lived outside Mandalay and unknown spouse HIV status were significantly associated with late ART (duration of ART/ARV ≤12 week) and no ART/ARV before or after delivery.

Characteristics		Total	Unfavourable ART/ARV status n (%)	Unadjusted Rate Ratio (95% CI)	p value	Adjusted Rate Ratio (95% CI)	p value
Total		570	384(67)				
Age group	≤20	32	22(69)	1			
	20-30	311	201(65)	0.94(0.73-1.2)	0.627		
	>30	227	161(71)	1.03(0.8-1.32)	0.806		
Patients resident	Outside Mandalay	134	102(76)	1.18 (1.05-1.32)	0.007	1.18 (1.05-1.33	0.005
	In Mandalay	436	282(65)	1		1	
Spouse HIV status	Unknown Spouse HIV status	259	194(75)	1.23 (1.09-1.37)	<0.001	1.23 (1.1-1.38)	<0.001
	Known Spouse HIV status	311	190(61)	1		1	

[Characteristics and factors associated with Unfavo]

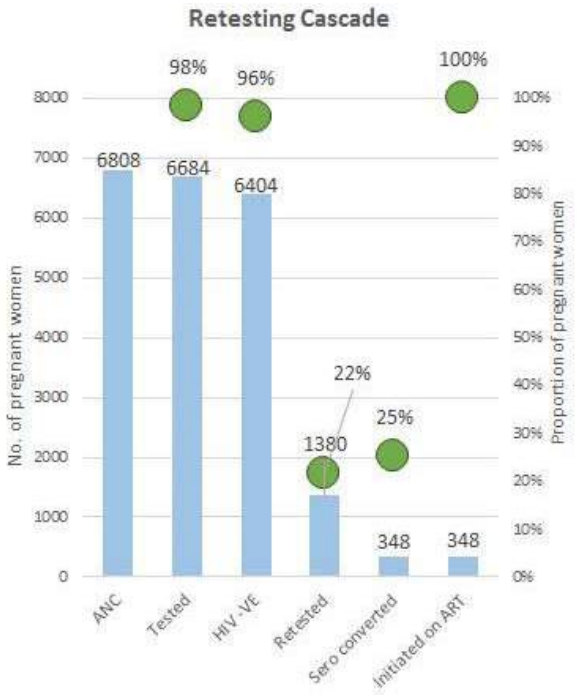
Conclusions: There is an urgent need to increase early uptake of antenatal care and early diagnosis of HIV in pregnant mothers to maximize the duration of ART before delivery to prevent mother to child transmission of HIV by addressing the challenges.

MOPEC0617

Retesting in pregnancy at Zambian Defense Force (ZDF) health facilities: an important strategy for preventing new infections and achieving the 90-90-90 UNAIDS targets

C.J. Mwale[1], L. Aladesanmi[2], J. Banda[2], E. Banda[3], E. Lifuka[4], L. Oseni[5], K. Grabbe[5], K. Asiedu[2], N. Kasonka[2]
[1]Jhpiego, Affliate of Johns Hopkins University, Lusaka, Zambia, [2]Jhpiego, Lusaka, Zambia, [3]Zambia Defense Force, Lusaka, Zambia, [4]United States Department of Defense, Lusaka, Zambia, [5]Jhpiego, Baltimore, United States
Presenting author email: joyce.mwale@jhpiego.org

Background: In Zambia, provider-initiated HIV testing is conducted routinely for pregnant women during their first antenatal care (ANC) visit, as part of prevention of mother-to-child HIV transmission (PMTCT). Per Zambia national guidelines, HIV-positive women immediately initiate antiretroviral treatment (ART; Option B+), and HIV-negative women irrespective of risk profile, retest every 3 months, at delivery or postpartum, due to the high risk of infection during pregnancy.
Methods: We assessed the degree of adherence to national HIV testing guidelines at 14 ZDF ANC clinics supported by Jhpiego through DOD PEPFAR funding. Retesting coverage for 6,808 pregnant women from October, 2015 to September, 2016 was reviewed and health care providers were interviewed to determine retesting barriers.
Results: 6,808 pregnant women attended ANC during the review period; 6,684 (98%) tested for HIV at first ANC visit (known positives were not tested). 6,404 (96%) tested HIV-negative and 280 (4%) tested HIV-positive. 1,380 (22% of negatives) retested, leaving a high proportion (78%) failing to retest. 348 (25%) seroconverted and were initiated on ART. Barriers to retesting included women not attending all four ANC visits (4th Visit Rate: 60%); providers experiencing heavy workloads and failing to check for retest eligibility; and stock outs of test kits. The reasons for the high seroconversion among retested women could however not be determined from routine data.



[Resting Cascade 2]

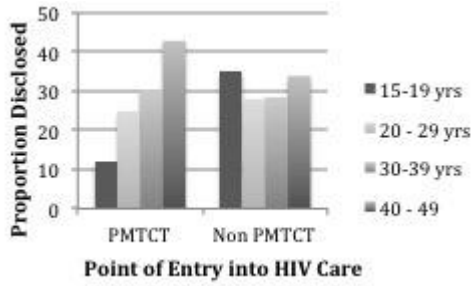
Conclusions: Retesting HIV-negative pregnant women is an important strategy for identifying women who have seroconverted during pregnancy, who can benefit from ART, PMTCT, oral PREP for partner, and early infant diagnosis. The high rate of seroconversion among the re-testers (though only 22% of initial negatives) suggests a need to not just improve retesting for pregnant women but to also offer testing to male partners at subsequent ANC visits, thus preventing transmission during pregnancy and contributing to achieving the UNAIDS 90-90-90 targets.

MOPEC0618

Reasons for lost to follow-up and levels of HIV sero-status disclosure among traced patients receiving routine care in urban Uganda

A. Kiragga, P. Nyakato, M. Ssuuna, E. Katunguka, B. Castelnuovo, J. Kigozi
Infectious Diseases Institute, Makerere University, Kampala, Uganda
Presenting author email: akiragga@idi.co.ug

Background: Retention in HIV care remains critical in achievement of the UNAIDS 90-90-90 goals for the HIV continuum of care. Understanding the reasons for dropping out of care is crucial and HIV sero-status disclosure may be associated to low retention levels. We sought establish the reasons of LTFU and level of disclosure among patients who dropped out of HIV care.
Methods: Data was from 6 Kampala City Council HIV public clinics in Uganda. We included last seen >90 days, and traced between September 2012 and April 2016. Information collected at tracing included reasons for LTFU and HIV sero-status disclosure. Clinical data was obtained from the electronic medical records.
Results: From a total of 33850 patients registered in care, 4161 were LTFU, and 2766 were successively traced. Among traced patients, 2104(76.1%) were female, 984(35.6%) enrolled into HIV care through Option B-Plus, 1176(42.5%) through Out Patient department (OPD) and 606(21.9%) from other mechanisms.
Reasons for LTFU included structural 75.7%, psychosocial 29.5% and facility-related 11.2%. At the time of tracing, 197/662(29.8%) of the males had disclosed their HIV status compared to 542/2104(25.7%) women, (P=0.043).
Women on Option B-Plus had lower disclosure rates compared to OPD (24.6%versus 29.7%, P=0.018). HIV disclosure was low (11.1%) among women aged 15-19 years on B-Plus (see Figure).
B-Plus women spent least time in care 1.6 months (IQR:0.0, 8.9) compared to 3.3 months (IQR:0.5 - 16.9) from OPD, P<0.001. Disclosure was low among the early dropouts; with 18.7% disclosure among patients who stayed in care <6 months, 34.6% for those in care 6-12 months, and 39.8% >12 months in care.



[Disclosure among HIV positive women by age group]

Conclusions: We observed very low levels of HIV sero-status disclosure especially among young women on Option B-Plus. Strategies for disclosure during HIV care among young women on Option B-Plus are important in the global fight against HIV/AIDS.

MOPEC0619

"The co-authors of pregnancy": leveraging men's sense of responsibility and other factors to tailor male involvement interventions in antenatal and pregnancy-related services in Kinshasa

M.M. Gill[1], J. Ditekemena[2], V. Ilunga[2], F. Fwamba[3]
[1]The Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States, [2]The Elizabeth Glaser Pediatric AIDS Foundation, Kinshasa, Congo, Democratic Republic of the, [3]Programme National de Lutte contre le SIDA DRC, Kinshasa, Congo, Democratic Republic of the
Presenting author email: mgill@pedaids.org

Background: Despite efforts to improve male involvement (MI) in EGPAF-supported facilities in Kinshasa, few male partners attend antenatal care (ANC), PMTCT, and delivery services. MI has been shown to increase acceptability of and adherence to PMTCT interventions and is an entry point for partner HIV testing. The study aimed to describe barriers and facilitators to partners' attendance and identify MI interventions considered effective within a Congolese context.
Methods: This exploratory study involved two women-only and two men-only focus group discussions (FGD) conducted with 8-10 participants, in high-ANC volume facility catchment areas in Kinshasa. Pregnant women and men of reproductive age were recruited from ANC clinics and surrounding communities. Key informant interviews were conducted with purposively selected participants from health facil-

ity leadership and central government HIV and reproductive health departments. FGD and interviews took place in June 2016. Topics included factors influencing MI in ANC/PMTCT, experiences with male HIV testing and couples' ANC attendance and perspectives and recommendations on current or proposed MI interventions. Qualitative thematic analysis of barriers, facilitators and interventions was conducted using in MAXqda (V10).

Results: Thirty-five FGD participants and three key informants participated. The table lists the most promising interventions participants identified (invitation letters, service quality improvement, peer-to-peer outreach) linked to frequently reported MI facilitators and barriers. Only men identified responsibility, referring to themselves as "authors of the pregnancy," and wanting to be tested for HIV as facilitators. Receipt of clinic staff advice was the most commonly-reported facilitator. No time off work was the most commonly-reported barrier.

Most Promising Intervention Identified by Participants	Facilitating MI factors addressed by intervention	Barriers to MI addressed by intervention
Improvements to the male partner invitation letter, with content referring to men's responsibility as father, love for his family and a need to understand progression of pregnancy and expectations for delivery. HIV testing should not be specifically mentioned but addressed once at the clinic.	• Sense of male responsibility • Desire to receive counseling/ information from clinic staff • Assess partner's pregnancy or delivery • Love of wife and child • Authority conveyed by doctors	• Consider pregnancy to be the woman's domain • Men's fear of HIV testing • Men's ill-preparedness at time of delivery
Improvement to quality of ANC/ delivery services for men and couples, such as the addition of male-specific services and more inclusion of men during ANC/ delivery, expanded clinic hours, separate spaces for couples and health workers who are sensitive to couples' needs.	• Desire to receive counseling/ information from clinic staff • Assess partner's pregnancy or delivery • To be tested for HIV	• Time/work commitment • Unwelcoming facility environment for male partners • Consider pregnancy to be woman's domain • Men's ill-preparedness at time of delivery
"Expert" Peer to Peer Community Outreach, in which peers would serve as a conduit to the clinic and refer men for counseling and services, discuss importance of attending ANC and what to expect during delivery. This would provide men with opportunities to discuss pregnancy and other issues without women present.	• Sense of male responsibility • Desire to receive counseling/ information from clinic staff • Assess partner's pregnancy or delivery	• Time/work commitment • Unwelcoming facility environment for male partners • Consider pregnancy to be the woman's domain • Men's ill-preparedness at time of delivery

[MI Interventions, Facilitators and Barriers]

Conclusions: This study moved beyond an identification of MI barriers and facilitators by eliciting feedback from program recipients and planners on existing and proposed MI interventions. Men expressed responsibility for their partners' pregnancies and their unborn children. They indicated that greater information and a clinic setting more conductive to couple's needs would result in improvement in male attendance at pregnancy-related services.

MOPEC0620

Factors influencing HIV-testing practice in Zambia: a systematic review

S. Qiao[1], Y. Zhang[2], X. Li[1]
[1]University of South Carolina, Health Promotion Education and Behavior, Columbia, United States, [2]University of South Carolina, Columbia, United States
Presenting author email: shanqiao@mailbox.sc.edu

Background: HIV-testing is a critical entry-point of HIV treatment cascade especially for countries with high HIV prevalence including Zambia. There is no recent literature review to address its latest HIV-testing practices shaped by evolving government strategies and application of new testing approaches. This study aims to systematically review multi-level factors that influence HIV-testing in Zambia.

Methods: Literature was searched among six electronic datasets using the algorithm "(HIV OR "human immunodeficiency virus") AND Zambia* in [Title]". After screening, 35 empirical studies published in English in peer-reviewed journals prior to November 2016 with a focus on HIV-testing in Zambia were included. Two researchers independently extracted key information using structured summary table. The disagreements were discussed and resolved in coding process.

Results: Multi-level factors that influenced HIV-testing practices including socio-demographic characteristics, family structure and relationship, sociocultural context, health facility, and government policies. Generally, adults with higher perceived risk and higher education attainment were more likely to accept and take HIV-testing. The impacts of age and marital status were fixed and dependent on the sub-population. Family relationship was a significant factor influencing decision-making regarding HIV-testing for women and adolescents. Fear of partner reaction and lack of family support hindered women's uptake of HIV-testing service. Discussion with family was positively associated with HIV-testing among adolescents. Gender inequality, HIV-related stigma, and traditional health beliefs remained as barriers. The lay belief that knowing HIV-positive status led to rapid physical deterioration of death resulted in delayed HIV diagnosis. Trust of counsellor, confidentiality issues, quality of post-testing counselling and care, distance to clinics, supply of testing kits, training and supervision of lay healthcare workers shaped the acceptance and practice of HIV-testing. Integration of HIV-testing with immunization service for infants and home-based testing service suggested promising outcomes.

Conclusions: HIV-testing intervention needs individualized strategies for diverse populations. The success of task-shift strategy depends on appropriate training and supervision of lay healthcare workers and capacity building of health facilities. Novel HIV-testing approaches may promote uptake of HIV-testing but need to address challenges in sociocultural changes (family structure, gender equality, health beliefs) since modernization and introduction of new medicine technology in Zambia.

MOPEC0621

Rate and causes of mortality in the first 12 months of life among HIV-exposed infants in rural Nigeria: results of an adapted verbal autopsy

C. Isah[1], M. Bathnna[1], G. Nwanne[1], S. Erekaha[1], N.A. Sam-Agudu[1,2]
[1]Institute of Human Virology Nigeria, International Research Center of Excellence, Abuja, Nigeria, [2]Institute of Human Virology, University of Maryland School of Medicine, Epidemiology and Prevention, Baltimore, United States
Presenting author email: cisah@ihvnigeria.org

Background: At 71.2/1,000, Nigeria has one of the highest infant mortality rates (IMR) globally. Leading causes of infant mortality in sub-Saharan Africa are preterm birth, pneumonia, birth asphyxia, diarrhea, malaria and HIV/AIDS. Little is known about HEI mortality in Nigeria, especially in rural areas. We present data on HEI mortality from a prospective PMTCT study in rural North-Central Nigeria.

Methods: Perinatal and fetal/infant mortality data was collected from mothers, relatives and healthcare workers using a 21-item mini verbal autopsy (VA) form. VA was conducted within 2-4 weeks of loss; in English or local language by trained multilingual research staff. Data on miscarriages at < 20 weeks gestational age (GA)), stillbirths (≥20 weeks GA), neonatal (1-28 days) and postneonatal (>28 days-12 months) deaths were abstracted. IMR was calculated as number of infant deaths per 1,000 live births. VA data were systematically organized into attributable cause-of-death categories based solely on data available.

Results: Data from 445 women revealed 408 (89.7%) livebirths and 455 products of conception. By 12 months post-delivery, there were 75/455 (16.5%) fetal and infant losses, of which 37/75 (49.3%) were live-born infants. Approximately 50% of fetuses/infants deceased were delivered at a health facility; 43% at home, and 7% elsewhere. IMR for the 408 live births was 90.7/1,000. Table 1 presents detailed results.

Timing/Cause of Death		n	%
Miscarriage:9.3% of losses (N=7)	Not otherwise specified	6	85.7
	Known (anencephaly)	1	14.3
Stillbirth: 41.3% of losses (N=31)	Not otherwise specified	28	90.3
	Known (maternal infection, labor complications)	3	9.7
Neonatal: 25.3% of losses (N=19)	Not otherwise specified	5	26.3
	Birth asphyxia	5	26.3
	Other known causes (hyperbilirubinemia, SIDS, infection)	9	47.4
Post-neonatal: 24.0% of losses (N=18)	Not otherwise specified	7	38.9
	Known (diarrhea, febrile illness, infection, electrolyte imbalance, poisoning)	11	61.1

[Causes of Fetal/Infant Losses among HEI (N=75)]

Conclusions: IMR among rural HEI in our study was higher than national, however our small sample size warrants cautious interpretation. Nevertheless, crude mortality among study HEI appears high, despite targeted Maternal-Child Health programming for this population. Most in utero deaths could not be assigned an attributable cause. Birth asphyxia was the single most common attributable cause of neonatal death. Neonatal death accounted for more than 50% of infant deaths. To improve HEI infant survival in rural areas, general obstetric, perinatal and neonatal care and relevant documentation has to be improved.

MOPEC0622

Empowering rural women to prevent mother to child transmission (PMTCT) of HIV through WORTH

C. Isiugo[1], K. Oyeniyi[2], S. Ojemuyide[1]
[1]Pact Nigeria, Programs/Monitoring and Evaluation, Yenagoa, Nigeria, [2]Pact Nigeria, Programs, Yenagoa, Nigeria
Presenting author email: koyeniyi@pactworld.org

Background: The uptake of PMTCT and ANC services have been affected by barriers such as poor health seeking behavior, poverty and other factors at community level in Bayelsa, Nigeria (WHO, 2007) Researches have shown that women and children are the most vulnerable groups in sub Saharan Africa. For example, women and girls are less likely to receive formal education, have generally low income and at higher risk of HIV infection and death than men. Evidence has also shown that women made significant contributions to the overall wellbeing of their families. This paper reviews the role Women Empowerment Program (WORTH) plays in providing access to ANC/ PMTCT services for women in Southern Ijaw, Bayelsa, Nigeria.
Methods: The WORTH model is tied to the community based PMTCT project designed to increase PMTCT uptake, prevent new pediatric HIV infections and mobilize community and government support for prioritizing and sustaining PMTCT in Bayelsa. This intervention focuses on promoting health care seeking behaviors among women of reproductive age (15 - 49 years). WORTH aims to serve people whose fragile economic position prevents them from meeting their basic needs. 3 WORTH literacy volunteers,15 management committees and 85 WORTH members have been trained and participates the group savings and loans.
Results: Preliminary findings have shown that WORTH groups despite the prevailing harsh economic situation, have started weekly mandatory savings and have contributed for more than 10 weeks. These self-contributions assist group members with loans for small scale businesses with little interest as low as 5% per month. Women acquired shared understanding on improved income generation and developed a savings culture to pay for ANC/PMTCT services. Available records show increase in uptake of PMTCT/ ANC services by 5 pregnant women resulting from referrals in one of the communities - Anyama, Ijaw. Integrating WORTH into community based prevention of mother to child transmission (PMTCT) has a strong potential of improving uptake of PMTCT/ANC services among women of reproductive age.
Conclusions: Onsite mentoring support is required to ensure women channel and utilize a certain percentage of their savings to access PMTCT/ ANC services. Health facility records will be strengthened to showcase evidence based intervention.

MOPEC0623

Mother to child HIV transmission in adolescents and young women: findings from an 18-month prospective observational cohort of a nationally representative sample of mother-infant pairs, Zimbabwe, 2013-2014

A.B. Burrage[1], A. Mushavi[2], R.W. Shiraishi[1], B.A. Barr[3], G. Shambira[4], J. Nyakura[4], S. Balachandra[3], P.H. Kilmarx[1,3], T.-H. Dinh[1]
[1]US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV & TB, Atlanta, United States, [2]Ministry of Health & Child Care of Zimbabwe, AIDS & TB Department, Harare, Zimbabwe, [3]US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV & TB, Harare, Zimbabwe, [4]University of Zimbabwe, Division of Community Health, Harare, Zimbabwe
Presenting author email: wcx2@cdc.gov

Background: Mother-to-child transmission (MTCT) of HIV accounts for 90% of pediatric HIV cases. Mother-to-child transmission is observed to be higher in adolescents than older mothers; however, understanding of the reasons is limited. We assessed 18-month cumulative MTCT risk and prevention service coverage among HIV-positive adolescents aged ≤19 years and young women aged 20-24 years.
Methods: We analyzed data from a prospective cohort that used multistage sampling to recruit a nationally-representative sample of 6051 mothers and their 4-12 week-old infants from 151 immunization clinics in Zimbabwe from February to August 2013. HIV-exposed infants were followed until HIV diagnosis, death, or age 18 months. Infant HIV infection was defined by positive HIV DNA polymerase chain reaction test. We analyzed data collected from maternal interviews, child-health cards, and infant HIV test results. Findings were weighted and adjusted for complex survey design and non-response. Data were analyzed with STATA version 14.1.
Results: Among mothers, 16.3% were adolescents and 29.8% were young women. HIV prevalence was 7.5% (95% confidence interval [CI]: 6.1%-9.3%) and 14.8% (95% CI: 12.8-16.9), respectively. In both age groups, 95% of mothers had ≥1 antenatal care (ANC) visit, 97% had ≥1 HIV test, and 99% knew their HIV status. No difference in gestational age at first ANC visit was found. A higher proportion of HIV-positive adolescents, compared to HIV-positive young women, reported no ARV use during pregnancy (20.6%, 95% CI: 12.6-31.7 vs. 13.5%, 95% CI: 9.9-18.1). Infant ARV prophylaxis did not differ between adolescents and young women (95%). The cumulative 18-month MTCT was 12.1% for adolescents and 7.5% for young women; however, these values were not significantly different (p=0.22). At age 4-8 weeks, the first of six timepoints measured, MTCT was 8.4% for adolescents and 3.2% for young women (p=0.056).
Conclusions: Uptake of maternal ARVs in pregnancy is lower in adolescents than young women. Although 18-month MTCT is not significantly higher among adolescents compared to young women, our findings suggest a trend towards higher early MTCT among adolescents. Targeted approaches to increase ARV use among pregnant adolescents could further reduce MTCT in this vulnerable age group.

MOPEC0624

Importance of antenatal care attendance and mother's awareness of status on early childhood HIV testing in a cohort of female sex workers living with HIV in Cameroon

A. Rao[1], S. Schwartz[1], S. Billong[2], G. Fouda[3], F. Ndonko[3], I. Njindam[1], D. Levitt[4], A. Bissek[5,6], O. Njoya[5], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]University of Yaounde, Yaounde, Cameroon, [3]CARE Cameroun, Yaounde, Cameroon, [4]CARE USA, New York, United States, [5]University of Yaounde, Faculty of Medicine and Biomedical Sciences, Yaounde, Cameroon, [6]Ministry of Public Health, Division of Operational Research in Health, Yaounde, Cameroon
Presenting author email: arao24@jhu.edu

Background: Female sex workers (FSW), many of whom are mothers, are disproportionately affected by HIV and have limited access to treatment. Testing for HIV-exposed infants is crucial in monitoring for and reducing vertical transmission. This study explores associations between antenatal care attendance(ANC) and early childhood HIV testing among FSW in Cameroon.
Methods: This is a secondary analysis of a cross-sectional study of 2272 FSW in Cameroon between Dec/2015-Dec/2016. Women were included in these analyses if they were living with HIV and had ≥1 child. Characteristics of FSW by ANC attendance were compared using Fisher's exact tests. Ordered logistic regression was used to model proportional odds ratios for number of a woman's children who had been tested for HIV before age 5, categorized as none, some, or all tested.
Results: A total of 481 FSW living with HIV who had ≥1 child were included with a median age of 35(IQR 30-41). 18% of FSW did not report any form of contraception, with those attending ANC being more likely to use long-acting reversible contraceptives than those not attending(p=0.005). Nearly 70% reported none of their children had been tested for HIV before age 5(326/481), and 17(3.5%) reported one or more of their children had been diagnosed with HIV. ANC (OR 3.49[1.66, 7.38]), knowledge of HIV status (OR 3.94[2.62, 6.16]), and higher education (OR 3.94[2.62, 6.16]) were all independently associated with increased odds of women having a greater number of children tested before age 5.

Proportional odds ratios were estimated using ordered logistic regression. aEighteen women were excluded from analysis due to missing data on proportion of children tested before age 5 (n=4) or not applicable pregnancy intentions (n=13).*Statistically significant at p <0.05; **p <0.01; ***p<0.001. Bolded results represent results that are statistically significant at least at the p<0.05 level.

[Proportion. odds ratios of children tested for HIV]

Conclusions: While exact timing of mother's diagnosis was unknown, vertical transmission of HIV was high and testing among children low. ANC and promotion of mother's health were associated with better testing outcomes. For women at high risk of HIV and for whom engagement in the health care system low, finding unique strategies to promote and ensure ANC is essential.

Presenting author email: trisha.ramraj@mrc.ac.za

Background: Adolescents and young women (15-24 years) contribute to 20% of all new HIV infections globally and seroconvert 5-7 years earlier than their male peers, making them a high-risk population for mother-to-child transmission of HIV (MTCT). In the context of global goals to eliminate MTCT the differential risks of MTCT amongst adolescents, young women and adults was quantified using nationally representative data from South Africa, where HIV prevalence amongst women 15-24 years is 11.4%. We previously reported MTCT amongst adolescents versus other women, without disaggregating other women into young (≤24 years) versus older.
Methods: A secondary analysis was performed using data collected from three facility-based, nationally representative cross-sectional surveys conducted in 2010, 2011-12 and 2012-13 in South Africa. Mothers with infants aged 4-8 weeks receiving their six week immunization, were enrolled and interviewed to collect data on maternal socio-demographics, antenatal and postnatal care and uptake of prevention of MTCT services. Infant dried blood spots were collected and tested for HIV exposure and infection. Weighted analysis, accounting for sample ascertainment, South African livebirths, and survey design was conducted to determine early MTCT risk amongst adolescents (≤19 years), young women (20-24 years) and adults (≥25 years).
Results: Data from 4814 adolescents, 9190 young women and 16525 adults were analysed. Early MTCT percentage (95% confidence interval, with a p-value for comparison with adults), among adolescents, young mothers and adults, respectively, was 7.2% (4.1-12.1,p=0.040), 3.6% (2.4-5.5,p=0.538) and 3.1% (CI:2.4-3.9) in 2010; 5.8% (3.3-10.1,p=0.031), 3.5% (2.3-5.3,p=0.079) and 2.1% (1.5-2.9) in 2011-12; 6.8% (3.4-13.4,p=0.034), 4.4% (2.8-6.7,p=0.008) and 1.7% (1.1-2.5) in 2012-13. Pooled analysis using data from all three surveys revealed significant associations between early MTCT and age ≥25 years (adjusted odds ratio, AOR: 0.04 (0.01-0.21,p< 0.0001) and gestational age at first ANC booking: every one week delay in gestational age at first ANC booking increased early MTCT by 9% (AOR 1.09 (1.01-1.18,p=0.025).
Conclusions: In a high HIV prevalence setting like South Africa, mother's ≤24 years have higher early MTCT compared with mother's ≥25 years, and the MTCT difference between adult and adolescent/young mothers seemed to increase with time. Targeting women ≤24 years is critical to achieve elimination of MTCT.

MOPEC0626

Prevention of mother to child transmission of HIV in Tanzania: the case of pregnant adolescents in Morogoro region

H. Lila[1,2]

[1]Hope Centre for Children, Girls and Women in Tanzania, Dar Es Salaam, Tanzania, United Republic of, [2]Tanzanian Training Centre for International Health, Morogoro, Tanzania, United Republic of
Presenting author email: 2658808@myuwc.ac.za

Background: In Tanzania youth aged 15 - 24 years account for 60 percent of new HIV infections. Adolescents age 15-19 have higher birth rate of 116 per 1000. HIV prevalence for women who attended antenatal care is 6.9%. The burden of HIV extends deeply to children having children. HIV contributes to a high portion of maternal deaths in Tanzania. Transmission rates of HIV from mother to infant is 8.6%. In Morogoro 38.5% of adolescents age 15-19 have begun child bearing and the prevalence of HIV infections is 3.8%. The objective of this study is to show the need of PMTCT amongst pregnant adolescent in rural, Morogoro.
Methods: Mixed research approach. Qualitative research approach used in order to get in-depth interview from the 5 health centre selected. The study reached 50 adolescents mothers. In quantitative research approach, the study used 2016 Tanzania Demographic and Health Survey and 2016 Tanzania National Road Map Plan II.
Results: Some participants didn't know about the PMTCT services and only got tested for HIV during the first clinic visit. Over half of the participants said they came late for the clinic because of the traditional and norms that limits early clinic attendance, no friendly services and lack of knowledge to prevention services. The TDHS shows 38.5% adolescents age 15-19 have begun childbearing; 9.9% of 15-19 adolescents are pregnant with their first child and that teenagers with no education and those in the lowest income tend to start childbearing earlier than others and this increase risk of HIV. TNRMPII suggests that male involvement in PMTCT is very low and comprehensive knowledge of HIV prevention is still low among adolescents.
Conclusions: This study revealed important unmet prevention needs for female adolescents in Morogoro. Adolescent requires access to services to prevent HIV. Adolescents need to be educated; awareness of the importance of educating girls should be priority and provided in the communities. Safe corners and mobile services is urgently needed. Engagement of boys and men in sexual health and rights initiatives is key for prevention.

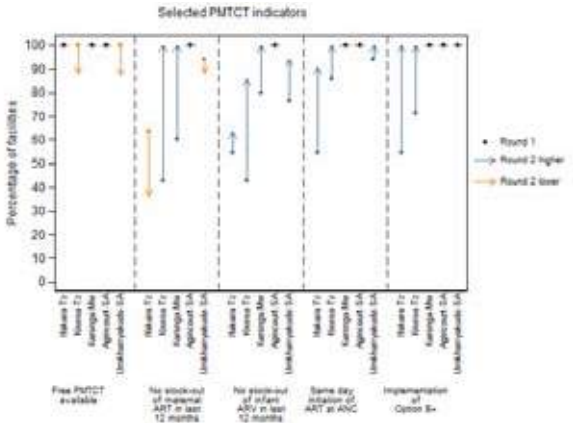
Assessing the implementation status of programmes for the prevention of mother to child transmission of HIV in three sub-Saharan african countries between 2013 and 2016: findings from sequential heath facility surveys

J. Renju[1], J. Ambrie[2], P. Mee[2], J. Todd[1], E. Geubbels[3], M. Urassa[4], M. Crampin[5], N. Chimbindi[6], X. Gomez-Olive[7], B. Zaba[1], M.A. Nyamhagatta[8], A. Wringe[1]

[1]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [4]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [5]MEIRU, Lilongwe, Malawi, [6]AHRI, Durban, South Africa, [7]Witwatersrand, Johannesburg, South Africa, [8]Ministry of Health, Community Development, Elderly and Children, Department of Preventive Services, Dar es Salaam, Tanzania, United Republic of
Presenting author email: mukomen@yahoo.com

Background: In 2012, the World Health Organisation recommended the immediate initiation of anti-retroviral therapy (ART) for all HIV-positive pregnant women (Option B+). Countries adopted different roll-out approaches: Malawi, an early adopter, implemented it across the whole country in 2011; Tanzania, a mid-term adopter, chose a staggered scale-up beginning in 2013 at the tertiary level then decentralising to peripheral facilities. South Africa, a late adopter, also used a staggered approach starting in 2015, but implemented one province fully at a time. We aimed to assess the implementation status of these prevention of mother-to-child transmission (PMTCT) programmes.
Methods: Two rounds of health facility surveys took place in 43 health facilities situated within health and demographic surveillance sites in Karonga, Malawi (n=6), Ifakara and Kisesa, Tanzania (n=14) and Hlabisa and Agincourt, South Africa (n=23). A standardised questionnaire was used in 2013/2014 (round 1) and 2015/2016 (round 2). Descriptive statistics were used to compare key indicators of PMTCT implementation across the rounds.
Results: Overall, 43 (96%) of facilities offered PMTCT in round 1; by round 2, 100% offered Option B+. The proportion of facilities offering free PMTCT, reporting no ART stock-outs and offering same-day ART initiation increased or remained at 100% across the rounds and in all sites (Figure 1).



[Figure 1: Changes to selected PMTCT indicators]

However, in Tanzania and South Africa, some facilities imposed charges for PMTCT services and stock-outs still occurred. In Tanzania, same-day ART initiation at antenatal clinics was not fully implemented.
Conclusions: Regardless of the strategy chosen for Option B+ implementation, all countries demonstrated improvements in service delivery illustrated by 100% achievement of key PMTCT indicators in many settings. However sub-optimal implementation, particularly in charging for "free" services or in ensuring ART supplies jeopardizes access and availability. As countries strive for universal access, care needs to be taken to consolidate these impressive gains.

MOPEC0628

Efficacy of option B-plus in a cohort of mothers with high retention in averting paediatric transmission: low rates of transmission but high proportion of unreported outcomes

B. Castelnuovo, F. Mubiru, I. Kalule, S. Nakalema, H. Mackline, A. Kiragga
Infectious Diseases Institute, Research, Kampala, Uganda
Presenting author email: bcastelnuovo@idi.co.ug

Background: Since 2012, the WHO recommend start of lifelong ART constituted by TDF+FTC/3TC+EFV for all HIV-positive pregnant and breast feeding women (Option B-plus). There is limited information on the infants' sero-status due to poor documentation and high rates of lost to program, up to 68% in sub-Saharan Africa. In this analysis we describe proportion of early and late transmission in a cohort of mothers with high (92%) retention.
Methods: At the Infectious Diseases Institute, Kampala, Uganda, women found to be pregnant are referred to the HIV-Sexual Reproductive Health integrated clinic to receive both HIV and antenatal care. We included women enrolled from January 2012 to August 2014 with a follow-up extended to August 2016, and retained up to the end of the pregnancy. We extracted data on baseline demographics and clinical information. Infants HIV-DNA PCR tests at week 6, month 6 and 18 were traced in the clinic files.
Results: Seven hundred women were included, median age 34 years (IQR: 26-35), 36.3% in WHO stage 3 /4, median CD4 count was 447(IQR:301-651)cells/μL; 76% joined during the 1st or 2nd trimester, the parity was >2 for 36.3%, and 73.3% were already on ART for a median time of 28(IQR:10-57) months; 48% of the infants were female, median weight was 3.2 Kg (IQR:2.5-3.5).
Table 1 shows the sero-status of the babies; 22 (3.1%) infants died, all with unknown sero-status; 3 tested positive at week 6, and 1 additional at month 12 and 18. Two of the mothers of the 4 HIV-positive infants were ART-naïve at the time of the pregnancy.

Time of HIV test	Total number	N(%)Positive	N(%) Negative	N(%) Unknown
6 weeks	700	3 (0.4)	562 (80.3)	135 (19.2)
12 Months	675	4 (0.6)	469 (69.5%)	202 (29.9)
18 Months	655	4 (0.6)	437 (66.7)	216 (32.7)

[Serostatus of babies at week6, month 12, month18]

Conclusions: We report very low documented HIV transmission comparable with those reported in clinical trials settings (PROMISE study, 13 sites in sub-Saharan Africa: 0.6% at month 12); however demonstrating the efficacy of Option B-plus in terms of averted transmission in routine settings is challenging since high proportion of infants don't have a documented HIV tests due to lack of traceable documentation, or mothers attending clinic visits without their babies.

Presenting author email: aajibola@cihpng.org

Background: The use of family planning services is reportedly low among HIV positive women in Nigeria. Traditionally, HIV and Family planning services function as parallel programs even in the same hospital, resulting in missed opportunities for family planning services uptake by People Living with HIV (PLHIV). In order to increase use of family planning services among PLHIV, Centre for Integrated Health Programs, Nigeria with funding from Centre for Disease Control (CDC) implemented Family Planning/HIV (FP/HIV) integration program in Benue and Kaduna States, Nigeria. The aim of this study was to assess the utilization of family planning methods amongst People Living with HIV (PLHIV) in Kaduna and Benue States, Nigeria.
Methods: Using a pre-defined criteria, a structured questionnaire was used to assess 187 health facilities where100 health facilities were selected. 349 trained HIV counsellors were trained on FP methods focusing on short term methods (pills,injectables) Long Acting Reversible Contraceptives (LARC) and integration of services. 200 PLHIVs were selected using purposive sampling to create demand for family planning. In the HIV clinics, spaces for family planning service were created and equipped with instruments and FP commodities. FP services were integrated into HIV Testing Services (HTS), the ART clinic and Prevention of Mother to Child Transmission of HIV (PMTCT) services. Tools to capture data for FP methods were developed and distributed to the health facilities. Data was collected between April and September, 2016. The collected data was collated and compared with the baseline data.
Results: Compared to 172 PLHIV accessing FP methods at baseline, a total of 17,009 (9,888%) PLHIV were reached with various FP methods in the HIV clinics within a space of 6months of data collection. Out of which 11677(68.7%) women accepted short term methods while 5332 (31.3%) women accepted long term methods.
Conclusions: This finding revealed integration of Family planning into HIV services greatly improves access and uptake of Family Planning services among PLHIV.

MOPEC0630

An economic evaluation of the integrated approach for triple elimination of mother to child transmission of HIV, hepatitis B and syphilis

L. Zhang[1], Y. Tao[1], J.V. Woodring[2], M. Nagai[2], L. Ferradini[3], Y.-R. Lo[4], N. Ishikawa[4]
[1]Monash University, School of Public Health, Melbourne, Australia, [2]World Health Organization, Regional Office for the Western Pacific, Reproductive, Maternal, Newborn, Child and Adolescent Health, Division of NCD and Health through Life-Course, Manila, Philippines, [3]WHO Cambodia, Phnom Penh, Cambodia, [4]World Health Organization, Regional Office for the Western Pacific, HIV, Hepatitis and Sexually Transmitted Infections Unit, Division of Communicable Diseases, Manila, Philippines
Presenting author email: ferradinil@who.int

Background: The prevention and ultimate elimination of mother-to-child transmission (EMTCT) of HIV, hepatitis B and syphilis share a common platform of maternal and child health services and related interventions. An integrated framework for triple elimination of mother-to-child transmission of HIV, hepatitis B and syphilis in Asia and the Pacific is under development aiming at proposing an integrated and coordinated approach to achieve elimination in an efficient and sustainable manner. The study aims to develop an economic evaluation tool to assess the cost-effectiveness of the integrated approach.
Methods: Based on existing frameworks for the EMTCT for each individual infection, we constructed an integrated framework that combines infection prevention procedures with routine antenatal care (ANC). The integrated approach provides

the same services to pregnant women and exposed children. We then evaluated the potential reduction in the investment of the integrated approach as a result of resource pooling and improvements in service coverage and coordination, based on a decision tree analysis. We further conducted an economic evaluation to assess the cost required to avert one infection in exposed infants. The tool was constructed using Microsoft Excel and ratified on simulated epidemiological data that resemble epidemics in Asia-Pacific countries.
Results: The tool provided detail estimates on the number of pregnant women and children on each stage of continuum of care. Based on this, it demonstrated that coverage of ANC and provision of screening are crucial to the reduction of mother-to-child transmission of these infections. The integrated approach substantially reduces 30-55% personnel costs and maximizes the screening coverage by allowing pregnant women to be screened for all three infections in a single antenatal visit. The integrated approach was shown to be cost-saving in most simulated cases. Sensitivity analyses on the model parameters indicated the evaluation tool was robust and findings were reliable.
Conclusions: We developed a feasible and reliable economic evaluation tool and demonstrated the integrated approach using maternal, perinatal and postnatal care as a platform for triple elimination of HIV, hepatitis B and syphilis is highly cost-effective.

MOPEC0631

Prevention of mother to child transmission of HIV in an urban area of the USA: are we doing too much?

N. Ellenberger[1], C. Griffith[1], K. Ferrer[1], N. Hussein[1], A. Matulich[2], N. Chamma[2], N. Rakhmanina[1,2,3]
[1]Children's National Medical Center, Washington, United States, [2]George Washington University, Washington, United States, [3]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States
Presenting author email: nellenbe@childrensnational.org

Background: Special Immunology Services (SIS) at Children's National Medical Center serves the majority (>95%) of perinatally HIV-exposed infants (HEIs) in the high HIV prevalence (2%) metropolitan Washington, DC area, USA. The study aimed to analyze the current approaches to and outcomes of prevention of mother-to-child transmission (MTCT) in the DC area.
Methods: This was a retrospective cohort analysis of SIS HEIs referred for HIV testing, care and treatment. We collected maternal demographics, antiretroviral treatment (ART) during pregnancy and delivery, HIV viral load (VL) pre-delivery and delivery type; infant data included post-partum ART prophylaxis and final HIV status. Descriptive statistics were used for analysis.
Results: Data were abstracted from 262 records of 328 HEIs referred to SIS during 2013-2015. Mean maternal age was 30 years (range 15-48) and 94% (n=245) were Black. The majority (96%; n=252) received ART during pregnancy. The most frequently used backbone was fixed dose combination (FDC) of zidovudine+lamivudine (35%; n=89) and emricitabine+tenofovir (41%; n=103), with lopinvair/ritonavir (37%; n=92), and atazanavir/ritonavir (34%; n=86). A small proportion of mothers took novel ART including rilpivirine (10%; n=24), dolutegravir (0.4%; n=1) and raltegravir (4%; n=9). A majority (75%; n= 196) of mothers received intravenous zidovudine during labor and 98% (n=258) of infants received zidovudine prophylaxis postpartum. Only 15% (n=40) of mothers were considered high-risk based on high (>1000 copies/mL) or unknown pre-delivery VL; 13 HEIs (5%) received triple and 13 HEIs (5%) dual ART prophylaxis. More than half of all deliveries (58%; n=152) were conducted via C-section; 111 (73%) of which occurred in low-risk mothers with mean VL < 20 copies/mL (range 0-767). One infant (0.38%) was confirmed HIV-infected and initiated on ART.
Conclusions: Low MTCT risk was observed among the majority of HEIs; however, a majority of mothers (75%) received intravenous zidovudine and more than half (58%) had a C-section. Evaluation of indications for the C-section is ongoing to identify whether it was based on MTCT risk assessment. Despite national USA guidelines recommending intravenous zidovudine in labor for high-risk deliveries only, we observed frequent use of intrapartum zidovudine prophylaxis within our cohort of HEIs in urban settings in the USA.

MOPEC0632

Retention of mother/baby pairs along the PMTCT cascade: a systematic review and meta-analysis of current evidence of options B and B+ strategies

L.N. Ahoua, S. Arikawa, R. Becquet, F. Dabis
ISPED, INSERM U1219, Bordeaux, France
Presenting author email: laurence_ahoua@yahoo.fr

Background: Since 2010, a growing number of sub-Saharan African (SSA) countries have revised their national PMTCT guidelines to include either Option B or Option B+ to phase out Option A. A comprehensive PMTCT program must guarantee follow-up, care and antiretroviral treatment (ART) / prophylaxis for HIV+ mothers and their exposed infants until 18 months post-partum.
This study aims to systematically review published literature to estimate retention and lost-to-follow up (LTFU) rates of mother/infant pairs from maternal ART initiation to Early Infant Diagnosis (EID) and to explore reasons of poor retention under B/B+ strategies.
Methods: We searched electronic databases for relevant quantitative and qualitative studies, published between January 2010 and December 2016, reporting retention and/or LTFU of mother/infant pairs as a primary outcome. To increase sensitivity, we reviewed gray literature databases and reports. The review was performed according to the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) guidelines. Quality of evidence was assessed using the GRADE strategy. Heterogeneity was appreciated by the I_2 statistic.
Results: Of the 96 records identified, 25 articles were included (analysis in progress), the majority being from sub-Saharan Africa. For HIV+ pregnant and breastfeeding women, pooled retention estimates were 81% [95%CI: 73-87; I_2=88%] at 6 months and 70% [95%CI: 62-77; I_2=98%;] at 12 months on ART. Pooled estimates of LTFU were 20% [95%CI: 16-25; I_2=85%] at 6 months and 17% [95%CI: 3-35; I_2=98%] at 12 months on ART. Pooled proportion of HIV-exposed infants tested for HIV by PCR at 6-8 week post-partum was 66% [95%CI: 57%-75%; I_2=86%]. Frequent reported reasons for poor retention were initiation of ART on the same day as HIV diagnosis, facility resource constraints (e.g. long waiting hours, staff and drug shortages) and high-volume health facilities.
Conclusions: Retention of mother/infant pairs under Option B/B+ is affected at each step of the PMTCT care cascade, especially after birth. PMTCT national and sub-national programs should be aware of the potential negative impact of low retention rates on the effectiveness of option B/B+ in reducing HIV transmission. Enhanced patient-oriented pre-ART counseling, referral to smaller sites for ART initiation should be considered to maximize follow-up of the mother/infant pairs.

MOPEC0633

Induced abortion, migration and HIV: an analysis of migrants from sub-Saharan Africa living in Île-de-France, France

F.B. Pilecco[1], A. Ravalihasy[2], A. Guillaume[2], A. Desgrées du Loû[2], the Parcours Study Group
[1]Universidade Federal de Minas Gerais, Department of Preventive and Social Medicine, Belo Horizonte, Brazil, [2]Centre Population et Développement (UMR 196 - Université Paris Descartes/IRD), Paris, France
Presenting author email: a.ravalihasy@ceped.org

Background: Migration can strongly affect fertility due to adaptation to new socioeconomic and cultural context. The aim of this study was to examine abortion practice in regard to migration in women living with HIV/Aids (WLHA) and women not living with HIV/Aids (WNLHA).
Methods: Data analyzed came from the ANRS Parcours study, a retrospective life event survey conducted in health facilities with two groups of migrant women born in sub-Saharan Africa and living in Île-de-France: WLHA (HIV group) and women attending primary care centers (reference group). Association between migration and induced abortion was evaluated through Generalized Estimating Equation in unadjusted and adjusted models. Adjustment considered variables linked to women (age, level of education and practice of religion at the survey) and to the pregnancy (before/after migration, age at pregnancy, contraceptive use at the beginning of pregnancy, intendedness, type of relationship and history of previous abortions). A clustered chi square was used to evaluate association between intendedness of pregnancy and migration.
Results: A total of 1,822 pregnancies at HIV and 1,377 at reference groups were analyzed. In the HIV group, 22.8% of pregnancies occurred before and 16.1% occurred after migration were ended by induced abortion, same situation for 15.6% and 11.0% of pregnancies in the reference group. These proportions differed for HIV and reference groups, both, before (p=0.010) and after (p=0.012) migration. In both groups, probability that a pregnancy was ended by abortion decreased after migration in unadjusted analysis (HIV group: OR 0.66, CI95% 0.51-0.85; reference group: OR 0.59, CI95% 0.42-0.84).

However, after the inclusion of intendedness of pregnancy, this association was undone (HIV group: OR 0.82, CI95% 0.56-1.19; reference group: OR 1.52, CI95% 0.91-2.54). For both groups, there is a statistically significant decrease of unplanned and unwanted pregnancies after migration.
Conclusions: Although the determinants of abortion are virtually the same for WLHA and WNLHA, its practice is more frequent among the firsts, and it is especially motivated by their greater social and programmatic vulnerability. After migration in France, abortion practice decreases among African sub-Saharan women, due to a decrease of unplanned and undesired pregnancies, either in WLHA or WNLHA.

MOPEC0634

Maternal health and ART use at 4-26 weeks postpartum in Option B+ in Malawi

M. Landes[1,2], M. van Lettow[2], E. Schouten[3], H. Phiri[3], J.J. van Oosterhout[2], A. Jahn[4,5]
[1]University of Toronto, Department of Family and Community Medicine, Toronto, Canada, [2]Dignitas International, Malawi, Malawi, [3]Management Sciences for Health, Malawi, Malawi, [4]Ministry of Health, Department of HIV/AIDS, Malawi, Malawi, [5]I-TECH, University of Washington, Seattle, United States
Presenting author email: mclandes@gmail.com

Background: The PMTCT Option B+ rationale proposed that lifelong ART reduces mortality and morbidity in pregnant/breastfeeding HIV-infected women. We report factors associated with maternal health of a cohort of HIV-infected women at 4-26wks postpartum at enrollment in the National Evaluation of the Malawi PMTCT Programme (NEMAPP).
Methods: In a cross-sectional study, structured interviews collected socio-demographics, ART use, and self-reported health status and function (ie.Karnofsky scale). We measured BMI, CD4 and HIV1 RNA for intensified clinical monitoring in a nested cohort.
Results: Of1307 Option B+ women, most were 6-12wks postpartum (n=879;67.3%) and on ART (n=1151;88.1%).
For self-reported health status at ART initiation, 171 (13.1%) women had minor illness and 51 (3.9%) major illness; most reported improved health status at study enrollment (155/171 (90.6%) and 47/52 (90.4%), respectively).
Of the 580 in the nested cohort, the following functional health status was measured at enrollment: 545 (94.0%) normal, 21 (3.6%) minor illness not affecting normal activities and 4 (0.7%) major illness requiring daily assistance. In the 3 months before enrollment, women reported the following conditions: malaria (n=53;9.1%), pneumonia (n=32;5.5%), diarrhea (n=40;6.9%), TB (n=11;1.9%) and hospitalizations (n=7;1.2%). Twenty-six(4.5%) women had BMI< 18.5, 326 (56.2%) had a CD4>500 and 417 (71.9%) had viral loads< 50 copies.
More women on ART reported normal functional health than women who stopped ART (95.6% vs 87.5%, p< 0.001), and more women with CD4 >500 reported normal functional health than those with CD4 < 500 (97.2% vs 92.8%, p=0.02). No associations were seen between ART status or CD4 count and recent malaria, TB, pneumonia, diarrhea or hospitalization.
In multivariable analysis, poor functional health was associated with CD4< 500 (aOR2.6,p=0.03) when controlled for ART status and duration of known HIV-status.
Conclusions: Overall, women had low mortality and morbidity at 4-26 weeks postpartum consistent with increased ART uptake in asymptomatic women via Option B+. ART use was high amongst this cohort and ART was associated with improved self-reported health status, affirming the rationale for implementing Option B+ in Malawi. Further research should explore maternal health and ART use over time to inform long-term benefits of Option B+.

MOPEC0635

Retention and viral suppression of newly diagnosed and known HIV-positive pregnant women on Option B+ in Kenya

L. Abuogi[1], E. Akama[2], A. Nimz[3], C. Blat[4], C. Cohen[4], P. Oyaro[2]
[1]University of Colorado, Denver, Pediatrics, Aurora, United States, [2]Kenya Medical Research Institute, FACES, Research Care and Training Program, Kisumu, Kenya, [3]University of Colorado, Denver, School of Medicine, Aurora, United States, [4]University of California, Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States

Background: Kenya introduced continuous antiretroviral treatment (ART) for all pregnant women living with HIV (Option B+) in 2014. We describe the uptake of viral load (VL) testing and outcomes, comparing newly diagnosed HIV positive (NP) and known positive (KP) pregnant women in western Kenya.
Methods: This is a retrospective cohort study among 164 HIV-positive pregnant women presenting for antenatal care (ANC) at five clinics September to November 2014 and followed through February 2016. Virologic testing was conducted per Kenyan National Guidelines for pregnant women six months after (ART) initiation or six months from last VL if already on ART. KPs (n=92, defined as women with HIV diagnosis prior to current pregnancy) were compared to NPs (n=72) regarding virologic suppression and retention in care.
Results: At first ANC visit, NP were younger (24.2 years (SD 4.6) vs. 28.2 years (SD 5.6), p<0.001) compared to KP (Table 1). The majority of NP (96%) were initiated on Option B+ while over half of KP (58%) started ART for clinical/immunological criteria (p<0.0001). KPs were more likely than NPs to have a VL performed following guidelines (64% vs. 33%; p< 0.001). Among those tested, virologic suppression was high in both groups (92% KP vs. 100% NP; p=0.31). More KPs (83%) vs. NPs (66%) remained active in care at end of the follow up (p=0.02). Uptake of infant testing was higher among KP (87%) vs. NP (69%) (p<0.01). Two (2%) infants were HIV infected at six weeks, both from newly diagnosed mothers (p=0.15).
Conclusions: Women newly diagnosed with HIV during pregnancy show poorer uptake of VL and worse retention in care than those diagnosed prior to pregnancy. Elimination of mother-to-child transmission targets will require a greater focus on women newly diagnosed with HIV in pregnancy.

MOPEC0636

Food insecurity and intimate partner violence among HIV-infected pregnant women in Western Kenya

M.A. Onono[1], S.M. Collins[2], G.O. Boateng[2], P.N. Wekesa[1], S.L. Young[2]
[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]Northwestern University, Department of Anthropology, Chicago, United States

Background: Potential interactions between pregnancy, food insecurity (FI), intimate partner violence (IPV) and HIV have not been well characterized. The aim of this study was to explore associations between FI and IPV among a mixed cohort of HIV infected and uninfected women in pregnancy. We hypothesized that FI would be associated with IPV, probable depression, adverse birth outcomes among all women and decreased adherence among HIV-infected women.
Methods: Pregnant Kenyan women (n=368) of mixed HIV status were enrolled into the Pith Moromo observational cohort study and were surveyed on demography, FI, physical and psychosocial health and any type of violence. IPV was operationalized as any physical, sexual or psychological harm by a current or former partner within the incident pregnancy. Maternal probable depression was measured using

the Center for Epidemiological Studies Depression Scale (CES-D 20). Adverse birth outcomes comprised of miscarriage (< 22wk), stillbirth (≥22 wk), and infant death. Multivariate logistic-regression analysis was conducted to analyze factors that were independently associated with IPV.
Results: The mean age of the 368 participants was 24.8 years. Of these, 333(90.49%) were married or cohabiting. One hundred and eighty three (49.73%) were HIV-infected and on antiretroviral therapy. At baseline, the proportion of those with FI was 67.93% and did not differ by HIV status. In the index pregnancy, IPV (any type) was reported by 104 women (28.26%). Approximately 11.48% was emotional, 4.92% physical and 4.1% was sexual violence. IPV did not differ by HIV status (30.05% vs. 26.49%). In multivariate analysis, we found that among HIV-infected women reporting IPV, there were: i)high odds of moderate and severe FI (aOR 3.06, 95%CI: 1.29-7.26); ii)high odds of maternal probable depression (aOR 2.26, 95%CI: 1.06-4.81); iii)no evidence of non-adherence to HAART during pregnancy (aOR 0.86, 95%CI: 0.28- 1.40 and; iv)no evidence of adverse birth outcomes (aOR 1.86, 95%CI: 0.63-5.50).
Conclusions: Almost two in three women had FI and one in three suffered IPV in the index pregnancy. Having IPV and mental health screenings coincide with nutrition assessments during pregnancy may help identify women who would benefit from resources designed to increase physical safety, psychological well-being, and food security.

MOPEC0637

Pregnant and breastfeeding women healthcare seeking in a high HIV prevalence area, Ndhiwa sub-county, Kenya: a qualitative study

K. Ondeng'e[1], V. Akelo[1], W. Hennequin[2], S. Wanjala[2], A. VandenBulcke[2], W. Omwoyo[3], A. Nikuze[4], V. Opollo[1], D. Maman[4]
[1]Kenya Medical Research Institute, HIV Research Branch, Kisumu, Kenya, [2]Medecins Sans Frontieres, Nairobi, Kenya, [3]Ministry of Health, Goverment of Kenya, Homa Bay, Kenya, [4]Epicentre, Intervention Epidemiology and Training Department Southern Africa Medical Unit (SAMU) - Médecins Sans Frontières, Cape Town, South Africa
Presenting author email: kondenge@gmail.com

Background: The number of newly infected children per year in Kenya is still high at 13,000 despite increased provision and uptake of prevention of mother to child (PMTCT). Better understanding of health seeking is critical to improve and design PMTCT programs. We assessed women's healthcare seeking during pregnancy and breastfeeding.
Methods: Individual in-depth interviews were conducted with 40 pregnant and breastfeeding women and 20 men. Key informant interviews were conducted with 20 healthcare workers across antenatal care facilities in Ndhiwa sub-county. This qualitative data collected between March and June 2016 was managed using Nvivo 8.0. A descriptive, exploratory and explanatory approach was used in the analysis of healthcare seeking behavior.
Results: Main sources of healthcare included both alternative (trusted traditional birth attendants (TBA), faith healers, herbalists and traditional healers) and modern (public and private hospitals, chemists, shops and market pill vendors). TBA was consulted mainly because they were trusted and allowed convenient modes of payments not necessarily monetary. Alternative sources of healthcare were preferred for conditions that were believed to be not understood by modern medicine. Hospitals was preferred for monitoring the safety of the baby, health education, availability of complications and emergency resources (e.g. blood) and to acquire the antenatal care card as proof of compliance and symbol of a being a good patient in case of future need. Barriers to seeking facility care included distance to the facility, transport costs, costs of facility care, long queues, time spent waiting, poor provider's attitude, perception of the illness, and fear of HIV test.
Conclusions: It may be useful for health providers to appreciate the full reality of medical pluralism and its implications on healthcare utilization. Involving alternative care providers through education and training programs can be used for prevention, referral and linkages to requisite skilled care.

MOPEC0638

A retrospective study on still birth rate of HIV-infected pregnancy and related contributory factors in West Bengal, India

S. Ganguly[1], P. Sarkar[2], K. Sachdeva[3], A. Hegde[4], P. Sujith[3]
[1]West Bengal AIDS Control Society, Basic Services, Kolkata, India, [2]Department of Health and Family Welfare, HIV, Kolkata, India, [3]National AIDS Control Organisation, Basic Services, Delhi, India, [4]National AIDS Control Organisation, Basic Services, Thane, India

Background: In HIV infected pregnancies, pregnancy does not seem to alter the course of HIV infection significantly but HIV apart from vertical transmission may result in adverse obstetric outcomes. Several factors like maternal immunological status, status of Anti Retroviral treatment and adherence , Literacy status, family support, etc may also be contributory.
Methods: A retrospective cohort study was carried out through analysis of secondary data from 252 Integrated Counselling and Testing Centres across the state of West Bengal from April' 2012 to March'2016. A total number of 1729 HIV infected pregnancies were followed up and financial year wise still birth rate was calculated and it was compared with still birth rate of the state among all pregnancies as per SRS figure of 2012. Year wise trend analysis was done and test for statistical significance was undertaken to substantiate probable association between HIV infected pregnancy and still birth.
Z Tests (Two Tailed) for two means and two proportions were performed to find out the effects of other contributory factors like maternal baseline CD4 count during pregnancy, whether on Anti Retroviral treatment or not during pregnancy, age of conception, literacy status of mother, family involvement in terms of spouse testing for HIV.
Results: Still Birth Rate was found significantly higher (28 per 1000) in HIV infected pregnancies compared to all pregnancies (5 per 1000) in West Bengal. With initiation of anti retroviral treatment still birth rate was found to be reduced significantly and if the spouse of HIV positive pregnant woman was tested for HIV which was considered indirectly related to family involvement in PPTCT (Prevention of Parent to Child Transmission) / PMTCT (Prevention of Mother to Child Transmission) / program, adverse obstetric outcomes were minimized significantly.
Conclusions: Since HIV infection may cause adverse obstetric outcomes, early initiation of antiretroviral treatment and ensuring family involvement in PPTCT/ PMTCT program can decrease the still birth rate significantly.

MOPEC0639

Prevention of HIV transmission among young girls under 19 in Boulmiougou, Burkina Faso: backtracking

T. Aminata Hambougnan[1], O. Roger[2]
[1]Association Dounia Solidarité+, Ouagadougou, Burkina Faso, [2]Association Dounia Solidarité, Ouagadougou, Burkina Faso
Presenting author email: aminata_taro@yahoo.fr

Background: - Determine the prevalence of risk behaviors among girls under 19 years of age
- Evaluate residual risk factors
- Assess the prevention coverage of the target group in the area
Methods: - This is a survey that involved 1000 girls under 19 years of high schools and colleges
- A free screening counseling with specific maintenance guide was administered followed by a blood sample and delivery of the results after a post-test
- An analysis of the results was carried out which allowed to characterize the dynamics of risk behaviors
- A survey on the services offered by the health structures and the associations has been carried out
Results: - This survey involved 1000 girls aged 14-18, 67% of whom were sexually active,
- Of the 670, 85% came out with older men for economic reasons and occasionally protected themselves, 65% had multiple partners, 75% poorly defined modes of transmission and means of prevention or planning, 16% Already practiced a voluntary abortion,
- The prevalence of risk behaviors reported in the target group is much higher than among adults (2.8 vs. 1.6)
- 100% of the positive cases were referred to the medical and psychosocial care structures
- Coverage of the target group for prevention is zero
- Highlighting potential contradictions between strong political mobilization and program sustainability
- A preventive program in schools is awaiting implementation provided that it receives funding

Conclusions: Our findings highlight the current lack of prevention among young girls in the area. It is clear that the TFPs are abandoning prevention, which explains the lack of coverage and the silent rebound of the epidemic among young people. There is a need for intensive and specific strengthening of prevention programs for girls. New strategies for the involvement of partners and prevention programs should be developed.

MOPEC0640

"Key" yet marginalised: an analysis of the HIV prevention response and "Key" populations in Zambia - a case study of the Southern province

P. Mbozi
University of Zambia, Institute of Social and Economic Research (INESOR), Lusaka, Zambia
Presenting author email: pmbozi5@yahoo.com

Background: Zambia's and southern province adult HIV prevalence measured at 14.3% and 14.5% respectively. Recent data suggests that Key populations are disproportionately infected with HIV compared to the general population. The Measure Know Your Response (KYR) study took place from September 2013 to July 2014 in the Southern Province of Zambia with support from USAID. The aim was to map and characterize the HIV response and to identify gaps in the response, in particular to key populations - MSM, migrants, incarcerated, PLWHIV, transgender and sex workers.
Methods: Mixed method - survey and FGDs - were used to collected data on:
1. broad view of the policy environment for HIV prevention vis key populations and gender;
2. Interventions of Government and NGOs; strategic information to help identify high risk groups and geographical areas where HIV and associated problems are common;
3 extent district-level health facilities provided health services to a range of groups;
4. HIV-prevention interventions by the Government sectors other than health; and,
5 interventions of NGOs and their services. Data from the quantitative questionnaires was analysed using SPSS.
Results: There are no specific policies to guide program implementers on dealing with key populations. Activities of key populations - MSM, sex workers and transgenders are illegal in Zambia, hence major key populations and sexual minorities excluded from both government and NGO HIV prevention programs. Limited advocacy to amend policies and laws. No data routinely collected on key populations due to lack of policy guidance. No government health facilities in the 12 districts targeted key populations and none of the three prisons provided condoms to prisoners as a means of HIV prevention.
Fewer than three of the 93 organizations surveyed targeted key populations. Few catered for sex workers.
Conclusions: Key populations remain marginalized in HIV prevention interventions of both government and NGOs in Southern Province of Zambia. Implementers prohibited by law and policies from providing services for some key populations and no data are collected on key populations. Legal and policy environment needs to be changed to allow implementers to cater for key populations. Activities needed to reduce stigma around sexual minorities and key populations.

MOPEC0641

PMTCT program utilization and HIV transmission rates in young and adolescent mothers compared to adult mothers: a nationally representative sample of women screened at 4-26 weeks postpartum in Malawi

M. van Lettow[1], M. Landes[1], J.J. van Oosterhout[1], E. Schouten[2], H. Phiri[2], E. Nkhoma[2], T. Kalua[3], A. Jahn[4]
[1]Dignitas International, Zomba, Malawi, [2]Management Sciences for Health, Lilongwe, Malawi, [3]Ministry of Health, Lilongwe, Malawi, [4]ITECH, Lilongwe, Malawi
Presenting author email: m.vanlettow@dignitasinternational.org

Background: Evidence from limited studies indicate that prevention of mother-to-child-transmission (PMTCT) outcomes in young and adolescent women are worse than for adult women. In this study we compare utilization of PMTCT services (uptake of antenatal testing and antiretroviral treatment (ART)) and mother-to-child transmission (MTCT) rates between young (< 25yrs) or adolescent (< 20yrs) mothers, and adult mothers (≥25yrs) in a national PMTCT evaluation in Malawi.
Methods: Mothers were consecutively consented and screened in 54 under-5 clinics with their 4-26 week old infant between October 2014 and May 2016. Structured interviews with mothers confirmed uptake of antenatal testing and ART. Maternal HIV rapid-testing was conducted at site. Exposed infants underwent infant virological HIV testing. Weighted survey design analysis was conducted using SPSS.
Results: A total of 33,744 mother-infant-pairs were included; 17,928 (53.8%) were young (12-24yrs), 6,427 (20.5%) were adolescent (12-19yrs) mothers. Among all, 33,276 (97.8%) reported being tested for HIV before or during last pregnancy. Young mothers had more likely missed antenatal HIV testing than adult mothers [OR 1.8(95%CI1.2-2.7)]. Overall, 3,233 (11.3%) mothers were identified HIV-infected before or during pregnancy; this prevalence was lower in young (4.6%) and adolescent (2.8%) mothers. At time of study, 286 new infections were identified (244 previously negative; 42 previously unknown). Adolescents were less likely newly identified infected (previously negative) then young and adult mothers [OR 0.5(95%CI0.2-0.9)]. However, newly identified HIV-infected (previous unknown) young mothers may have missed earlier diagnoses than adult mothers [OR 3.5(95%CI0.9-14.4)]. Among the known HIV-infected women, 3,034 (94.7%) reported being on ART, with no difference between young or adolescent and adult mothers. Overall MTCT rate at 4-26 weeks was 4.7%, with no difference between young or adolescent and adult mothers.
Conclusions: Over half of mothers attending under-5 clinics in Malawi are under 25 years. Utilization and effectiveness of PMTCT services in Malawi is high and MTCT rates are relatively low. HIV prevalence is much lower among young and adolescent compared to older mothers, but the risk of missing antenatal HIV testing appears higher among younger and adolescent women. There appears little difference in PMTCT outcomes between younger and older mothers in Malawi.

MOPEC0642

Beliefs and practices underlying *"undetectable = uninfectious"* in a study of serodiscordant couples enrolled in the Positive Plus One study in Canada

S.L. Bullock[1], L. Calzavara[1], J. Iveniuk[1], J. Mendelsohn[2], D. Tan[3,4], A. Burchell[5], J.-P. Routy[6], B. Lebouche[6,7], A. Daftary[8], D. Allman[1], T. Thompson[9], T. Myers[1], R. Masching[10], B. Conway[11], and The Positive Plus One Team
[1]University of Toronto, Dalla Lana School of Public Health & Social Research Centre in HIV Prevention, Toronto, Canada, [2]Pace University, College of Health Professions, New York, United States, [3]St. Michael's Hospital, Division of Infectious Diseases and Centre for Urban Solutions, Toronto, Canada, [4]University of Toronto, Dept. of Family Medicine, Toronto, Canada, [5]St. Michael's Hospital, Dept. of Community and Family Medicine and Li Ka Shing Knowledge Institute, Toronto, Canada, [6]McGill University Health Centre, Division of Hematology and Chronic Viral Illness Service, Montreal, Canada, [7]McGill University, Dept. of Family Medicine, Montreal, Canada, [8]McGill University, Dept. of Epidemiology, Biostatistics & Occupational Health, Montreal, Canada, [9]Western University, School of Health Studies, Faculty of Health Sciences, London, Canada, [10]Canadian Aboriginal AIDS Network, Vancouver, Canada, [11]Vancouver Infectious Disease Centre, Vancouver, Canada
Presenting author email: s.bullock@utoronto.ca

Background: The idea that "undetectable=uninfectious" has increasingly received endorsement from HIV experts and AIDS Service Organizations (ASOs). Yet controversy remains, with many advising continued condom use to ensure the greatest protection. We examine whether the behavior of people in serodiscordant relationships is in keeping with this message - namely whether they use condoms at a lower rate when the positive partner's viral load (VL) is undetectable.
Methods: People were recruited via 143 Canadian ASOs and clinics to participate in a survey of serodiscordant couples. Both partners were asked to complete a survey addressing sociodemographics, HIV-transmission management, health status, and more. Descriptive statistics and ordered logistic regressions (OLR) were used.
Results: A total of 244 current HIV-serodiscordant relationships were represented in the data; 115 relationships were male-female, 116 were male-male, and 13 were a mix of gender identities. Sixteen percent of couples reported no sexual activity, 8.5% reported sex but no intercourse, 27.1% reported intercourse always using condoms, 24.5% sometimes used condoms, and 23.9% never used condoms. When asked if they agreed/disagreed with the statement: "when a person's VL is undetectable VL they can safely have intercourse without a condom, 47.2% agreed. There were no significant differences in agreement by HIV status or relationship-type; those who were neutral were more likely to have abstained from sex. The positive partner's latest VL was: undetectable in 81.9%, detectable in 10.1%, and unknown in 8% of couples. In an OLR of condom use, when the HIV-positive partner was insertive, controlling for relationship-type and socio-demographics, we found condoms were less likely to be used by those with an undetectable VL (AOR=0.11, 95%CI 0.020—0.64). Condom use was also lower when the HIV-positive partner was receptive and undetectable (AOR=0.23, 95%CI 0.060—0.87).
Conclusions: Although VL suppression is high and many support the idea that "undetectable=uninfectious" Canadian serodiscordant couples are cautious in avoiding transmission. Couples with undetectable VL are less likely to use condoms; however, as many as a quarter reported no sex or no intercourse. For serodiscordant couples discussions on this issue may be most effective including both partners so they are encouraged to assess the complexity of their relationship risk factors.

MOPEC0643

Sexual behaviour among people with HIV in Brazil according to antiretroviral treatment and viral load status

R. Reis[1], J.D.S. Caliari[1], E. Gir[1], E.S. Melo[1], M. Antonini[1], J.G.M. Argolo[1], G.J. de Jesus[1], B. Spire[2]
[1]*College of Nursing at Ribeirao Preto of Universty of São Paulo, General and Specialized, Ribeirão Preto, Brazil,* [2]*Aix-University Marseille, Faculty of Medicine, Marseille, France*
Presenting author email: rkreis@eerp.usp.br

Background: Transmission of HIV in the Brazil continues to be high with average of 41,1 thousand cases of AIDS per year in the last five years being the sexual transmission the main route. Since 2013, the country has adopted the combined prevention strategy as treatment as prevention, with the early use of ART for all persons diagnosed regardless of CD4 count, with a view to reducing transmissibility of HIV and achieve the 90-90-90 treatment target. Objective : To evaluate the association between the condomless sex self-reported with HIV-serodifferent partner and viral load status and sociodemographic factors.
Methods: The cross-sectional study was conducted on HIV adults in Brazil, in 2014 to 2015. A standardized questionnaire was administered, socio-behaviour and clinical data were collected. The condomless sex in the past 12 months self-reported and the latest documented viral load were analysed using the laboratory examination control system (SISCEL). The HIV-transmission risk was defined as condomless sex with HIV-serodifferent partner with clinic-recorded viral load more than 40 copias/ml in the last 12 months.
Results: A total of 258 participants and 57.4% had a sexual partner in the last 12 months, in which 67.6% had a partner with negative or unknown serology. The condomless sex were self-reported by 41.9%, 40.6% and 31.8% among men, women and men who have sex with men, respectively and viral load were detectable (more than 40 copies/ml/detectable) betwen 39.9% of individuals. The HIV-transmission risk was 10.1 % and 66.7% were associated with age ranging from 20 to 39 years (p = 0.005).
Conclusions: The goal of ART is to reduce viral load, ideally to an undetectable level, however, optimal treatment adherence is required. Support to improve adherence to HAART are needed as well as counseling for the use of HIV transmission prevention guidelines for HIV-infected PLHIV and use of condom with HIV seronegative partner. Understanding patterns of sexual behavior accord to antiretroviral treatment use among people diagnosed with HIV has implementation for clinical care and public health.

MOPEC0644

Disclosure of HIV-serodiscordant relationships to healthcare providers is associated with viral suppression in the HIV-positive partner: preliminary findings from the Canadian Positive Plus One Study

J. Mendelsohn[1], L. Calzavara[2], S. Bullock[2], J. Iveniuk[2], A. Daftary[3], D. Allman[2], A. Burchell[4], L. Bisaillon[5], B. Lebouché[6], T. Myers[2], D. Tan[7], R. Masching[8], M. Loutfy[9], the Positive Plus One Team
[1]*Pace University, College of Health Professions, New York, United States,* [2]*University of Toronto, Dalla Lana School of Public Health & CIHR Social Research Centre in HIV Prevention (SRC), Toronto, Canada,* [3]*McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada,* [4]*St. Michael's Hospital, Department of Community and Family Medicine & Li Ka Shing Knowledge Institute, Toronto, Canada,* [5]*University of Toronto Scarborough, Department of Anthropology & Health Studies, Toronto, Canada,* [6]*McGill University & Royal Victoria Hospital, Montreal, Canada,* [7]*St. Michael's Hospital, Department of Medicine & Li Ka Shing Knowledge Institute, Toronto, Canada,* [8]*Canadian Aboriginal AIDS Network, Dartmouth, Canada,* [9]*Women's College Hospital, Women's College Research Institute, Toronto, Canada*
Presenting author email: jmendelsohn@pace.edu

Background: Although disclosure of one's HIV-status to sexual partners is well studied, less is known about associations between disclosure of HIV-serodiscordant relationships by both partners to healthcare provider(s) and HIV outcomes. As many as 23% of people living with HIV in Canada may be in an HIV-serodiscordant relationship. In this investigation, we hypothesized that HIV-positive partners would be more likely than HIV-negative partners to disclose their relationship to their respective healthcare provider(s) and that relationship disclosure by either partner would be associated with HIV viral suppression.
Methods: We used data from a Canadian national sample of people currently engaged in HIV-serodiscordant relationships in online and telephone-based surveys. Analyses used generalized estimating equations with a logistic link function to address non-independence of individuals within dyads and Firth logistic regression to address small-sample bias.
Results: At the time of writing, the study has recruited N=331 participants (138 HIV-negative; 193 HIV-positive; 87 dyads), all in current relationships. Compared with HIV-negative partners, HIV-positive partners had twice the odds of disclosing their relationship to healthcare provider(s) (AOR=2.0; p=0.02). For HIV-positive partners, disclosure of the relationship was less likely for those diagnosed after their relationship began, compared to those diagnosed prior to the relationship (AOR=0.09; p<0.001). While HIV-positive partners who had disclosed their relationship to healthcare provider(s) had 3x greater odds of reporting viral suppression compared with those who had not disclosed (AOR=2.98; p=0.05), HIV-negative partners who had similarly disclosed their relationship had 7.5x greater odds of reporting that their HIV-positive partner had attained viral suppression when compared with those who had not disclosed (AOR=7.46; p=0.004).
Conclusions: Disclosure of HIV-serodiscordant status by HIV-positive and HIV-negative partners to their respective healthcare provider(s) was associated with viral suppression. Although HIV-negative partners were less likely to disclose their relationship, their disclosure was associated with more than twice the odds of viral suppression when compared with disclosure by HIV-positive partners. These results suggest that HIV-negative partners represent an important HIV-prevention opportunity within HIV-serodiscordant relationships. Future work should consider the reasons for (non)disclosure and ways to incorporate HIV-negative partners in activities that help their partners sustain viral suppression.

MOPEC0645

Psychological wellbeing of children orphaned by HIV/AIDS: a comparative study in public primary schools of Jimma town, Southwest Ethiopia

M. Tadesse[1], M. Tigistu[2], D. Seyoum[3]
[1]*Jimma University, Medical Laboratory Sciences, Jimma, Ethiopia,* [2]*Jimma University, Psychology, Jimma, Ethiopia,* [3]*Jimma University, Statistics, Jimma, Ethiopia*
Presenting author email: mulualem.tadesse@ju.edu.et

Background: In developing countries the number of children orphaned by AIDS is growing rapidly. Consequently, the psychological well-being of these children has become a serious concern. This study explored and compared the psychological status of orphan and non-orphan children in Jimma town, Ethiopia.
Methods: A comparative cross-sectional study was employed on 270 children who were between 10-18 years of age. Eighty five orphaned children (those who lost at least one parent due to HIV/AIDS) and 185 non-orphaned children (control, who had two parents alive) were selected by systematic sampling technique from child clubs of selected schools. The psychological wellbeing of the orphans and non-orphans was measured using the psychological wellbeing scale. The scale consists of a series of statements reflecting the six areas of psychological well-being: autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance. Higher scores on each scale indicate greater wellbeing on that dimension.
Results: A total of 270 children (85 orphaned and 185 non-orphaned children) were included in the study. About 61.2% (52/85) of orphaned and 60.5% (112/185) of non-orphaned children were females. Interims of age, 62% of orphaned and 80% of non-orphaned (controls) were found between age groups of 10-14 years. Our findings demonstrated that orphaned children (children from HIV/AIDS-affected families) showed significantly lower total psychological wellbeing (t=6.05, p=0.001), autonomy (t=3.06, p=0.002), environmental mastery (t=3.7, p=0.001), positive relation with others (t=4.32, p=0.000), and self acceptance (t=5.58, p=0.000) than those from unaffected families (non-orphaned). The main psychological problems of orphaned children included lack of confidence in their opinions, lacks sense of control over external world, frustrated in interpersonal relationships and feeling dissatisfied with self.
Conclusions: The psychological wellbeing of orphaned children was lower than those of non-orphans (controls). Our study illustrates that HIV/ AIDS has impacted negatively on the psychosocial wellbeing of children. Thus, a new type of orphan support project which provides not only material support but also psychosocial support is required to improve the quality of life of children orphaned by HIV/AIDS.

MOPEC0646

Identifying pathways between depression, substance use and sexual risk practices can inform HIV and sexually transmitted infections prevention strategies for young women in the northwest territories, Canada

C.H. Logie[1], C. Lys[2], M. Okumu[1], N. MacNeill[2], C. Leone[1], G. Adrian[3]
[1]University of Toronto, Toronto, Canada, [2]Fostering Open Expression Among Youth, Yellowknife, Canada, [3]University of Windsor, Windsor, Canada
Presenting author email: adrian.guta@uwindsor.ca

Background: There are profound sexual and mental health disparities in the Northwest Territories (NWT), with youth sexually transmitted infections (STI) rates 10-fold higher, and youth suicide rates double, the Canadian average. Despite these co-occuring epidemics, little is known about syndemics of mental health and HIV/STI vulnerabilty in the NWT. This study examined associations between depression and multiple sex partners among young women in the NWT, Canada.
Methods: We conducted a cross-sectional study with a venue-based sample of young women aged 14-17 in secondary schools in 14 NWT communities. We examined factors associated with multiple sex partners (2 or more past year sex partners). We tested a multi-step mediation analysis model with 10,000 bootstrap samples to examine the effects of depression (X) on multiple sex partners (Y), with peer support (M1) and substance use (M2) as mediators.
Results: Among 199 participants (mean age: 13.8, SD: 1.27), 77.4% (n=154) identified as Indigenous, one-fifth (20.5%; n=39) as sexual minority, one-quarter (26.6%, n= 53) were currently dating, and 16.1% (n=32) reported multiple sex partners (MSP). Depression symptoms were higher among sexual minorities than heterosexuals, and among those dating vs. not dating. Substance use was higher among Indigenous vs. non-Indigenous participants, and among those dating vs. not dating. There was a direct relationship between depression and MSP (B=0.13, p<0.001, CI 95%: 0.37-0.264). Substance use (M2) significantly mediated the effect of X on Y (X→ M2→Y). Depression was directly associated with substance use (B=0.2, p<0.05, CI 95%: 0.04-0.36), in turn substance use predicted MSP (B=0.451, p<0.001, CI 95%: 0.22-0.68). When controlling for substance use, the beta for the relationship between depression and MSP reduced from 0.29 to 0.13, suggesting partial mediation. Depression was negatively significantly associated with peer support (B= -0.25, p<0.01, CI 95%: -0.47- -0.023). However, peer support did not predict MSP (B= -0.14, p= -0.136, CI 95%: -0.31- 0.04).
Conclusions: Depression was associated with MSP, and substance use partially mediated the effect of depression on MSP. Findings highlight the need for HIV and STI prevention interventions to focus on syndemics of depression, substance use and sexual risk among young women in the NWT, Canada.

MOPEC0647

A randomized trial of brief assessment interventions to reduce HIV/STI sexual risk and drug use among young adults who use drugs

S. Kurtz[1], M. Buttram[1], M. Pagano[2], H. Surratt[3]
[1]Nova Southeastern University, Center for Applied Research on Substance Use and Health Disparities, Miami, United States, [2]Case Western Reserve University, Department of Psychiatry, Cleveland, United States, [3]University of Kentucky, Department of Internal Medicine, Lexington, United States
Presenting author email: steven.kurtz@nova.edu

Background: Although the intersections of drug use and sexual HIV/STI risk behaviors and infections are well documented within the social context of clubs, raves, and circuit/dance parties, efficacious interventions to reduce HIV/STI risk behaviors and drug use for club drug using populations are not apparent in the literature. We tested interviewer- (CAPI) and self-administered (ACASI) comprehensive health and social risk assessments as distinct interventions compared to waitlist control, hypothesizing that those assigned to the assessment conditions would reduce their sexual risks and drug use to a similar degree and to a significantly greater extent than waitlist control.
Methods: 750 men and women ages 18-39 with multidrug use and heterosexual behavior were recruited between September 2011 and November 2014 using respondent driven sampling, and randomized in equal proportions to the three conditions. Instrumentation included well-tested measures of condomless sex, drug use, mental distress and substance dependence. Hierarchical linear models (HLMs) examined the effects of study condition on sexual HIV/STI risk, drug use, and comorbid health outcomes, measured as effect size (Cohen's d) differences.
Results: The sample was 56% male; mean age=25; 65.7% Hispanic; 20.4% Black, 11.6% White and 2.3% other race/ethnicity. HLM analyses showed a significant main effect of assigned condition on all outcomes. CAPI participants had greater reductions in sexual HIV/STI risk, drug use, and mental distress and substance dependence symptoms, compared to ACASI intervention or control participants at 12 months, except that the CAPI and ACASI conditions had similar efficacy for reductions in drug use. Effect sizes for CAPI versus ACASI participants were d=0.2-0.3, and between CAPI and controls d=0.2-0.4. Effect sizes for improved outcomes between ACASI compared to controls were small to non-significant.
Conclusions: The study established the therapeutic benefit of interviewer interaction in reducing HIV/STI sexual risk behavior and drug use among young adults who use drugs. The study is the first to demonstrate the efficacy and acceptability of a low threshold intervention in reducing HIV/STI sexual risk, drug use, and related co-morbidities among a not-in-treatment young population that exhibits severe and complex levels of drug use, but that is also highly resistant to intervention.

MOPEC0648

Reasons for not using PrEP in a national on-line sample of U.S. men who have sex with men (MSM)

K.H. Mayer[1,2,3], K. Biello[1,4], D.S. Novak[5], D. Krakower[1,2,3], M.J. Mimiaga[1,4]
[1]Fenway Health, The Fenway Institute, Boston, United States, [2]Harvard Medical School, Medicine, Boston, United States, [3]Beth Israel Deaconess Medical Center, Medicine, Boston, United States, [4]Brown University, Epidemiology, Providence, United States, [5]On-, Cambridge, United States
Presenting author email: kmayer@fenwayhealth.org

Background: Although the CDC estimates that >400,000 U.S. MSM could benefit from oral PrEP, many have not initiated it, prompting this analysis
Methods: An on-line survey was mounted on 2 popular MSM sexual networking sites during March 2016 to assess socio-demographics, HIV risk, PrEP knowledge, attitudes and use. Factors independently associated with never using PrEP were evaluated using multivariable logistic regression with backward selection.
Results: Of 4,698 respondents, 21% were 18 to 24 y.o. and 38% were 40 or older. Almost half (47%) were White, 25% Black, 11% Hispanic/Latino, and were from all U.S. states. Almost 12% were born outside the U.S. Nearly 60% had private health insurance; 12% had none. About two-thirds reported condomless anal intercourse (CAI) at least once in the prior 3 months. Most (85%) had not used PrEP previously, with 22% unaware of PrEP. Among 2,926 PrEP-informed non-users, the most common reasons cited for non-use were: concerns about costs (40%), side effects (31%), not knowing where to access PrEP (31%), worries about effects on insurance (20%), and/or not feeling at risk (19.3%). Older MSM were more likely to cite side effects, and less likely to cite access concerns as reasons for non-use. Black MSM were also more likely to cite access concerns, but less likely to cite insurance barriers than other MSM. Less educated MSM were more likely to report access issues but less likely to cite cost, insurance or anticipated side effects, as barriers to using PrEP. MSM born outside of the U.S. were more likely to identify access as a major barrier to PrEP use. MSM who reported monogamous relationships were more likely to report low risk as a reason for PrEP non-use, whereas those who reported more than 2 CAI acts in the prior 3 months, or a history of syphilis, were less likely to cite low risk as a PrEP barrier.
Conclusions: The major barriers to PrEP uptake endorsed by U.S. MSM included structural factors (cost, access, insurance), anticipated side effects, and low perceived risk, and their importance differed between subgroups. Additional programs to educate at-risk MSM about how to address these issues are warranted.

MOPEC0649

Crystal methamphetamine initiation among HIV-positive and HIV-negative men who have sex with men in Vancouver, Canada: a longitudinal analysis

N.J. Lachowsky[1,2,3], Z. Cui[2], J. Zhu[2], H. Armstrong[2,4], M. Taylor[5], J. Edwards[5], G. Olarewaju[2], R. Hogg[2,6], E.A. Roth[3,7], D.M. Moore[2,4], Momentum Health Study
[1]University of Victoria, School of Public Health and Social Policy, Victoria, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Division of Epidemiology & Population Health, Vancouver, Canada, [3]Centre for Addictions Research BC, Victoria, Canada, [4]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [5]Health Initiative for Men, Vancouver, Canada, [6]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [7]University of Victoria, Department of Anthropology, Victoria, Canada
Presenting author email: nlachowsky@cfenet.ubc.ca

Background: Crystal methamphetamine is associated with HIV acquisition among HIV-negative men who have sex with men (MSM) and unsuppressed viral load among HIV-positive MSM. We used prospective behavioural cohort data from MSM to measure temporal trends and initiation predictors of crystal methamphetamine use.
Methods: Sexually-active MSM aged ≥16 years were recruited using respondent-driven sampling (RDS) and from 02/2012-02/2016 they completed study visits every six months, which included a computer-assisted self-interview and nurse-

administered HIV/STI screening. We used multi-level generalized estimating equations to evaluate temporal trends in crystal methamphetamine use and univariable survival analysis to identify predictors of crystal methamphetamine initiation (hazard ratios [HR]; 95% confidence intervals [95%CI]).
Results: Over the 4-year study period, 581 participants completed at least 1 follow-up visit for a median follow-up of 2.49 years. At baseline, 20.1% of MSM reported recent crystal methamphetamine use, which was significantly higher among HIV-positive (44.3%) than HIV-negative MSM (10.3%, p< 0.001). Route of use did not differ by HIV status (all p>0.05): 79.3% smoking, 55.0% snorting, 27.9% injecting, and 26.4% hooping. Frequency of use did not differ by HIV status (p=0.237): 43.6% used less than monthly, 20.7% used monthly, and 35.7% used at least weekly. There were no statistically significant temporal trends overall (p=0.069) or for HIV-negative (p=0.179) or HIV-positive (p=0.087) MSM.
During follow-up, 32 HIV-negative MSM (8.5%) and 14 HIV-positive MSM (15.2%) initiated crystal methamphetamine use (no difference by HIV status, p=0.10). This table presents predictors of initiation:

	HIV-Negative HR (95%CI)	HIV-Positive HR (95%CI)
Number of recent male anal sex partners, per partner	1.01 (1.01-1.02)*	1.02 (1.00-1.05)*
HIV treatment optimism scale score, per point	1.07 (1.00-1.15)*	0.98 (0.89-1.09)
Self-esteem scale score, per point	1.11 (1.03-1.20)*	1.10 (0.99-1.09)
Anxiety scale score, per point	1.08 (1.00-1.17)*	0.98 (0.87-1.11)
Sought sex online at least monthly (ref: none)	4.66 (2.15-10.11)*	2.91 (0.69-12.25)
Recent escort/sex work (ref: none)	5.05 (1.53-16.68)*	2.97 (0.38-23.62)
Recent group sex participation (ref: none)	2.72 (1.31-5.65)*	3.51 (1.23-10.03)*
Recent STI diagnosis (ref: none)	3.23 (1.24-8.45)*	1.63 (0.21-12.67)
Recent anal sex behaviour (ref: none) NB: only levels of categorical variable with statistically significant associations shown	Any condomless anal sex with an HIV serodiscordant or unknown status partner: 3.45 (1.16-10.26)*	Any condomless anal sex with an HIV seroconcordant partner: 10.30 (1.24-85.74)*

*[*denotes statistical significance at p<0.05]*

Despite initiators reporting greater objective HIV risk (i.e. more anal sex partners, group sex, condomless sex), they did not self-perceive this risk: 100% of HIV-positive MSM and 78.1% of HIV-negative MSM self-assessed their risk of transmitting or acquiring HIV as "low", respectively.
Conclusions: Crystal methamphetamine use was prevalent, stable over time, and initiation was common. Renewed population-specific interventions and health promotion efforts are desperately needed.

MOPEC0650

High HIV incidence among married couples in fishing communities: implications for achieving epidemic control

Z.A. Kwena, C. Makokha, D. Angawa, E.A. Bukusi
Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya
Presenting author email: kwena.zachary@gmail.com

Background: Global efforts to achieve HIV epidemic control by 2030 focus on identifying and shutting down sources of new infections through targeted interventions. We sought to establish HIV incidence and associated risk factors among married people in the fishing communities on Lake Victoria.
Methods: We conducted a 3-year resurvey of 545 couples who had previously been enrolled in a cross-sectional survey conducted between September 2011 and June 2014. Although the target was to trace and re-interview all couples, we only contacted 903 individuals of whom 89.5% were couples. Among those contacted were 371 men and 356 women who had tested HIV negative during the first survey. On contact, the individuals or couples were asked to return to the study clinic to participate in a follow-up survey. Returning couples were consented and invited for concurrent face-to-face interviews in private rooms. We invited them for HIV test using Kenyan rapid HIV testing protocol. For those testing positive, we assumed infection to have occurred midpoint between first and second surveys. We calculated incidence rates and factors associated with new infections using Cox regression.
Results: Fifty three new infections occurred between the surveys; 23 in men and 30 among women; giving an overall HIV incidence of 4.5% (95% CI: 3.4%-5.9%) with no significant difference between men 3.8% (2.5-5.7) and women 5.2% (3.6-7.4) (p=0.27). The majority of the people who participated in second survey as couples were concordant negative (68%) with 15% being concordant positive and, 9% discordant women positive and 8% discordant men positive. For men, new HIV infection was associated with being recently married (aOR 0.11; 95%CI: 0.02-0.84); uncircumcised (aOR 2.93; 95%CI: 1.03-8.37), polygynous (aOR 0.18; 95%CI: 0.05-0.61) and reporting protected sex (aOR 0.26; 95%CI: 0.07-0.97). For women, new HIV infection was associated with increasing income (aOR 0.98; 95%CI: 0.95-0.99); and being separated from spouse (aOR 4.39; 95%CI: 1.47-13.10).
Conclusions: Married people in the fishing communities on Lake Victoria have high HIV incidence. This HIV hotspot need to be targeted with appropriate interventions such as PrEP rollout to shut down new infections.

MOPEC0651

High prevalence of syphilis, hepatitis B and HIV among men who have sex with men in Tanga region, Northern Tanzania

H. Kigumi[1,2], S.E. Msuya[3], Men who Have Sex with Men
[1]Local Government Training Institute, Health, Dodoma, Tanzania, United Republic of, [2]Kilimanjaro Christian Medical University College, Community Health, Moshi, Tanzania, United Republic of, [3]Kilimanjaro Christian Medical University College (Tumaini University), Community Health, Moshi, Tanzania, United Republic of

Background: Whilst studies have shown a high prevalence of HIV and sexually transmitted infections (STIs) among men who have sex with men (MSM) globally and in Africa, few studies have been conducted in Tanzania.
Methods: A cross sectional study was conducted between April and June 2015 in four districts of Tanga region in north-east Tanzania. Interviews were conducted with 266 MSM followed by serological testing for syphilis, hepatitis B surface antigen and HIV.
Results: The mean age of the participants was 27.2 (SD 6.7) years, 48% were married or cohabiting, with median of 20 lifetime male partners and 23% reported consistent condom use. The prevalence of Hepatitis B, syphilis and HIV were 28.2%, 31.2%, and 33.8% respectively. Syphilis seropositivity was significantly higher in HIV-positive (54%) compared to HIV-negative men (24.6%), p< 0.001.
Conclusions: An effective response is needed in this setting to address the high prevalence of both sexually transmitted infections (STIs) and HIV amongst MSM. Programs that reach MSM and offer systematic screening for HIV and STIs, early entry in HIV antiretroviral treatment and effective treatment for STIs are urgently required to reduce HIV transmission among MSM themselves and in the general population.

MOPEC0652

The comparative ability of two network interventions to locate undiagnosed positives and recently infected individuals in Odessa, Ukraine: the TRIPLE (TRIP-LitE) intervention, designed for improved implementation feasibility

L. Williams[1], A. Korobchuk[2], P. Smyrnov[3], G. Nikolopoulos[4], S. Friedman[1]
[1]National Development and Research Institutes (NDRI), Institute for Infectious Disease Research, New York, United States, [2]Alliance for Public Health, Odessa, Ukraine, [3]Alliance for Public Health, Kyiv, Ukraine, [4]University of Cyprus, Medical School, Nicosia, Cyprus
Presenting author email: lwilliams@ndri.org

Background: The TRIP study showed that a complex network intervention was effective at locating recently infected HIV+ individuals (at its Athens, Greece site) and previously undiagnosed HIV+ individuals (at Athens; Chicago; and Odessa sites). Since TRIP is labor-intensive and might be difficult to translate to large-scale public health practice, we developed the lower-cost TRIP-LitE (TRIPLE), and compared it to TRIP on its ability to locate/recruit undiagnosed positives and recent infections.
Methods: Recruitment started with recently-HIV-infected (in last six months, as determined based on Limiting Antigen Avidity (LAg) assay, testing history, and viral load) "seeds." Members of seeds' sexual and injection networks were recruited for two network "steps": seeds' direct network connections (Step 1), and the direct connections of those in Step 1 (Step 2). Network members received the same intervention (TRIP or TRIPLE) as the seeds whose networks precipitated their recruitment. TRIP seeds and Step 1 network members were asked to name all individuals they personally had sex with and/or injected drugs with, and all venues where they met people to have sex and/or inject drugs. We attempted to recruit all named individuals to the study using recruitment coupons given to the seeds or Step 1 members. TRIPLE participants received brief education from intervention staff about recent infection and its associated risks and prevention. TRIPLE seeds and Step 1 network members were asked to name anyone they knew who they thought might have been recently infected (regardless of whether they personally had direct sexual/injection ties). We asked them not to name/recruit people they thought had been infected a long time. Finally, TRIPLE participants were given five extra recruitment coupons to give to anyone they had forgotten or deliberately not named who might have been recently infected.
Results: TRIPLE was not significantly different from TRIP in its ability to recruit undiagnosed positives (see Table), and recruited a larger proportion (n.s.) of recent infections.

Intervention Type	N	Previously Undiagnosed Positives (OR = 0.94; 95% CI 0.67, 1.30)	Recently Infected (OR = 2.23; 95% CI CI 0.84, 5.87)
TRIPLE (03/2016-12/2016)	399	55 (13.8%)	7 (1.8%)
TRIP (11/2013-03/2016)	1131	165 (14.6%)	9 (0.8%)

[Comparing Network Yields from TRIPLE and TRIP]

Conclusions: TRIPLE is an appropriate choice for regular public health practice since it does as well or better at meeting its goals and is easier to implement.

MOPEC0653

The high-risk sexual practices among adolescents accessing HIV/AIDS care services in the central region of Uganda

C. Ntulume Kyesswa[1,2]
[1]*Kyambogo University, Sociology, Kampala, Uganda,* [2]*Sim's Medical Centre, Clinical, Kampala, Uganda*
Presenting author email: cephasntulume@yahoo.com

Background: HIV positive adolescents in Uganda are sexually active just like their uninfected peers and with the availability of Antiretrovirals, the surviving population of adolescents perinatally infected with HIV is increasing and they are becoming sexually active with most of them engaging in unprotected sex.
Objectives: This study aimed at determining whether HIV positive adolescents disclose their HIV status to sexual partners, identifying factors associated with sexual activity among them, finding out if they practice safe sex and determining age at first sex debut among them.
Methods: A descriptive cross-sectional study with an analytical component. Quantitative data was collected from a probability selected sample of 330 HIV positive adolescents aged 14- 19 years using interview schedules and qualitative data from 4 key informants. Data was analysed using both quantitative and qualitative methods.
Results: Overall, 47.7% of them have ever been in a sexual relationship with a higher likelihood among females (RR 1.51; p =0.0014). Peer pressure was the major cause of the sexual relationships (54.6%). 16.6% of them had non penetrative sexual activities only. HIV positive adolescents in urban areas had a higher likelihood of not engaging in sexual relationship than those from rural areas (OR 0.41; p =0.0032). Over 35% of the respondents were sexually active with females showing a greater likelihood (RR 1.65; p =0.0035). About 66.7% had disclosed their HIV status to sexual partners, 84.3% were of the same HIV status as their sexual partners (p =0.002). 36% of those who had not disclosed to their partners felt guilty. HIV positive males had a higher likelihood of having sexual partners of the same HIV status (RR 1.39; p =0.02). Only 41.9% used condoms during last sexual activity and 87.2% had one sexual partner. About 33.6% had first sexual debut when they were below 15years with (females 25.2%, males 8.4%, p =0.87).
Conclusions: HIV positive adolescents were sexually active especially females, more in rural areas. There was low condom use which was likely to propagate the spread of HIV and AIDS in Uganda. This calls for reproductive health needs of HIV positive adolescents to be addressed and integrated into HIV care programs.

MOPEC0654

Clinical, psychosocial and structural reasons for disengagement in routine HIV care in urban Uganda: results of a cohort study

P. Nyakato[1], A. Kiragga[1], M. Ssuna[2], J. Kigozi[2]
[1]*Infectious Diseases Institute - Makerere University, Research, Kampala, Uganda,* [2]*Infectious Diseases Institute - Makerere University, Outreach, Kampala, Uganda*
Presenting author email: pnyakato2@gmail.com

Background: The recent WHO test and Start guidelines recommend all newly diagnosed HIV patients initiated on ART irrespective of CD4 count. These guidelines are also a way of pushing the global effort to reach the 90-90-90 UNAIDS target. However, loss to follow up (LTFUP) still remains a big set back in the successful implementation and achievement of the goals. We sought to ascertain the clinical, psychosocial and structural reasons for LTFUP in six Kampala clinics in Uganda.
Methods: This was a prospective cohort study carried out between January 2013 and August 2016. Patients who were ≥3 months late for their visits were outreached through telephone calls and/or home visits. Reasons for disengagement, disclosure status were sought from all the patients successfully traced and interviewed. Socio-demographic and clinic variables were obtained from the clinics. Reasons for LTFUP were categorised into 3 broad groups; structural (lack of transport, moving homes), clinical (long waiting hours, drug stock out) and psychosocial (doubtful of HIV status, stigma and discrimination). Comparisons of socio-demographic and clinic variables with the categories of LTFUP and point of entry into care (PMTCT/ out patients department (OPD)) were examined.
Results: From a total of 33,850 registered patients, 4,161 were lost and 2,767 traced. 2,107 (76%) were females with a median (IQR) age in years; 27 (23, 32). The median CD4 count cells/uL at enrolment was 480 (IQR 300, 675) with 71% on ART. 986 (46%) registered into clinics through PMTCT and 1,176 (54%) via the OPD. Structural barriers were the major reason reported for stopping care (76%) followed by psychosocial barriers (29%) and clinical barriers (11%). Patients completely disengaged from care reported more psychosocial reasons compared to those self-transferred and in care elsewhere (81% vs 19%, p< 0.0001). Women on PMTCT reported more psychosocial reasons compared to those entering through OPD (54% vs 46%, p=0.015). Patients reporting psychosocial and clinical reasons for disengagement were less likely to have disclosed compared to those reporting structural reasons (p=0.021).
Conclusions: In order to achieve the 90-90-90 target, there is need to address the structural, and psychosocial barriers to engagement in HIV care, particularly among women.

MOPEC0655

Linkage to HIV care among transgender women in Lima, Peru

R.H. Novoa[1], K.A. Konda[2,3], J. Chow[4], L.R. Carrera[3], S.R. Leon[3], G.M. Calvo[3], B. Brown[5], J.D. Klausner[4], C.F. Caceres[3]
[1]*Universidad Peruana Cayetano Heredia, Public Health, Lima, Peru,* [2]*David Geffen School of Medicine, University of California Los Angeles, Medicine, Division of Infectious Diseases, Lima, Peru,* [3]*Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Investigation in Sexuality, AIDS, and Society, Lima, Peru,* [4]*University of California, Medicine, Division of Infectious Diseases, Los Angeles, United States,* [5]*University of California, Social Medicine and Population Health, Riverside, United States*
Presenting author email: rommy.h.novoa@gmail.com

Background: The prevalence of HIV infection in transgender women (TW) in Peru reaches up to 30% and their needs are not adequately addressed by current HIV care programs. Our objective is to explore if being a male-to-female TW is an obstacle to linkage to HIV care in Lima, Peru.
Methods: We evaluated cross-sectional relationships between self-definition as a TW and linkage-to-care. The data collected from two sexually transmitted infection (STI) clinics that provide specialized services for men who have sex with men (MSM) and TW. Linkage-to-care was defined as having at least one self-report visit with the national HIV care program after HIV diagnosis. Associations with linkage-to-care were analyzed using Poisson regression to estimate adjusted prevalence ratios.
Results: The study included 101 MSM and 29 TW living with HIV whose mean age was 31.4 ± 9 years. College education was reported by 30.0% of participants and 56.7% had a monthly income greater than the local minimum wage ($250/month). A recent STI was diagnosed in 55 (42.3%) participants. In the adjusted multivariable model, the probability of linkage-to-care was 23% lower among TW (aPR = 0.77; 95% CI 0.61-0.98). Among the 31 MSM/TW participants diagnosed during the study, 21 (67.7%) were linked to care and linkage took an average of 3.1 months. Among all participants, 93 (71.5%) received HAART at some period during the study.

Characteristic	Crude PR	95% CI	Adjusted PR*	95% CI	p-value
Transgender woman	0.84	0.65 - 1.09	**0.77**	0.60 - 0.99	0.040
Age (years)	1.01	1.01 - 1.02	**1.01**	1.00 - 1.01	0.002
Diagnosis of STIs, last 6 months	0.87	0.72 - 1.05	0.86	0.73 - 1.02	0.090
Time of diagnosis of HIV					
Before starting the study	Ref.		Ref.		
At baseline	0.68	0.50 - 0.93	**0.67**	0.49 - 0.90	0.010
During the study	0.75	0.58 - 0.97	0.80	0.63 - 1.01	0.062
*Adjusted for self-definition as transgender, age and STI diagnosis in the last 6 months.					

[Factors associated with linkage-to-care among MSM]

Conclusions: These findings shed light on the need for additional interventions to improve linkage-to-care among TW as a part of achieving the WHO's „90-90-90 objective".

MOPEC0656

Condom use behaviour among people living with HIV: A 7-country community-based participatory research in the Asia-Pacific region

K. Deuba[1], V. Kohlbrenner[2], S. Koirala[3], G. Marrone[1], A.M. Ekström[1]
[1]*Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden,* [2]*Programme to Foster Innovation, Learning and Evidence in HIV and Health Programmes of German Development Cooperation, GIZ, Bonn, Germany,* [3]*Asia Pacific Network of People Living with HIV/AIDS, Bangkok, Thailand*
Presenting author email: keshab.deuba@ki.se

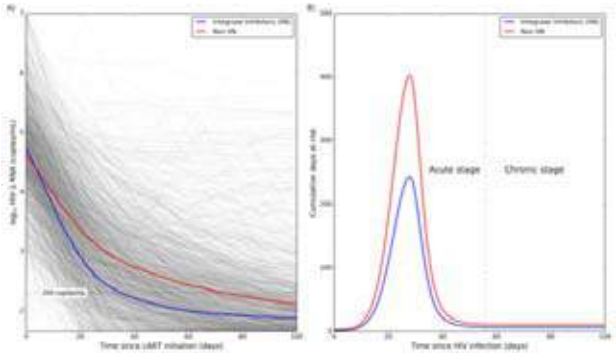
Background: Sexual transmission still drives HIV incidence among key populations in the Asia-Pacific region. Thus, understanding current risk factors and patterns of sexual risk behaviour among people living with HIV (PLHIV) is important for effective prevention. We examined the prevalence of inconsistent condom use and its correlates among PLHIV in the Asia-Pacific region.
Methods: Between 1 October 2012 and 31 May 2013, a total of 7 843 PLHIV aged 18 to 50 years were recruited using targeted and venue-based sampling in Bangladesh, Indonesia, Lao, Nepal, Pakistan, Philippines and Vietnam. Condom use behaviour in the past six months was assessed both at sexual intercourse with a regular partner and at sex with a casual partner ("In the past six months, how frequently did you use condoms when you had sex?"). Condom use behaviour was dichotomized into consistent use ("always") and inconsistent use ("never", "sometimes" or "most of the time"). Logistic regression was used to explore the association between condom use behaviour and demographics, social support, stigma and discrimination, HIV-related literacy and various health-related variables.
Results: Overall, 43% of 3 827 PLHIV practised inconsistent condom use at sexual intercourse with their regular partner. An even higher proportion, 46% of 2 044 PLHIV admitted that they practised unprotected sex with a casual partner. Participants from Lao reported the lowest prevalence of inconsistent condom use for both regular and casual partners, while participants from the Philippines had the highest risk behaviour. Inconsistent condom use was significantly associated with belonging to a key population (drug user, sex worker or refugee sub-population), not knowing that condoms are still needed if both partners are HIV positive, having a regular partner whose HIV status was either positive or unknown, having experienced physical assault as well as with not receiving antiretroviral treatment.
Conclusions: This large 7-country study highlights a high prevalence of inconsistent condom use among PLHIV in the Asia-Pacific region. In addition to knowledge imparting interventions, the adoption and expansion of the ‚Test and Treat' strategy (most of the countries in the Asia-Pacific region still use CD4 criteria for treatment) could help to maximise the prevention benefits of antiretroviral treatment.

MOPEC0657

The potential effect of initiating combination antiretroviral therapy with integrase Inhibitors on HIV transmission risk in British Columbia, Canada

I. Rozada, M. Lu, J.S.G. Montaner, V.D. Lima
British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada
Presenting author email: irozada@cfenet.ubc.ca

Background: Integrase Inhibitors (IIN) represent one of the most efficacious classes of antiretroviral drugs currently available to achieve virologic suppression. Our objective was to estimate possible reductions in HIV forward-transmission risk from antiretroviral-naïve individuals initiating combination antiretroviral therapy (cART) with IIN-based regimens.
Methods: The change in plasma viral load (pVL) levels from cART initiation to virologic suppression, defined as < 200 HIV-1 RNA copies/mL, was calculated from a cohort of 1426 individuals who initiated cART between 2011 and 2014 with at least one year of follow-up; of those, 191 individuals initiated IIN-based cART. Cumulative risk of HIV transmission (CRHT) between the time of cART initiation and virologic suppression was estimated from the area under the pVL curves (Figure1A), using a mathematical formula derived from the Rakai study. CRHT depended on the stage of HIV at cART initiation, and was measured as the number of days at-risk based on the chronic stage of HIV, (one acute day corresponds up to 26 days at-risk; one suppressed day corresponds to 0.04 days at-risk).
Results: Time to virologic suppression for IIN regimes was 35.4 days (95% confidence interval (CI) 30.7-40.7), compared to 73.9 days (95% CI 69.3-78.7) for non-IIN. CRHT when initiating cART in the chronic stage was estimated to be equivalent to 6.4 days at-risk for IIN regimens, compared to 10.7 days for non-IIN. If cART were initiated in the acute stage, CRHT can be up to 243.4 days at-risk for IIN, compared to 402.6 days for non-IIN (Figure1B).
Conclusions: IIN regimens achieve faster virologic suppression, but the difference in cumulative risk with respect to other regimens is small in patients initiating cART in the chronic stage of HIV. The difference in cumulative risk is much greater for patients that start cART in the acute stage.



*[Figure 1. A) Cohort pvl trajectories, in the background, were aggregated to generate population-wide pVL curves. Non IIN regimes include Boosted and Non-Boosted Protease Inhibitors and Non-Nucleoside Reverse Transcriptase Inhibitors.
B) The number of days at-risk, from cART initiation to virologic suppression, based on the stage of HIV at cART initiation.]*

MOPEC0658

Reducing sexual risk and promoting acceptance of MSM living with HIV in India: outcomes and process evaluation of a pilot randomised multi-level intervention

V. Chakrapani[1,2], P.P. Vijin[1], T. Subramanian[3], T. Kershaw[4], R. Nelson[1], M. Rajan[3], A. James[1], M. Shunmugam[1]
[1]*Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India,* [2]*Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India,* [3]*National Institute of Epidemiology (NIE), Chennai, India,* [4]*Yale School of Public Health, Yale University, New Haven, United States*
Presenting author email: cvenkatesan@hotmail.com

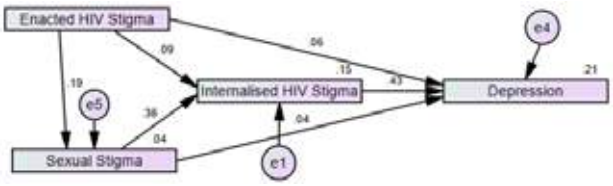
Background: MSM living with HIV (MSMLH) in India require culturally-relevant interventions to promote safer sex and reduce stigma. We developed and tested a theory-based (social personal model) multi-level intervention among MSMLH: one-to-one counselling intervention using motivational interviewing techniques to promote safer sex, and a community-level intervention to promote acceptance of MSMLH among MSM communities.
Methods: In 2015/16, we conducted a 2x2 factorial randomised controlled trial (RCT) with 119 MSMLH randomised to receive either individual-level intervention (ILI), community-level intervention (CLI), a combination of ILI+CLI, or standard-of-care. MSMLH were recruited through community agencies in Tamil Nadu. In ILI, MSMLH received a 4-session tailored sexual risk reduction counselling; and in CLI, activities included community events to promote acceptance of MSMLH and speeches by MSMLH role models. Participants completed assessment at baseline (pre-intervention) and at 3rd and 6th months (endline). The primary outcome measure was sexual risk (e.g., unprotected anal/vaginal sex) in the past 1/3 month(s). Mixed ANOVA analysis was conducted with standard-of-care, ILI, CLI, ILI+CLI conditions as between-subjects factor, and time (baseline/endline) as within-subjects factor. CLI's effectiveness on community stigma was assessed by a cross-sectional pre-/post-CLI survey among 300 ‚general' MSM. Process evaluation included activities to assess intervention fidelity and post-intervention satisfaction survey.
Results: Participants´ mean age was 38.4 (SD 9.1) and monthly income was INR 7602 (~USD 126). Self-identification of participants were: kothis=57.1%; double-deckers=24.4%; panthis=7.6%; bisexuals=6.7%, and gays=4.2%. Out of the 119 MSMLH randomized, 105 (88%) completed pre- and post-intervention assessment. Intent-to-treat analysis showed a decrease in sexual risk across all four conditions (Time effect: F=32.5, p=.001), although only the three intervention groups showed a significant decrease. The ILI+CLI group showed a marginally significant decrease in sexual risk over time compared to the standard-of-care group (p=.08). Further, effect sizes are medium/large (d>.50) for the ILI+CLI group and CLI group. High intervention fidelity and high satisfaction were found among intervention participants.
Conclusions: This pilot RCT among MSMLH has demonstrated feasibility and potential effectiveness of theory-based interventions to reduce sexual risk. A combination of individual (motivational interviewing-based counselling) and community level (stigma reduction) interventions could effectively reduce sexual risk among MSMLH.

MOPEC0659

Associations between HIV-related discrimination, sexual stigma, internalised HIV stigma and depression: testing an extended minority stress model among HIV-positive MSM in India

V. Chakrapani[1,2], P.P. Vijin[1,2], T. Subramanian[3], T. Kershaw[4], R. Nelson[1], M. Rajan[3], M. Shunmugam[1]
[1]*Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India,* [2]*Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India,* [3]*National Institute of Epidemiology (NIE), Chennai, India,* [4]*Yale School of Public Health, Yale University, New Haven, United States*
Presenting author email: vijinpandara@gmail.com

Background: Limited data is available on the associations between stigma and mental health outcomes among men who have sex with men living with HIV (MSMLH) in India. In line with Meyer's minority stress model and prior research, we tested the hypothesis that HIV-related enacted stigma and sexual stigma will predict depression, and their effects on depression will be mediated through internalised HIV stigma. Based on our qualitative formative research findings that MSMLH might blame their same-sex sexuality for having become HIV positive, we also hypothesised that HIV-related discrimination experiences could heighten sexual stigma (See Figure), thus extending the minority stress model.
Methods: In 2015/16, we conducted a baseline survey among 119 MSMLH as part of a multi-level intervention to promote safer sex and reduce community stigma. Standardised scales measured: two key predictors - HIV-related enacted stigma (discrimination due to HIV) and sexual stigma (stigma due to same-sex sexuality); a mediator - internalised HIV stigma; and an outcome variable - depression. Path analysis was conducted with SPSS Amos-22.
Results: Participants´ mean age was 38.4 (SD 9.1) and mean monthly income was INR 7602 (~USD 126). A majority identified as kothis (57.1%) or double-deckers (24.4%), with others identifying as panthis/bisexuals/gays. Internalised stigma significantly mediated the effects of HIV-related stigma (indirect effect=.24, p=.02) and sexual stigma (indirect effect=.09, p< .001) on depression. Sexual stigma significantly predicted internalised stigma (direct effect=.36, p<0.001) and depression. HIV-related stigma did not significantly predict depression. As hypothesised, HIV-related stigma significantly predicted sexual stigma (direct effect=.18, p=.03).



[Testing an extended minority stress model - MSMLH]

Conclusions: The findings offer evidence for the influence of both HIV-related stigma and sexual stigma on depression, and the influence of HIV-related stigma on sexual stigma, supporting an extended minority stress model among MSMLH. Interventions to prevent/reduce depression among MSMLH need to target internalised stigma, in addition to reduction/elimination of HIV-related discrimination and sexual stigma.

MOPEC0660

Substance use and high-risk sexual behaviour in PLWH in France: results of the EQUIPIER study

M. Duracinsky[1], P. Carrieri[2], C. Goujard[3], C. Duvivier[4], P. Sellier[5], L. Bodard[6], L. Weiss[7], S. Herrmann[8], C. Lalanne[1], O. Chassany[1]
[1]*EA 7334 REMES, Patient-Centered Outcomes Research, University Paris-Diderot, Sorbonne Paris Cite, Paris, France,* [2]*INSERM, Marseille, France,* [3]*AP-HP, Bicetre Hospital, Internal Medicine & Infectious Disease Department, Kremlin Bicêtre, France,* [4]*Hôpital Necker, Paris, France,* [5]*Hôpital Lariboisière, Paris, France,* [6]*Institut Montsouris, Paris, France,* [7]*Hôpital Européen George Pompidou, Paris, France,* [8]*Murdoch University, Murdoch, Australia*
Presenting author email: duracinsky.m@gmail.com

Background: Substance use and associated risk behaviors are common in PLWH and require harm reduction interventions. We aimed to better understand how they relate to health-related quality of life, anxiety / depression, and to personality traits among French PLWH.
Methods: French PLWH were enrolled from hospitals or the community using a web-based survey. Addictive behaviors included specific psychoactive substance use and consumption modes. Health-Related quality of life (HRQL) was measured using the PROQOL-HIV four dimensions: physical, mental, social health and treatment impact (scores ranging from 0 to 100, 100 reflecting better HRQL). Anxiety/depression was measured by HADS (2 dimensions). Temperament and Character Inventory questionnaire (TCI) assessed the personality traits.
Results: 517 PLWH were recruited (mostly in hospitals: 81%). 30% were women, mean age was 48 years, 89% had undetectable viral load. 15% reported daily alcohol use and 34% binge drinking at least once per month. One third of the sample smoked. Most commonly used drugs were cannabis (16%), poppers (14%), cocaine (6%), ecstasy (4%) and GHB (4%). Injecting drug use (IDU) was associated with lower HRQL : physical (64 vs 73), mental (62 vs 70) , social (58 vs 61) and higher anxiety (8,5 vs 7,3) and depression (6,8 vs 5,4) scores. 34% of patients reported unprotected sex and 5% sex for money. Most consumed substances during sex were poppers (18%), alcohol (12%), and cocaine (7%). From the entire sample 12% reported always or often using drugs or alcohol during sex. Use of these substances was significantly associated with unprotected sex (65% vs 35%, p 0.001). Risk-seeking behaviour and personality trait was significantly associated with alcohol, tobacco smoking and drug use but not with unprotected sex.
Conclusions: In EQUIPIER study, risky sexual behaviour was seen to be predominantly associated with drug and alcohol use; while IDU was associated with lower HRQL and increased depression/anxiety. Interventions to reduce rates of substance use continue to be needed for this population.

MOPEC0661

Mass incarceration, prison release, and HIV incidence in the US South

B. Ojikutu[1], S. Srinivasan[2], L. Bogart[3], K. Mayer[4]
[1]*Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States,* [2]*Tufts University, Medford, United States,* [3]*RAND Corporation, Santa Monica, United States,* [4]*The Fenway Institute, Boston, United States*
Presenting author email: bojikutu@partners.org

Background: In the United States, the prevalence of HIV among incarcerated individuals is 5 times greater than among the non-incarcerated. The southern region of the US has the highest rates of incarceration, HIV incidence, poverty and economic inequality. Individuals living with HIV frequently cycle in and out of prison with return to home communities. We sought to determine the impact of prison release on HIV incidence in the US South.
Methods: Using 5-year cumulative case counts for new HIV diagnoses (2010-2014), we calculated HIV incidence rates at the ZIP code level for nine cities in the US South: Atlanta, Houston, Miami, Orlando, Tampa, Jacksonville, Columbia, New Orleans and Baton Rouge. Regression models were estimated for HIV incidence rates. Independent variables included number of people released from prison per 1000 population (prison release rate), economic inequality (GINI index), % population living in poverty, % Black residents in the population, and a spatial variable to control for clustering of HIV.
Results: Mean incarceration rate across all 9 jurisdictions was 560 per 100,000 adult population. Mean 5-year HIV incidence across all cities in the analysis (600 ZIP codes) was 215 per 100,000 population. Across the nine cities, HIV incidence was significantly associated with prison release overall (r=0.43, p< 0.01) and for each city: Atlanta (r=0.46, p< 0.01), Houston (r=0.58, p< 0.01), Miami (r=0.59, p< 0.01), Orlando (r=0.40, p< 0.01), Tampa (r=0.41, p< 0.01), Jacksonville (r=0.67, p< 0.01), Columbia (r=0.45, p< 0.01), New Orleans (r=0.64, p< 0.01), and Baton Rouge (r=0.88, p< 0.01). In multivariate analysis including all nine cities, controlling for economic inequality, % living in poverty and % Black population, prison release rate remained significantly associated with HIV incidence. A 10 person increase in prison release rate was associated with a 4.8% increase in overall HIV incidence—approximately 10 additional cases per 100,000 population.
Conclusions: In the US South, prison release is significantly associated with HIV incidence. HIV prevention interventions should promote timely linkage to ongoing treatment for released inmates living with HIV, as well as HIV testing, condoms, pre-exposure prophylaxis and safer injection equipment for all inmates and their partners to decrease onward HIV transmission post-release.

MOPEC0662

Short message service communication between HIV patients and their health care providers in a randomized controlled trial in Nairobi, Kenya

S. Muhula[1], M. Lisa van der Kop[2], K. Smille[2], S. Karanja[3], P. Nagide[3], B. Abunah[3], R. Gichuki[3], R. T Lester[2]
[1]*Amref Health Africa in Kenya, Monitoring, Evaluation and Research, Nairobi, Kenya,* [2]*University of British Columbia, Department of Medicine, Vancouver, Canada,* [3]*Amref Health Africa in Kenya, Nairobi, Kenya*
Presenting author email: samuel.muhula@amref.org

Background: Weekly short message service (SMS) conversation between people initiating ART and their health care providers (HCP) lead to improved ART adherence and viral load supression, and provides and opportunity for outpatient support. We conducted an analysis of weekly SMS conversation between patients newly diagnosed with HIV and thier HCPs in the intervention arm of a randomized controlled trial (Weltel Retain NIH R01 MH097558-01) on retention in HIV care.
Aims: to assess reasons for patients' non-respondence to weekly SMS and document health and psychosocial related problems reported by patients who respond to the SMS.
Methods: Trial participants were randomly allocated to intervention and control groups at a ratio of 1:1 at two HIV clinics in informal urban settlements in Nairobi. Those in the intervention arm received weekly SMS to check in on how they were doing by asking "Mambo?"and provide them the opportunity to identify whether assistance is required within 48 hours by responding "Sawa"or "Shida". A HCP experienced in HIV care followed-up all patients who responded "Shida" for appropriate advice. Those who did not respond within 48 hours were called by the HCP. The participants were followed-up for one year and all phone conversation from the SMS and voice calls recorded in the WelTel automated technology platform and clinic charts.
Results: The 352 intervention arm participants were followed-up for an average of 49 weeks. Almost all (98%, n=346) the participants failed to respond at least once to the weekly texts; 94% (n=332) ever responded "Sawa" and 43% (n=151) ever reported "Shida". Main reasons for non-responce were; lack of airtime, responce with unrecorgnized text, no phone and difficulty operating phone to send SMS. Some of the health and psychosocial issues reported include: abdominal pains, body itchines, chest pains, diarrhoea, misplacement of drugs, not able to get time off work, termination of employment because of positive HIV status and lack of bus fare to clinic.
Conclusions: SMS communication may be an effective way to engage patients newly diagnosed with HIV for timely identification of communication challenges, health and psychosocial related problems faced for appropriate medical and social engagement.

How can we improve development, implementation and evaluation of HIV prevention interventions in sub-Saharan African schools? A qualitative study with researchers

A.S. Sadiq[1], C. Abraham[1], S. Denford[1], C. Mathews[2]
[1]*University of Exeter, University of Exeter Medical School, Exeter, United Kingdom,* [2]*South African Medical Research Council, Health Systems Research Unit, Cape Town, South Africa*
Presenting author email: a.sadiq@exeter.ac.uk

Background: To date, trials have shown limited effectiveness of school-based sexual health interventions on prevention of sexually transmitted infections including HIV. Limitations in content, implementation or evaluation are some of the reasons for the limited effectiveness. We explore facilitators and challenges to designing, implementing and evaluating sexual health interventions in sub-Saharan African Schools from the perspectives of researchers.
Methods: We conducted 27 semi-structured interviews with researchers that have developed, implemented or evaluated a school-based sexual health intervention in sub-Saharan Africa. Researchers were purposely selected based on a published interventions and suggestions by experts. Interviews were conducted face-face or via Skype video call, lasted 30-60 minutes and audio recorded. Interview audios were transcribed verbatim and analysed thematically. Intervention Mapping framework was used to organise themes that emerged from our data.
Results: Researchers interviewed are international experts with 2 to over 30 years of experience and were involved in at least one intervention in one of the following countries- Kenya, Niger, Nigeria, Rwanda, South Africa, Tanzania, Uganda, Zambia and Zimbabwe. We identified 33 themes that mapped onto the six steps of Intervention Mapping framework. During development, social factors such as poverty and school infrastructures including quality of teaching, in addition to sexual health needs, should be addressed. School-based HIV prevention interventions should be culturally sensitive, address inter-generational and open communications on sexual issues, and clearly state aims to avoid any misunderstanding. Curriculum should also address contemporary issues in HIV prevention (Treatment as Prevention, Pre-exposure Prophylaxis, Voluntary Medical Male Circumcision and Gender-Based Violence). During implementation, interventions should be prepared for oppositions at various levels for which we have also identified effective approaches for overcoming them. Due to limited teachers' training in sub-Saharan Africa, provisions of simple but detailed facilitators' manual together with supportive supervisions may be critical in ensuring delivery fidelity. During evaluation, computerised audio devices and qualitative interviews with participant observations may facilitate collection and improve validity of adolescents' sexual behaviours data respectively.
Conclusions: We identified specific recommendations useful for improving design, implementation and evaluation of school-based sexual health interventions in sub-Saharan Africa.

MOPEC0664

The crystal meth factor in the dynamic of HIV epidemic

N. Machouf[1], J.-G. Baril[1], E. Huchet[1], J.-C. Brière[2], E. Lefebvre[1], S. Vézina[1], S. Dufresne[1], B. Lessard[3], B. Trottier[1], P. Coté[1]
[1]*Clinique Médicale du Quartier Latin, Research, Montréal, Canada,* [2]*Université de Montréal, École de Santé Publique, Montréal, Canada,* [3]*Nadaal Médicale du Quartier Latin, Research, Montréal, Canada*
Presenting author email: btrottier@cmql.ca

Background: We are on the way of reducing considerably the transmission of HIV in Canada since effective strategies to impede the epidemic, including TasP, PEP and PrEP are multiplying and easy to access here. However, chemsex (using new synthetic drugs, including crystal-methamphetamine in a sexual context) raises concern about reaching this goal. The objective of this study was to assess the impact of crystal use on risk factors of HIV transmission.
Methods: We conducted a single site, clinical based, anonymous survey at Clinique Médicale du Quartier Latin in Montreal, from Oct to Dec 2016. Information was self-reported through a questionnaire and all patients consulting at the clinic were eligible to the study. Data were analysed by ANOVA, Chi2-test and HIV determinants were assessed by logistical regression, using SPSS.
Results: 529 patients filled the questionnaire, 73% were male, 65% MSM, mean age was 48 (IQR 36-60). Lifetime drug experience was high: cannabis (75%), cocaine (46%), speed (37%), ecstacy (35%), ketamine (20%), GHB (25%) and crystal (15%). 45% of crystal users were HIV+ (compared to 18% of other drugs users and 19% of non drug users, p< 0.001). As shown in the table, crystal users have distinct behaviour compared to other participants.

	total (N=529)	No drug (N=112)	Drug other than Crystal (N=234)	Crystal (N=77)	p-value
HIV-positive	111	19%	18%	45%	< 0.001
Often/sometime combine Sex&drug	98	-	19%	56%	< 0.001
Use drug to have a different sexual experience	80	-	16%	59%	< 0.001
Number of sexual partners x last12months (mean,IQR)	9	4 (1 - 3)	8 (1 - 6)	51 (1 - 38)	< 0.001
Had STI x last 12months	86	9%	18%	34%	< 0.001
Use ALWAYS condom with occasional partners	196	45%	45%	14%	< 0.001
Use NEVER condom with occasional partners	83	16%	17%	38%	
MSM/Bisexual	309	53%	64%	89%	< 0.001
Found sexual Partner by apps	130	18%	38%	71%	< 0.001

[Table. Bivariate analyses for lifetime drug use]

HIV infection was 10 time more prevalent in recent crystal users (OR=9.14; 95%CI= 3.55-23.55) even after controlling for other major risk factors (IDU, number of sexual partner, anonymous sexual partner, MSM).
Conclusions: A particular attention should be given to the assessment of crystal-methamphetamine use in patients who come for STI screening, HIV prevention and also HIV care. Crystal users have high number of sexual partners; low condom use consistency; sexual intercourse with person they don't know; high rate of STIs and high rate of HIV. Crystal specific harm reductions strategies should be developed rapidly to avoid losing the control over HIV epidemic.

MOPEC0665

Barriers of HIV testing in health care facilities, knowledge, attitude and practice of health care providers in the country of Georgia

K. Shermadini[1], N. Badridze[1], O. Chokoshvili[1], A. Abutidze[1], M. Tsintsadze[1], T. Tsertsvadze[1], K. Nelson[2]
[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia, [2]Johns Hopkins Blumberg School of Public Health, Baltimore, United States
Presenting author email: shermadinik@yahoo.com

Background: Georgia is a small country with HIV prevalence less than 0.5%. There is universal access to HIV treatment and care; however 50% of all HIV infected persons are not diagnosed until late in their infection.
In order to evaluate the knowledge, attitude and practice of health care providers and barriers to HIV testing, we surveyed health care providers to develop recommendations for improving the current strategies for HIV testing in health care facilities in Georgia.
Methods: Anonymous interviews were conducted of 330 randomly sampled physicians from June 1 to November 30, 2016. They were asked multiple questions concerning their knowledge, attitudes and practices concerning HIV and their perceived barriers to HIV screening. Data were analyzed using Epi_Info 7 survey module.
Results: Mean age of physician respondents was 43; 71% (234) were women with the mean work experience of 19 years. 44% (144) reported having received training on HIV and 87.5% (289) were aware of the national free HIV testing program. 79% (261) of providers reported that in their clinical settings HIV testing is performed. Clinical symptoms of HIV/AIDS were incorrectly identified by 65% (216) of respondents and 16% (52) did not know the means of HIV transmission. Disclosure of patients HIV status to ensure physicians safety was considered mandatory by 84% (277). Among respondents 32% (106) considered stigma, 48% (157) lack of information and 58% (190) financial resources and governmental and administrative support as barriers for HIV testing.
Conclusions: The main barriers of HIV testing in health care facilities of Georgia include: low level of knowledge on HIV testing, treatment and prophylactic strategies; poor motivation; HIV related stigma among health care workers; lack of HIV training programs, and insufficient financial or administrative support. Based on these findings, we suggest the need to improve HIV testing performance in health care facilities, in order to increase the early diagnosis and effective treatment of HIV patients, education of health care providers concerning the importance of screening for early diagnosis and treatment to preserve the health of HIV patients and prevent transmission is critically needed.
Acknowledgment: Study is supported by the International Science and Technology Center.

MOPEC0666

Reported impact of intimate partner relationships on adherence to the vaginal ring in the MTN 020/ASPIRE trial

E. Pleasants[1], T. Tauya[2], K. Reddy[3], B.G. Mirembe[4], K. Woeber[5], T. Palanee-Phillips[3], E.T. Montgomery[6]
[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]University of Zimbabwe-University of California San Francisco Collaborative Research Program (UZ-UCSF), Harare, Zimbabwe, [3]University of the Witwatersrand, Wits Reproductive Health and HIV Institute (Wits RHI), Johannesburg, South Africa, [4]Makerere University - Johns Hopkins University Research Collaboration (MU-JHU), Kampala, Uganda, [5]South African Medical Research Council (SAMRC), HIV Prevention Research Unit, Durban, South Africa, [6]RTI International, Women's Global Health Imperative, San Francisco, United States
Presenting author email: epleasants@rti.org

Background: Two recent trials have demonstrated that the dapivirine vaginal ring is a safe and effective method of female-initiated HIV prevention whose efficacy increases with adherence. A variety of factors impact product adherence, including intimate partner relationship dynamics and male partner support.
Methods: In-depth and focus group interviews were conducted with 214 participants in Malawi, South Africa, Uganda, and Zimbabwe during the nested qualitative component of the MTN-020/ASPIRE trial, a phase III placebo-controlled trial of a dapivirine vaginal ring. Women were asked about their intimate partner relationships (type and number), the impact of ring use on their relationships, disclosure, perceptions of partners' attitudes and support of ring use, partner engagement with the study, and challenges associated with ring use. Interviews were conducted in local languages, transcribed and translated into English, and coded and analyzed thematically using Nvivo.
Results: Intimate partnerships of ASPIRE participants varied in power dynamics and levels of traditionalism, trust, and commitment. The dynamics of each relationship, particularly the balance of power between participants and male partners, shaped their influence on adherence. Women whose narratives suggested higher independence from male partners, either because their relationships were casual or egalitarian, were more likely to describe using the ring without pre-emptively gaining partner acceptance. They also reported fewer partner-related barriers to adherence, often emphasizing that ring use was their decision alone. By contrast, among women who described engaging in relationships aligned with culturally-traditional, gender-imbalanced norms, there were more reports of challenges to ring use related to partners, including experiences of physical violence or forced ring removals. The majority of women described being in stable, non-casual partnerships that were neither fully equitable nor inequitable. These women commonly discussed a dual sense of obligation and interest in sharing decisions about ring use with their partners, with some facing barriers in the process of disclosing and negotiating ring within their partnership.
Conclusions: The ways in which gender equality and dynamics are experienced individually by a woman, her partner, and within each relationship are important factors influencing women's adherence. Strategies to involve men, and to address gender norms and relationship barriers more proactively could positively impact ring adherence.

MOPEC0667

Keeping HIV status secret from steady partners: gender differences among migrants from sub-Saharan Africa living in France

J. Pannetier, A. Ravalihasy, A. Desgrées du Loû
CEPED, Gender & Health, Paris, France
Presenting author email: julie.pannetier@ceped.org

Background: Gender roles induce gender differences in keeping HIV status secret from steady partners that should be considered in HIV prevention. In Europe, sub-Saharan African migrants are a key population for HIV infection. The aim of this study was to assess the prevalence and determinants of HIV status secrecy to steady partners among sub-Saharan African migrants living with HIV in France.
Methods: The ANRS-PARCOURS study is a life-event survey conducted in 2012 in health-care facilities in the Paris region among a random sample of sub-Saharan migrants living with HIV (N=926). Migrants were retrospectively asked whether they had disclosed their HIV status to all their steady partners (i.e. a partner for at least a year) since HIV diagnosis to data collection. Characteristics associated with HIV secrecy were identified using mixed-effects logistic regression models, including time and place of diagnosis (i.e. before or since migration), relationships' characteristics (their duration, whether partners were married, had a child; lived in different countries or had other partners during the relationship) and partners' characteristics (their age, educational level and nationality).
Results: Keeping HIV status secret from steady partners was more frequent among men than among women (31.3% versus 24.8%, p=0.05). Among men, keeping HIV status secret from steady partners was associated with transnational relationships (ORa=1.75[1.06-2.91]) and steady partners with no or primary educational level (ORa=2.09[1.00-4.37]). Among women, keeping HIV status secret from steady partners was associated with not being married to partners (ORa=3.77[1.73-8.20]), to the fact that partners had other partners during the relationships (ORa=1.91[1.11-3.29]) and to the fact that partners had no or a primary educational level (ORa=4.20 [1.93-9.15]).
Conclusions: Our study shows gender differences in level and determinants of HIV secrecy within the couple. Secrecy was higher among men and must be related to norms of masculinity that prevent men from seeking testing, care and talk about their HIV infection. Secrecy was linked to physical distance for men and social distance with the partner for women in contexts of polygamy, whether formal or informal.

MOPEC0668

Social oppression, sexual coercion and marital duty: the drivers of HIV among immigrant Afro-Caribbean women in Canada

E. Amoako[1], A. Daftary[2], L. Calzavara[3], W. Tharao[4], T. Mbulaheni[5], L. Leonard[6], M. Loutfy[7], R. Kaul[8], S.T. Ryan[9], A. Burchell[10]

Presenting author email: elsieamoako@hotmail.com

Background: Afro-Caribbean women account for the largest number of new HIV infections in women in Canada, especially those emigrating from countries with generalized HIV epidemics. The MSAFIRI Study uses mixed methods to characterize the social drivers of HIV acquisition in African, Caribbean and Black (ACB) immigrants post-migration to Ontario, Canada. We present a novel analysis of the relationship dynamics leading immigrant women to acquire HIV.
Methods: In-depth interviews were conducted with a purposive sample of ACB participants enrolled in the MSAFIRI study, who identified their source partner and were infected post arrival. Analysis based in grounded theory.
Results: Participants included 21 women (4 Canadian born) of median 41 years´ age (range, 28-63); 52% were from Africa and 42% from the Caribbean. Participants had immigrated at diverse time-points; median time to HIV diagnosis post-migration was 14.5 years (range, 2-38). Participants´ source partners were either their immigration sponsors, or men still residing in participants´ countries of origin (whereupon infection occurred post-migration during a trip „home"). Relationship dynamics - many marital - were governed by women's precarious immigration status, and financial and emotional dependence on the source partner, which disempowered them from asserting any dominance or decision-making capacity in the relationship and in their social environment. This lack of control surfaced in participants' accounts of sexual activities that led to HIV acquisition, ranging from their partner's infidelity to subtle sexual pressures, but also more overt oppressive acts such as rape and incest. Sexually coercive acts were consistently reported by study participants, regardless of socio-demographic characteristics, acts that they were seldom able to openly acknowledge or resist.
Conclusions: HIV acquisition among Afro-Caribbean immigrant women is reflected in a culture of social oppression, marital duty and silent sexual coercion. The hierarchal structure of participants' intimate relationships, coupled with fear, trust and dependence upon their partners - all tied to their immigration status - left them in a state of HIV vulnerability. There is cause to explore culturally competent HIV prevention strategies for this racialized population by addressing gender inequality, and delivering sustainable programming that builds immigrant women's capacity to resist the oppressive dynamics that drive their risk for HIV.

MOPEC0669

Trust issues: perspectives of male and female partners navigating dapivirine vaginal ring (VR) use in dyadic relationships; formative research outcomes from the CHARISMA study in Johannesburg, South Africa

L.D. Wagner[1], A. Ayub[2], F. Mathebula[3], T. Palanee-Phillips[3], S. Tenza[3], M. Hartmann[4], S. O'Rourke[4], E.T. Montgomery[4]
[1]RTI International, Women's Global Health Imperative, San Diego, United States, [2]RTI International, Child and Adolescent Research and Evaluation Program, Waltham, United States, [3]Wits Reproductive Health and HIV Institute (WRHI), Johannesburg, South Africa, [4]RTI International, Women's Global Health Imperative, San Francisco, United States
Presenting author email: wagner@rti.org

Background: Research suggests that women prefer to seek male partner agreement to use microbicides, and partners' knowledge and acceptance of microbicide use promotes product acceptability and self-reported adherence. To inform development of the CHARISMA intervention to address gender inequalities in ring/prevention use, we aimed to better understand how partners influenced disclosure and support for use.
Methods: Using semi-structured guides, we conducted 42 in-depth interviews with former participants of the MTN-020/ASPIRE trial of the dapivirine vaginal ring and their male partners in Johannesburg, South Africa, to explore how ring use and partnership dynamics interacted. We purposively sampled women who reported social harms or partner non-support (n=14; 33%) and women with supportive partners (n=14; 33%). We recruited a convenience sample of male partners (n=14; 33%). Interviews explored participants' intimate partner relationships and their partner's interaction with the trial. Thematic analysis of interview data was conducted using Dedoose software.
Results: Male and female narratives suggested that relationship trust was a key factor influencing HIV testing and partner disclosure and acceptance of study participation/ring use. Women's perception of HIV risk was influenced by the level of trust within their relationships, and several women sought sharing HIV test results (by both partners) as a method of building or maintaining trust. Women reported that partner-related mistrust motivated ring use, and some male partners worried that ring use indicated their partner's mistrust in them. ASPIRE participation also had negative and positive impacts on men's trust in their partners. Some men indicated ring use strengthened their partnership, while more commonly, men suggested women may have used the ring to safely have side partners. The risk of generating male partner mistrust made some women apprehensive about disclosing ring use to their partner. Key elements influencing trust were communication style, tracking whereabouts, perceived in/fidelity, and dynamics around socializing.
Conclusions: Results indicate trust is an important factor impacting open communication and male partner acceptance of ring use. As the dapivirine ring proceeds closer to licensure, interventions supporting women's agency to use microbicides safely and effectively are a priority, and trust issues are an important topic to address in counseling directed to ring users.

MOPEC0670

Free HIV tests on public spaces: a strategy which allows easy access to diagnose in the Autonomous City of Buenos Aires (CABA)

A.L. Arévalo[1], A. Durán[1], E. Carrizo[1], L. Betti[2], L. Marachlian[2], F. Vulcano[2], M. Nan[3], M.L. Carones[2], D. Serantes[2], B. Carrozzi[2], S. Vulcano[2], P. Orge[2], C. Hirsch[2], G. Minissale[2], L. Goldin[2], F. Portnoy[2]
[1]Ministerio de Salud, Coordinación Salud Sexual, Sida e ITS, Buenos Aires, Argentina, [2]Ministerio de Salud, Buenos Aires, Argentina, [3]Ministerio da Saude, Buenos Aires, Argentina
Presenting author email: ana_lucia@live.com.ar

Background: To reduce the negative impact caused by late HIV diagnoses in CABA (44% in men), since 2013, 25 testing centres and a new diagnose method, consisting in the use of a rapid test in the screening and viral load in the confirmation, were created. Different campaigns took place on public areas to promote the quick HIV test and increase the demand of diagnose.
Methods: In 2015, the Ministry of Health started the campaign "Rapid HIV test on your neighbourhood". This campaign consists in the use of sanitary trailers where the test is offered voluntarily, free and confidential with pre and post-test advice. For preliminary positive cases, the patient is transferred to the nearest hospital. The trailers are located in strategic points of the City of Buenos Aires.
We analysed the surveys for the people who took the test between 2015 and 2016.
Results: A total of 3847 tests were executed - 2087 men (54%) and 1760 women (46%) around 33 years of age on average. 48% of the total had never had an HIV test before (45% women and 52% men). 28% showed low level of instruction (incomplete high school education or lower), no mayor difference between men and women.
There were 49 preliminary positive results (38 men and 11 women, from which 9 and 4 were tested for the first time respectively) with a global prevalence of HIV infection of 1.27%.
The prevalence according to sexual practices in the male population was: MSM 6.75% and HTS 0.71%.
In most of the cases, people who took the test said they approached the trailer by seeing it while they were walking, by reading about it in articles on the media or in social networks.
Conclusions: The results of the campaign showed a greater influx of males than usual in the health system. Compared to the general population data (0,4%), there's a higher prevalence of HIV infection in heterosexual men (0.71%). This reaffirms the importance of continuing with the promotion of rapid tests on public areas.

MOPEC0671

HIV risks among Thai transgender women and potential technology-based HIV prevention interventions

T. Anand[1], C. Nitpolprasert[1], S.J. Kerr[2,3,4], T. Nakpor[5], W. Champa[6], D. Linjongrat[7], S. Janyam[8], S. Nonenoy[1], J. Jantarapakde[1], R. Meksena[2], P. Phanuphak[1,2], N. Phanuphak[1], on behalf of the Adam's Love Study Team
[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]University of Amsterdam, Institute for Global Health and Development, Department of Global Health, Academic Medical Center, Amsterdam, Netherlands, [5]Sisters Foundation, Chon Buri, Thailand, [6]Caremat Organization, Chiang Mai, Thailand, [7]Rainbow Sky Association of Thailand, Bangkok, Thailand, [8]Service Workers In Group Foundation, Bangkok, Thailand
Presenting author email: tarandeepsinghanand@gmail.com

Background: Transgender women (TG) in Thailand with HIV prevalence ranging between 10-17%, experience unique health inequities and face multiple barriers to accessing HIV services. A paucity of research exists on their HIV vulnerability and how interventions should be designed to address TG-specific needs. We examined HIV risk characteristics and elicited strategies for HIV prevention interventions from a sample of Thai TG.
Methods: TG participants were randomly recruited from community-based organizations (CBOs), TG-focused and gender-friendly clinics, websites, and online TG networks. Self-administered survey links, containing questions on socio-demographic, stigma, risk behaviors, technology use and preferences for technology-based interventions, were distributed via e-mail, instant-messaging (IM) applications and social media networks to interested participants.
Results: Of 541 TG recruited, 212 (39.2%) responded to the survey from CBOs (45.3%), clinics (21.2%), websites (24.5%) and TG online networks (9%). Median age was 25 years (IQR: 22-30), 7.7% reported HIV-positive status, and 59.4% reported previous STIs. Mean HIV/AIDS knowledge score was 9.56 (SD = 3.4) out of 16. Mean age at first sex was 14.1 years (SD = 6.75).
In the past 6 months, 23.6% had >5 partners and 47.2% inconsistently used condoms. In the past 3 months, 35.5% had exchanged sex for money, 18.8% used recreational drugs, and 10.3% had group sex. Gender identity had caused fear among 45.8% to receive health care and 39.1% had ever been rejected from providers. More than half (54.7%) spent >8 hours using Internet per day and 43.4% had sought sex online in the past 3 months.
To optimize HIV prevention, a credible website featuring TG-friendly HIV testing sites (61.3%), TG-specific health videos (51.9%), health forums (57.6%) and eCounseling (56.2%) was desired. A TG counselor (63.2%) was the most preferred eCounselor, followed by a woman (18.4%), and a man (10.4%). Personalized HIV and health-related reminders were acceptable for 84.4% with IM applications (44.7%) and SMS (21.8%) being the most preferred platforms.
Conclusions: Among Thai TG who were mainly young, at high-risk, and felt stigmatized by health care system, technology-based interventions proved to have very high potential to deliver needed support in non-stigmatizing settings and link TG from online to offline HIV clinical services.

MOPEC0672

Factors that promote occupational substance use and related HIV risk: a qualitative assessment among female sex workers in Tijuana, Mexico

M. Salazar[1,2], K. Brouwer[1], L. Urada[2], B. West[1], M.G. Rangel-Gomez[3], E. Reed[2]
[1]University of California, San Diego, Medicine, La Jolla, United States, [2]San Diego State University, San Diego, United States, [3]Commission de Salud Fronteriza, Tijuana, Mexico
Presenting author email: marissa.m.salazar@gmail.com

Background: HIV prevalence among Female Sex Workers (FSW) in Tijuana, Mexico is 5-8% and as high as 14% among FSW who inject drugs. Factors related to work environment are primary in contributing to HIV risk among FSW. Occupational substance use (i.e., use of drugs/alcohol while working) is a critical work-related risk factor associated with inconsistent condom use with clients and increased HIV risk. However, more work is needed to better understand the factors promoting occupational substance use and the pathways by which such use heightens HIV risk.
Thus, the present study aimed to investigate the specific scenarios and factors in the work environment that promote occupational substance use and how such use increases HIV risk among FSW.
Methods: Qualitative data were from substance-using FSW (n=30) participating in a longitudinal study assessing HIV risk environments among a venue-based (e.g., bars, clubs) sample of FSW in Tijuana. Qualitative interviews were conducted to explore the specific scenarios of occupational substance use and how such use heightens risk for violence and HIV among FSW. Atlas Ti was used to code interviews for themes related to occupational substance use.
Results: Factors promoting occupational substance use among FSW included: a) making more money for sex trades that involve substance use with clients, b) using substances to facilitate working longer hours in sex work and c) substance use as a means to cope with stressors associated with sex work, particularly experiences of client violence. Factors identified by FSW to explain how occupational substance use increases HIV risk included: a) heightened experiences of client violence during sex trades when clients and/or FSW were using substances, and b) reports that substance use (either with clients or while working) prior to sex with clients decreased condom use negotiation power among FSW.
Conclusions: Findings highlight economic motivations and emotional coping as primary in contributing to occupational substance use among FSW, and violence was identified as a primary mechanism explaining the link between occupational substance use and HIV risk. Findings suggest that reducing economic vulnerability and violence will be critical to address occupational substance use and related HIV risk among FSW.

MOPEC0673

Masculinity and uptake of HIV testing: validity of the conformity to masculine norms inventory-22 in Malawi and Zambia

P. Indravudh[1], B. Hensen[2], E. OtteimKampe[2], M. Kumwenda[1], M. Simwinga[3], N. Desmond[1,4], C. Johnson[5], K. Hatzold[6], H. Ayles[2,3], L. Corbett[1,2], M. Neuman[2], UNITAID/PSI Self-Testing Africa (STAR)
[1]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Zambart, Lusaka, Zambia, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]World Health Organization, Geneva, Switzerland, [6]Population Services International, Harare, Zimbabwe
Presenting author email: peach.indravudh@gmail.com

Background: Men across sub-Saharan Africa are less likely to test for HIV or link to care than women. Qualitative research has highlighted the potential influence of masculine norms. We explored the Conformity to Masculine Norms Inventory (CMNI) scale in Malawi and Zambia, aiming for a validated scale to investigate associations between masculinity and previous HIV testing.
Methods: We reviewed psychometric scales measuring constructs related to masculine norms, behaviours or attitudes. The CMNI was selected based on previous validation in Kenya, reported association with health-seeking outcomes, and simplicity. The short version (CMNI-22) was amended for applicability, translated and back-translated into local languages, and piloted in Malawi. The scale was administered as part of a baseline household questionnaire to men in rural Malawi (n=485) and periurban Zambia (n=334). Iterated principal factor analysis was used with oblique rotations. Factor loadings below 0.3 were disregarded. Eigenvalues and variance captured were used to select retained factors.
Results: Sampling adequacy (Kaiser-Meyer-Olkin) was 0.80 and 0.65 in Zambia, respectively. Cronbach's alpha (scale reliability) was 0.75 and 0.68 in Malawi and Zambia. In Malawi, three factors were retained based on items relating to virility, violence and power over women; items associated with dominance and winning; and items pertaining to pursuit of status. In Zambia, two factors were retained. The first was associated with virility, violence and winning; the second, emotional control, dominance and power over women.
Conclusions: The interpretability of the items loading onto the retained factors was mixed and the tool performed differently in Malawi and Zambia, suggesting poor performance of the short-form scale. No masculinity-related scales have been validated in a rural or peri-urban African context. More research is needed to develop locally validated and generalizable scales for African settings: successful development would facilitate investigation of masculine norms and their effect on uptake of HIV services.

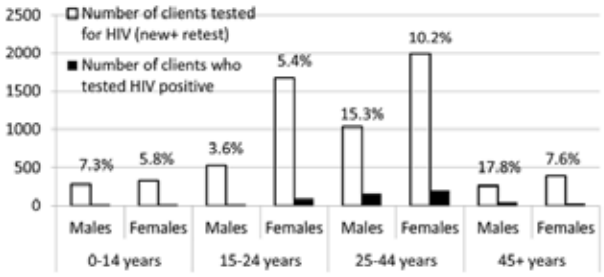
MOPEC0674

High HIV test yield among older men testing for the first time in Zimbabwe: implications for reaching 90-90-90 and preventing incident infections in young women

K. Webb[1], V. Chitiyo[1], S. Page-Mtongwiza[1], D. Patel[1], J. Murungu[2], T. Maphosa[1], B. Engelsmann[1]
[1]Organisation for Public Health Interventions and Development, Harare, Zimbabwe, [2]Ministry of Health and Child Care, AIDS & TB, Harare, Zimbabwe
Presenting author email: kwebb@ophid.co.zw

Background: Recent evidence highlights how sexual networks between young women and older men are driving HIV transmission in sub Saharan Africa. With a national HIV prevalence of 14.6%, reaching 90-90-90 in Zimbabwe will require

supporting undiagnosed individuals to know their status and initiate ART. Our objective was to explore HIV testing rates and yields by age, sex and health service entry points at 29 health facilities in Zimbabwe.
Methods: We conducted a retrospective cohort analysis of de-identified data from clients accessing HIV testing services at 29 purposively selected PEPFAR prioritised health facilities in 3 Districts of Zimbabwe (Bulilima, Mangwe, Mutare). All clients accessing HIV testing services from May-Aug 2016 were traced through multiple registers to document HIV test result and subsequent access to HIV Care and treatment services. Proportions were compared using Chi-squared tests in STATA V12.
Results: From May-Aug 2016, 7,027 HIV tests were conducted with a prevalence of 10.4% (95%CI:9.7-11.2). The majority of tests were conducted among women (67.3%; n=4,717), in antenatal care (28.3%; n=1,991). Men aged 25 and above had significantly higher HIV test yields than women of the same age (15.8% vs. 9.7%, p<0.0001).



[HIV test rate, new positives and test yield (%)]

Older men (45+yrs) HIV testing for the first time had the highest test yield (22%). Due to higher test rates, females accounted for 57.7% (n=423; 95%CI:54.0-61.3) of new positives identified. Men testing HIV positive presented at older median[IQR] age (37[30-43] vs. 31[27-39]), had significantly lower ART initiation rates (75% vs. 82%, p=0.05), and lower median CD4 cell count[IQR](186 cell/μL[101-316] vs. 334 cell/μL[186-519] than their female counterparts.
Conclusions: We observed lower HIV test rates, higher yields and lower linkages to HIV care among adult men. Reaching 90-90-90 and preventing new infections in Zimbabwe will require investment in evidence-based differentiated models of care to support timely uptake of HIV testing and treatment among adult men with unknown HIV status.

MOPEC0675

Qualitative findings of an HIV prevention intervention that empowers young women: Rise club case studies of social cohesion

L. Letsela, S. Goldstein, P. Kodisang
Soul City Institute Social Justice, Monitoring and Evaluation, Johannesburg, South Africa
Presenting author email: lebohang@soulcity.org.za

Background: Soul City Institute Social Justice introduced the RISE Young Women's Clubs to build social cohesion, self-efficacy and resilience and access to health, social and economic services. The clubs are a space for young women (15 -24 years) to support each other, work as a group to undertake projects in the community and, ultimately, prevent HIV through addressing structural drivers of HIV including discriminatory gender norms and gender based violence. Over 1000 clubs with 15000 members were established across 6 provinces.
Methods: A qualitative study was conducted with young women across 6 provinces. This was in the form of a series of case studies that utilised focus group discussion and in-depth interviews with stakeholders to measure the success of clubs in building social cohesion, resulting in young women being linked to required services to prevent HIV. Data was analysed thematically on Atlas Ti.
Results: Young women were linked to services such as social grants, access to condoms, health services including access to Sexual and Reproductive Health and HIV testing. The girls talked about having fun together. They felt empowered with life skills to protect themselves from HIV, substance abuse, violence and intimidation. Activities included, fundraising and gardening to support poverty stricken club members and families, as well as discussions about career guidance, tertiary studies and bursaries, dealing with finances and how to become leaders and role models in their communities.
The girls reported how clubs foster an environment for supporting each other, thereby building social cohesion and resilience around health, social and educational outcomes.
Conclusions: The Rise clubs play an important role in building self-esteem and social cohesion among young women, and often fill a gap in their social support structures. Together addressing gender based violence, poverty and positive peer pressure are some of the ways that the clubs function to enable young women to remain HIV free.

MOPEC0676

Changing the game for girls: encouraging results from a longitudinal study of a soccer-based HIV and SGBV prevention programme for adolescent girls in South Africa

B. Sanders[1], C. Barkley[1], N. Advani[1], M. Das[2], A. Cooper[3], B. Moolman[3], C. Coakley[1], R. Banciu[4]
[1]Grassroot Soccer, Cape Town, South Africa, [2]International Center for Research on Women (ICRW), New Delhi, India, [3]The Human Sciences Research Council (HSRC), Cape Town, South Africa, [4]Grassroot Soccer, Lusaka, Zambia
Presenting author email: ccoakley@grassrootsoccer.org

Background: More than a third of women in South Africa experience violence before the age of 18. Women are at a much higher risk of HIV infection than men, with young women aged 15-24 accounting for 60% of all new infections among young people. Gender inequality and intimate partner violence have been linked to increased risk of HIV. Grassroot Soccer (GRS) designed SKILLZ Street Plus (SSP), a programme that combines girls' soccer with educational activities meant to empower at-risk adolescent girls to form gender-equitable attitudes and negotiate healthy relationships; respond better to violence in their lives and gain HIV-related knowledge, thus reducing the chances of risky sexual relationships and HIV infection. A longitudinal study and external evaluation measured changes in knowledge, attitudes and experiences of violence among girls before and after SSP.
Methods: Baseline and endline questionnaires were administered to girls (n=146, average age = 13.6) in two intermediate and two secondary schools in Soweto over an 18-month period. Project monitoring data were collected, including uptake of HIV testing and disclosure of experiences requiring follow-up. An external evaluation investigated quantitative results through rapid ethnographies, focus group discussions (n=6) and interviews (n=19) with staff, coach mentors, SSP participants as well as male participants in mixed-sex GRS programmes.
Results: We observed increased percent of girls who reported intimate partner violence (IPV) as unacceptable (70% baseline; 89% endline) and reported decreases in justification and experiences of IPV. Some girls chose to leave physically and emotionally abusive relationships. HIV testing uptake (ever tested for HIV and tested for HIV in last 3 months) increased from 12.3% to 43.9% and from 4.8% to 27.4% respectively. Girls reported greater confidence, self-efficacy and improved decision making. Disclosure of violence doubled from baseline to endline.
Conclusions: The SSP intervention has the potential to empower girls to pursue healthy and gender equitable partnerships and leave violent relationships, which put them at higher risk of HIV. It highlights the important role that families, friends and other support systems play, including schools, police and clinical services. GRS will use these encouraging findings to develop a more robust programme that tackles violence at multiple levels.

MOPEC0677

Lessons learned: employing Indigenous methodologies and women-centred approaches to understand Indigenous women's experience of HIV prevention and care in Quebec, Canada

N. O'Brien[1,2], C. Martin[3], D. Peltier[4], A. Kaida[5], M. Becker[6], C. Bourassa[7], S. Bruce[8], M. Loutfy[9], A. de Pokomandy[1,2], on behalf of the CHIWOS-PAW Team
[1]McGill University Health Center, Chronic Viral Illness Service, Montreal, Canada, [2]McGill University, Family Medicine, Montreal, Canada, [3]Native Women's Shelter of Montreal, Montreal, Canada, [4]Canadian Aboriginal AIDS Network, Dartmouth, Canada, [5]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [6]University of Manitoba, Centre for Global Public Health, Winnipeg, Canada, [7]First Nations University of Canada, Indigenous Education, Regina, Canada, [8]University of Manitoba, Community Health Sciences, Winnipeg, Canada, [9]Women's College Hospital, Women's College Research Institute, Toronto, Canada
Presenting author email: obrien.nadia@gmail.com

Background: Approaches to HIV-prevention and care with Indigenous Women in Canada must integrate and address challenges, and build on this population's strengths. For Indigenous women (First Nations, Métis, Inuit), vulnerability to HIV is structured by gender inequity, colonization, racialization and social immobility (poverty, education). These structural inequities lead to disproportionate HIV rates; although Indigenous women are 4.3% of the Canadian female population, they represent 30.6% of new female diagnoses. Importantly, these vulnerabilities coexist with resilience, cultural continuity and strength. This abstract details lessons learned for prevention and care programming, drawn from our process conducting four full-day workshops with Indigenous women in Quebec, Canada.

Methods: The research is embedded within the Canadian HIV Women's Sexual and Reproductive Health Cohort Study - Prioritizing the Health Needs of Positive Aboriginal Women (CHIWOS-PAW). In Quebec, the purpose was to understand Indigenous women's perspectives regarding women-centered strategies to improve HIV prevention, care and overall health. Between December 2015 and December 2016, under the direction of an all-female team of Indigenous leaders, and drawing on Indigenous Methodologies, two research retreats, a community analysis workshop, and a celebration event were conducted with 14 Indigenous women.
Results: From our process we draw the following recommendations for the creation of accessible and acceptable prevention and care strategies for Quebec Indigenous women. Lessons learned included:
1) incorporating women-centered, culturally-adapted sharing circles, arts, and ceremony, encouraged participation, safety and comfort;
2) conducting numerous workshops with the same women was valuable to participants and facilitators to build trust and adapt subsequent workshops to participants needs;
3) confirming findings with participants was essential to ensuring that the knowledge, experience, and priorities of Indigenous women were respected.
Facilitators to our process included:
1) existing networks with Indigenous Elders, art-therapists, musicians;
2) a strength-based, neutral space to conduct the workshops (e.g. Aboriginal Art Gallery);
3) experienced Indigenous researchers with facilitation skills; and
4) sufficient funds and coordination support to carry out multiple events.
Conclusions: Adopting a women-centered, strength-based, culturally adapted, peer-lead approach is essential to ethical, effective and appropriate prevention and care for Indigenous women. Further work by and with Indigenous women is needed to address HIV in Canada.

MOPEC0678

Barriers to care and non-prescribed sex hormone use among trans women in São Paulo, Brazil

L.F. Maschião[1], A.B.M. Rocha[1], B.R.L. Redoschi[1], T.P. Pinto[1], C. Turner[2], E.C. Wilson[2], W. McFarland[2], M.A. Veras[1], Muriel Study Group
[1]Santa Casa de São Paulo School of Medical Sciences, São Paulo, Brazil, [2]San Francisco Department of Public Health, San Francisco, United States
Presenting author email: lucafm@icloud.com

Background: Transwomen face significant discrimination and barriers to healthcare worldwide. Lack of trans-specific care has not only been associated with HIV-related risk behaviours as gender affirming coping practices, but often results in non-prescribed sex hormone use and other medically unsupervised transition methods, leading to significant health complications. However, little is known about barriers to trans-specific care among transwomen in Brazil, where few facilities provide such services. To address this research gap, we analyzed factors associated with non-prescribed sex hormone use by transwomen in 7 municipalities of São Paulo state in Brazil.
Methods: Muriel Project was a cross-sectional consecutive snowball sampling study conducted from November 2014 to October 2015. A total of 673 transgender persons were recruited through health care and social welfare services and answered a face-to-face interviewer-administered survey. This analysis focused on transwomen (n=616 out of 673). Descriptive statistics and poisson bivariable and multivariable regression models with robust variance were employed to assess, respectively, sample characteristics and non-prescribed sex hormone use associations with sociodemographic factors, discrimination experiences, gender identity, transition procedures, sex work and health care access.
Results: Overall, 90.7% (n= 559) transwomen reported ever taking sex hormones, with mean age for starting at 17 years. Most (79.2%; n=444) of those who took sex hormones detailed non-prescribed use, which was associated with sex work (adjusted Prevalence Ratio [aPR]=1.23; CI95%=1.12-1.35) and medically unsupervised filler use (aPR=1.11; CI95%=1.01-1.21). Furthermore, use of chosen name in public health services (aPR=0.87; CI95%=0.76-0.99), and gender identity of woman (aPR=0.77; CI95%=0.65-0.91) or transsexual (aPR=0.89; CI95%=0.80-0.98) were found to be protective against medically unsupervised sex hormone use.
Conclusions: A high unsupervised sex hormone use prevalence was observed in our sample, possibly underestimated given the high proportion of participants recruited from health care services. Such findings may indicate barriers to trans-specific care and resort to medically unsupervised transition procedures, which might be exacerbated for sex workers. Ensuring social rights and providing adequate health and trans-specific care services may lessen non-prescribed sex hormone use and other unsupervised transition procedures, preventing subsequent risk behaviours and ensuing better health outcomes for transwomen.

MOPEC0679

Social Network Analysis of Women with HIV in South India

H. Tamir[1], A.L. Rodriguez[2], D.P. Stephens[2], P. Madhivanan[2], B. Melendrez[2]
[1]Columbia University, ICAP- Epidemiology, Brooklyn, United States, [2]Florida International University, Miami, United States
Presenting author email: ht2453@columbia.edu

Background: Stigma is a global challenge to the prevention and treatment of HIV. Intersectionality, or layered stigma has compounded these barriers for women. Previous literature suggests health disparity among women with HIV compared to their male counterparts, with women reporting less support and greater stigma. In order to disentangle various contributors to stigma and its impact on mental health and overall wellbeing it is necessary to first understand the support systems and social networks in the general population compared to those of people living with HIV. The objective of this study was to map ego-networks of Indian women with HIV and demonstrate differences when compared to women without HIV. It also sought to uncover alters (people) providing primary support and substitutes who replaced traditional support-givers.
Methods: This study used a mixed-method design.
Four hundred South Indian women (300 HIV-negative and 100 HIV-positive) between the ages of 18-40 (m=24) completed surveys on support, quality of life, and social networks. Sixty of these women (30 HIV-negative and 30 HIV-positive) also joined semi-structured focus group discussions (6-8 women per group) on social networks, support, and HIV-knowledge. The following statistical tools were used for analyses: Atlas.ti for qualitative analysis, EgoWeb2.0 for social network analysis, and SPSS-21 for Anovas and multiple regressions.
Results: Preliminary results demonstrate significant between group differences, with women identifying as HIV-positive reporting fewer and weaker links in the between alters (people) in their networks when compared to HIV-negative counterparts. Furthermore women with HIV reported significantly less friends, but greater support from their adult children, particularly daughters and substitute alters, such as HIV-support group members.
Conclusions: HIV-related stigma may impact social and support network structures. It is necessary to further research this topic in order to improve prevention and intervention programs to include social awareness and support, with the eventual goal of improved mental health outcomes for people living with HIV.

MOPEC0680

Psychological challenges and coping strategies among pregnant HIV-positive women aged 15-24 years in Lagos state

P.A. Utah[1], I.P. Okafor[1], C.S. Ejekam[2]
[1]University of Lagos, Department of Community Health, Lagos, Nigeria, [2]Lag, Community Health, Lagos, Nigeria
Presenting author email: bfchioma@yahoo.com

Background: in Sub-saharan Africa, 76% of young people (15-24) living with HIV are female. an unplanned pregnancy can be an emotionally wrenching experience for woman and can be especially frightening for an unmarried adolescent, who may be unprepared to raise a child. Given the combination of stressors that are likely, the need for information about the psychological impact of HIV infection during pregnancy is imperative. The objective of this study is to identify the psychological challenges and coping strategies adopted among pregnant HIV positive young women aged 15-24 years.
Methods: The study design was descriptive cross-sectional. Two hundred and three young women aged 15-24 PLWHA from PMTCT centers located across the urban Lagos state in Nigeria were consecutively selected. A structured interviewer-administered questionnaire was used to collect data on socio-demographics, assessed psychological challenges using adapted WHOQOL-HIV and coping strategies using adapted Ways of Coping. Data was analyzed with SPSS version 20. Quantitative data were analyzed using inferential statistics and qualitative variables using percentage.
Results: Two hundred and three pregnant HIV positive young women were confronted with various negative experience including: shame, confusion, anxiety over non-disclosure, poverty, lack of employable skill, interrupted education, lack of access to age appropriate sexual health information and services, social isolation and stigma and depression. A significant proportion of respondents were in psychological distress (40%). Findings showed that,respondents who were married or co-habiting with a partner or in supportive relationships experienced less psychological distress. Employment status and income of respondents were significantly associated with the experience of psychological distress. In response to these challenges, majority of them 72.9% adopted problem focused coping strategy while about 27.1% used emotion focused strategy. They reported relatively high use of accepting responsibility and distancing but poor use of social support , self controlling and positive reappraisal which are positive constructs. The negative constructs used were confrontative coping and escape-avoidance coping.

Conclusions: HIV infected pregnant young adults faced many serious psychological and social challenges. These challenges elicit both positive and negative coping and survival strategies. The coping strategies selected highlights need for interventions to aid healthier coping choices among those experiencing psychological distress.

MOPEC0681

Relationship power imbalance and history of partner HIV testing among pregnant women in Uganda

C. Vrana[1], J. Korte[1], J. Matovu[2], E. Buregyeya[2], H. Chemusto[3], W. Musoke[3], R. Wanyenze[2]
[1]Medical University of South Carolina, Public Health Sciences, Charleston, United States, [2]Makerere University, School of Public Health, Kampala, Uganda, [3]Mildmay Uganda, Kampala, Uganda
Presenting author email: korte@musc.edu

Background: In some societies, a power dynamic is shifted towards greater power and resources given to males over females, and this imbalance can have a negative impact on health, including HIV prevention. Here we investigate the association between gender power imbalance and male partner testing for HIV among pregnant women attending antenatal care (ANC) in central Uganda.
Methods: This analysis uses baseline data from a cluster-randomized HIV self-testing intervention from three ANC clinics in central Uganda. Pregnant women with HIV- male partners were recruited and randomized by day into standard of care or intervention (HIV self-testing kits for the male partner). Screening and baseline interviews were conducted using REDCap software on electronic tablets. Women were asked about history of partner testing, characteristics of their relationship, and other factors. Analyses were performed in SAS (9.4), with chi-square tests and a p-value <0.05 for significance.
Results: 1,473 women were recruited across the three sites between July and November of 2016 (698 in the standard of care arm, 767 in the intervention arm). Only 17.7% of the women's partners had ever accompanied them to ANC (17.7%) and of the women who asked, only 39.6% of male partners had ever tested for HIV. Among women under 26, women's contributions to household expenses were different by partner testing (overall p<0.001), with 36.3% of women whose partners tested making no contribution to expenses compared to 64.2% of women whose partners did not test. Relationship status also differed by partner testing (overall p=0.03), but 11.95% of women whose partners tested had a sometimes difficult relationship with their partner vs. only 5.6% of women whose partners did not test. Among women aged 26+, decision making for visiting family differed by partner testing (overall p=0.002), with 54.6% of women making joint decisions with partners who tested compared to 36.9% whose partners did not test.
Conclusions: A higher relationship power balance is significantly associated with increased HIV testing among male partners testing when measured by household expenses and decision making, but not relationship status. Interventions aiming to increase relationship power balance could increase HIV testing among males in Uganda.

MOPEC0682

Sociodemographic factors related to relationship power imbalance among pregnant women and their partners in Uganda

J. Korte[1], C. Vrana[1], J. Matovu[2], E. Buregyeya[2], H. Chemusto[3], W. Musoke[3], R. Wanyenze[2]
[1]Medical University of South Carolina, Charleston, United States, [2]Makerere University School of Public Health, Kampala, Uganda, [3]Mildmay Uganda, Kampala, Uganda
Presenting author email: korte@musc.edu

Background: In relationships where the power dynamic is shifted to males, the female partner may have numerous disadvantages, including lack of self-efficacy to prevent adverse health outcomes and obtain health care. We investigated sociodemographic variables related to relationship power imbalance among pregnant women and their male partners in central Uganda.
Methods: We have completed recruitment into a cluster-randomized trial of HIV self-testing to increase partner testing in central Uganda. We recruited pregnant women from three ANC clinics. Women enrolled had a male partner aged 18+ whom she saw at least once a week, who she believed to be HIV-, and who did not test for HIV in the previous 6 months. We sought to determine at baseline, the relationship between sociodemographic factors and measures of relationship power imbalance within the couple.
Results: 1,473 women were recruited from July to November 2016 (698 standard of care, 767 intervention). Among women aged 25 and under, decision-making regarding her health care differed by her education status (overall p=0.0463), with 12.15% of women with secondary education making joint decisions versus 6.49% of women with less education. Decisions on use of the woman's income differed by partner's education (overall p<0.001), with the man alone making the decision in 11.37% of couples where the man had secondary education or higher, versus 26.64% among couples where the man had less education. Among women aged 26 and older, decisions regarding visiting family differed by the woman's education level (overall p=0.004), with 50.98% of women with secondary education making joint decisions, versus 36.62% of women with less than secondary education.
Conclusions: While higher educational attainment in the male partner was related to increased decision making by the male only, we found that higher educational attainment by the female was related to more joint decision making. Educational parity within the couple, and in particular higher educational attainment by the woman, may help improve gender equity and health outcomes among couples in Uganda.

MOPEC0683

Effect of adding TB/HIV referral coordinators on TB and HIV screening: a programme evaluation in Benue state, Nigeria

J. Okpala[1], J. Sagay[2], I. Kuku[1], P. Christopher-Izere[1], I. Abutu[1], B. Oyeledun[2]
[1]Centre for Integrated Health Programs, Abuja, Nigeria, [2]Centre for Integrated Health programs, Abuja, Nigeria
Presenting author email: janychino@yahoo.com

Background: Nigeria has the fourth largest TBHIV burden in the world. Benue state, in North Central, Nigeria has a high TB burden attributable to its high HIV prevalence of 5.6%.An assessment of the implementation of ICF among PLHIV in HIV care and treatment settings in Benue state by the US Centre for Disease Control revealed significant drop offs in the cascade from TB screening to treatment of co-infected patients.
We assessed the impact of introducing TBHIV referral coordinators on the number of people screened as well as diagnosed and started on TB treatment in five Local Government Areas (LGAs) of Benue State, Nigeria supported by the Centre for Integrated Health Programs.
Methods: 59 TBHIV volunteers and 5 LGA referral coordinators were trained in cough triaging, presumptive case identification, data management and linkages to comprehensive ART sites and were provided with monthly stipend. PLHIV were symptomatically screened for TB, Presumptive TB cases were referred to the DOTS clinic for sputum sample collection and follow up. The LGA coordinators supervised the volunteers.
Data from four months (October 2015-January 2016) before implementation of the TB referral coordinators and four months after implementation (February -May 2016) were analysed using three TB indicators (PLHIVs screened for TB, Number of presumptive TB cases identified, number of TB cases diagnosed and placed on TB treatment) to evaluate the impact of the intervention.
Results: The number of clients offered TB screening increased by 91% within the period under review from 10,676 to 20,444 this was accompanied by a significant increase in number of presumptive TB cases identified (934 vs. 2567, p=0.00) However, there was no statistically significant increase in the case detection rate amongst the screened cases (5.8% vs. 7.1%, p >0.05).
Conclusions: The use of TBHIV referral coordinators improved TB screening and referrals in the LGAs.Additional measures need to be put in place to improve the case detection rate.

MOPEC0684

Tuberculosis intensified case finding among people living with HIV in Côte d'Ivoire: coverage, caveats and way forward

A.F. Ouffoue[1], F. Traore-Toure[1], G.D. Etheredge[2], G. Morineau[3], K. Abo[4], B.Y. Adja[4]
[1]Family Health International (FHI 360), Abidjan, Cote D'Ivoire, [2]Family Health International (360), Washington, United States, [3]Family Health International (FHI 360), Gaborone, Botswana, [4]Ministry of Health, Abidjan, Cote D'Ivoire
Presenting author email: fouffoue@fhi360.org

Background: Intensified case finding (ICF) for tuberculosis (TB) among people living with HIV (PLHIV) is not performed routinely by health staff in Côte d´Ivoire (CI) despite being a mandatory routine practice since 2010. Implementation of TB-ICF in 39 CDC-sponsored HIV care centers (HCC) was assessed to quantify the extent of the application of national guidelines and to provide recommendations for improvement.
Methods: A retrospective cohort study extracting data from PLHIV medical records was conducted. PLHIV were selected through two-stage cluster sampling. First, HCC were selected proportional to the current number of PLHIV on treatment. Second, a fixed number of PLHIV medical records were selected among those aged 15 or older who had attended the HCC between September 2014 and March 2015. Data from selected patients' last visit during the study period were recorded.

Results: A total of 4410 patient records were used from 39 HCC spread nationwide. PLHIV had a mean age of 42.0 years and 72.6% were women. TB-ICF was performed for 79.0% of PLHIV. A multivariate logistic regression was used and odds ratios were estimated with 95% confidence intervals. Predictors of the absence of TB screening (p< 0.001) included attending facilities with more than 50 PLHIV per health care provider (HCP) (OR: 0.3583; 0.3075-0.4173) and HCC located in Abidjan (OR: 0.4353; 0.3730-0.5078), being older (>40 years; OR: 0.9824; 0.9755-0.9895), having a higher CD4 count (OR: 0.9995; 0.9992-0.9997), and attending HCC with greater numbers of PLHIV (OR: 0.9998; 0.9998-0.9999). The implementation of TB-ICF was not associated with the existence of a diagnostic and treatment center for TB in the HCC (p=0.146).
Conclusions: TB-ICF in CI is hampered by understaffing at HCCs, and elderly people are less likely to receive TB screening, possibly because they require lengthier consultation time than younger patients or because of a possible impact of survivor bias. Task shifting TB-ICF to lower level cadres at the HCC or community has the potential to improve coverage. Mentoring HCP on the need to attend to all patients, regardless of their CD4 count, and to older PLHIV are possible strategies for improving health service delivery in the short term.

MOPEC0685

Access to and utilization of health and social services for people who inject drugs (PWID) in two urban areas of Mozambique, 2013: results from a formative assessment

L.C. Dengo Baloi[1], M. Boothe[2], I. Sathane[3], C. Sema Baltazar[4], K. Ngale[5], C. Inguane[3], E. Fazito[6], R. Horth[2]
[1]Instituto Nacional de Saúde, Moçambique, Health Surveillance, Maputo, Mozambique, [2]University of California, San Francisco (UCSF), Maputo, Mozambique, [3]Global Programs for Research and Training, Maputo, Mozambique, [4]Instituto Nacional de Saude, Maputo, Mozambique, [5]Pathfinder International, Maputo, Mozambique, [6]UNAIDS, Maputo, Mozambique
Presenting author email: liliana.dengo.baloi@gmail.com

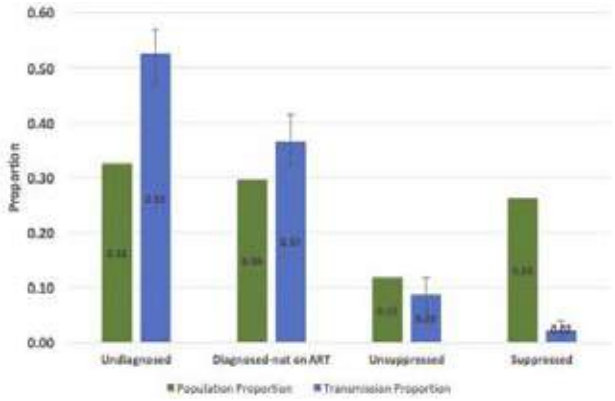
Background: Prior to the 2014 Integrated Biological and Behavioral Survey (IBBS) among PWID in Mozambique, data about health seeking behaviors or service uptake for PWID did not exist. We present the results from the formative assessment component of the IBBS.
Methods: Standardized interview guides were used during key informant interviews (KII) and focus group discussions (FGD) in Maputo and Nampula/Nacala to discuss issues related to risk behaviors and access to and utilization of health and social services by PWID. The target sample size was not defined a priori, but instead KII and FGD were conducted until responses reached saturation. Data analysis was based on the principles of grounded theory related to qualitative research. Transcripts were double coded and analyzed using NVivo (QSR International Pty Ltd. v10).
Results: Eighty-four respondents, ages 15 to 60, participated in KIIs and FGDs. Participants were majority male from diverse income levels and included current and former PWID, non-injection drug users, health and social service providers, peer educators, and community health workers. Respondents reported that PWID engage in high-risk behaviors such as needle and syringe sharing, exchange of sex for drugs or money, and low condom use. According to participants, PWID would rather rent, share or borrow injection equipment at shooting galleries than purchase them due to stigma, fear of criminalization, transportation and purchase costs, restricted pharmacy hours, personal preference for needle sharing, and immediacy of drug need. Barriers to access and utilization of health and social services include distance, the limited availability of programs for PWID, lack of knowledge of the few programs that exist, concerns about the quality of care provided by health providers, lack of readiness as a result of addiction and perceived stigma related to the use of mental health services.
Conclusions: Mozambique urgently needs to establish specialized harm reduction programs for PWID and improve awareness of available resources. Services should be located in hot spot areas to address issues related to distance, transportation and the planning required for safe injection. Specific attention should go to the creation of PWID-focused health and social services outside of state-sponsored psychiatric treatment centers.

MOPEC0686

The risk of HIV transmission at each step of the HIV care continuum among people who inject drugs

D. Escudero[1], M. Lurie[2], K. Mayer[3], M. King[2], S. Galea[4], S. Friedman[5], B. Marshall[2]
[1]Harvard University, Epidemiology, Boston, United States, [2]Brown University, Epidemiology, Providence, United States, [3]Fenway Health, Boston, United States, [4]Boston University, Boston, United States, [5]National Development and Research Institutes, New York, United States
Presenting author email: escudero@hsph.harvard.edu

Background: People who inject drugs (PWID) are at continued risk for HIV in the US, and experience disparities across the HIV care continuum compared to other high-risk groups. Estimates of the risk of HIV transmission at each stage of the care continuum may assist in identifying public health priorities for averting incident infections among PWID, and sexual transmissions to those outside this risk group.
Methods: We created an agent-based model simulating HIV transmission and the HIV care continuum for PWID in New York City (NYC) in 2012. Using surveillance data and estimates from the National HIV Behavioral Surveillance system, we simulated a dynamic sexual and injecting network. We estimated the proportion of HIV transmission events attributable to PWID in the following categories, those: without an HIV diagnosis (‚Undiagnosed'); diagnosed but not on antiretroviral therapy (ART) (‚Diagnosed−not on ART'); those who initiated ART but were not virally suppressed (‚Unsuppressed'); and, those who achieved viral suppression (‚Suppressed').
Results: We estimated HIV incidence among PWID to be 113 per 100,000 person-years in 2012. The main results are presented in Figure 1; despite accounting for only 33% of the HIV-infected PWID population, the Undiagnosed were associated with 52.6% (95% simulation interval [95% SI]: 47.1-57.0%) of total transmission events. The Diagnosed−not on ART population contributed the second-largest proportion of HIV transmissions, with 36.6% (95% SI: 32.2-41.5%). The Unsuppressed population contributed 8.7% (95% SI: 5.6-11.8%), and Suppressed 2.1% (95% SI: 1.1-3.9%), relatively little of overall transmission.



[Figure 1. Population size and transmission attributable to HIV care continuum steps among people who inject drugs in New York City, 2012]

Conclusions: Among PWID in NYC, more than half (53%) of transmissions were from those who were unaware of their infection status and more than 36% were due to PWID who knew their status, but were not on treatment. Our results indicate the importance of early diagnosis and interventions to engage diagnosed PWID on treatment to further suppress population-level HIV transmission.

MOPEC0687

Regional differences in injection drug use behaviors: baseline results from the HPTN 074 vanguard HIV prevention trial

W. Miller[1], S. Rose[2], I. Hoffman[3], E. Piwowar-Manning[4], B. Hanscom[5], D. Burns[6], T.V. Ha[7], Z. Djoerban[8], K. Dumchev[9]
[1]The Ohio State University, Epidemiology, Columbus, United States, [2]FHI360, Science Facilitation, Durham, United States, [3]University of North Carolina, School of Medicine, Chapel Hill, United States, [4]Johns Hopkins University, Pathology, Baltimore, United States, [5]SCHARP-FHCRC, Biostatistics, Seattle, United States, [6]US NIH, Division of AIDS, Bethesda, United States, [7]UNC Chapel Hill, Bioinformatics, Chapel Hill, United States, [8]University of Indonesia/Cipto Mangunkusumo Hospital, Faculty of Medicine, Jakarta, Indonesia, [9]Ukrainian Institute on Public Health Policy, Research, Kiev, Ukraine
Presenting author email: srose@fhi360.org

Background: High-risk sharing practices among people who inject drugs (PWID) are thought to be primary sources of HIV transmission in several parts of the world, including Eastern Europe and Southeast Asia. PWID in these regions face significant barriers to HIV testing and engagement in care. Understanding regional differences among PWID is essential to developing effective intervention strategies.
Methods: The HPTN 074 trial is a two-arm, randomized, vanguard study designed to determine the feasibility of an integrated intervention combining psychosocial counseling and supported referral for antiretroviral therapy and substance use treatment for HIV-infected PWID in Vietnam, Ukraine and Indonesia. Network units consisting of an HIV-infected index with VL >= 1000 copies/ml and up to five of his/her HIV-uninfected injection partners were randomly assigned to the intervention or standard of care. Here we evaluate baseline demographic and behavioral data by country.
Results: Between April 2015 and June 2016, 504 networks (504 indexes and 656 partners) were enrolled. The majority of enrollees were men (87%), with 82% of the enrolled women coming from Ukraine. The overall mean age was 34. Drug use and injection practices varied substantially by country. In Vietnam heroin was almost exclusively used (99%), while in Indonesia participants reported using both heroin (82%) and buprenorphine (38%). In Ukraine there was little reported heroin use (9%) but significant injection of diverted methadone (84%), homemade opioids (75%), and amphetamines (36%). In Indonesia 73% reported using non-injectable stimulants, compared to 28% in Ukraine and 18% in Vietnam. Risky injection practices also varied, with 42% of HIV-negative partners in Ukraine reporting using a needle after someone else, compared to 33% in Indonesia and only 18% in Vietnam. Over 70% of partners in Vietnam reported no needle sharing in the past three months, compared to 45% in Ukraine, and 0% in Indonesia. Ukrainian indexes reported an average of seven injection partners, compared to four in Indonesia and three in Vietnam.
Conclusions: Demographics and drug-use behaviors differ dramatically across the three HPTN 074 sites. These differences highlight the heterogeneity of substance-use-related HIV epidemics and suggest the need for flexible, region-specific strategies for combating HIV among PWID.

MOPEC0688

Predictors of HIV seroconversion in people who inject drugs in Ukraine

A. Meteliuk[1], A. Mazhnaya[2], S. Filippovych[1], F.L. Altice[3]
[1]ICF Alliance for Public Health, Kyiv, Ukraine, [2]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior and Society, Baltimore, United States, [3]Yale University School of Medicine, Section of Infectious Diseases, AIDS Program, New Haven, United States
Presenting author email: meteliuk@gmail.com

Background: While there were 39,664 people who inject drugs (PWID) officially registered with drug addiction clinics in 2016, WHO estimates 310,000 PWID in Ukraine. Even though harm reduction services for PWID were introduced in Ukraine in 2001, national surveillance studies show that in 2015 the prevalence of HIV in PWID was 20.1%. The objective of this analysis was to assess the level of HIV seroconversion in PWID in Ukraine and its predictors.
Methods: The data were collected in 2014-2015 within 'Access to Medication Assisted Therapy' project implemented in partnership with Yale School of Medicine. Respondent-driven sampling was used to recruit current PWIDs (n=521) and random sampling was used to recruit opioid antagonist treatment (OAT) patients (n=434) in 5 regions of Ukraine. Interviews were followed by rapid HIV testing. Seroconversion was defined as present if the respondent stated he had been tested HIV-negative before and was tested HIV-positive after the interview. The predictive model using logistic regression weas built with HIV seroconversion as the outcomes. Potential confounders included demographics, risky sexual behavior, risky injecting behavior, length and frequency of injecting, alcohol intake, and history of incarceration.
Results: Mean age of participants was 37.3 years (s.d.8.2); most of respondents were male (73.8%); lived with their partner (40.5%); mean length of injecting was 22.2 years (s.d.9.1). Prevalence of HIV in the sample was 47.7%. Prevalence of seroconversion was 4.1%(n=39). The mean interval for HIV seroconversion was 2.9 years (s.d.3.3; range: 1-20). The results of logistic regression showed that OAT had a protective effect against HIV(OR=0.45, 95%CI=0.26-0.78) seroconversion. Neither risky injecting behavior nor length/frequency of injecting were statistically significant.
Conclusions: Despite large coverage of PWID with harm reduction services countrywide, the prevalence of HIV seroconversion in this key population remains very high. As of January 2017, OAT programs cover only 22.5% of PWID officially registered with drug addiction clinics. Given the low coverage of PWID with OAT, transition to governmental funding of OAT programs as well as OAT being proved to be effective in HIV prevention, there is an urgent need in large OAT programs scaling up in Ukraine on national level.

MOPEC0689

Injecting drug use and sex work: two interconnected risky behaviors in Egypt

C. Khoury[1], Y. Elkei[1], M. Abdel Malak[1], S. Elkamhawi[1], W. Elbeih[2], N. Elkot[3], N. Sanan[4], E. Elkharrat[5], H. Ramy[6], S. Kozman[7], C. Soliman[1]
[1]FHI 360, Cairo, Egypt, [2]Drosos Foundation, Cairo, Egypt, [3]Hayat, Cairo, Egypt, [4]Befrienders, Cairo, Egypt, [5]Freedom, Cairo, Egypt, [6]Ain Shams University, Cairo, Egypt, [7]YAPD, Alexandria, Egypt
Presenting author email: ckhoury@fhi360.org

Background: Injecting drugs and involvement in sex work are often interrelated and populations involved in both behaviors are at higher risk of acquiring HIV. According to the Bio BSS conducted in 2010, an estimated 13.1% in Cairo and 10.8% in Alexandria of Male Injecting Drug Users (IDUs) had sex with commercial sex workers. The Drosos and Ford Foundations, in collaboration with FHI 360, have established the Network of Associations for Harm Reduction (NAHR) in Egypt in an attempt to reduce risky behaviors among key populations.
Methods: Biological and behavioral data were collected from six NAHR Comprehensive Care Centers (CCCs) in Greater Cairo and Alexandria between March 2013 and August 2016. The population sample was selected using two main indicators; males ever injecting drugs and ever having sex in exchange for money or goods.
Results: NAHR CCCs received 934 male IDUs involved in sex work. The majority was between the ages of 25 and 35 (64.4%). About one quarter were married (24.7%), 44.0% received some university education, and 53.1% were employed. More than two thirds of the sample started injecting drugs between the ages of 16 and 24 (71.3%). Ever sharing needles or syringes was reported by 82.4% while 91.5% ever shared paraphernalia. Injection of Heroin last month was reported by 67.1% whereas 76.8% had sex last month. Exchanging sex for drugs in the last six months was reported by 37.1% of the visitors. During the last sex, only 3.1% and 3.0% used condoms with steady and non-steady partners respectively while 59.3% expressed their willingness to use condoms. The HIV prevalence was 3.3% among the studied population.
Conclusions: Given the high rate of drug injection and needle sharing, coupled with extremely low condom use, there is a need to integrate a double faceted approach in Harm Reduction projects targeting populations at risk. An interlocked method of safe sex safe injection should lead the new era of an HIV-free generation.

MOPEC0690

Large scale respondent driven sampling among persons who inject drugs in Haiphong, Vietnam: involvement of peer-support groups is key for success

H. Duong Thi[1], D. Des Jarlais[2], T.H.O. Khuat[3], M.K. Pham[1], J.P. Moles[4], G. Hoang[1], T.T. Nham[3], V. Vu Hai[5], J. Feelemyer[2], K. Arasteh[2], R. Vallo[4], C. Quillet[4], D. Rapoud[4], L. Michel[6], T. Hammett[2,7], D. Laureillard[4,8], N. Nagot[4]
[1]Hai Phong University of Medicine and Pharmacy, Hai Phong, Vietnam, [2]Icahn School of Medicine at Mount Sinai, New York, United States, [3]Supporting Community Development Initiatives, Ha Noi, Vietnam, [4]Inserm U 1058, Etablissement Français du Sang, University of Montpellier, Montpellier, France, [5]Viet Tiep Hospital, Dept of Infectious and Tropical Diseases, Hai Phong, Vietnam, [6]CESP/Inserm U 1018, Pierre Nicole Centre, French Red Cross, Paris, France, [7]Abt Associates, Cambridge, United States, [8]Caremeau University Hospital, Infectious Diseases Department, Nîmes, France

Background: Haiphong has seen a high prevalence of HIV and HCV infections among persons who inject drugs (PWID); recruitment of drug users can often be difficult due to the stigmatized nature of their behavior. In this study, we assess the efficiency and obstacles of respondent driven sampling (RDS) survey in Hai Phong, Vietnam.

Methods: Using RDS we enrolled participants into a large HIV care and prevention intervention. The PWID peer support groups acted as Community-Based Organizations (CBO). The RDS participants were recruited in 2 offices of CBOs, who were also critical in the RDS implementation, by examining sensitive topics such as the amount of the honorarium, the use of the fingerprint reader (to avoid participating multiple times in the study) and on-site urine analysis (to confirm recent drug use eligibility criterion). In addition, CBO members also were involved in adapting RDS procedures to the increased police pressure on traditional hot spots and its subsequent changes in the drug scene. Initially, a total of 20 seeds were used to launch the RDS and enroll participants from two sites, both CBO offices. An additional estimation of coupon distribution was conducted to understand locating PWID.
Results: RDS recruitment was particularly efficient, with 1385 subjects recruited in 13 weeks; the average age of participants was 39 (SD 9) years and 94% were male. The rate of recruitment was most affected by the changing drug "market" among PWID in Hai Phong. Changes in the RDS procedures included increased number of coupons given to participants, recruitment of new seeds and increased participation fees. Among the coupons distributed to participants, approximately 50% were given to other potential participants. The main reasons participants could not distribute their coupons included difficulties in locating PWID, the clearing of hot spots by the police and PWID being uncomfortable with disclosing their injection status.
Conclusions: RDS is still efficient for recruitment of PWID, but modification of RDS procedures will require adaptation of RDS network analyse. The involvement of CBO members well connected with the drug milieu is crucial for this purpose.

MOPEC0691

Increased methamphetamine use among persons injecting heroin in Vietnam: time to rethink harm reduction and addiction care for HIV control? ANRS 12299/NIDA P30DA011041 DRIVE-IN study

H. Duong Thi[1], L. Michel[2], O. Khuat Thi Hai[3], G. Hoang Thi[1], K. Pham Minh[1], M. Peries[4], T. Nham Thi Tuyet[3], V. Vu Hai[5], R. Vallo[4], C. Quillet[4], T. Nguyen Thi[6], J.P. Moles[4], T. Hammett[7], K. Arasteh[7], J. Feelemyer[7], D. Laureillard[4,8], D. Des Jarlais[7], N. Nagot[4]

Background: In Vietnam, HIV and HCV epidemics are much concentrated among persons who inject drugs (PWID). A national control program including combined interventions have decreased the rate of new HIV infections. However, recent increase in methamphetamine (Ice) use is alarming, since it has been associated with HIV/HCV risky behaviors and therefore could alter the program efficacy. The objective of this survey is to assess Ice use and associated HIV/HCV risks among intravenous heroin users.
Methods: A respondent driven sampling (RDS) survey was first conducted to identify drug use and characterize HIV risky behaviors among PWID in Haiphong, Vietnam, through a face-to-face questionnaire, urine testing for drug use and HIV/HCV testing. A sample of PWID was then included in a one-year cohort study to describe community-based organization (CBO)-supported access to care (methadone treatment) and the evolution of drug use over time. Methamphetamine and cannabis use were based on self-report or urine detection.
Results: Among the 603 PWID included in the RDS survey, all were injecting heroin with 2.6 injections per day on average, 186 (30.9%) were also using methamphetamine (Ice) including 3 injectors. In multivariable analyses, not having a medical insurance (OR=1.70, 95%CI: 1.01-2.85), having a household registration in Hai Phong (OR=2.33, 95%CI: 1.09-5.01), having methadone in urine (OR=1.70, 95%CI: 1. 12-2.59), having several sexual partners during the last 3 months (OR=2.28, 95%CI: 1.43-3.65), having their syringes used by others (OR=2.15, 95%IC: 1.06-4.37), number of injections in a typical day (OR=1.34 per 1 injection increase per day, 95%IC: 1.10-1.63) and having ever been tested for HIV (OR=1.78, 95%CI: 1.17-2.68) were associated with a higher risk of methamphetamine use (self-report+urine test). Among the 250 RDS participants enrolled in the cohort, Ice use increased dramatically from 30.4% to 49.0% at one year, and was clearly associated with not starting methadone during follow-up (OR=3.34, 95%IC: 1.92-5.79).
Conclusions: Ice use increased dramatically among PWID in Vietnam. PWID using heroin together with Ice had a higher-risk profile and a lower likelihood to enroll in the methadone program, despite CBO support. Current HIV harm reduction strategies should be tailored for this subpopulation in a comprehensive way.

MOPEC0692

New strategy to implement HIV, HCV and HBV screening and surveillance in Centers for Drug Addiction, Italy North-West

G. Orofino[1], V. Ghisetti[2], P. Monaci[3], E. De Vivo[4], E. Bignamini[5], R. Diecidue[6], I. Arnaudo[7], D. Aguilar[7], G. De Santis[8], M. Bellinato[9], A. Gramoni[8], I. Conterno[10], F. Mancuso[11], D. Zeme[12], M. Tabone[13], Screening Infettivologico nei SERD Piemontesi Study Group

Background: In spite of excellent results to decrease new HIV infections, as demonstrated by the national HIV surveillance system, in the last 20 years in the Italian Drug Addiction Services (DAS), due to educational and preventive programs, drug users (DU) remain a vulnerable population. Recent data shows a generally low coverage of screening testing for the major drug-use-related infections in DAS. In this context, a project aimed to increase HIV, HCV and HBV testing coverage and build up specific recommendations was conducted over two years (2014 and 2015) involving the 66 local DAS in Piemonte, Italy North-West.
Methods: Four key points were focused and developed:
1) educational and testing training of about 180 health care providers;
2) set up of an electronic database to monitor testing activity (SPEDI);
3) offering oral HIV rapid test in the so called "refractory" patients (i.e. person repeatedly not compliant to HIV testing;
4) linkage to care for new infected people.
DUs with a least one visit were included and offered HIV, HCV and HBV testing with conventional serology.
Results: The DUs population consisted of 16,931 people (20% females, median age 42.5). The global testing rate significantly increased from 2014 to 2015 (from 25.1 % to 30.7 % for HIV; 33.7% to 44.3 % for HCV and 37.6 to 44.3 % for HBV). The percentage of "never tested" people fell down by about 10% for each virus (from 50.5 % to 40.6 % for HIV, 61.7 % to 51.9 % for HCV and 50.2 % to 40.4 % for HBV). The prevalence rate of HIV, HCV and HBV infections was 4.1 %, 28.2 and 14.7 %, respectively. Regional recommendations on HIVand Hepatitis screening in DAS setting were developed considering critical issues such as testing in not compliant clients.
Conclusions: The project was successful in enhancing HIV and Hepatitis testing in DAS; HIV rapid testing on oral fluid helped to screen difficult-to test clients. The prevalence HIV, HCV and HBV infection was significantly high, thus justifying new strategies of testing coverage for disease prevention and linkage to care of patients.

MOPEC0693

Testing and linkage to care for injecting drug users (TLC-IDU) in Kenya: a baseline assessment in western region

J. Lizcano[1,2], A. Kurth[1], C. Cleland[3], H. Musyoki[2], P. Cherutich[2]
[1]Yale University, New Haven, United States, [2]Ministry of Health, Nairobi, Kenya, [3]New York University, New York, United States
Presenting author email: john.lizcano@yale.edu

Background: HIV infections in sub-Saharan-Africa increasingly occur among people who inject drugs (PWID). The World-Health-Organization (WHO) recommends antiretroviral-therapy (ART) to enhance viral-suppression among persons at high-risk of transmission including PWID. We present data from an behavioral and biomedical study of a baseline-assessment in the Western region in Kenya among PWID.
Methods: We used respondent-driven-sampling (RDS) to reach PWID for HIV-1 and Hepatitis-C-virus (HCV) prevalence and viral load determination, using established procedures from the parent TLC-IDU study done in Nairobi and Coast. In western Kenya we collected study data in a six-month period in PWID service sites, including behavioral data collected using computer tablets, rapid HIV and HCV testing, point of care (POC) CD4 determination and referral to HIV clinics for HIV-positives for follow-up and early ART initiation for those with CD4 < 500/µL, before the recent change of ART guidelines.
Results: 655 have been screened with 649 found eligible (99.1%). Most eligible participants are male (97.1%). Median age is 30 years. Median age at first injection is 26 years. Median number of injections per day is 2. Use of marijuana is common (42.6%). 24.3% had vaginal or anal sex without a condom in the past 12 months. Most men are circumcised (89.3%). 4.3% (n = 28) are HIV positive. 80% of those

with HIV infection reported having been prescribed anti-HIV medication. 10.7% of those with HIV infection were newly diagnosed by our study. 0.5% (n = 3) are HCV reactive/PCR confirmed. 1 of those screened (0.2%) participated in the study in an earlier survey period in Nairobi.
Conclusions: Current Kenyan guidelines have facilitated access to ART among PWID. The combination of RDS and rapid HIV testing has been an effective strategy for finding PWID with HIV and HCV infection in the Western region of Kenya, including those not previously diagnosed. POC CD4 was helpful in terms of early ART-initiation for those who are HIV-positive; under the new guidelines everyone should initiate ART right after testing HIV-positive regardless of CD4 count. HCV-prevalence among PWID appears to be still low in the western Kenya region, presenting an important opportunity to avoid further HCV (and HIV) transmission.

MOPEC0694

Differences in characteristics by preferred point of access for sterile injection equipment among people who inject drugs (PWID) in Washington, DC

A. O'Rourke[1], M. Ruiz[2], S. Allen[3]
[1]American University, Department of Sociology, Washington, United States, [2]George Washington University, Milken Institute School of Public Health, Washington, United States, [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States
Presenting author email: sallen63@jhu.edu

Background: Research indicates that people who inject drugs (PWID) who use syringe service programs (SSPs) engage in fewer risky injection behaviors and have lower rates of HIV and Hepatitis C. Those who engage with SSPs receive additional wrap around services (i.e. HIV testing, referrals for PrEP, etc.) which are not available through other methods of syringe access, such as intermediaries who distribute sterile injection equipment obtained at SSPs among other PWID, also known as secondary syringe exchange (SSE). We examined the demographic and substance use characteristic differences of PWID in Washington, DC by preferred method of accessing sterile injection equipment.
Methods: Surveys were collected from 514 PWID between March and April 2014. Variables included demographic and drug use information. Of those sampled, 345 participants reported a preferred method for accessing syringes: 236 preferred SSPs, 76 preferred SSE, and 33 indicated no preference (NP). Qualitative data describing participant preference provided context for understanding preference and bivariate analyses identified characteristic differences between groups.
Results: When asked why they preferred their specified method for obtaining clean syringes, both SSP and SSE PWID reported trust and ease of access/convenience as primary reasons for their preference. Those preferring SSP also used words like safe and clean while those preferring SSE used the word privacy to describe their preference. Bivariate analysis found that compared to those preferring SSPs, SSEs were significantly ($p<0.05$) younger, preferred injecting heroin and cocaine combined, reported less preference for heroin injection alone, and reported more illicit drug use (particularly cocaine and marijuana). Compared to SSEs, those with NP were significantly ($p<0.05$) older, reported using more channels to obtain clean syringes, and more alcohol use (but less cocaine and marijuana use).
Conclusions: These data shed valuable insights into HIV prevention among PWID populations. Specifically, SSPs can use this information to devise new strategies for gaining access to marginalized segments of PWID populations and provide more intensive services (e.g., PrEP) that support their HIV prevention needs (including linkage to treatment for HIV+ PWID). SSPs should strive to understand client preferences for service delivery and the factors that characterize different preference groups.

MOPEC0695

Assessment of the risky behavior among female PWIDs at harm reduction program in Georgia

M. Gogia[1], K. Stvilia[2], G. Jikia[1], S. Asatiani[2], I. Khonelidze[3]
[1]Georgian Harm Reduction Network, HIV Prevention, Tbilisi, Georgia, [2]National Center for Disease Control and Public Health, HIV Management, Tbilisi, Georgia, [3]National Center for Disease Control and Public Health of Georgia, Tbilisi, Georgia
Presenting author email: marine_gogia@yahoo.com

Background: Needle sharing practice remains the main factor for spreading HIV (47.3%) among PWIDs in Georgia. In spite of 5 times increased coverage of female IDUs by Needle and Syringe program (NSP) women IDUs remain hard to reach population. The objective of this study was to analyse risky injection/sexual behavior of PWIDs/female IDUs who are the clients of NSP, if there is a difference in behavior of male and female PWIDs.
Methods: Consecutive sampling was used to recruit PWIDs during 5 months in 2015. The selection criteria was:
a) Drug injection practice during last month;
b) Being a beneficiary of NSP program for more than 6 month;
c) Age more than 17 years.
Sample size was 1032, among them females were 129 (12,5%). Structured questionnaire of Risk Assessment Battery (RAB) was used to assess Drug Risk and Sex Risk Items separately and calculate RAB Score.
Results: Female IDUs reported not using drugs in a close environment. They inject drugs with more than 2 person and mostly don't share injectable equipment (94.9%) While 38% of male PWIDs stated needle sharing practice at least once during last month, among them 43.8% shared with one person and 56.1% with more than 2 persons ($p< 0.05$). As referring to sexual practice, 15.97% female IDUs had more than 2 sexual partners during the last 6 months with whom 22.7% use condoms regularly, 21.1% sometimes and 32.3% always. It was meaningful to find that 10.08% of female study participants (2 times less than men) never had an HIV test and 34.45% of them had HIV test a year ago. Total RAB Scale Score for female PWID study participants was 0.26 (Range=0-1).
Conclusions: The study results demonstrate that female IDUs practice risky behavior but their practice is less risky than men IDUs. This refers to both sexual and injection behaviors. HIV testing rate is low among female PWIDs and reasons behind this need further investigation. The findings of this study will be used to address the risks female IDUs face, to modify program according to their needs, to develop and test new approaches for attracting, retaining and increasing safe behaviors of female IDUs.

MOPEC0696

PrEP interests among people who inject drugs in Baltimore, Maryland, USA: A missed opportunity in prevention

S. Sherman[1], J. Park[2], S. Allen[1], P. Chaulk[3], B. Weir[4]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Health Behavior and Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]Baltimore City Health Department, Baltimore, United States, [4]Johns Hopkins Bloomberg School of Public Health, Health Behavior and Society, Baltimore, United States
Presenting author email: ssherman@jhsph.edu

Background: PrEP is indicated for those most at risk of HIV including people who inject drugs (PWID). In the U.S., there has been a lag in engaging PWID in PrEP initiation and maintenance compared to other high-risk populations. Among PWIDs (N=298) in Baltimore, Maryland, USA, we examined PrEP knowledge, interest, and uptake among HIV-uninfected participants (n=267), as well as correlates of PrEP interest.
Methods: Interviews were administered via CAPI to PWIDs who were recruited from the Baltimore Syringe Exchange Program (SEP). Demographic, drug use, and PrEP-related frequencies were explored and multivariate associations with ever having heard of PrEP.
Results: Study participants reported being a median of 45 years old, were 31% female, 55% Black, and 36% White. The sample was socioeconomically vulnerable with 82% reporting having ≤high school degree and 58% currently homeless. The majority (87%) reported daily injection, 14% reported having engaged in receptive syringe sharing, and 38% reported primarily injecting in public (e.g., street, park, stairwell, car, bathrooms, shooting gallery, abandoned house). HIV infection was reported by 11%. Among HIV-negative uninfected participants, 83% had tested for HIV in the past year, 25% had ever heard of PrEP, 62% were interested in being on PrEP, and 86% endorsed that they could easily take a pill daily. The majority of those interested in PrEP reported that they would use sterile needles (94%) or condoms (90%) while on PrEP. In a multivariate model, being interested in PrEP was associated with receptive syringe sharing (AOR 3.3: 95%CIs: 1.4-8.2) and primarily injecting in a public place in the past 30 days (AOR 1.9, 95%CIs: 1.1-3.4).
Conclusions: In an urban US city, HIV-uninfected PWIDs are largely unaware yet interested in receiving PrEP. As with ART roll-out and coverage, PWID have been largely underserved in regards to PrEP. Their PrEP interest was driven by the risky injection practices of receptive syringe sharing and public injection. Three decades into their HIV epidemic, HIV persists at high rates. Programs are needed to promote PrEP to PWID and engage them in PrEP care. Their ritual drug use potentially bodes well for taking oral PrEP daily.

MOPEC0697

A comprehensive HIV and stimulant use prevention intervention for Cambodian female entertainment and sex workers reduces psychological distress and improves economic well-being

A. Carrico[1], J. Evans[2], E. Stein[2], C. Sophal[3], Y. Neak[4], M. Sokunny[5], S. Ngak[5], M.-C. Couture[6], C. McCulloch[2], L. Maher[7], K. Page[8]
[1]University of Miami, Public Health Sciences, Miami, United States, [2]University of California, San Francisco, San Francisco, United States, [3]Ministry of Health, Department of Mental Health and Substance Abuse, Phnom Penh, Cambodia, [4]National Authority for Combating Drugs, Phnom Penh, Cambodia, [5]FHI 360 Cambodia, Phnom Penh, Cambodia, [6]University of San Francisco, San Francisco, United States, [7]UNSW Australia, Kirby Institute for Infection and Immunity, Syndey, Australia, [8]University of New Mexico, Albuquerque, United States
Presenting author email: adamwcarrico@icloud.com

Background: HIV prevention services for female entertainment and sex workers (FESW) could function as a platform for targeting key risk factors for HIV infection, including amphetamine-type stimulant (ATS) use and economic distress. We examined the effectiveness of sequentially delivered interventions to decrease ATS use and improve economic well-being for addressing psychiatric as well as structural outcomes relevant to HIV prevention with FESW.
Methods: This cluster randomized stepped-wedge trial in 10 Cambodian provinces enrolled 1,198 FESW to test the effectiveness of a comprehensive HIV and ATS use prevention package leveraging SMARTGirl, an existing HIV prevention platform for Cambodian FESW. The prevention package included a conditional cash transfer with cognitive-behavioral aftercare (CCT+AC) intervention to reduce ATS use followed by a microenterprise (ME) opportunity. Outcomes assessed in 600 FESW purposively targeted for the 18-month follow-up were:
1) clinically significant distress (≥ 25 on the Kessler -10);
2) monthly income 3) housing instability; and
4) food insecurity. After baseline, FESW with problematic patterns of ATS use were allocated to receive a 4-month CCT+AC intervention. All FESW who were abstinent from ATS at six months were allocated to receive a ME opportunity, which included a 3-day financial literacy training and optional microloan application.
Results: At 12 months, relative to baseline participants had 79% lower odds of reporting clinically significant psychological distress (Adjusted Odds Ratio [AOR]=0.21; 95%CI 0.07-0.64; p=.006) and 68% lower odds of any housing instability AOR=0.32; 95%CI 0.13-0.78; p=0.01). At 18 months, FESW had 89% lower odds of any food insecurity (AOR=0.11; 95%CI 0.02-0.53; p=0.006) but significant reductions in psychological distress and housing instability were not maintained. There were no concurrent increases in monthly income over the 18-month follow-up (p's>0.14).

	Psychological Distress	Monthly Income	Any Housing Instability	Any Food Insecurity
	AOR (95% CI)	*ARR (95% CI)*	*AOR (95% CI)*	*AOR (95% CI)*
6 Months	**0.43 (0.22 - 0.83)***	1.12 (0.91 - 1.39)	0.67 (0.41 - 1.12)	0.55 (0.28 - 1.08)
12 Months	**0.21 (0.07 - 0.64)***	1.21 (0.94 - 1.56)	**0.32 (0.13 - 0.78)***	**0.18 (0.05 - 0.59)***
18 Months	0.26 (0.06 - 1.18)	1.08 (0.79 - 1.49)	0.63 (0.19 - 2.12)	**0.11 (0.02 - 0.53)***

[Table. Intent-to-treat analyses (N = 1,198 at Baseline)]

Conclusions: Integrating interventions to reduce ATS use and improve economic well-being with HIV prevention services can address psychiatric as well as structural risk factors for HIV with Cambodian FESW.

MOPEC0698

Cost-utility analysis of a national six-site retention in care program

C. Maulsby[1], B. Enobun[1], K. Jain[1], B. Weir[1], M. Riordan[2], M. Werner[2], D.R. Holtgrave[1]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]AIDS United, Washington, United States
Presenting author email: cmaulsby@jhsph.edu

Background: Engaging people living with HIV (PLWH) into ongoing, high-quality HIV primary care is critical for the health of PLWH and a key strategy for United States (U.S.) HIV prevention policy.
However, little is known about the costs associated with implementing HIV retention in care programs, especially in real-world settings and with vulnerable populations. This abstract presents findings from the cost-utility analysis the six Retention in Care (RiC) intervention sites. RiC was a national multi-site program implemented from 2011-2016.
Methods: This cost-utility analysis used standard methods from the U.S. Panel on Cost-effectiveness in Health and Medicine. We modeled the cost per quality adjusted life year (QALY) saved using the formula (R=C-AT (AQ)) where R was the cost-utility ratio. The cost for implementing the program (C) was estimated from the societal perspective and thus took into consideration costs to the participant. The number of HIV infection averted (A) was estimated based on changes in viral suppression among program participants. T, the lifetime cost for HIV care, came from the HIV literature. Q included both discounted QALYs saved for improvements in individual quality of life associated with HIV viral suppression as well as QALYs saved through each averted HIV infection. The return on investment (ROI) was calculated using the formula: ROI = TA/C.
Results: The cost-utility ratio estimated the net cost per QALY. The cost-utility ratio ranged from $-42,242.34 to $126,570.23. All Retention in Care programs were cost-effective, as the cost utility ratio for all programs was less than the threshold of $163,889, or the amount society is will to pay per QALY. Four programs were cost-saving. The return on investment ranged from $0.28 to $1.80.
Conclusions: The findings from the cost-utility analysis overwhelming support the assertion that retention in care programs are a productive use of resources. Despite varying program models, RiC programs were cost-effective and the majority were cost-saving.

MOPEC0699

Addressing the ‚risk environment': changes in substance use patterns amongst people living in an HIV-specific housing facility in Vancouver, Canada

A. Collins[1,2], S. Lyndon[2], K. Salters[1,2], K. Stacey[3], Z. Cui[2], J. Zhu[2], S. Parashar[1,2]
[1]Simon Fraser University, Burnaby, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]McLaren Housing Society of British Columbia, Vancouver, Canada
Presenting author email: sparashar@cfenet.ubc.ca

Background: Housing stability has been shown to decrease substance use and improve health outcomes for people living with HIV (PLHIV) who use drugs. However, little is known about how HIV-specific housing impacts substance use, as well as social-structural factors in ‚risk environments'. We examined changes in drug use for PLHIV after entry into an HIV-supportive housing facility in Vancouver, Canada.
Methods: Surveys were conducted with participants at baseline (after admission to housing facility) and 12-18 month follow-up from March 2015 to October 2016. The biviariate analysis compared socio-demographic and drug use differences between those with reported decrease in drug use versus those without decrease in drug use at follow-up. Fisher's exact test was used for categorical values and Wilcoxon rank sum test for continuous variables.
Results: Among the 69 participants who completed both interviews, 27 (39.1%) reported a decrease in drug use at follow-up, 25 (36.2%) reported either an increase in drug use or no change in drug use since moving, and 16 responded not applicable. Comparatively, those reporting a decrease in drug use at follow-up (n=27) were more likely to be living at the housing facility for fewer months (median 33 vs. 35, p=0.019) and lived alone before entry into the facility (77.8% vs. 40.0%, p=0.010). Feeling emotionally supported (56.0% vs. 20.0%, p=0.034), having a better sense of community (81.5% vs. 40.0%, p=0.004), and having no depressive symptoms (66.7% vs. 24.0%, p=0.003) were also more likely among those reporting decrease in drug use at follow-up.
Conclusions: Despite nearly 40% of our sample reporting a decrease in drug use after entry into supportive housing, a large proportion reported an increase in drug use or no impact at all. This suggests that supportive housing facilities must consider social, as well as physical, aspects of housing as determinants of health, and work to address the complex and interrelated challenges faced by this population within their immediate risk environments.

MOPEC0700

Knowledge of human rights and uptake of social protection schemes: findings from a community mobilization intervention for female sex workers in Southern India

D. Ganju[1], S.K. Patel[1], B. Mahapatra[1], P. Prabhakar[2], N. Saggurti[1]
[1]Population Council, HIV/AIDS, New Delhi, India, [2]India HIV and AIDS Alliance, Hyderabad, India
Presenting author email: deeganju@gmail.com

Background: Female sex workers (FSWs) experience extreme health and gender inequities and rights violations, elevating HIV risk. Promoting knowledge of rights and saturating social protection coverage can address the multiple structural determinants of the HIV epidemic and reduce vulnerability. In India, HIV prevention

interventions for FSWs are promoting access to government-provided social protection schemes, such as pension, nutrition, livelihood and shelter, in an effort to address individual and household vulnerability; however, little is known about their effectiveness. This study examines knowledge of human rights, uptake of social protection schemes, and the association between rights knowledge and uptake of protection schemes among FSWs who are part of a community mobilization program in Andhra Pradesh, a high HIV prevalence state in India.
Methods: Data are drawn from a cross-sectional survey (2014) among 2400 FSWs who are community organization members. Human rights knowledge was determined based on knowledge of any of the following five rights: Health; Dignity/Equality; Education; Property; Freedom from Discrimination. Univariate and multivariate analyses were used.
Results: Most FSWs were 30 years or older, had no formal education, were currently married, and living with spouse /family. Overall, 22% of FSWs were not aware of any human right and 43% had not availed a social protection scheme in the past year. Awareness of human rights was significantly associated with uptake of social protection schemes. Compared to those not aware of any right (46.9%), FSWs aware of any one right (62.7%; adjusted odds ratio [AOR] 1.88; 95% CI 1.51-2.33), any two rights (59.6%; AOR 1.71; 95% CI 1.34-2.19) and three of more rights (55.5%; AOR 1.52; 95% CI 1.15-2.00) were significantly more likely to have recently availed a protection scheme.
Conclusions: Findings highlight that despite intensive program efforts, not all FSWs are aware of their basic human rights or have recently availed any social protection scheme. As rights knowledge is positively associated with access to social protection schemes, future interventions must prioritize strategies to make all FSWs aware of their rights, including their right to access multiple social protection schemes. Additionally, programs must support FSWs to access these schemes to reduce vulnerability and mitigate their HIV risk.

MOPEC0701

Measuring strength of community organizations implementing large scale HIV focused intervention using Community Organizations Preparedness Index

B. Madhusudana, S.K. Patel, B. Mahapatra
Population Council, HIV/AIDS Programs, New Delhi, India
Presenting author email: battalamadhusudana@gmail.com

Background: Measuring impact of community mobilization is always challenging as the process often driven participatory practices. Assessing strength of COs is crucial for sustained organization to delivery programs effectively. The study aims to measure the strength of COs.
Methods: Baseline data collected as part of evaluation of community mobilization of Avahan phase III program from 87 COs (COs) during May- July 2015 has been used. Community Organizations Preparedness Index (COPI) tool was adopted to measure strength of COs in seven domains; Board meetings(BM), events conducted(EV), financial security(FS), social protection(SP), Social security & justice (SSJ), resource mobilization (RM) and second line leaders (SL) domains. Each domain further classified into six categories; basic, foundation, promising1&2 and vibrant 1&2. Univariate and bivariate analysis was done. Association between strength of COs by typology, age, size and TI implementation status were examined.
Results: Higher proportion of COs, were in vibrant category in the domains of BM, board meetings (72.4%), SP (58.6%), SSJ (60.9%), in promising stage for FS(59.7%) and EV (80.3%) and in basic/foundation for domains-SL (57%), RM (52.9%). By topology, higher proportion of COs were in vibrant stage for BM (52% FSW, 92% MSM), (59% FSW, 58% MSM), and in SSJ (70% FSW, 75% MSM). Looking at the TI implementation status; non TI COs are more in vibrant in case of all COPI domains except in resource mobilization. Higher proportion of COs aged less than 5 years are in vibrant stage in most of the COPI domains except in second line leaders. With respect to CO size, it was evident that higher proportion of larger COs (>1200 members) are in vibrant categories in domains of EV, SSJ, RM and SL while younger COs in FS and SP.
Conclusions: Though majority of the COs demonstrated their strength in domains of BM and EV, they are yet to reach promising levels in other components. Given that most of the COs irrespective of their characteristics were in very initial stage (Basic/foundation) in domains of SL and RM domains which are crucial in strengthening COs. Grouping of smaller COs into cooperatives, assigning implementation of TI programs may lead to strengthen COs.

MOPEC0702

Impact of supportive housing on immunological and virological status and antiretroviral therapy adherence amongst people living with HIV and at risk of homelessness in Vancouver, Canada

S. Parashar[1,2], A. Collins[1,2], K. Salters[1,2], A. Enjetti[1], P. Sereda[1], A. Palmer[1]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Simon Fraser University, Burnaby, Canada
Presenting author email: sparashar@cfenet.ubc.ca

Background: Despite advances in antiretroviral therapy, people living with HIV (PLHIV) who are homeless or unstably housed continue to experience poor clinical outcomes compared to their stably housed counterparts. We sought to characterize antiretroviral therapy adherence levels, plasma viral load, and CD4 cell counts for a sample of previously homeless or housing insecure PLHIV following entry into an HIV-specific supportive housing facility in a Canadian setting offering universal access to HIV treatment and care.
Methods: The 100 residents of the HIV-specific supportive housing facility were invited to participate in baseline interviewer-administered surveys after admission to the housing facility with the objective of assessing the impact of housing on HIV outcomes. Self-reported demographic and behavioural survey data were linked with clinical data made available through a linkage with the provincial HIV treatment registry at the BC Centre for Excellence in HIV/AIDS.
Results: Between March and August 2015, 95 participants completed the baseline survey, of which 88 participants had available clinical data. The median age at baseline survey was 51 years (Q1-Q3: 48-57). Of the 88 participants, 73.9% were male, 55.1% identified as gay, and 51.5% self-reported Indigenous ancestry. History of injection drug use and homelessness were common in the cohort (72.5% and 84.1%, respectively). At baseline interview, 83% of participants were receiving antiretroviral treatment and 56.8% had achieved optimal adherence (adhering to ≥95% of prescribed treatment). Clinical data nearest to baseline interview suggest that 78.4% of participants achieved a viral load < 50 copies/ml and 68.2% had a CD4 cell count of ≥350 cells/µl. Overall, 67.2% of participants reported improved access to health services and 69.4% perceived an improvement in physical health.
Conclusions: Baseline data suggest that access to this HIV-specific housing facility may improve virological and immunological status and self-reported improved health amongst participants with a history of injection drug use and homelessness, known barriers to care. Preliminary findings suggest that supportive housing is a structural intervention that may facilitate access to care and treatment, and improve health outcomes amongst PLHIV at risk of homelessness. Follow-up data (after 12-18 months from move in) will be available for future longitudinal analyses.

MOPEC0703

Intimate partner violence, sex work-related stigma, and risk of HIV acquisition among female sex workers in Zambia

C. Oldenburg[1], M. Chanda[2], K. Ortblad[3], M. Mwale[2], S. Chongo[2], N. Kamungoma[2], C. Kanchele[2], T. Bärnighausen[3,4,5]
[1]University of California, San Francisco, F.I. Proctor Foundation, San Francisco, United States, [2]John Snow, Inc., Lusaka, Zambia, [3]Harvard T H Chan School of Public Health, Boston, United States, [4]University of Heidelberg, Heidelberg, Germany, [5]Africa Health Research Institute, Somkhele, South Africa
Presenting author email: catherine.oldenburg@ucsf.edu

Background: Intimate partner violence (IPV) and dimensions of stigma are thought to increase HIV risk by increasing stress and changing power dynamics that may lead to reduced self-protected behaviors. These factors may be especially important among members of groups with historically elevated HIV risk, including female sex workers (FSW). We report IPV and sex work stigma among FSW in Zambia and their association with HIV risk-related factors.
Methods: In September-October 2016, a quantitative survey was conducted with 965 HIV-uninfected FSW in Livingstone, Chirundu, and Kapiri, Zambia. IPV was measured by asking if participants had been physically or sexually abused in the previous 12 months, or if they had had sex because they were afraid not to. Sex work-related stigma was measured by a scale consisting of six questions measuring experiences of stigma related to sex work. The scale was summed and had a range of 1-24 (higher numbers indicate more stigma). Factors affecting HIV risk included HIV testing history and condom use with clients. Multivariable logistic and linear regression models were built to determine the association between 1) HIV testing and 2) condom use with clients and IPV and sex work stigma, adjusted for sociodemographic variables.
Results: Median age was 25 years (IQR 21-30 years) and 560 (59.0%) reported a monthly income of < 500 ZMK (~USD$50). Most participants (61.1%) reported at least one form of IPV in the previous 12 months. Median stigma score was 18 (IQR 14-21). Most participants reported inconsistent condom use with clients (74.6%),

and most had tested for HIV at least once (79.3%). IPV and sex work stigma were associated with decreased odds of HIV testing (IPV: aOR 0.59, 95% CI 0.41-0.85; sex work stigma: aOR 0.94, 95% CI 0.89-0.99). IPV (aOR 1.73, 95% CI 1.34-2.23) but not sex work stigma (aOR 1.04, 95% CI 0.99-1.09) were associated with non-condom use with clients.
Conclusions: Experiences of IPV and sex work-related stigma were high in this population, and may contribute substantially to HIV acquisition risk. Interventions mitigating IPV and stigma may be an important component of comprehensive HIV prevention programs for FSW in Zambia.

MOPEC0704

Prevalence and circumstances of forced sex after migration among sub-Saharan migrant women living in France and post-migration acquisition of HIV

J. Pannetier[1], A. Ravalihasy[1], F. Lert[1], N. Lydié[2], A. Desgrées du Loû[1]
[1]CEPED, Gender & Health, Paris, France, [2]Santé Publique France, Saint-Maurice, France
Presenting author email: julie.pannetier@ceped.org

Background: Studies on sexual violence on migrant women in destination countries are scarce and the impact of this violence on their sexual health, especially HIV infection, is even more rarely assessed.
This study evaluates the prevalence of forced sex after migration and its association with post-migration acquisition of HIV among sub-Saharan African women living in France. It also investigates the associations between forced sex after migration and sexual partnerships, housing, economic and administrative situations after migration.
Methods: The ANRS-PARCOURS study is a retrospective life-event survey (2012-2013) conducted in health-care facilities in the Paris region, among two random samples of sub-Saharan migrant women: 570 receiving HIV care and 407 not diagnosed with HIV consulting in primary health-care facilities. The frequencies of forced sex from 15 years old onwards after migration were compared between women who acquired HIV after migration and women not diagnosed with HIV using a multivariate design-based Poisson regression model. Associations between having experienced forced sex from 15 years old onwards each year since migration and sexual partnerships, housing, economic and administrative situations each year since migration were computed using a mixed-effects generalized structural equation model.
Results: Forced sex from 15 years old onwards after migration was more frequent for HIV infected women who acquired HIV after migration than women not diagnosed with HIV (15.1% versus 3.5%, p<0.001). Women were significantly more at risk of being subjected to forced sex when hosted by family or friends [β=0.95(0.19-1.72)] and when they had no stable housing [β=1.10(0.17-2.03)]. Administrative insecurity was related to forced sex through the mediation of sexual partnerships. Having no resident permit was significantly associated with casual and concurrent relationships, (respectively: [β=0.61(0.22-1.01)]; [β=0.90(0.53-1.27)]), which both increase the likelihood of being subjected to forced sex [β=1.54(0.81-2.27)]; [β=2.17(1.31-3.03)].
Conclusions: Among sub-Saharan migrant women living in France, the prevalence of forced sex after migration is high and related to post-migration acquisition of HIV. Being hosted by family and friends and having no stable housing expose women to sexual pressures and violence. Having no resident permit exposes women to forced sexual intercourse through the engagement in casual and concurrent partnerships.

MOPEC0705

Assessment of prevalence of HIV, hepatitis C, HIV/hepatitis C co-infection and risk behaviours among female injecting drug users in Nepal

J. Damas[1], K. Deuba[1], U. Shrestha[2], B. Rawal[2], T. Paudel[2], M. Storm[1], G. Marrone[1]
[1]Karolinska Institutet, Public Health Sciences, Stockholm, Sweden, [2]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal
Presenting author email: gaetano.marrone@ki.se

Background: Injecting drug users (IDU) are at the greatest risk of being infected with HIV and Hepatitis C (HCV). Most of the studies on IDU have been performed on men, but evidence related to the burden of HIV, HCV and its co-infection is scarce among female IDU. One of the barriers researchers face for this hidden key population is prejudice and stigma affecting women who inject drugs, especially in low and middle-income countries. The aim of this study is to investigate the prevalence of HIV, HCV, HIV/HCV co-infection, and associated risk factors among female IDU in Nepal.
Methods: A total of 160 female IDU were recruited using modified network sampling from the capital city of Nepal from April to May 2016. The inclusion criteria was female at least 16 years old who had been injecting drugs for at least three months before the survey period. Serum samples were collected and all tested for HIV and HCV by the WHO certified rapid test kit.
Results: The prevalence of HIV and HCV was respectively 8.8% and 21.9%, with a co-infection rate of 5.6%. Almost one in every five participant (19.1%) declared to have used shared syringes in the past month, while only 31.9% declared to have used condoms during the last sexual intercourse. As many as 68.1% of female IDU reported ever getting an HIV Test, 89.0% of them did it voluntarily. Only 31.3% acknowledged receiving some treatment or help from any organization, without significant difference in condom use or needle exchange behavior between those who have received treatment or help and those who did not.
Conclusions: The prevalence of HIV and Hepatitis C was much higher among female IDU than the official national figures previously reported among male IDU. Regardless many health care centres for key populations are available in the Kathmandu Valley, a low uptake of their service and a high-risk behaviour were found among female IDU. A better understanding of the reach and performance on these help and support services must be assessed to mitigate the high prevalence of HIV and especially of Hepatitis C among this group.

MOPEC0706

Burden and determinants of violence and negative police interactions among young women who self-identify as sex workers in Mombasa, Kenya

E. Mountain[1], M.-C. Boily[1], P. Bhattacharjee[2,3], M. Becker[3], S. Mishra[4], E. Cheuk[3], S. Isac[2,3], J. Blanchard[3], M. Pickles[1,3]
[1]Imperial College London, London, United Kingdom, [2]Karnataka Health Promotion Trust, Bangalore, India, [3]University of Manitoba, Winnipeg, Canada, [4]University of Toronto, Toronto, Canada
Presenting author email: elisa.mountain08@imperial.ac.uk

Background: Human rights violations (HRVs) against sex workers (SWs) are widespread, and associated with HIV risks. We determined the burden and determinants of three HRVs among young female SWs in Kenya: sexual violence (SV), physical violence (PV) and negative police interactions (NPI; including assault/arrest).
Methods: We conducted a cross-sectional survey of 408 self-identified SWs aged 14-24 years in Mombasa, Kenya. We estimated the prevalence of HRVs by time period (lifetime and since self-identifying as SWs). We used multivariate logistic regression to identify individual, interpersonal and structural determinants of lifetime SV, PV and NPI; and conducted univariate logistic regression to examine the association between HRVs experienced in the first month and most recent month of sex work.
Results: 30%, 30%, and 45% of SWs reported SV, PV, and NPI in their lifetime, respectively, with 65% reporting any HRV and 10% reporting all three. Prevalence of any HRV increased from 12% to 24% between the first and most recent month of sex work (about 2 years apart). 50% of SWs reported their first SV experience before self-identifying as SWs whereas most SWs (78%) reported PV after self-identifying as SWs. In multivariate analysis, lifetime SV was associated with being coerced/deceived into sex with your first 10 clients (AOR=2.5; 95%CI=1.4-4.6) and lifetime PV (AOR=6.9; 95%CI=4.0-12.1). Lifetime PV was associated with daily alcohol use (AOR=2.5; 95%CI=1.1-6.0), regular income (AOR=0.5; 95%CI=0.3-0.9), and lifetime SV (AOR=6.6; 95%CI=3.6-12.0). Lifetime NPI was associated with being inebriated 1-3 times (AOR=2.7; 95%CI=1.5-5.1) or 7+ times (AOR=4.1; 95%CI=1.3-12.5) per month, ≥ 3 years in sex work (AOR=1.7; 95%CI=1.0-2.7) and ≥1 non-paying partner in the past week (AOR=0.5; 95%CI=0.3-0.8). SWs who experienced HRVs in the first month of sex work had higher odds of experiencing the same HRV in the most recent month of sex work (ORs 7.5-15.9; p-values< 0.001).
Conclusions: Self-identified young SWs in Mombasa have high burdens of SV, PV and NPI. Violence prevention and response for these women is crucial and should focus on those with prior history of HRVs and heavy alcohol use. Programmes aiming to reach young SWs could use violence prevention and response as an entry point to reach them.

MOPEC0707

Use of social name in the antiretroviral treatment system as the identification of transgender people living with HIV in Brazil

M. de Queiroz, A. Krüger, M. Meireles, A. Benzaken, A.R. Pascom
Brazilian Ministry of Health, Department of STIs, HIV/AIDS and Viral Hepatitis, Brasília, Brazil
Presenting author email: alicia.kruger@aids.gov.br

Background: Studies suggest that transgender women are a high burden population for HIV. Despite that, they are often classified as men who have sex with men in epidemiological studies, which leads to a poor understanding of HIV epidemics in this population group. However, Brazilian government has granted the use of social name by transgender people. A 2016 law recognizes every person's right to be acknowledged according to their gender identity.
We assessed data for social name available in the national antiretroviral therapy (ART) database to analyze the use of social name before and after the law enforcement, and its impact on ART data.
Methods: We analyzed records from the national ART dispensation system from 2009 to 2016. We considered as transgender people those whose registries contained a social name that differed from the birth name. For the analysis, we included individuals aged 18 and over.
Results: Between 2009 and 2016 we observed an annual average increase of 10% in the identification of transgender people on ART. In 2016 the number of transgender people on ART was 137% higher than the previous year, representing 2.3% of all people living with HIV on ART in Brazil. In the same year, the registration of transgender persons initiating ART was 860% higher than in 2015, representing 8.4% of all new antiretroviral treatments.
Conclusions: Gender identity is part of every person´s dignity and humanity, and its recognition is a human rights matter. The increasing number of data regarding transgender people in ART systems shows a gradual improvement in quality of information, very likely to be associated with the law enforcement in 2016. The more we know about transgender people within the HIV scenario, the better we can design prevention and assistance policies. The main limitation of this analysis is not being able to distinguish between transgender men and women in this population stratum.

MOPEC0708

Sexual partner violence and HIV treatment and care among female sex workers participating in a multilevel HIV intervention in Santo Domingo, Dominican Republic

A. Rock[1], C. Barrington[2], H. Gomez[3], M. Perez[3], Y. Donastorg[3], D. Kerrigan[4]
[1]UNC Gillings School of Global Public Health, Health Behavior, Washington, United States, [2]UNC Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [3]Instituto Dermatológico y Cirugía de Piel Dr. Huberto Bogaert Díaz, Santo Domingo, Dominican Republic, [4]The Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States
Presenting author email: ameliacr@live.unc.edu

Background: Female sex workers (FSW) are 13.5-times more likely to be living with HIV than other women in low and middle income countries, and globally, up to 75% ever experience sexual partner violence (SPV). Among FSW living with HIV in Santo Domingo, Dominican Republic (DR) who participated in the Abriendo Puertas intervention, our team found that 18% had experienced SPV within the last six months. Experiencing SPV—more commonly perpetrated by non-paying partners than clients-- was associated with multiple negative HIV treatment and care outcomes, which limit treatment-as-prevention (TasP) effectiveness. Here we identify the context of SPV, pathways through which it negatively affected treatment and care, and how intervention participation influenced factors along these pathways.
Methods: Abriendo Puertas is a multi-level intervention including individual counseling, peer navigation, clinician sensitivity training, and community mobilization among FSW living with HIV in the DR. In 2013-2014, 250 women enrolled in a 10-month pilot study and scale up with 90 women in three government-sponsored HIV clinics occurred in 2015-2016. In 2016, we conducted in-depth interviews with 20 original cohort members and 20 scale up participants regarding the intervention, treatment, substance use, and violence. Textual data was coded and analyzed using thematic content analysis.
Results: Participants perceived alcohol and jealousy to cause SPV, and economic dependency to prevent women from ending abusive relationships. Some experienced stigma from partners upon HIV status disclosure; others avoided disclosure, fearing violence. Violence caused stress and depression, which decreased treatment adherence and care engagement, and produced negative immunologic effects. Participation in Abriendo Puertas - especially counseling-- intervened in this cascade of effects by greatly improving their sense of well being, self-esteem, and resilience feelings, which enabled some to leave violent relationships. Participants recommended peer support groups focused on SPV within community mobilization activities for aiding SPV survivors.
Conclusions: Multilevel interventions for FSW that address SPV's mental health impacts through counseling and peer support, and increase FSWs' economic independence hold promise for reducing undermining effects of SPV on HIV treatment, care and TasP. Intervening upon contextual factors enabling SPV perpetration against FSW, namely alcohol, gender norms, and stigma, will also be necessary for reducing these effects.

MOPEC0709

Preventing intimate partner violence in the context of the HIV response: the MAISHA study in Tanzania

S. Harvey[1], S. Kapiga[2,3], A. Khalie Muhammad[3], H. Stöckl[1], G. Mshana[4], R. Hashim[3], C. Hansen[2], S. Lees[1], C. Watts[1]
[1]London School of Hygiene & Tropical Medicine, Global Health and Development, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [3]Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of, [4]National Institute for Medical Research, Mwanza, Tanzania, United Republic of
Presenting author email: sheila.harvey@lshtm.ac.uk

Background: There is increasing evidence linking women's experience of intimate partner violence (IPV) and enhanced risk of acquiring HIV. In a study conducted in rural communities in Uganda, the adjusted population attributable fraction of incident HIV attributable to IPV was 22.2% (95% CI 12.5-30.4). With increasing interest in addressing violence against women in the context of the HIV response, we are conducting the MAISHA study to evaluate the impact of two contrasting social and economic intervention approaches in northwest Tanzania
Methods: We are conducting trials to evaluate the incremental impact on participants' experience of IPV of a participatory gender training curriculum for women in existing microfinance groups and for women in newly-formed groups not receiving microfinance. To date, we have enrolled 1021 women in microfinance groups and 1052 women not receiving microfinance. At baseline, ever partnered women were interviewed by trained, same sex interviewers about their lifetime and past 12-month experience of IPV, economic abuse, emotional abuse and controlling behaviour.
Results: Among women enrolled into the study, 61% (95% CI: 58-64%) of women receiving microfinance and 67% (95% CI: 64-70%) not receiving microfinance reported ever experiencing physical and/or sexual IPV with 27% (95% CI: 24-29%) and 36% (95% CI 33-39%) reporting IPV in the previous 12 months. Partner controlling behaviour was the most prevalent type of abuse - 82% of women receiving microfinance and 78% not receiving microfinance reported having experienced it in their lifetime, while 63% and 64% reported experiencing it in the previous 12 months. Other abuses were also common; more than one third (34% microfinance, 39% non-microfinance) of women reported economic abuse and a high proportion of women reported emotional abuse (39% microfinance, 56% non-microfinance) during the previous 12 months. Higher prevalence rates were observed among younger women, women with young partners, and less educated women. Intervention delivery is ongoing, with the results expected in 2018.
Conclusions: Levels of violence and abuse are very high in this study population, particularly among younger women, who are also at highest risk of HIV infection in Tanzania. These findings underline the importance of developing and testing appropriate violence prevention interventions.

MOPEC0710

Sexual relationship power and periconception HIV-risk behavior among men living with HIV in serodiscordant relationships

H. Khidir[1], K. Bennett[2], C. Milford[3], R. Greener[3], N. Mosery[3], A. Kaida[4], C. Psaros[5], S.A. Safren[6], D.R. Bangsberg[7,8,9], J. Smit[3], L.T. Matthews[1,7,8]
[1]Harvard Medical School, Boston, United States, [2]Bennett Statistical Consulting Group, Ballston Lake, United States, [3]MaTCH Research Unit (MRU), Department of Obstetrics and Gynaecology, University of the Witwatersrand, Durban, South Africa, [4]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [5]Massachusetts General Hospital, Behavioral Medicine Program, Department of Psychiatry, Boston, United States, [6]University of Miami, Department of Psychology, Miami, United States, [7]Massachusetts General Hospital, Global Health, Boston, United States, [8]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, [9]Oregon Health and Science University-Portland State University School of Public Health, Portland, United States
Presenting author email: ltmatthews@mgh.harvard.edu

Background: The risk for HIV transmission within HIV-serodiscordant partnerships is high and and may be highest when couples try to conceive. Gender norms affect HIV risk and likely impact reproductive decision-making. We assessed sexual relationship power and its association with periconception HIV risk behaviors among men living with HIV (MLWH) in serodiscordant partnerships.
Methods: We conducted in-person surveys with MLWH reporting a recent partner-pregnancy with an HIV-negative or unknown-serostatus partner in a township outside of Durban, South Africa. Surveys assessed partnership characteristics, Decision-making Dominance (DMD) subscale of the Sexual Relationship Power Scale, and HIV risk behaviors including disclosure, condom use, ART use, and sexual and reproductive health communication. The DMD subscale assesses whether the participant, his partner, or both partners make decisions in the relationship (e.g. Who has more say about whether you have sex?). Higher DMD scores indicate that the participant has more leverage in making decisions. Logistic regression models evaluated associations between DMD score and HIV-risk behaviors.
Results: 82 MLWH were median age of 34 (Range 22, 44) years, and 61 (74%) were employed. Fifty-three (65%) reported their recent pregnancy partner was a casual partner, 27 (33%) reported disclosing HIV-serostatus to their partner prior to the pregnancy and 23 (28%) reported condomless sex since pregnancy. The median DMD score was 3.06 (IQR 2.88, 4), and men in casual partnerships had higher DMD scores than those in stable partnerships (p≤0.01). Higher DMD scores were independently associated with non-disclosure of HIV-serostatus to pregnancy partner, not knowing partner's HIV status, condomless sex since pregnancy, and poor reproductive health communication.

Associations Between Higher DMD Score and HIV Risk Behaviors	Adjusted OR (95% CI) per point increase on Decision-making Dominance scale, n=82	P Value
Non-disclosure of HIV status to partner*	22.96 (3.45, 152.76)	0.001
Not knowing pregnancy partner's HIV status*	4.65 (1.31, 16.49)	0.02
Condomless sex since pregnancy*	3.24 (1.06, 9.96)	0.04
Concurrent sexual partners*	4.59 (0.90, 23.37)	0.07
Rarely/ never discuss sex with partner**	13.53 (3.93, 46.60)	<0.0001
Rarely/never discuss HIV prevention with partner*	10.00 (2.18, 45.70)	0.003
Rarely/never discuss having children with partner*	6.86 (2.43, 19.38)	0.0003
Rarely/never discuss contraception with partner**	8.85 (3.02, 25.93)	<0.0001
*Adjusted for education, type of partnership: casual vs. stable (i.e. main partner), partner age **Adjusted for education, type of partnership		

[Table 1]

Conclusions: MLWH dominate sexual and reproductive health decisions within partnerships. Efforts to minimize periconception HIV risk behavior must address gender norms and power inequities to promote the health of men, their partners and families.

MOPEC0711

Addressing intimate partner violence in HIV testing services: positive results of a randomized controlled trial in Nairobi, Kenya

N. Haberland[1], C. Ndwiga[2], K. McCarthy[1], J. Pulerwitz[3], R. Kosgei[4], M. Mak'anyengo[5], S. Kalibala[6]
[1]Population Council, New York, United States, [2]Population Council, Nairobi, Kenya, [3]Population Council, HIV and AIDS Program, Washington, United States, [4]University of Nairobi, Nairobi, Kenya, [5]Kenyatta National Hospital, Nairobi, Kenya, [6]Palladium, Washington, United States
Presenting author email: jpulerwitz@popcouncil.org

Background: Intimate partner violence (IPV) undermines women's uptake of HIV services, plus violates their human rights. This intervention study piloted enhanced HIV counseling and testing (HCT) sessions in a public hospital in Nairobi, Kenya to address IPV and gender-based power disparities in relationships.
Methods: A randomized controlled trial design was used to assess the efficacy of an integrated IPV-HCT pilot compared to HCT alone. Study participants were ANC clients aged 15-49 (N=698) interviewed immediately after the IPV-HCT or standard HCT session, and again at their subsequent ANC visit (N=545). In-depth interviews with providers were conducted before and after piloting the intervention to assess feasibility and perceived utility of enhanced HCT. Quantitative data were analyzed using an intent-to-treat approach. Chi-square tests assessed cross-sectional differences between study groups; generalized linear mixed modeling measured change over time, adjusting for repeated measures.
Results: In total, 35% of women reported experiencing IPV (physical, sexual or psychological) in the past year, 33% reported low power in their relationship, and 6% were HIV+. Qualitative findings suggest integrated IPV-HCT counseling was well-accepted by providers, although it took on average 6.5 minutes longer to implement. Compared to women who received standard HCT, intervention group participants were more likely to report receiving IPV screening (86% vs. 21%) and disclose violence to the provider (32% vs. 7%) (p< 0.0001, respectively). Women in the intervention group scored higher on a 6-point IPV knowledge index (p=0.049); and were more likely to report that speaking with the provider made a positive difference to them (AOR 19.8; p< 0.0001). The study was not powered to detect statistically significant differences among subgroups, nonetheless, evidence suggests positive health outcomes such as a greater percent of HIV+ women intending to adhere to their PMTCT regimen (62% intervention vs. 48% control, ns).
Conclusions: Results demonstrate the feasibility and positive intermediate outcomes of integrated IPV-HCT counseling in an urban public ANC setting in Kenya. Given the high prevalence of IPV and its role in hindering HIV testing, treatment and retention in care, this strategy to address structural issues like IPV and power in relationships should be further tested through a larger evaluation.

MOPEC0712

Peer counselor an essential position & effective strategy to improve the uptake of HIV services: meaningful involvement of drug users in generating demand for OST and uptake of ART adherence

G.C. Sharma[1,2], V. Arumugam[3], S. W Beddoe[3], S. Mehta[3]
[1]India HIV/AIDS Alliance, Program & Policy - Harm Reduction, New Delhi, India, [2]Manipur University, Health, Imphal, India, [3]India HIV/AIDS Alliance, New Delhi, India
Presenting author email: csharma@allianceindia.org

Background: The Indian government currently reports the population of PWID in India to be approximately 200,000 with an estimated HIV prevalence of 9.19 (NACO, 2014-15). In the states where the Hridaya (Community Action on Harm Reduction) is being implemented, 58% (Bihar-49%; Haryana-50% and Uttarakhand-94%) of the PWID living with HIV are registered in ART centers of which 22% (59%-Bihar; Uttrakhand-26% and Haryana-11%) were initiated and on ART treatment. Among those registered with ART center, the regular follow up for CD4 testing and ART adherence is very low in comparison to other key population.
Methods: Dutch government-funded five-country Community Action on Harm Reduction (CAHR) initiative, India HIV/AIDS Alliance implements the Hridaya programme in Bihar, Haryana, Jammu, Uttarakhand and Manipur. The programme supplemented staffing for the government's HIV prevention strategy for PWID and added Peer counsellor. Capacities of peer counsellors were developed through training, refresher training, mentoring and handholding support on harm reduction and service delivery. They educated PWID and their families mainly on treatment linkages and importance for retention on OST and ART - adherence for medication in addition education on safer sex and safer injecting practices, overdose prevention and management with provision of procurement of Naloxone and HIV/STI treatment services.

Results: 12,643 PWID and their family members were educated on harm reduction services including treatment linkages (ART and OST). There is significant increase in uptake of services (P <0.05); OST linkages increased from 46% to 51% and registration for HIV care increased from 86% to 92%, de-addiction services uptake increased from 47% to 57% as per Hridaya's impact assessment study.
Conclusions: The Peer counsellor is an important position and role has been acknowledged by PWID community and the project.Community Involvement directly supports enhancing harm reduction and services uptake. It is included in Phase-II of he project to increase the number of Peer Counselor for retention in prevention, care and support services. The whole process from identification, induction, capacity building, ToR will be documented to share with national harm reduction program to sustain the position and ensure meaningful involvement PWID in direct service delivery

MOPEC0713

A randomized controlled trial of a resilience-based intervention for children affected by HIV/AIDS in central China: effects at 6- and 12-month follow-up

S. Harrison[1], X. Li[1], A. Fairchild[2], P. Chi[3], J. Zhao[4], G. Zhao[4]
[1]University of South Carolina, SC SmartState Center for Healthcare Quality/ Department of Health Promotion, Education, and Behavior, Columbia, United States, [2]University of South Carolina, Psychology, Columbia, United States, [3]University of Macao, Psychology, Macao, China, [4]Henan University, Psychology, Kaifeng, China
Presenting author email: xiaoming@mailbox.sc.edu

Background: Global literature suggests that resilience-based interventions may yield improvements in wellbeing for vulnerable children. However, attempts to rigorously evaluate such approaches for children affected by HIV/AIDS have been limited. Thus, with the support of the National Institutes of Health, we developed a multi-level, resilience-based intervention for children affected by parental HIV/AIDS in central China. We then evaluated the efficacy of the intervention in improving psychosocial wellbeing and resilience-related outcomes at 6- and 12-months post-intervention.
Methods: Seven hundred and ninety (N=790) children, 6 to 17 years of age were recruited from Henan Province. Children were either AIDS orphans or lived with a parent infected with HIV/AIDS. Children and primary caregivers were randomly assigned by community cluster to participate in a 4-arm trial to evaluate the Child-Caregiver-Advocacy Resilience (ChildCARE) intervention. This psychosocial HIV intervention provides programming at three levels. At the child level, children affected by parental HIV receive 20 hours of intervention to build a number of skills (e.g., positive thinking, emotional regulation, coping, problem solving). At the caregiver level, caregivers receive 10 hours of programming to increase positive parenting skills and to build the capacity for self-care and social support. At the community level, trained community advocates (e.g., teachers, village nurses) conduct home visits and organize activities to strengthen the capacity of local communities to offer support for HIV-affected families.
Initial survey data were collected at baseline, 6-months, and 12-months. To assess the impact of the child-only and child+caregiver interventions, we ran a series of random effect difference score models to compare mean change over time across treatment arms from baseline to 6- and 12-month follow-ups.
Results: Intervention groups displayed improvements in several resilience-related outcomes at 6- and 12-month follow-ups, including self-reported coping skills, hopefulness, emotional regulation, and self-control. The child-only intervention arm showed some fading of intervention effects by 12-months.
Conclusions: Preliminary findings suggest that ChildCARE may be efficacious in promoting wellbeing for children affected by parental HIV/AIDS. Targeting both children and caregivers for psychosocial intervention may be effective in increasing resilience. Additional evaluation and modifications should be considered to further strengthen the program.

MOPEC0714

Measuring the levels of HIV stigma in Buenos Aires, Argentina: development of a new instrument for stigma reduction programmes

P.D. Radusky[1], V. Zalazar[2], O. Sued[2], I. Arístegui[2,3], E. Fojo[2], I.M. Mikulic[1]
[1]Universidad de Buenos Aires, Department of Psychology, Buenos Aires, Argentina, [2]Fundación Huésped, Buenos Aires, Argentina, [3]Universidad de Palermo, Buenos Aires, Argentina

Background: Valid and reliable instruments are required to measure HIV stigma and the efficacy of stigma reduction programmes. The expression of stigma is culturally determined and has changed through decades, assuming more subtle, but still harmful forms. Therefore, measures should be periodically reviewed and new local instruments designed to capture particularities in specific contexts. Three dimensions of stigma are recognized in most theoretical frameworks: internalized, anticipated (both internal) and enacted (external).
The objective of this study was to describe the level of stigma among people living with HIV (PLWH) from Buenos Aires and to obtain evidence of validity and reliability of a new measurement instrument.
Methods: Eighty eight items were designed based on interviews with PLWH, other valid instruments and main theories of stigma. Five experts evaluated this first set of items' clarity, relevance and content validity. A depurated version of 77 items was administered. The statistical analysis included item analysis, Cronbach´s alpha to evaluate reliability and correlations with the Spanish short version of the HIV Stigma Scale, for criterion-related validity.
Results: The final sample consisted of 46 PLWH (67% men, 31% women and 2% transgender women). Mean age was 41 years (SD=10.68). More than half (52%) were men who have sex with men, 44% heterosexual and 4% homosexual/bisexual women. Fifty items with adequate skewness, kurtosis and item-total correlation were retained in the final version. Subscales showed adequate reliability (Cronbach's Alphas: Internalized=.86; Anticipated=.85; Enacted=.86). Each subscale significantly and positively correlated with its criterion (Internalized: r=.68; Anticipated: r=.81 and .47; Enacted: r=.79). Half of the sample (50%) had experienced HIV stigma. Higher levels of anticipated stigma were observed (M=58.54, SD=13.72), followed by internalized (M=41.85; SD=13.02) and enacted stigma (M=33.76; SD=13.19).
Conclusions: PLWH showed higher levels of anticipated and internalized stigma compared to enacted stigma. The newly developed instrument, designed to measure HIV stigma considering local particularities, demonstrated adequate validity and reliability. This instrument can be useful to gather information about stigma to design more effective stigma reduction programmes for PLWH and assess their efficacy. The following step of this study will be a factor analysis with a larger sample to increase evidence of validity.

MOPEC0715

Perceptions of community empowerment approaches for HIV among female sex workers in fishing villages in Uganda: a qualitative study

A. Kalbarczyk[1], C. Kennedy[1,2], N. Nakyanjo[2], C. Payne[1], V. Burke[1], K. Grabowski[2,3], L. Chang[1,2,3], G. Nakigozi[2], M. Wawer[2,3], F. Nalugoda[2], S.J. Reynolds[4,5]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Rakai Health Sciences Program, Entebbe, Uganda, [3]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [4]Johns Hopkins University School of Medicine, Baltimore, United States, [5]US National Institute of Allergy and Infectious Diseases, US National Institutes of Health, Division of Intramural Research, Bethesda, United States
Presenting author email: jreynolds@niaid.nih.gov

Background: Community empowerment approaches have been found to be effective in responding to HIV among female sex workers (FSWs) in South Asia and Latin America. To date, little is known about the acceptability and effectiveness of these approaches in sub-Saharan Africa. One setting where community empowerment approaches might be beneficial is fishing communities along Lake Victoria in East Africa. HIV prevalence is as high as 44% in these communities overall and 74% among sex workers.
We sought to better understand perceptions and acceptability of sex worker community empowerment programs in fishing communities to inform more effective, tailored strategies for the HIV response.
Methods: We conducted in-depth interviews with 18 FSWs in Kasensero, a Lake Victoria fishing community in south-central Uganda. Semi-structured interview guides covered personal experiences with and barriers to HIV services in addition to perspectives on community empowerment approaches among FSWs. Findings were analyzed for both inductive and deductive themes using a framework analysis approach.

Results: Sex work was viewed as a common profession in fishing communities. FSWs were identified as home-based, bar-based, or lodge-based and could either be permanent members of the community or mobile (moving to and away from the community frequently and with little advanced planning). A few participants identified existing community groups which primarily provided financial support; none of these existing groups were formally established or affiliated with academic or non-governmental institutions. Participants identified potential benefits of community empowerment groups, which included financial (savings and loan) services and health and safety support. Important barriers to community empowerment groups included mobility of FSWs across communities and perceived competition between types of FSWs. Some participants also felt that FSWs of different ages could not form groups due to generational differences.
Conclusions: Mobility, perceived competition, and other occupational factors present challenges to community empowerment approaches in Lake Victoria fishing communities, but FSWs also felt such approaches could provide benefits. Tailored community empowerment approaches should emphasize financial and health benefits and consider the unique geographic, occupational, and social characteristics of FSWs in these hotspot communities.

MOPEC0716

Synergistic impact of sexual stigma and psychosocial well-being on HIV testing among Nigerian men who have sex with men: a mixed methods study

C. Rodriguez-Hart[1], C. Bradley[2], D. German[2], I. Orazulike[3], B. Kayode[4], H. Liu[5], T.A. Crowell[6,7], S. Baral[2], M. Charurat[4], R.G. Nowak[4]
[1]University of Maryland Institute of Human Virology, Sunnyside, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]International Center on Advocacy and Rights to Health, Abuja, Nigeria, [4]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [5]University of Maryland School of Public Health, College Park, United States, [6]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [7]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States
Presenting author email: rnowak@ihv.umaryland.edu

Background: Uptake of HIV testing is consistently low across studies of Nigerian men who have sex with men (MSM). Sexual stigma may explain low levels of HIV testing but the mechanisms by which this occurs remain poorly understood. The aim of this study was to explore how stigma and suicidal ideation impact HIV testing among MSM in Nigeria.
Methods: This study leveraged baseline data from 1,480 MSM in Abuja and Lagos recruited into the TRUST/RV368 cohort study from March/2013-February/2016. The study clinics are co-located with community-based organizations that provide non-stigmatizing services to MSM. Latent class analysis and structural equation modeling were used to develop stigma classes and assess whether suicidal ideation moderated the association between stigma and HIV testing. 24 semi-structured in-depth interviews were conducted with participants who had experienced elevated stigma in the parent cohort in order to understand barriers and facilitators to HIV testing. Interviews were transcribed and coded using thematic analysis.
Results: Participants were classified into low(n=633), medium(n=663), and high(n=184) sexual stigma classes. While there was no association between stigma and HIV testing, there was a negative association between suicidal ideation and HIV testing. There was a synergistic negative interaction between stigma and suicidal ideation, with a combined effect greater than for suicidal ideation alone (Table). The qualitative data showed that prior stigma experiences often generated psychological distress and perceptions of feeling unsafe, which could in turn decrease willingness to disclose same-sex practices or receive health services and counseling appropriate to MSM, including the avoidance of HIV testing. In contrast, MSM reported feeling safe at the study clinic but still described a need for psychosocial support services.
Conclusions: Addressing unmet mental health needs among Nigerian MSM has the potential to mitigate stigma's negative interaction with suicidal ideation and to improve feelings of safety in health settings. Such an approach may increase HIV testing and enhance existing stigma reduction approaches at MSM-friendly venues.

Main effect of association between suicidal ideation and HIV testing and interaction effects of stigma´s assocation with HIV testing moderated by suicidal ideation, in a sample of 1,480 Nigerian men who have sex with men.

Covariates of HIV Testing*	AOR	95% CI		p-value
Main Effect: HIV Testing on Suicidal Ideation	0.79	0.74	0.86	0.000
Interaction Effects: HIV Testing on Stigma, moderated by Suicidal Ideation				
High Stigma vs Low Stigma	0.65	0.20	2.11	0.543
Medium Stigma vs Low Stigma	0.46	0.39	0.55	0.000

Community level intervention among MSM to reduce stigma towards HIV-positive MSM in India: outcomes and process evaluation

V. Chakrapani[1,2], P.P. Vijin[1,2], T. Subramanian[3], T. Kershaw[4], R. Nelson[1], M. Rajan[3], M. Shunmugam[1]
[1]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [2]Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, [3]National Institute of Epidemiology (NIE), Chennai, India, [4]Yale School of Public Health, Yale University, New Haven, United States
Presenting author email: vijinpandara@gmail.com

Background: Little attention is given to stigma/discrimination faced by MSM living with HIV (MSMLH) within MSM communities. Risk of discrimination prevents MSMLH from getting social/emotional support and accessing services. We implemented and evaluated a theory-based (social-personal model) pilot community level intervention (CLI) to reduce stigma/discrimination faced by MSMLH from other MSM. CLI included cultural events, talks by positive speakers, and messages to promote acceptance of MSMLH in outreach educational sessions with MSM.
Methods: In 2016, as part of a multi-level RCT, we implemented this CLI in two cities (Chennai and Kumbakonam) in Tamil Nadu, India. Baseline and endline surveys were conducted among a total of 300 ‚general' MSM. Based on the degree of exposure to CLI, 150 endline participants were classified into three groups: Unexposed endline group (n=21); Low-exposure endline group (n=63); and High-exposure endline group (n=66). We conducted One-way ANOVA, with planned comparisons, among four groups (baseline and three endline groups), and t-test (baseline vs. endline groups). Survey measures included: sociodemographics, symbolic stigma, and negative attitudes towards sexual behavior of MSMLH. Process evaluation included observations of CLI activities and satisfaction assessments among intervention participants.
Results: Participants' mean age was 31.8 years and mean monthly income was INR 10,054 (~USD 166). There were no differences in sociodemographics of baseline (n=150) and endline (n=150) participants. Endline participants had lower mean scores in: negative attitude towards sexual behavior of MSMLH (22.6 vs. 20.5, p< .001), and symbolic stigma (7.6 vs. 5.5, p< .001). Scores on symbolic stigma (SS) and negative attitudes towards sexual behavior of MSMLH (NASB) were significantly lower among Low-exposure and High-exposure endline groups (SS=21/20; and NASB=5.7/4.7, respectively), when compared to baseline group (SS=22.6/ NASB=7.6). Process evaluation found high intervention fidelity and high satisfaction levels among intervention-exposed participants. No other interventions to reduce stigma faced by MSMLH were implemented during the period of this CLI.
Conclusions: The findings indicate the feasibility and effectiveness of a theory-based community level intervention in reducing stigma faced by MSMLH from general MSM. As the intervention activities were conducted within the local communities by community agencies working with MSM, this community level intervention model can be easily scaled up.

MOPEC0718

Effects on HIV stigma, homophobia and HIV testing of CHHANGE: challenge HIV stigma and homophobia and gain empowerment

V. Frye, CHHANGE Study Group
City University of New York School of Medicine, Community Health and Social Medicine, New York, United States
Presenting author email: vfrye@med.cuny.edu

Background: Reducing barriers to HIV treatment and prevention is critical to addressing the HIV epidemic in the United States (US) among gay, bisexual and other men who have sex with other men (MSM). This is particularly true for African-American or Black MSM, who are disproportionately affected by HIV/AIDS. HIV stigma and homophobia are barriers to treatment and prevention, with stigma reducing access to HIV testing, anti-retroviral treatment (ART), and uptake of biomedical HIV prevention technologies, such as pre/post-exposure HIV prophylaxis (PrEP/PEP). Homophobia, although less studied than HIV stigma, has also been identified as a barrier to prevention access. Project CHHANGE, Challenge HIV Stigma and Homophobia and Gain Empowerment, is a community-level, multi-component intervention designed to reduce HIV stigma and homophobia and increase access to HIV prevention, including testing. CHHANGE provided trainings/ workshops, space-based events and bus shelter ads in a high HIV prevalence, primarily African-American, Black and Afro-Caribbean, neighborhood in New York City (NYC).
Methods: To evaluate CHHANGE we used a quasi-experimental, matched neighborhood, pre- and post-intervention study design. Serial cross-sectional, street intercept surveys among residents of the invention neighborhood and matched con-

trol neighborhood were conducted before and after the intervention. Propensity score matching and generalized estimating equation regression models assessed the impact of CHHANGE on HIV stigma and homophobia. In addition, we analyzed post-intervention, street intercept survey data to assess relations among key intervention components and self-reported HIV testing. Finally, we assessed administrative HIV testing data before and after CHHANGE.
Results: We did not find a significant treatment effect of CHHANGE on HIV stigma and homophobia among residents of the intervention neighborhood as compared with control community residents. However, HIV testing increased by 350% at the testing site in the intervention community after the intervention implementation. Further, lower HIV stigma, attending an HIV stigma workshop and having friends or family living with HIV were independently associated with past six-month HIV testing among post-intervention respondents in both neighborhoods.
Conclusions: CHHANGE was feasible and acceptable to community residents. Our triangulated evaluation approach yielded conflicting results, which may be due study to design limitations. Further research is needed to understand whether and how CHHANGE affected HIV testing.

MOPEC0719

Victim impact: analyzing dispartiies by race, gender, and sexuality under U.S. HIV exposure and disclosure laws, 1992-2015

T. Hoppe
University at Albany, SUNY, Sociology, Albany, United States
Presenting author email: thoppe@albany.edu

Background: During the summer of 2014, an explosive arrest was splashed across Midwestern newspapers: A young gay Black man in a conservative county in Missouri and the accusations against him quickly became a flashpoint for racial and sexual politics - leading some critics to charge that HIV-specific criminal laws in the U.S. target gay Black men. This paper draws on an original dataset of convictions under HIV-specific criminal laws in 6 states to evaluate whether the enforcement of HIV exposure and disclosure laws has discriminatory effects.
Methods: Deidentified datasets describing cases in which a defendant was convicted under an HIV disclosure or exposure law were obtained from state agencies in Arkansas, Florida, Louisiana, Michigan, Missouri, and Tennessee. The defendant was subsequently identified in 431 cases between 1992 and 2015 using a variety of sources, including newspaper reports, online mugshot websites, and court records systems. Demographic data on each defendant was then collected. These data are compared against data obtained from state public health agencies describing the population of individuals diagnosed as HIV-positive during the same time period.
Results: Contrary to expectations, the analysis shows that heterosexual men and white female defendants are convicted at greater rates than expected. Heterosexual men are convicted at rates seven times that of men who have sex with men (MSM): 146 convictions per 10,000 HIV diagnoses as compared to 23 for MSM. Black and white heterosexual men are convicted at similarly high rates (234 and 211, respectively) as compared to Black and white MSM (16 and 15, respectively). White women are convicted at rates twice that of HIV-positive Black women (22 versus 11, respectively).
Conclusions: Findings suggest that victim characteristics - rather than defendant demographics - shape uneven patterns in the application of the law. MSM and Black female defendants may be less likely to have been convicted because their potential accusers are less willing to make contact with law enforcement. Further, this study observes an inverse correlation between a demographic group's HIV prevalence and the conviction rate. This study finds that communities less impacted by HIV (namely, heterosexual men and white women) are more impacted by criminalization.

MOPEC0720

Incarceration history and HIV testing among female sex workers in Zambia

M. Chanda[1], K. Ortblad[2], M. Mwale[1], S. Chongo[1], N. Kamungoma[1], C. Kanchele[1], T. Bärnighausen[2,3,4], C. Oldenburg[5]
[1]John Snow, Inc., Lusaka, Zambia, [2]Harvard T H Chan School of Public Health, Boston, United States, [3]University of Heidelberg, Heidelberg, Germany, [4]Africa Health Research Institute, Somkhele, South Africa, [5]University of California, San Francisco, F.I. Proctor Foundation, San Francisco, United States
Presenting author email: michael_chanda@zm.jsi.com

Background: Criminalization of sex work is thought to be a major structural driver of the HIV epidemic among female sex workers (FSW). Incarceration may lead to marginalization, which can reduce access to healthcare and HIV prevention services. Here, we investigated the association between incarceration history and recent HIV testing among FSW in three transit towns in Zambia.
Methods: A quantitative questionnaire was conducted among FSW without known HIV infection in Livingstone, Chirundu, and Kapiri Mposhi, Zambia. Participants were eligible if they were 18 years or older, reported exchanging sex for money or goods at least once in the past month, and were self-reported HIV uninfected or status unknown. Participants were asked if they had ever been arrested or incarcerated, if they had ever had an HIV test, and if so, months since their last test. Logistic regression models were used to determine the association between incarceration history and HIV testing, adjusting for sociodemographic characteristics.
Results: Of 965 participants enrolled, median age was 25 years (interquartile range 21-30 years), 722 (75.3%) were literate, and 560 (59.0%) reported a monthly income of < 500 ZMK (~USD$50). Most (760, 79.5%) reported ever testing for HIV and 617 (65.1%) reported testing for HIV in the previous 12 months. More than one-quarter (275, 28.5%) had a history of incarceration. Most (89.8%) of women reporting incarceration reported that it was related to their engagement in sex work. In an adjusted model, incarceration was associated with 38% reduced odds of HIV testing in the previous year (aOR=0.61, 95% CI 0.45-0.83, P=0.002).
Conclusions: FSW with a history of incarceration significantly less frequently reported recent HIV testing. In this population, incarceration may increase barriers to HIV testing, possibly through increased marginalization or fear of disclosure of sex worker status or police harassment for HIV testing. This may contribute to the disproportionate burden of HIV in this population. Decriminalization of sex work may increase accessibility of HIV testing, and could have profound effects on the HIV epidemic among FSW in Zambia.

MOPEC0721

Predictors of police behaviors that shape the drug user HIV risk environment in Tijuana, Mexico: the role of occupational safety, legal knowledge and attitudes on harm reduction programs

J. Cepeda[1], S. Strathdee[1], J. Arredondo[1], T. Rocha[1], M.L. Mittal[1], E. Clairgue[1], E. Bustamante[1], A. Banuelos[2], M. Morales[1], D. Abramovitz[1], I. Artamonova[1], L. Beletsky[1]
[1]University of California - San Diego, Medicine, La Jolla, United States, [2]Secretaría de Seguridad Pública Municipal, Department of Planning and Special Projects, Tijuana, Mexico
Presenting author email: jacepeda@ucsd.edu

Background: The HIV epidemic in Tijuana, Mexico is concentrated among people who inject drugs (PWID). Policing practices, such as syringe confiscation and arrest, are structural drivers of HIV transmission among PWID. Conversely, police referral of PWID to health/social services may protect against transmission. Little is known about drivers of police practices critical to HIV risk. Our objective was to evaluate how legal knowledge and harm reduction attitudes associate with police behaviors that shape the HIV risk environment among PWID in Tijuana, Mexico.
Methods: In a context of a department-wide police training initiative, between February 2015 - May 2016, 1751 municipal police officers self-administered a baseline survey on drug law enforcement practices, occupational safety, legal knowledge, attitudes related to harm reduction and drug user health. We used ordinal logistic regression to assess whether legal knowledge and attitudinal factors predicted syringe confiscation, arrest, and referral to health/social programs. The analysis focuses on respondents reporting any contact with syringes as part of their duties (N=1319).
Results: Respondent median age was 38 (IQR: 32-43), mostly male (88%, N=1150), and worked for a median of 11 years (IQR: 9-18). Thirty seven percent reported incorrect legal knowledge about syringe possession and 71% were unaware that small amounts of heroin were decriminalized under recent reforms. Officers who had ever been stuck by a needle were 1.39 (aOR: 1.03 - 1.88) times as likely to confiscate syringes. Those reporting favorable views of methadone maintenance were 1.26 times as likely to refer PWID to health/social programs (95% CI: 1.00 - 1.57). Additionally, police who believed that their role is to refer PWID to health/social programs were 2.52 (aOR: 2.04 - 3.12) times as likely to refer PWID to these programs. Male officers who believed that laws that treat addiction as a public health problem were 0.72 (aOR: 0.57-0.90) times less likely to arrest someone for heroin possession.
Conclusions: Police practices that shape HIV risk for PWID are independently associated with legal knowledge, needle stick injuries, and attitudes on harm reduction. These novel findings help rationalize interventions targeting police occupational safety, knowledge, and attitudinal factors as structural modalities to reduce PWID HIV risk.

MOPEC0722

Universal access? Legal and regulatory barriers to accessing HIV treatment across Europe that damage public health and hinder treatment as prevention

L. Power[1], J. Hows[2], S. Finne Jakobsen[3], A. von Lingen[4]
[1]OptTEST/EATG, Cardiff, United Kingdom, [2]GNP+, Amsterdam, Netherlands, [3]University of Copenhagen, CHIP, Copenhagen, Denmark, [4]EATG, Brussels, Belgium
Presenting author email: mezzmezzrow@hotmail.com

Background: Universal HIV treatment access is a key tool in reducing ongoing transmission. Regulations in many countries restrict access to state-provided HIV treatment for one or more key populations, leaving people diagnosed but untreated, often with transmissible virus. GNP+ and EATG set out to map the extent and diversity of these barriers within Europe as part of the OptTEST project.
Methods: A questionnaire to assess legal and regulatory barriers across the WHO Europe region was developed. More than 160 individuals and organisations from 49 countries provided responses which were analysed and cross-checked with other data sources. The resulting website *"Barring The Way To Health"* provides an updatable, searchable, cross-comparable database of the most common barriers to testing and treatment access including key populations affected.
Results: Only 9/49 countries reported genuine, legal universal access to free HIV treatment. These included EU (6), EFTA (2) and non-EU/EFTA (1) countries. Restrictions reported related primarily to migrants, with 5/49 also excluding current PWID.
Of EU countries, 9/27 had exceptions to free access for other EU nationals, 2/27 had no legal access for non-EU migrants and 10/27 reported exceptions to access for some non-EU nationals. Refugees and asylum seekers had some restrictions in 9/27 EU countries and no access in 2/27 countries (a further 2 could not answer).
Of the 3 EFTA countries, the only one not providing universal access excluded undocumented migrants from treatment access.
Among non EU/EFTA countries, 5/19 gave no legal, free treatment access to any migrants; a further 3/19 had some exceptions. 5/19 gave no legal access to asylum seekers/refugees while a further 2/19 had exceptions to this and 5/19 could not answer. Six did not give access to undocumented migrants while a further 5 could not answer.
Conclusions: Treatment access laws and regulations across Europe are complex, sometimes contradictory and often fall short of universal access. They particularly restrict migrant access to HIV treatment, often including those legally resident. This barrier to public health and preventing onward HIV transmission deserves closer scrutiny and challenge.

MOPEC0723

Awareness of HIV non-disclosure case law among women living with HIV in Canada: a call to build women centered knowledge and support around HIV disclosure and the law

S. Patterson[1], V. Nicholson[1], M.-J. Milloy[2], G. Ogilvie[3], R. Hogg[1,2], A. Carter[1,2], E. Ding[2], P. Sereda[2], S. Greene[4], A. de Pokomandy[5], M. Loutfy[6,7], A. Kaida[1]
[1]Simon Fraser University, Burnaby, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, Vancouver, Canada, [4]McMaster University, Ontario, Canada, [5]McGill University Health Centre, Montreal, Canada, [6]University of Toronto, Toronto, Canada, [7]Maple Leaf Medical Clinic, Toronto, Canada
Presenting author email: kangela@sfu.ca

Background: Canada has one of the strictest approaches to the use of criminal law against people living with HIV (PLWH) globally. In 2012, the Supreme Court of Canada (SCC) ruled that PLWH must disclose their HIV-serostatus to sexual partners unless they use a condom and have a low viral load (VL) (< 1500 copies/mL). Awareness and understanding of this ruling remain undefined among women living with HIV (WLWH), who experience gendered barriers to healthcare engagement.
Methods: We analysed wave 2 cross-sectional data (June 2015-January 2016) from the peer-led Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS). Participants were asked if they were aware of the 2012 SCC ruling. The law was then defined and those reporting awareness were asked how similar their understanding was to the provided definition. Existing and preferred sources of information about the law, and perceived impacts, were also assessed. Multivariable logistic regression identified correlates of ruling awareness.
Results: 584 of 1425 CHIWOS participants were included. Median age was 45 (IQR: 37-52), and 84% reported an undetectable VL (<40 copies/ml). Overall, 74% (n=431) were aware of the ruling, and of those, 47% (n=204) had accurate understanding of the legal obligation to disclose. Among the 431 aware, 36% had discussed disclosure and the law with healthcare providers. Regular HIV physicians (61%), peer workers (25%), and community workers (25%) were identified as preferred providers with whom to discuss disclosure laws. Most participants (65%) believed disclosure laws might affect the type of information WLWH would share with providers. Participation in community HIV work (Adjusted Odds Ratio [AOR]: 1.74, 95% confidence interval [CI]:1.10,2.76) was positively associated with ruling awareness, whereas experience of violence in adulthood (AOR: 0.39, 95% CI:0.21,0.70), self-reporting a detectable/unknown HIV VL (AOR: 0.52, 95% CI:0.30,0.90) and lack of awareness of HIV prevention benefits of ART (AOR: 0.59, 95% CI:0.38,0.91) were negatively associated with awareness.
Conclusions: Awareness and understanding of HIV non-disclosure law is suboptimal among WLWH. Women more socially marginalized were least likely to be aware of the law. Efforts are needed to build women centered knowledge and support around HIV disclosure and the law.

MOPEC0724

Estimating the current and potential future impact of the Mexican drug law reform on HIV incidence among people who inject drugs (PWID) in Tijuana, Mexico, using mathematical modeling

A. Borquez[1], L. Beletsky[1,2], S. Strathdee[1], D. Abramovitz[1], C. Rafful[1,3], P. Vickerman[4], M.C. Boily[5], N. Thomson[6,7], N.K. Martin[1,4]
[1]University of California San Diego, Medicine, La Jolla, United States, [2]Northeastern University, School of Law & Bouvé College of Health Sciences, Boston, United States, [3]San Diego State University, San Diego, United States, [4]University of Bristol, Bristol, United Kingdom, [5]Imperial College London, London, United Kingdom, [6]Johns Hopkins, Baltimore, United States, [7]University of Melbourne, Melbourne, Australia
Presenting author email: natasha-martin@ucsd.edu

Background: Mexico's ‚Narcomenudeo reform' depenalized possession of small amounts of drugs and instituted drug treatment instead of incarceration. Additionally, in Tijuana, the main hub for injecting drug use in Mexico, the federal government has funded non-evidence-based centers for involuntary drug treatment. We used mathematical modeling to investigate potential impacts of this reform on HIV incidence among PWID in Tijuana.
Methods: We developed a deterministic model of injecting and sexual HIV transmission among PWID disaggregated by sex, incarceration status, recent exposure to syringe confiscation, and exposure to drug treatment - either opioid agonist therapy (OAT) or involuntary drug treatment. We calibrated the model to HIV prevalence and incidence data among PWID in Tijuana, parameterized with local data on elevated syringe sharing among PWID exposed to recent (5.3 and 6.7-fold higher among men and women, respectively) and non-recent (1.4 and 1.6-fold higher among men and women, respectively) incarceration versus not, as well as recent syringe confiscation (1.9-fold higher among exposed men versus not), and involuntary drug treatment (1.7-fold higher versus never). We estimated the impact on HIV incidence of observed changes in policing since reform enactment 2012-2016 [i.e. significant decline in recent syringe confiscation, from 11% to 0%, but no change in recent incarceration] and predicted the impact of different levels of future reform enforcement (reduced incarceration by 80%, diversion to OAT, or to involuntary drug treatment) from 2017-2030.
Results: The model estimated that observed reductions in syringe confiscation averted only 3%[95%Credible Interval (CrI): 0.5-7%] of new HIV infections among PWID between 2012-2016. If appropriate reform implementation additionally reduces incarceration by 80%, then 14%[95%CrI: 4-28%] of the estimated 784[95%CrI: 557-1017] new HIV infections between 2017-2030 could be averted, with 18%[95%CrI: 7%-31%] averted if PWID were referred to OAT instead of incarcerated. However, referral to involuntary (non-evidence-based) drug treatment would avert fewer infections (10%[95%CrI: -12% to 29%]), and could even increase incidence.
Conclusions: Current implementation of drug policy reform has had limited impact on the HIV epidemic among PWID in Tijuana. Appropriate enforcement has the potential to markedly reduce HIV incidence especially if linked to OAT referral, but expansion of involuntary drug treatment could increase transmission.

Infrastructure and Delivery Models for the Scale Up of HIV Services

MOPED1060

Modifications to ART service delivery models by health facilities in Uganda to accommodate increased patient volumes: a mixed-methods study

H. Zakumumpa[1], S. Bennett[2], F. Ssengooba[3]
[1]Makerere University, School of Public Health, Health Policy Planning and Management, Kampala, Uganda, [2]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [3]Makerere University, School of Public Health, Kampala, Uganda
Presenting author email: zakumumpa@yahoo.com

Background: The rapid expansion in antiretroviral treatment (ART) coverage in resource-limited settings and the continually increasing demand for treatment will require modifications to traditional ART service delivery models. We identify modifications to ART service delivery models by health facilities in Uganda to accommodate increased patient volumes over a ten-year period (2004-2014).
Methods: A mixed-methods approach involving two study phases was adopted. In the first phase,
a survey of a nationally-representative sample of health facilities (n=195) in Uganda was conducted between February and April 2015. The second phase involved semi-structured interviews (n=18) with ART clinic managers of 6 of the 195 health facilities purposively selected from the first study phase.
A thematic framework consisting of four categories of modifications (format, setting, personnel and population)was adopted. Descriptive statistics were used for expansion of these four broad themes.
Results: The majority of health facilities 185 (95%) reported making modifications to ART interventions between 2004 and 2014.Of the 195 health facilities, 157(81%) rated the modifications made to ART as ‚major'. Modifications to ART were reported under all the four themes.
Format: Reducing the frequency of Clinic appointments and pharmacy-only refill programs were identified as important strategies for decongesting ART Clinics. Setting: Home-based care programs were introduced to reduce provider ART delivery costs. Personnel: Task shifting to non-physician cadre was reported in 181(93%) of the health facilities. Population: Visits to the ART Clinic were rationalized in favor of the sub-population deemed to have more clinical need. Two health facilities focused on patients living nearer the health facilities to align with ART adherence targets set by funders.
Conclusions: Over the study period, health facilities in Uganda made several modifications ART interventions to accommodate increased patient volumes. Further research evaluating the effect of these modifications on patient outcomes and perceived reductions in ART delivery costs is recommended.

MOPED1061

Scale-up of treatment as Prevention® in British Columbia, Canada: opportunities and challenges identified by policy makers and service providers

R. Knight[1,2], R. McNeil[2,3], J. Shoveller[2,4], W. Small[1,2]
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada, [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada
Presenting author email: rodney.knight@sfu.ca

Background: The Canadian Province of British Columbia (BC) was among the first jurisdictions to scale up TasP to the population level, including funding and policy commitments that enhanced HIV testing efforts (e.g., expansion of routine, opt-out testing; targeted testing campaigns among high-risk groups), while also ensuring that all medically eligible persons living with HIV in BC have access to free antiretroviral therapy. As such, BC represents a critical context within which to identify the factors that influenced the scalability of TasP (e.g., acceptability, adoption, fidelity, equitable reach, sustainability), including key opportunities and challenges.
Methods: We draw on in-depth, semi-structured interviews regarding the scale up of TasP with 11 key stakeholders, including high-level policy makers, front-line service providers, and representatives from ASOs. We use thematic analysis to identify the key themes identified within the interviews.
Results: Key factors that influenced scale up included:
(i) social and political factors that created opportunities to implement new ‚systems level' approaches to HIV intervention;
(ii) organizational factors, including the capacity to adapt features of TasP programming based on ‚real-time' program data;
(iii) provider-related factors, including training and resources for frontline service providers and community stakeholders; and
(iv) innovation-related factors, including a growing body of scientific evidence supporting the effectiveness of TasP in BC and elsewhere.
Key challenges included:
(i) maintaining "nimble and evidence-informed" adaptations across a highly-decentralized service delivery system; and
(ii) integrating TasP approaches with other aspects of the care deliver system, including addictions medicine.
Conclusions: Based on our findings, we identify a set of TasP implementation trajectories that have resulted in a highly adaptive approach to systems-level scale up of TasP. We show how the program continues to adapt to the evolving HIV landscape, including new funding mechanisms to respond to newly-identified HIV outbreaks (e.g., clusters of HIV-resistant strains) as well as new and revised clinical guidelines and policies to better articulate HIV practice approaches with other related specialties (e.g., addictions medicine).

MOPED1062

Strong preference for rapid oral over blood HIV testing among patients and providers at an urban public health facility in Kampala, Uganda

J. Nangendo[1], E.A. Obuku[1], I. Kawooya[1], J. Mukisa[1], A. Nalutaaya[1], A. Musewa[1], F.C. Semitala[1,2], C.A. Karamagi[1], J.N. Kalyango[1]
[1]Makerere University, College of Health Sciences, Kampala, Uganda, [2]Makerere University Joint AIDS Program, Kampala, Uganda
Presenting author email: joannangendo@gmail.com

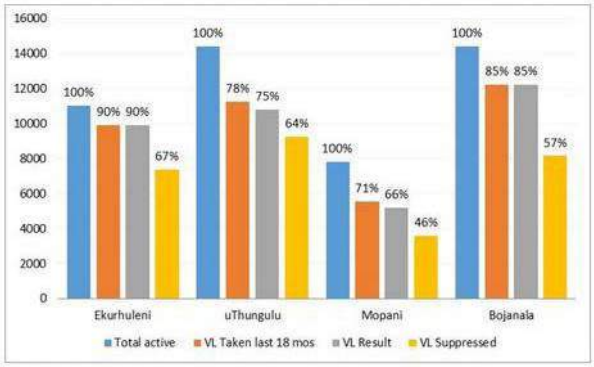
Background: The prevalence of HIV in Uganda is high at 7.3% and approximately 40% of people living with HIV (PLHIV) are unaware of their HIV sero-status. Currently Uganda's HIV testing policy is strictly blood-based. However, this method poses several challenges including demands for high level laboratory skills, stringent waste disposal needs and invasive sample collection. Introducing a rapid, non-invasive and painless alternative HIV oral-fluid test will likely increase the uptake of HIV testing. We determined the performance and preference of rapid HIV oral testing (versus blood-based testing) among clients and providers in Kisenyi Health Centre IV in Kampala, Uganda.
Methods: We conducted a cross-sectional study to assess the preference for and performance of the oral-fluid (OraQuick® Rapid HIV-1 antibody test) and blood-based national HIV serial testing algorithm (Determine® through Statpak® and Unigold®, as a tiebreaker) among 440 consecutive adults at Kisenyi Health Centre IV from January to March 2016. We also assessed for patient and provider preference of oral over blood HIV testing through three focus group discussions with the patients and seven key informant interviews with providers. The providers were also favorable since their reasons could be a little different.
Results: HIV prevalence among study participants was 14.8%. The blood and oral-fluid results were 100% concordant in all 400 patients. The majority of participants; 87% (95%CI; 83.6 - 89.9) preferred oral to finger-prick blood HIV testing because it was painless (91%, n=399), did not require blood draw (82%, n=360), had an easy sample collection process (58%, n=257), convenient (41%, n=180) and could motivate more frequent testing (28%, n=124). Similar themes for preference of oral testing also emerged from the subsequent qualitative study.
Conclusions: Our data show that the performance of the oral was as good as the blood HIV test in our high HIV prevalence population. More importantly, our findings suggest a strong preference for rapid HIV oral testing over blood among clients and providers. These attributes suggest that increased use of oral testing strategies may increase access to HIV testing services in Uganda.

MOPED1063

Gaps in care or data issues? The challenges to reaching the 90-90-90 targets in South Africa

S. Pascoe[1], M. Fox[2], A. Huber[1], J. Murphy[1], M. Phokojoe[3], M. Gorgens[4], S. Rosen[5], D. Wilson[4], M. Ndhlalambi[4], N. Fraser-Hurt[4], G. Meyer-Rath[6,7]
[1]Wits Health Consortium, Health Economics and Epidemiology Research Office, Jhannesburg, South Africa, [2]Boston University, Departments of Epidemiology and Global Health, Boston, United States, [3]National Department of Health, Pretoria, South Africa, [4]World Bank, Washington, United States, [5]Boston University, Department of Global Health, Boston, United States, [6]Boston University, Center for Global Health and Development, Boston, United States, [7]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa
Presenting author email: gesine@bu.edu

Background: To reach 90-90-90 targets requires strong healthcare systems, improved patient care and adherence and robust data systems to identify gaps. Preparations for an evaluation of South Africa's national adherence guidelines provided insights into gaps in care and data issues.
Methods: Routine patient data collection systems were reviewed at 24 clinics in 4 districts. Completion of viral load (VL) testing in the previous 18 months was assessed in TIER.Net (South Africa's electronic HIV patient record) to identify patient and provider gaps. The number of VLs captured at the National Health Laboratory System (NHLS) (which records all labs done) and in TIER.Net (which represents facility records) were compared to estimate gaps in recording VL results.
Results: The proportion of ART patients with a VL in the last 18 months in TIER.Net varied greatly by district (range 71-90% - Figure 1) and facility suggesting some patient/provider gaps in testing. 32,073 VL measures were recorded in the NHLS between April-August 2016, but only 27,598 (86%) were captured on TIER.Net with variation between districts (Table 1) and facilities, indicating that recording of results also needs improvement.



Blue = total active in care adult patients who have been on ART for > 9 months (i.e. VL test)
Orange= total no. (%) of those patients with at least 1 VL recorded on TIER
Grey= Total no. (%) of patients who had a VL done who also have a VL result on TIER
Yellow= total no. (%) of patients who had a VL done, have a VL result and are suppressed (<400 copies/ml)

[Figure 1. Viral load (VL) tests done and results at 24 facilities by province (TIER Net 2015 data)]

District	April 16	May 16	June 16	July 16	August 16	Total
Ekurhuleni	0.86 (1331/1555)	0.89 (1495/1686)	0.86 (1421/1655)	0.8 (1361/1691)	0.75 (1282/1717)	0.83 (6890/ 8304)
Mopani	0.91 (842/ 921)	0.84 (920/ 1092)	0.86 (855/ 990)	0.88 (1021/1166)	0.89 (1020/1142)	0.88 (4658/ 5311)
Bojanala	0.86 (1222/1416)	0.92 (1122/1214)	0.93 (1821/1968)	0.91 (1890/2087)	0.89 (1498/1683)	0.9 (7553/ 8368)
uThungulu	0.79 (1527/1928)	0.89 (1542/1736)	0.78 (1316/1688)	0.86 (1711/2000)	0.88 (2401/2738)	0.84 (8497/ 10090)
Total	0.85 (4922/5820)	0.89 (5079/ 5728)	0.86 (5413/ 6301)	0.86 (5983/6944)	0.85 (6201/7280)	0.86 (27598/32073)

[Table 1 - Ratio of VLs captured in TIER to NHLS]

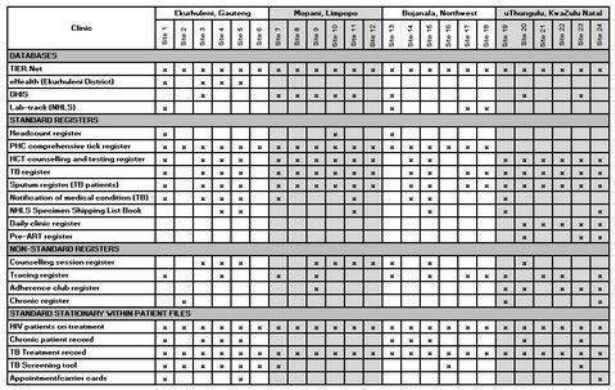
Conclusions: Efforts to improve coverage of VL testing and recording of results is essential to achieving 90-90-90 targets as complex and diverse data systems and missing data impact our ability to measure patient status accurately. Comparison across the two data systems identifies gaps in VL recording on TIER.Net .which must be rectified to enable provision of quality care, and accurate tracking of viral suppression. Further research is needed to better understand reasons why VL coverage often falls below the government target of 100%.

MOPED1064

Implementation of interventions aimed at improving linkage, retention and adherence: lessons learned from Phase 1 of the roll out of the National Adherence Guidelines for Chronic Diseases in South Africa

M. Fox[1], S. Pascoe[2], A. Huber[2], J. Murphy[2], M. Phokojoe[3], M. Gorgens[4], S. Rosen[5], D. Wilson[4], M. Ndhlalambi[4], N. Fraser-Hurt[5], K. Clouse[6,7]
[1]Boston University, Department of Epidemiology and Global Health, Boston, United States, [2]Wits Health Consortium, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]National Department of Health, Pretoria, South Africa, [4]World Bank, Washington, United States, [5]Boston University, Department of Global Health, Boston, United States, [6]Vanderbilt Institute for Global Health, Nashville, United States, [7]Vanderbilt University Department of Medicine, Division of Infectious Diseases, Nashville, United States
Presenting author email: kate.clouse@vanderbilt.edu

Background: South Africa, which has integrated HIV into primary health care, recently introduced National Chronic Disease Treatment Adherence Guidelines (AGL) to improve patient linkage, retention and adherence. The guidelines include ART fast-track initiation counselling, enhanced adherence counselling, early patient tracing, adherence clubs and decentralized medication delivery.
Methods: In preparation for an evaluation of AGL implementation (matched cluster-randomized study in 24 clinics, 4 provinces), we identified routine practices for tracking patients, documented current adherence strategies, described AGL training, and interviewed clinic staff about routine data collection, patient care documentation and facility resources. We report on lessons learned from the preparation phase.
Results: Numerous paper and electronic registers are used to track patient information including standardised government registers/stationery and non-standard registers developed locally each with varying degrees of completeness (Figure 1). AGL training was conducted in 2015 and supporting tools disseminated; final guidelines were disseminated early 2016. Some adherence support models were in place prior to AGL (22/24 facilities had fast-track initiation; 20/24 patient tracing; 10/24 adherence clubs; 13/24 counselling for unsuppressed patients) but implementation varied. Early implementation showed additional training needs resulting in partner-supported training for specific interventions and plans for staff mentoring. Resource issues (e.g. staff and stationery shortages) were also identified and mitigation plans developed.



[Figure 1: Databases and registers in use]

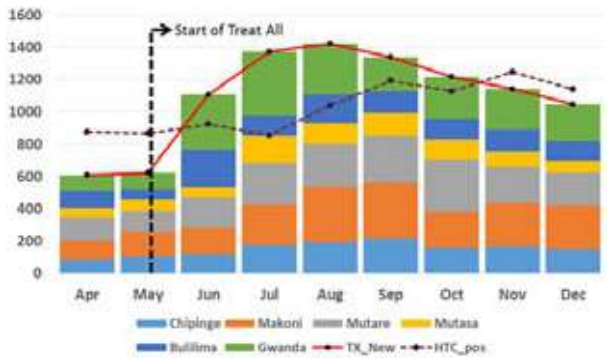
Conclusions: Early AGL implementation happened in the context of existing adherence models, diverse patient tracking systems, and other policy initiatives including universal test-and-treat. Balancing rationalisation of registers with collection of sufficient data to monitor health services in this context is challenging. The development of high-quality guidelines and supporting materials was well received by facilities although local interpretation and adaptation remains a challenge for standardisation. Optimal national-level implementation depends on sufficient staff (particularly non-clinical cadres), training, staff mentoring, and a clear communication strategy to support effective implementation of these guidelines and other strategies.

MOPED1065

Treat All: the magic bullet for the second "90"?!

B. Engelsmann, T. Maphosa, S. Page-Mtongwiza, P. Nesara, K. Webb
Organization for Public Health Interventions and Development, Harare, Zimbabwe
Presenting author email: bengelsmann@ophid.co.zw

Background: Attainment of the 90-90-90 goals is a priority for Zimbabwe. With 62% of PLHIV receiving ART in 2015, the country embraces the roll-out of TREAT ALL. This presentation reviews the impact of TREAT ALL implementation on the uptake of HIV services in 90 PEPFAR-prioritized health facilities in six learning districts in Zimbabwe.
Methods: Sites were prepared for TREAT ALL in May 2016 through introduction of the concept to provincial, district and site level leadership, community sensitization, capacity building of HCWs, readying the supply chain and distribution of implementation tools. Routine program data for patients newly identified as HIV positive and ART initiations was compiled and cleaned. Program performance/district was compared pre- and post TREAT ALL implementation using paired t-tests.
Results: From April to December 2016, the learning sites initiated 9875 patients on ART.
Before TREAT ALL was implemented, the numbers of patients initiated on ART are 30 % lower than the number of patients newly identified as HIV positive representing patients either not yet being eligible or lost to follow-up.
With the introduction of TREAT ALL, the mean number of ART initiations increased by 130% (p=0.0013) from May to August 2016, exceeding the number of patients newly identified as HIV positive. This reflects the efforts of clinics to follow up on previously not eligible patients recorded in pre-ART registers.
Five months post-introduction of TREAT ALL, initiation rates had declined and stabilized at a level 78% higher than pre TREAT ALL (p=0.0051).



[HIV service uptake pre-/post TREAT ALL]

Conclusions: TREAT ALL is an important strategy. In our dataset, as TREAT ALL is implemented, ART initiation increases sharply initially to stabilize at numbers only slightly lower (<10%) than the patients newly identified as HIV positive. Continued data collection will provide evidence whether the attainment of the second "90" can be sustained, whilst upholding the quality of service provision.

MOPED1066

Mapping of health facilities is a prerequisite for saturating the coverage of positive pregnant with PMTCT services in the private sector in India

M.K. Suryadevara[1], A. Hegde[2], N. Joevalan[1], J. Meloot[1], K.S. Sachdeva[2], K. Vaikundanathan[1], K.V. Suma[1], S. Yadav[1], P. Mohanty[1], S. Ebenezer[1], L. Ramakrishnan[1], L. Ramakrishnan[3], S.S. Raghavan[1], S.K. Angappan[3], Project Svetana Implementing Team Members from 14 States / Union Territories in India
[1]SAATHII, Project Svetana, Chennai, India, [2]National AIDS Control Organisation, Department of Health & Family Welfare, Government of India, New Delhi, India, [3]SAATHII, Chennai, India
Presenting author email: mahesh@saathii.org

Background: The national PMTCT program in partnership with GFATM and SAATHII, embarked on an ambitious expansion of PMTCT services in the private sector which accounts for 20% of the deliveries in India. First phase is focussed on scaling up in 14 states which accounts for 90% of the estimated HIV positive pregnant women in the private sector.
A comprehensive database of the vast and diverse private sector, which is a prerequisite for saturation of the coverage is lacking in the country. To address this gap, a rigorous mapping of private facilities was undertaken in 231 districts from the 14 intervention states.
Methods: The processes of mapping entailed compilation and assessment of the facilities. The sources of data for facility listing included; District health officials; electronic and hard copy directories of obstetricians, pediatricians, physicians, laboratories and nursing homes; and street walks. Facility assessment entailed validation of the site functioning and obtaining information on required infrastructure, human resources and service availability,.
Results: A list of 23,739 facilities spread across 1769 towns in 231 districts of 14 states was compiled; and 59% (13,987) of these were assessed. Among those assessed, majority (78%) were nursing homes and hospitals, 10% were outpatient clinics and 12% were laboratories. Fifty five percent of the facilities offer delivery services, however only 4% deliver positive pregnant women. Ninety four percent of the assessed facilities expressed their willingness to participate in the program and 54% of them were successfully enrolled in the PMTCT program. Facilities that offer delivery services were prioritized for enrollment for better yield.
Conclusions: Enlisting the universe of health facilities, prioritizing scale up at sites offering delivery services and periodic updation and validation are critical for saturating the coverage of pregnant women with PMTCT services in context of the dynamic private sector in India.

MOPED1067

Retention in care and deaths in a decentralized model for ART delivery: lessons from field

S. Chawla[1], P.B. Verma[1,2], V. Purohit[3], M. Bamrotiya[4], R.S. Gupta[4], M. Bhura[5]
[1]Gujarat State AIDS Control Society, Health and Family Welfare Department, Government of Gujarat, Ahmedabad, India, [2]GMERS Medical College, Community Medicine, Gandhinagar, India, [3]Independent Public Health Expert, New Delhi, India, [4]National AIDS Control Organization, New Delhi, India, [5]ART Centre, Jamnagar, India
Presenting author email: drsudhirchawla74@gmail.com

Background: The HIV Program in India started in 2004 and currently caters to 1.2 million PLHIV under care. In state of Gujarat, there are 30 ART centers that provide ART services to > 50000 PLHIV. In 2007-08, the concept of link ART centers (LAC) was introduced in the program to decentralize sites for dispensing ART to stable PLHIV on ART as defined under the program. The primary aim was to decongest the ART centers and to provide ART closer to homes for PLHIV thereby reducing the travel time and cost that could influence regular follow-up. As the LAC caters to stable PLHIV, deaths were not expected to occur at LAC. The death rates at the LAC was assessed in the state as the intervention nears 9 years of implementation.
Methods: The monthly report of the link ART centers were reviewed along with the reports from the nodal ART center, in November 2016. The LFU and death rates were calculated for each LAC. An analysis of the possible causes of death identified by the LAC staff was done to get insight into it.
Results: The number of LAC in state have been scaled up from 1 in 2008 to 61 in 2016. Total 4788 PLHIV on ART have been linked out to LAC of which 3012 are seeking care at LACs, there were 75 lost-to-follow-up and 147 deaths reported. 52(35%) deaths had clear documentation of an associated OI with TB as commonest reported cause and 07(5%) had malignancies, which includes Hodgkin's-lymphoma, cervical-cancer, brain-tumor, oro-pharyngeal caner. 64(44%) had non-HIV related natural death, of which 08(5%) reported as Myocardial Infarction, 3(2%)as respiratory diseases, while 02(1%)were due to accidents, 9(6%) PLHIV committed suicide and other reported causes of natural death were infection of gall bladder, COPD and bronchial asthma. The reason was not well established in 24(16%).
Conclusions: Decentralized care delivery model is effective and possible. However, there is need to address non HV related health needs and mental health of PLHIV. Capacity building of staff delivering decentralized care is essential. Adherence counseling should not be undermined while decentralizing services.

MOPED1068

Is hospital care an outdated approach in HIV and TB programmes? A pre-implementation assessment of admissions to a rural district hospital in Malawi

A. Flores[1], E. Goemaere[2], P. Mazuru[1], A. Chijuwa[3], A. Shigayeva[4], R. Ortuno[4]
[1]Medecins Sans Frontieres, Nsanje, Malawi, [2]Médecins Sans Frontières, Cape Town, South Africa, [3]Ministry of Health, District Health Office, Nsanje, Malawi, [4]Medecins Sans Frontieres, Blantyre, Malawi
Presenting author email: eric.goemaere@joburg.msf.org

Background: Médecins Sans Frontières (MSF) has supported the Ministry of Health (MoH) in Nsanje District since 2011 in an effort to deliver improved HIV and TB services to the population. In 2016, a decision was made to extend support to the District Hospital (NDH) because of an observed high mortality rate among patients admitted due to advanced HIV disease and TB. In order to set priorities, we undertook a review of admissions and deaths.

Methods: All adult HIV- and TB-related admissions as well as all-cause adult deaths at NDH from May to December 2016 were reviewed.
Results: There were 1183 adult admissions altogether. HIV-related admissions amounted to 25.6% of all admissions (n = 303), among which 65 (21% of all HIV-related admissions) were due to HIV/TB co-infection. Forty-one individuals of HIV-negative (n = 35) or unknown (n = 5) status were admitted due to severe tuberculosis. Overall, there were 149 deaths (death rate, 12.5%). The pooled risk of death from HIV-related causes or TB, regardless of HIV status, was 27.3% (94/344) vs 6.6% (55/839) in patients admitted for all causes other than HIV or TB (p<0.0001). In addition, at death, HIV-infected patients were younger than their peers of negative or unknown status (median age, 40 years vs 51 years, p<0.001). Among the HIV-related admissions, 90.7% of the patients had a known positive status upon arrival and 76.9% were ART-experienced. Among the HIV-infected patients, CD4 count was done in 102 patients. Median CD4 count was 142 cells/mm^3 (IQR, 56-315) and 79.4% of these patients had a CD4 count lower than 350 cells/mm^3, whereas 18.6% presented with a CD4 count lower than 50 cells/mm^3. A targeted viral load was ordered in 47 admissions, but no results were available at the time of outcome because of exceedingly long turnaround time.
Conclusions: HIV and TB are the main drivers of in-hospital mortality in Nsanje, Malawi and affect younger patients disproportionately. Despite treatment, advanced HIV disease was a frequent presentation to hospital. Investments in hospital care are needed to reduce mortality among defaulting and failing patients and thus put them back into the 90-90-90 loop.

MOPED1069

Evaluation of a PMTCT program in a resource-constrained setting: are we near virtual elimination of mother to child transmission of HIV?

T. Nyamundaya[1,2], B. Mutede[1], A. Mahomva[1], A. Mushavi[3], M. Mungati[2]
[1]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Harare, Zimbabwe, [2]University of Zimbabwe, Harare, Zimbabwe, [3]Ministry of Health and Child Care (MOHCC), Harare, Zimbabwe
Presenting author email: tnyamundaya@gmail.com

Background: In 2011, Zimbabwe developed a five-year national strategic plan to achieve virtual elimination of mother-to-chid HIV transmission (eMTCT). Zimbabwe's AIDS Prevention Project (ZAPP), working as a sub-grantee to EGPAF, partnered with Gweru City to reach eMTCT to implement this plan. The approach focused on HIV service demand-creation and increasing retention in care. An assessment of prevention of mother-to-child HIV transmission (PMTCT) sites was performed in Gweru in 2016 to ascertain whether eMTCT plan goals had been reached.
Methods: A logic framework processes-outcomes evaluation was conducted to assess PMTCT program performance at ZAPP-supported sites in 2016. Site-based and community health workers were purposively recruited for the evaluation. Records of women and children enrolled in the PMTCT program in 2011-2015 at these sites were also pulled and reviewed. Confidentiality was assured and maintained through collection of de-identified data and secure storage of questionnaires. Data were collected from health workers using semi-structured interviewer administered questionnaires and health facility checklists. Microsoft Excel and Stata were used for data analysis. Qualitative data were manually sorted by thematic content. Verbal informed consent was obtained.
Results: Two program managers, 13 community health workers and eight nurses were interviewed. Average HIV testing in antenatal care was 98.4% versus a set target of 97% for the five program years evaluated. Average proportion of HIV-positive pregnant women receiving ARV for PMTCT was 97% (higher than a set target of 95%). Average maternal retention rate at six months was 74% (below set target of 87%). Infant six-week DNA PCR positivity rates declined from 6.9% (19/267) in 2011 to 3.3% (19/582) in 2015. Seventy five percent (6/8) of all PMTCT sites had mechanisms to identify and track defaulters through use of PMTCT appointment diaries, mHealth and physical follow-up activities. Only two sites were fully implementing defaulter tracking mechanisms.
Conclusions: The eMTCT plan has been successful in Gweru at reducing the number of children infected in-utero and through delivery. Further evaluation of PMTCT rate at breastfeeding cessation is needed, but these results should help program implementers target implementation of defaulter tracing at all supported sites.

MOPED1070

Faith-based strategy for HIV sigma reduction: a Nigerian case study

I. Nwakamma[1], K. Onu[2], A. Erinmwinhe[3], C. Talla[4], G. Okoro[5]
[1]Nigerian Network of Religious Leaders Living with or Personally Affected by HIV, Monitoring, Evaluation and Learning, Abuja, Nigeria, [2]AIDS Healthcare Foundation, Clinical Services, Abuja, Nigeria, [3]Nigerian Network of Religious Leaders Living with or Personally Affected by HIV (NINERELA+), Program Management, Abuja, Nigeria, [4]Catholic Caritas Foundation of Nigeria, Clinical, Makurdi, Nigeria, [5]University of Benin, Nursing and Family Health, Benin, Nigeria
Presenting author email: amolabora2@gmail.com

Background: Religion has come to be recognized as a strong force that shapes the beliefs and actions of people, particularly in Nigeria where majority see life from the religious spectrum. The erroneous association of HIV with sexual immorality and the resultant stigma attached to it has been, to a larger extent, propagated by Religious teachings. This study is an assessment of a faith based strategy for fighting HIV related stigma using structured messages disseminated in religious gatherings in forms of sermons and information leaflets.
Methods: A simplified version of the Nigerian HIV anti-discrimination Act 2014 was produced with each component of the Act interpreted using relevant verses from the Bible and Quran. Twelve religious groups (7 churches and 5 mosques) were purposively selected and randomly grouped into intervention group (5 churches and 3 mosques) and control group (2 churches and 2 mosques). In the intervention group, the religious leaders (Pastors and Imams) were asked to share the information leaflets containing the simplified anti-discrimination Act to their congregations and preach briefly about the messages in their sermons once every week, while the control group received leaflets containing summary of the Nigerian HIV anti-discrimination Act 2014 with no religious interpretation. After six weeks, quantitative data were collected from 310 respondents (47% female) and qualitative data from 12 religious leaders in the two groups using a semi structured questionnaire that addressed issues around knowledge of the anti-discrimination Act and stigma related attitude.
Results: From the data analysis, knowledge of HIV anti-discrimination Act was low in both groups; however, the intervention group expressed less stigmatizing attitudinal disposition with no significant difference between the Christian and the Muslim groups. The religious leaders were of the opinion that the simplified religious version of the anti-discrimination Act appeals more to the conscience and triggers more empathy than the original National Act that sounds more punitive.
Conclusions: This study has once again supported the call to engage religious leaders and faith communities in initiatives targeted at behavioral change for social and public health importance. This is particularly true for developing countries like Nigeria where religion plays central role in the people's lives.

MOPED1071

Rapid initiation of antiretroviral treatment in newly diagnosed HIV at a London clinic

G. Whitlock[1], S. Blackwell[2], C. Michael[2], S. Patel[1], T. Suchak[1], M. Mohabeer[1], T. Barber[1], A. McOwan[1], N. Nwokolo[1]
[1]Chelsea & Westminster Hospital, London, United Kingdom, [2]Imperial College Medical School, London, United Kingdom

Background: Achieving viral suppression is associated with a reduced risk of HIV transmission. In primary HIV, guidelines recommend offer of immediate antiretroviral therapy (ART). ART is also recommended in chronic HIV infection. In July 2016, we increased capacity at our clinic to enable individuals with newly diagnosed HIV to have a first medical review within 48 hours of diagnosis rather than the standard 2 weeks. We set out the results from the first 6 months of the new service.
Methods: Case-note review of individuals newly diagnosed with HIV at a London clinic between 1st July and 31st December 2016 up to 3rd January 2017. Comparison data was taken from all new HIV diagnoses at our service between 1st May 2015 and 30th September 2015, before the new service was introduced.
Results: There were 149 new HIV diagnoses. Median age was 33 y. Median baseline CD4 was 469 cells/mm3 and viral load was 71738 copies/mL. 53% (72/135) tested positive on the recent infection testing algorithm (RITA), suggesting HIV acquisition within 4 months.
Of 149 new diagnoses, 13 had no further follow-up (7 moved away, 6 lost to follow-up) and 136 attended first doctor appointment, all were offered ART. Of these, 78% (106/136) started ART at first doctor appointment. Of those starting ART at first appointment, 29% (31/106) did so within 2 days of diagnosis. To 3rd January 2017, 96% (130/136) initiated ART.
Median time from HIV diagnosis to first doctor appointment decreased from 16 days (IQR 14 -21 d) in 2015 to 6 days (IQR 2 -12 d) (p< 0.05). Median time from diagnosis to ART initiation decreased from 26 days (16 - 55 d) in 2015 to 7 days (IQR 3 -16 d) (p< 0.05).

Early data suggest excellent outcomes at 6 months; of the 26 who initiated ART in July 2016, 24 had VL< 200 by 3rd January 2017 in median time from HIV diagnosis of 59 days.
Conclusions: Our new service has resulted in significantly shorter time to medical review and ART initiation. Uptake of ART is high suggesting that rapid initiation is acceptable and feasible for patients with newly diagnosed HIV.

MOPED1072

The impact of an integrated adolescent youth centre and clinic on sexual reproductive healthcare utilization and HIV testing in the Western Cape

A. Mendelsohn, K. Gill, R. Marcus, C. Van De Venter, L. Mzukwa, E. Mendel, D. Robbertze, L.-G. Bekker
University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa
Presenting author email: rebeccamarcus7@gmail.com

Background: Despite the increasing HIV incidence among young South African women, HIV counselling and testing (HCT) rates remain unacceptably low. One in three young women has a pregnancy by age 20. Alternative strategies need to be explored in order to increase prevention and screening among high-risk adolescents.
Methods: The Desmond Tutu HIV Foundation (DTHF) Youth Centre (YC) in Masiphumelele offers integrated health, educational and recreational programs in order to increase adolescent access to comprehensive sexual and reproductive health services (SRH). Participation is incentivized and clinic statistics tracked with a biometric data system. We compared HIV testing and contraception rates with data from a public clinic in Imizamo Yethu (IY), a community of similar demographics, to ascertain the impact of the YC on SRH and HCT utilisation rates for adolescents.
Results: In 2015, adolescent females under 18 had 3.74 times more contraception visits at the YC than adolescents at IY clinic. There was no difference in the type of contraception used, with both populations favouring injectable methods. Adherence to contraception was sub-optimal, with the average YC female using contraception for 6.1 months/year. Masiphumelele youth were 1.85 times more likely to have HCT at the YC than youth in IY. This difference was greater in boys, with those aged between 15-24 3.83 times more likely to test. Masiphumelele YC attendees were a third less likely to test HIV positive than their Imizamo Yethu counterparts. Female sex, older age, Clinic attendance for Family Planning and STI treatment, high incentive participation, and high Youth Centre attendance were all independent factors associated with increased HIV testing.
Conclusions: Adolescents from Masiphumelele were significantly more likely to access SRH and HCT services at the YC in comparison to the city clinic in Imizamo Yethu that has made adolescent friendly accommodations. The differences were most dramatic in contraception coverage for females under 18 and HIV testing rates in males. Lessons from the DTHF YC may be applied to public clinics in order to increase adolescent healthcare utilisation rates.

MOPED1073

Prevalence of testing and preference for self-testing in Malawi and Zambia: baseline data from the STAR (HIV self-testing in Africa) project

M. Neuman[1], H. Ayles[1,2], K. Fielding[1], B. Hensen[1], P. Indravudh[3], C. Johnson[4], P. Mkandawire[5], E. Otte im Kampe[1], E. Sibanda[6], H.A. Weiss[1], F.M. Cowan[6], K. Hatzold[7], E.L. Corbett[1,3]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]MLW, Blantyre, Malawi, [4]World Health Organization, Geneva, Switzerland, [5]PSI-Malawi, Blantyre, Malawi, [6]CeSHHAR, Harare, Zimbabwe, [7]PSI, Harare, Zimbabwe
Presenting author email: melissa.neuman@lshtm.ac.uk

Background: Substantial barriers to accessing HIV testing services (HIVST) in Sub-Saharan Africa remain, but HIV self-testing (HIVST) is a promising new tool. The STAR (HIV Self-testing in Africa) study is assessing interventions to improve uptake of testing and linkage to care in Malawi and Zambia.
Methods: The impact of community distribution of HIV self-tests on testing and on ART initiation at local clinics is being evaluated in cluster-randomised trials. In 22 rural communities in Malawi and 12 rural and peri-urban communities in Zambia, a population-based household survey was conducted at baseline. We describe baseline prevalence of prior ever HIV testing and recent testing (past 12-months), and preference for self-testing among prior testers.
Results: Baseline data were collected from 5,682 and 5,878 respondents in Malawi and Zambia, respectively. The age and sex distribution in both samples was similar (Malawi: median 31 years, IQR: 22-44, 57.2% female; Zambia: median 32 years, IQR: 23-44, 55.7% female) Prior testing was high in both countries, but less common among young men (less than 25 years) than among older men or women (see **table 1**). Within the past 12 months, 53.1% of all respondents in Malawi had tested, both only 29.3% of young men. The pattern was similar in Zambia, with 66.1% of all respondents testing recently, and only 36.1% of young men. Before distribution of self-testing, self-testing was the preferred mode for next test for 20.9% of respondents in Malawi and 33.3% in Zambia.

	Younger men (<25 yrs)	Older men (25+ yrs)	All Men	Younger women (<25 yrs)	Older women (25+ yrs)	All Women	Total (N)	Total (%)	P-value
Malawi - Total respondents (No.)	824	1463	2428	1158	1770	3254	5529	100	-
Malawi - Ever tested (% respondents)	64.1	78.1	73.1	85.1	84.9	84.9	4420	80.1	<0.001
Malawi - tested within past 12 mos. (% respondents)	29.3	41.4	36.3	68.6	62.4	64.6	1244	53.0	<0.001
Malawi - Preferred mode of next test is self-testing (% ever tested, extended survey n=1,387)	24.5	26.1	25.9	17.0	18.6	18.1	226	20.8	0.3324
Zambia - Total respondents (No.)	736	1791	2607	1080	2180	3271	5787	100	-
Zambia - Ever tested (% respondents)	61.4	83.6	75.4	82.8	89.7	87.3	3863	82.7	<0.001
Zambia - Tested within past 12 months (% respondents)	36.1	65.6	53.1	68.7	78.4	74.6	1574	66.1	<0.001
Zambia - Preferred mode of next test is self-testing (% ever tested, extended survey n=1,043)	31.2	30.7	30.9	34.9	34.1	34.4	280	33.3	0.8791

[Table 1. Testing and self-test preference]

Conclusions: Malawi and Zambia have made major progress towards scaling up HTS, but testing gaps remain, especially among men. Even before introduction, HIVST appears highly acceptable in these rural and peri-urban communities.

MOPED1074

The impact of a universal test-and-treat policy on CD4 at ART initiation at an urban, public-sector HIV treatment facility in Johannesburg, South Africa

K. Shearer[1,2], J. Golub[3], L. Long[2], M. Fox[2,4,5]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [3]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [4]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [5]Boston University School of Public Health, Department of Global Health, Boston, United States
Presenting author email: ksheare5@jhu.edu

Background: Prior to August 2016, antiretroviral therapy (ART) for people living with HIV (PLWH) was available in public sector facilities in South Africa for patients with CD4 < 500 cells/mm^3. In September 2016, test-and-treat was implemented, making all PLWH eligible for ART. We investigated whether this change resulted in an increase in baseline CD4 among initiating patients in an HIV treatment facility in Johannesburg.
Methods: We included all adult (≥18) patients initiating first-line ART at the Themba Lethu Clinic in Johannesburg between January-December 2016 and present the median (with interquartile range [IQR]) baseline CD4 count and the number of patients initiating with CD4 >500 cells/mm^3 over time. Patients without a baseline CD4 count recorded were excluded.
Results: 865 patients were included. 55.6% were female and the median (IQR) age at ART initiation was 38.4 (31.3-46.5). From January-August, 514 people initiated ART, 52 (10.1%) with CD4 >500 cells/mm^3, with a median (IQR) baseline

CD4 count of 176.5 (56-344) cells/mm³. The median (IQR) baseline CD4 count increased to 266 (85-482) cells/mm³ in 351 patients (22.8% >500 cells/mm³) who initiated between September-December.
We observed differences in the impact of test-and-treat by sex and age: the median baseline CD4 count increased by approximately 71 cells/mm³ for female patients compared to 46 cells/mm³ for male patients (Figure). Patients ≥45 (n=259) increased their median (IQR) baseline CD4 count from 146.5 (64-344) cells/mm³ from January-August to 259 (77-491) cells/mm³ from September-December. The median baseline CD4 count increased by approximately 81.5 cells/mm³ for patients aged 30-44 (n=417) and by 22 cells/mm³ for patients < 30 (n=189).

[Figure. Number of patients initiating ART monthly in 2016 with median baseline CD4 count, disaggregated by sex]

Conclusions: The implementation of test-and-treat has resulted in a 90 cells/mm³ increase in median baseline CD4 at this urban HIV treatment facility. Improvements were greatest in women and older patients, highlighting the need for further engagement of men and youths in HIV care in South Africa.

MOPED1075

Strategies for rapid initiation of test and start: validated tools tested in the field

P.F. Mwala, M. Moloto, M. Gaula, M. Ndlovu, Z. Maseko, M. Mokoatle, P. Crozier, M. Wilson, P. Mahasha, N. Sigwebela, EQUIP
Right to Care, EQUIP, Pretoria, South Africa
Presenting author email: philip.mwala@equiphealth.org

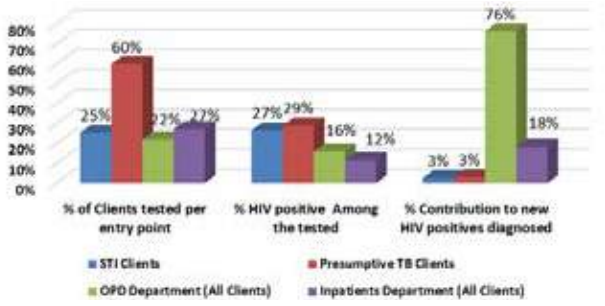
Background: The 90-90-90 UNAIDS targets are aimed at ending the AIDS epidemic by 2030. This entails bringing HIV treatment to all who need it, a major challenge in resource limited countries often faced with the greatest burden of disease. These targets are expected to significantly impact the human, financial and commodity resource needs to meet the increased programmatic demands. Determining the capacity needs of Test and Start nationally can be a daunting challenge. Due to the urgency of need, effective tools are needed that can be rapidly applied by governments and health planners to identify key bottlenecks and enablers. EQUIP, a consortium of African Partners, developed and validated an assessment tool that is easily adaptable for this purpose.
Methods: The questions for the first "90" focused on achieving maximum yield from targeted HIV testing. The second "90", addressed linkages to treatment, differentiated models of drug delivery and retention strategies. The third "90" targeted viral load scale-up and monitoring. The assessment in Lesotho was conducted on a sample of 85 facilities (public and private) across 10 districts.
Results: All facilities had at least one nurse trained in Test and Start and 39% trained in supply chain management. Pharmacy technicians and Records Officers were available in 34% and 33% of facilities, respectively. The average testing yield was 12.2%, but linkages to treatment were not consistently documented. Community ART Groups were operating effectively in 22% of facilities and viral load records were available in 54% of facilities. To strengthen service delivery recommendations included developing and implementing a structured facility-level mentorship support program in clinical care, inventory and data management.
Conclusions: The assessment provides comprehensive baseline information that facilitate the development of appropriate implementation plans. Collaboration with other implementing partners eliminated duplications, promoted synergies, ownership, efficiencies and decreased costs. The tool will support governments and stakeholders to establish the state of readiness to implement rapid roll-out of Test and Start, expediting achievement of the 90-90-90 goals.

MOPED1076

Entry point analysis of provider initiated HIV testing services: progress towards achieving the first 90 in Zimbabwe

V. Chitiyo[1], K. Webb[2], D. Patel[1], T. Maphosa[1], P. Nesara[1], S. Page-Mtongwiza[1], B. Engelsmann[1]
[1]Organisation for Public Health Interventions and Development, Operational Research, Harare, Zimbabwe, [2]Organisation for Public Health Interventions and Development, Knowledge Management and Impact Analysis, Harare, Zimbabwe
Presenting author email: vchitiyo@ophid.co.zw

Background: An estimated 74% of adults >15 years living with HIV in Zimbabwe know their status. Although remarkable progress, there is need to scale up efforts towards reaching undiagnosed individuals considering prevalence remains disproportionately high, 14.6%. Provider initiated testing and counselling (PITC) at every health service entry points has been a key strategy for HIV diagnosis. The evaluation objective was to estimate and compare PITC coverage and yield by entry point.
Methods: Modified sampling approach for conducting enhanced monitoring was used to select eight health facilities in three Families and Communities for Elimination of HIV supported districts namely Bulawayo, Kwekwe and Makoni. Data on attendances and HTC services among adults >15 years were retrospectively abstracted for July to September 2016 from the outpatients (with TB and STI as subentry points) and inpatients (medical and surgical wards as subentry points) departments. Descriptive and inferential analyses were conducted using STATA V12.
Results: Overall, 12050 adults accessed health services through the outpatients department and 3581 adults accessed services through inpatients department. Clients presenting with TB related symptoms had the highest proportion tested for HIV. The majority of new HIV+ cases, 76% were diagnosed through the OPD. While medical inpatients were more likely to be tested than surgical inpatients, 73% vs 36% (p<0.05), a higher proportion of medical inpatients tested positive when compared with surgical inpatients, 17% vs 8% (p<0.05).



[Distribution of HIV Testing and new diagnosis]

Conclusions: High yield entry points present an opportunity for early diagnosis and treatment subsequently reducing HIV transmission, morbidity, and mortality. Findings demonstrate that to achieve UNAIDS first 90 we need to strengthen PITC in OPD, with large patient volumes substantially contributing to our epidemic. High HIV testing rates among medical inpatients demonstrate feasibility of increased testing and should be replicated in other entry points. Further investigation is required on reasons for opting out of PITC.

MOPED1077

The acceptability and feasibility of community health worker-led home-delivery of antiretroviral therapy: early findings from a health systems trial in Dar es Salaam, Tanzania

J. Francis[1,2,3], P. Geldsetzer[2], N. Ulenga[1], D. Sando[2], I. Lema[4], E. Mboggo[4], M. Vaikath[2], S. Lwezaula[5], H. Koda[4], J. Hu[6], R. Noor[2,7,8], I. Olofin[2], W. Fawzi[2,7,9], T. Bärnighausen[2,10,11]
[1]Management Development for Health (MDH), Health Systems, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T H Chan School of Public Health, Global Health and Population, Boston, United States, [3]National Institute for Medical Research, Muhimbili Centre, Dar es Salaam, Tanzania, United Republic of, [4]Management Development for Health, Health Systems, Dar es Salaam, Tanzania, United Republic of, [5]National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [6]Duke University School of Medicine, Durham, United States, [7]Harvard T H Chan School of Public Health, Department of Nutrition, Boston, United States, [8]Africa Academy for Public Health (AAPH), Dar es Salaam, Tanzania, United Republic of, [9]Harvard T H Chan School of Public Health, Department of Epidemiology, Boston, United States, [10]Institute of Public Health, Heidelberg University, Heidelberg, Germany, [11]Africa Health Research Institute, Mtubatuba, South Africa
Presenting author email: joelmfrancis@gmail.com

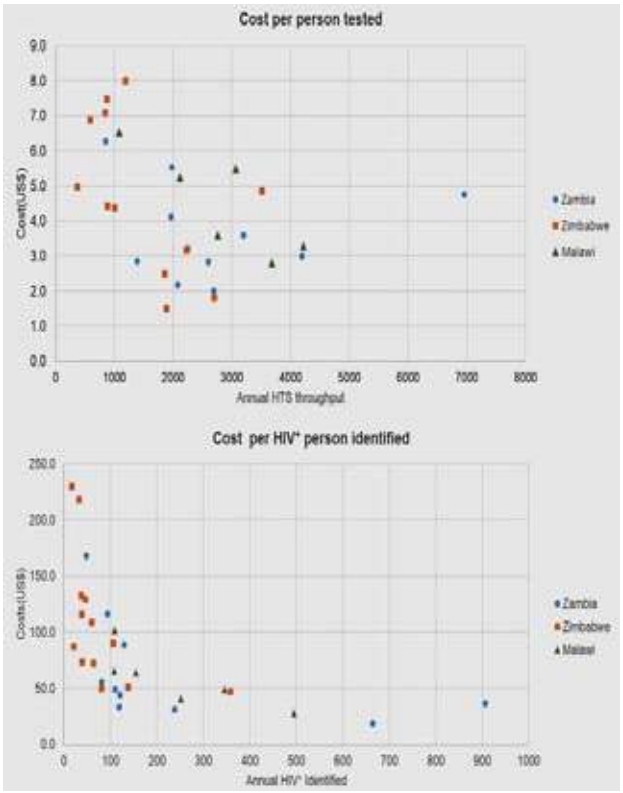
Background: Delivering antiretroviral therapy (ART) to patients' homes using community health workers (CHWs) could reduce patient volumes at healthcare facilities, improve ART adherence and retention, and decrease patients' out-of-pocket health expenditures. This study uses baseline data from a randomized health systems trial in Dar es Salaam to ascertain the acceptability and logistical feasibility of CHW-led ART home-delivery in Dar es Salaam.
Methods: We randomized 48 healthcare facilities in Dar es Salaam to either the standard of care (facility-based ART care) or CHW-led ART home-delivery. The CHW cadre is a long-standing public sector cadre in Dar es Salaam, called home-based carers. Patients had to be clinically stable on ART to be eligible for ART home-delivery. We present data from three questionnaires administered between March 1st 2016 and January 15th 2017: i) an enrolment questionnaire (n=1,572), ii) a patient exit questionnaire administered to a random sample of patients at the end of a HIV care visit (n=718), and iii) a healthcare provider questionnaire administerd to clinical personnel at the study healthcare facilities (n=102). In addition, we conducted semi-structured qualitative interviews with eight participants who were offered ART home-delivery but refused.
Results: Regarding acceptability, 14% (46/334) of participants who were offered ART home-delivery opted for standard facility-based care instead. The main reason for opting against ART home-delivery appeared to be confidentiality concerns, as suggested by both questionnaire and qualitative data. Regarding logistical feasibility, CHWs had conducted a total of 533 ART home-delivery visits by September 30th 2016 and there had not been any reports of a CHW being unable to locate a participant. Eight participants complained to the study team that their ART had not been delivered on time.
Conclusions: The home-delivery of ART by CHWs appears to be logistically feasible in Dar es Salaam and socially acceptable to a majority of patients who are stable on ART. In general, programs that deliver ART to patients' homes while minimizing the perceived risk of unintentional HIV-status disclosure would likely achieve the highest social acceptability in urban sub-Saharan Africa.

MOPED1078

HIV testing and counselling (HTC) costs in public sector settings in Southern Africa: evidence from Malawi, Zambia and Zimbabwe

L. Mwenge[1], L. Sande[2], C. Mangenah[3], N. Ahmed[4], M. d'Elbée[4], S. Kanema[1], H. Maheswaran[5], P. Indravudh[2], E. Sibanda[3], H. Ayles[6], A. Mwinga[7], L. Corbett[6], C. Johnson[8], K. Hatzold[9], F. Terris-Prestholt[4], PSI/UNITAID STAR Team
[1]Zambart, Health Economics Unit, Lusaka, Zambia, [2]Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [4]Faculty of Public Health and Policy, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Warwick Medical School, University of Warwick, Population Evidence and Technologies, Coventry, United Kingdom, [6]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Zambart, Lusaka, Zambia, [8]World Health Organization, Department of HIV/AIDS, Geneva, Switzerland, [9]Population Services International, Harare, Zimbabwe
Presenting author email: lawrence@zambart.org.zm

Background: Though substantial progress has been made to achieve the UN 90-90-90 targets, 27%-34% of people living with HIV (PLHIV) in Malawi, Zambia and Zimbabwe, are unaware of their status. We present the cost of HIV testing services (HTS) in 29 public facilities in these countries, and investigate throughput and HIV prevalence as potential causes of variance.
Methods: Standardised costing methods were collaboratively developed to ensure consistency across countries. Top-down and ingredient-based costing methods were applied from the provider's perspective, identifying the full annual costs for each facility reported in 2016 US$. Facilities were both rural and per-urban, clinics and hospitals. Quantities and costs of resources were collected through interviews, expenditure and outcome review. Annual costs per: facility; test; and HIV-positive individual identified were estimated.
Results: The annual economic costs of providing HTS were US$6,142, US$10,263 and US$11,521 per facility for Zimbabwe, Zambia and Malawi, respectively, with personnel being the largest category, driven by variations in staffing numbers and reimbursements. Facilities tested on average 1,552, 2,789 and 2,820 people in Zimbabwe, Zambia and Malawi, respectively. Reactivity rates ranged from 5% in Zimbabwe to 8% in Malawi and Zambia, with wide within country variation (1-14%). The cost per person tested was US$4-US$5 and US$58-US$108 per HIV-positive individual identified with wide variation across clinics (US$19-US$230). Economies of scale were evident, suggesting testing is more efficient in larger and/or high HIV prevalence facilities.



[HTS Unit costs]

Conclusions: Though HTS can be provided at relatively low cost, supply- and demand-side constraints stand in the way of achieving this more generally. Complementarity between clinic- and community-based testing, including HIV self-testing must be explored as a means to alleviating barriers to uptake and reaching untested populations.

MOPED1079

Soccer & vocational training: moving out of health care settings to engage men in HIV care

M.J. Rotheram[1], M. Tomlinson[2], J. Bantjes[2], A. Mayekiso[2], J. Stewart[2], K. Arfer[3]
[1]University of California, Psychiatry & Biobehavioral Sciences, Los Angeles, United States, [2]Stellenbosch University, Psychology, Stellenbosch, South Africa, [3]University of California, Psychiatry, Los Angeles, United States
Presenting author email: rotheram@ucla.edu

Background: Across Africa, men are not getting tested for HIV, are underutilizing HIV care and are less adherent to ARV than women. Rather than pushing men into care, placing prevention and care at soccer practices, games, and vocational training sites have the potential to attract men, destigmatize HIV, and increase HIV services uptake. A pilot study found significant increases in the uptake of drug testing over time and decreases of substance use over 6 months. This report focuses on a large randomized controlled study.

Methods: : All men aged 18-25 years old in 18 communities (n=900) in Cape Town, South Africa were recruited and randomized by community to receive either: 1) soccer practices/games three times weekly for one year; 2) 6 months of soccer and 6 months of vocational training; 3) or no intervention. At soccer, coaches provided HIV interventions, random rapid diagnostic tests (RDT) for alcohol/drugs once a week, and access to HIV testing and care. To date, outcomes have been monitored over the first six months.
Results: Over the first six months of soccer, attendance increased 250%, until an average of 75% of the communities' young men attended regularly, three times weekly. Alcohol use rose from 62.5% on average during the first 3 months of soccer to 70% the next 3 months of play. However, other substances decreased significantly between the first three months of soccer over the subsequent three months of practices. Marijuana use declined from 52% to 44%; methamphetamine use declined from 20% to 11%. Over 6 months, about 15% of men entered jail. The uptake of HIV testing, concurrent sexual partners, and condom protected sexual risk acts will be reported at the conference.
Conclusions: Attendance increased dramatically over time, as well as negative drug tests of more serious drugs; these drugs appear to be replaced with an 8% increase in alcohol use. A negative RDT became a source of team pride and cohesion. To engage men, HIV services must go to the men, capitalizing on their interests, in order to meet the goals of eliminating HIV by 2030.

MOPED1080

Improving relationships between needle and syringe programs and police: the potential role of in-service training

C. Strike[1], T.M. Watson[2]
[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]Centre for Addiction and Mental Health, Institute for Mental Health Policy Research, Toronto, Canada
Presenting author email: carol.strike@utoronto.ca

Background: Training police on the public health benefits of needle and syringe programs (NSPs) is viewed as a best practice to facilitate more collaborative relationships between police and these programs. To date, while the limited published literature contains promising cases of harm reduction in-service training for police, evaluative evidence is preliminary.
Methods: Using an online survey, we asked NSP managers across Canada about their programs and the quality of their NSP-police relationships.
Results: We analyzed data from the responses of 75 program managers among whom 69% reported that their program had a "positive" or "mostly positive" relationship with the police. In-service training about topics such as needle-stick injury prevention and NSP effectiveness was provided by less than 50% of the programs surveyed. Seventy-five percent reported no established protocols to resolve conflicts between NSP staff and police. Four variables, all related to in-service training, were significantly related to positive NSP-police relationships, including training about: NSP program goals (OR 7.7; 95% CI 2.0, 33.1); needle-stick injury prevention and basics of blood-borne virus transmission (OR 4.0; 95% CI 1.1, 15.34); the health and social concerns of people who use drugs (OR 3.9; 95% CI 1.1, 13.5); and evidence about the impact of injection equipment distribution (OR 3.9; 95% CI 1.1, 13.5).
Conclusions: Development of in-service training for police that is focused on harm reduction goals and initiatives is a new and evolving area. We highly encourage NSPs to offer and evaluate any such in-service training programs.

MOPED1081

Facility-level barriers to antiretroviral therapy experienced by men in Malawi

K. Dovel[1,2], K. Phiri[2], A. Schooley[1,2], M. Mphande[2], M. Chivwara[2], R. Hoffman[1,2]
[1]University of California, Department of Infectious Disease, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi
Presenting author email: kdovel@mednet.ucla.edu

Background: Men are underrepresented in antiretroviral therapy (ART) programs. In particular, facility-based services have failed to attract men. We examined the organization of ART services in Malawi to understand factors that may influence male participation and explored provider perceptions of facility-based barriers and facilitators to engaging men in ART programs.
Methods: A facility-level survey was conducted at 53 mid- and large-level health facilities across 4 districts in central and southern Malawi to assess the organization of ART programs within health facilities. Twelve focus group discussions were conducted with ART providers (n=31), HIV counselors (n=19), and community-based staff (n=29) from 6 facilities to understand provider perceptions of barriers to ART care for men and strategies to improve male participation.
Results: Forty-three percent (n=23) of 53 ART sites were located in stand-alone buildings separate from other health services. Thirty-two present (n=17) lacked privacy, with ART waiting areas easily seen by general clients or community members. Twenty-one percent (n=11) of ART sites were located in female-focused sections of the facility, such as antenatal, family planning, and/or children's clinics. Nine percent (n=5) of health facilities only offered ART on clinic days when family planning and/or antenatal services were offered. None of the sites offered male-friendly or tailored ART services.
In focus group discussions, providers believed the structure of ART programs increased men's risk of unwanted disclosure due to the location of ART sites, days of ART services that coincided with female-specific services, and health seeking behavior. Men are generally expected to attend health facilities during times of illness; therefore, men who seek regular facility-based care are assumed to be HIV+. Providers identified three strategies to address male-specific barriers to care:
(1) improve privacy in ART waiting spaces;
(2) integrate ART with other health services such as care for non-communicable diseases; and
(3) promote primary health care for men to reduce the assumption that men who regularly visit health facilities are HIV+.
Conclusions: Lack of privacy and male-friendly services are important barriers to increasing men's use of ART. Additional studies are needed to explore strategies to decrease male-specific barriers to care within health facilities.

MOPED1082

Provider perspectives on delivering HIV care in western Kenya: results of a qualitative study

B. Genberg[1,2], J. Wachira[2,3], C. Kafu[3], I. Wilson[1], N.C. Ware[4], R. Kamene-Owino[3], J. Akinyi[3], B. Koech[3], P. Braitstein[2,3,5]
[1]Brown University, Health Services, Policy & Practice, Providence, United States, [2]Moi University, College of Health Sciences, Eldoret, Kenya, [3]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [4]Harvard University School of Medicine, Global Health and Social Medicine, Boston, United States, [5]University of Toronto Dalla Lana School of Public Health, Toronto, Canada
Presenting author email: becky_genberg@brown.edu

Background: Given the dramatic rise in the numbers of people being diagnosed with HIV, entering care, and starting antiretroviral therapy (ART) in sub-Saharan Africa, as well as the additional volume projected due to the shift towards test and treat approaches in many settings, the burden on inadequate health systems will continue to rapidly increase. Providers are critical to the delivery of high quality HIV care and optimal implementation of ART. The goal of this study was to examine provider perspectives on their abilities to deliver high quality care within an increasingly over burdened system.
Methods: Sixty health care providers within the Academic Model Providing Access to Healthcare (AMPATH), a large HIV treatment and care program in western Kenya, were recruited to participate in this qualitative study. Providers included clinical officers, nurses, and support staff from three sites (Moi Teaching and Referral Hospital, Webuye, and Busia) selected to reflect a broad range of professional experiences from both rural and urban settings. We conducted in-depth interviews focused on providers' perspectives on facility and health system barriers and facilitators for patients engaging in HIV care. Interview transcripts were inductively content-analyzed to derive a set of descriptive categories representing provider experiences delivering care in their respective facilities.
Results: Providers described inefficient and disorganized systems for managing patients amidst limited resources in this setting. Provider motivation and satisfaction were generally low with high levels of stress and frustration, influenced by their perceptions of lack of interest by program managers, insufficient opportunities for professional growth, and barriers to participation in problem solving. Overall, providers perceived that their high strain, low-control roles in the system negatively influenced their ability to focus on patient needs, potentially translating to lower patient engagement with care and ART.
Conclusions: Changes in system-level factors such as the organization of care and programs for improving provider satisfaction and motivation may improve provider motivation and job satisfaction in high prevalence, low-resource settings. Additional research is needed to determine if such system-level improvements increase provider satisfaction, in turn impacting patient engagement in care, adherence to ART, and clinical outcomes.

MOPED1083

HIV/AIDS patients' perception of quality of service in Manaus, Brazil and its influence on treatment initiation and adherence to antiretroviral therapy

A. Schwartz Benzaken[1], C. Raposo[2], C. Leon[3], T. Koosed[3]
[1]Ministry of Health of Brazil, Department of STD, AIDS and Viral Hepatitis, Brasilia, Brazil, [2]AIDS Healthcare Foundation, Sao Paulo, Brazil, [3]MANAUS Consulting, Los Angeles, United States
Presenting author email: cleon@manausconsulting.com

Background: The study aims to understand HIV/AIDS patients' perception of quality of services provided in five health centers in Manaus, Amazonas, Brazil. It also evaluates the relationship between patient satisfaction and treatment initiation as well as adherence to antiretroviral therapy (ART). The study establishes a baseline of patient opinion ahead of a decentralization project led by Brazil's Ministry of Health (MOH) and the AIDS Healthcare Foundation. The decentralization seeks to improve quality of care by relieving the city's overburden main hospital, Fundação de Medicina Tropical Doutor Heitor Vieira Dourado (FMT), by routing patients to four HIV/AIDS-specialized health units (SAEs, for their acronym in Portuguese).
Methods: Researchers interviewed 812 patients (410 at FMT and 402 at the SAEs) between September and December 2016 during routine consultations. Samples included men and women, 18 years old or older, living with HIV/AIDS. Data was collected through a structured survey. Researchers also used viral load and CD4 count results obtained from government databases. Descriptive and inferential methods were used to analyze the data.
Results: Results validate the need for decentralization, showing lower patient satisfaction, longer wait times, and worse perceptions of communication with health staff at FMT than at SAEs. The convenience of the health center location, short wait times, and respectful treatment from nurses were found to be associated with higher satisfaction. While the study found similar patient adherence to ART at FMT and SAEs, FMT had a higher proportion of patients with CD4 counts under 200/mL, indicating late diagnosis/treatment initiation.
Although overall satisfaction with health services did not have an effect on adherence to ART, specific factors associated with patient satisfaction, such as wait times, time to reschedule appointments, and respectful treatment by doctors positively influenced ART adherence. Gender did not have a statistically significant influence on satisfaction levels.
Conclusions: Findings help the MOH understand patient satisfaction levels with health services and inform the decentralization process. Results also identify characteristics of health services that can be improved to increase ART adherence. Lastly, the study establishes a reference to understand whether the decentralization will effectively increase quality of service at FMT without creating adverse effects at the SAEs.

MOPED1084

Key population risk factors associated with differentiated HIV care in Tanzania

C. Casalini[1], D. Boyee[2], M. Ndolichimpa[1], N. Rutabanzibwa[1], R. Bandio[1], E. Mlanga[3], K. Curran[4]
[1]Jhpiego, Program, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, M&E, Dar es Salaam, Tanzania, United Republic of, [3]United States Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [4]Jhpiego, Program, Washington, United States
Presenting author email: caterina.casalini@jhpiego.org

Background: Recognizing the need to roll out differentiated care, Sauti project provides HIV combination prevention services to key population (KP) through mobile Community-Based HIV Testing and Counselling Plus (CBHTC+) sites and Drop-in Centers (DIC), both located at hotspots.
Methods: Between January and June 2016, data was collected from female sex workers (FSW: age 18 and above who exchange sex for cash or goods) and men who have sex with men (MSM), who accessed mobile CBHTC+ sites and 24 DIC in 11 regions and 24 districts in the Sauti project. Chi square and Mantel-Haenszel tests were used for statistical analysis.
Results: The program reached 39,180 KP (35,185 FSW and 3,995 MSM), through CBHTC+ (37,112: 33,797 FSW; 3,315 MSM) and DIC (2,068: 1,388 FSW; 680 MSM). Young KP were more likely to access DIC compared to CBHTC+ (p<0.001). The overall HIV prevalence was 3.5%, and KP accessing DIC were 2.4 times more likely to be HIV-infected compared to those at CBHTC+ (p <0.001), particularly for ages 25-49 (p <0.001). KP reporting alcohol or drugs use during sex in the last month were respectively 2.5 and 3.8 times more likely to access DIC compared to CBHTC+ (p <0.001).
Among all MSM, 35% reported vaginal sex, of whom 63% accessed DIC. Overall, about half of the KP reported lack of condom use at the last vaginal sex, particularly MSM accessing DIC were more likely to never use condom compared to those at CBHTC+ (46% vs 59%; p <0.001); when asked about condom use at last anal sex, KP accessing CBHTC+ were more likely to had never used it (FSW 86% vs 79%, p <0.001; MSM, 31% vs 23%, p <0.05).
Conclusions: Drop-in centers represent the ideal venue to reach young KP (ages 15-24), who use alcohol or drugs during sex, MSM in heterosexual relationships who do not use condom, and HIV-infected KP ages 25+. Such findings suggest that more investments could be channeled to drop-in centers, thus reaching higher risk populations, whose HIV acquisition and transmission can be prevented through HIV Testing Services, alcohol and drug risk reduction services, condom promotion and provision and pre-exposure prophylaxis.

MOPED1085

The role of needle and syringe programs (NSP) in linking people who inject drugs (PWID) to the HIV clinical care continuum in Kyrgyzstan

A. Deryabina[1], P. Patnaik[2], A. Dooronbekova[3], A. Isakova[3]
[1]ICAP at the Columbia University, Central Asia, Almaty, Kazakhstan, [2]ICAP at the Columbia University, New York, United States, [3]ICAP at the Columbia University, Bishkek, Kyrgyzstan
Presenting author email: anna@deryabina.com

Background: Although Kyrgyzstan has implemented NSPs in a range of settings since 1999, their role in facilitating access to HIV testing and care and treatment services (HCTS) for PWID had not been assessed.
Methods: We conducted surveys among 1153 PWID who use NSP services; 10 focus groups with 99 PWID (both users and non-users of NSP); interviews with 24 NSP staff and a review of 7449 NSP program records from January 1, 2015 to June 30, 2015. The assessment focused on 19 NSP sites (health facility-based, fixed NGO-based, and pharmacy-based sites) across six geographical areas.
Results: HIV Testing: Program data showed that on-site HIV testing was reported by only 3/19 (16%) NSPs and only 30% of NSP clients were referred for off-site HIV testing. Despite that, overall, 1140/1153 (99%) NSP clients surveyed reported ever being tested for HIV, 1089 of them (95.5%) knew the result of their last HIV test and 945 (82%) were tested ≤6 months ago. Among the 981 (90%) willing to disclose their HIV status, 90 (9%) reported being HIV-positive and 82 of them (91%) were enrolled in HIV care.
HIV Care & treatment: Approximately half of HIV-positve respondents (40/82 (49%) rated the support they got from NSP as being a factor that improved their adherence to HCTS in a manner that was "Very effective", 35 (43%) rated the support they were getting as "Somewhat effective", while 7 people (9%) did not receive any support from the NSP to access HCTS. Information on referrals from NSP to HIV services was not routinely collected or recorded. Many NSP staff reported not feeling sufficiently empowered or trained to counsel HIV-positive clients about HIV care and treatment. There were no differences detected between different types of NSP sites in linking and referring PWID to HIV testing, care and treatment.
Conclusions: NSPs could be better utilized to facilitate access of HIV-positive PWID to HIV testing, care and treatment, given the positive perception of NSP by PWID. However, as a prerequisite, NSP staff must be empowered to counsel HIV-positive PWID about care, and treatment services. Linkages between NSP and HCTS need to be strengthened and formalized.

MOPED1086

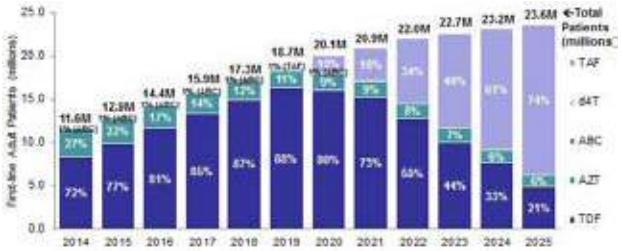
Forecasting the adoption of new antiretrovirals (ARVs) for first-line (1L) adults in generic accessible (GA) low- and middle-income countries (LMICs) through 2025

V.R. Prabhu, S. Nizami, S. McGovern
Clinton Health Access Initiative, HIV Access Program, Boston, United States
Presenting author email: vprabhu@clintonhealthaccess.org

Background: Several new generic ARVs will likely launch in LMICs by 2020, representing a range of clinical and cost advantages. These include low-dose efavirenz (EFV400), and dolutegravir (DTG), and tenofovir alafenamide fumarate (TAF). Further clarity on potential adoption is needed.
Methods: CHAI's annual forecast for currently available drugs in GA LMICs was used as baseline. Uptake curves based on historical analogs were used to model competition between new and current products. Country-specific launch years and uptake curves were chosen based on market intelligence from 12 countries representing ~75% of ART patients in GA LMICs in 2015. The "rest of world" population was modeled as one group, mirroring the least aggressive focal country. Forecast scenarios in 1L include EFV400 and DTG replacing EFV600 and nevirapine (NVP), and TAF replacing TDF.

Results: Assuming launch as a triple in H2 2017, EFV400 is modeled to gain 23% share of the "third-position" drug market by 2020, but then slowly decline to 8% by 2025 in favor of DTG. With launch of singles in H1 2017 and triples in H2 2018, DTG is projected to reach 35% share of that market in 2020, growing to 84% by 2025. Provided a H2 2019 launch, TAF is projected to gain 10% share of the "first-position" drug market by 2020, growing to 74% by 2025.

[Figure 1. Patient growth and share of first-line adult NNRTI/INSTI market in GA LMICs]



[Figure 2. Patient growth and share of first-line adult NRTI market in GA LMICs]

Conclusions: TAF, EFV400, and DTG are expected to disrupt the LMIC ARV market. Coordinated work from governments, funders, and suppliers to match supply and demand is crucial to ensure patients have access to the new drugs.

MOPED1087

Improving anal cancer screening rates among HIV-positive veterans: utilization of an electronic reminder tool

R. Plotzker[1], S.T. Brown[2,3], M. Gelman[2,3]
[1]*Icahn School of Medicine at Mount Sinai Hospital, Environmental Medicine and Public Health, New York, United States,* [2]*James J. Peters Bronx VA Medical Center, Infectious Disease, Bronx, United States,* [3]*Icahn School of Medicine at Mount Sinai Hospital, New York, United States*
Presenting author email: roz.plotzker@gmail.com

Background: Anal cancer rate among HIV infected individuals is 174/100,000 person-years versus 2/100,000 person-years for the general population. This project assesses a site-specific intervention used to evaluate anal cancer risk factors, and increase appropriate screening with anal pap smear at a Veterans Affairs Medical Center HIV clinic.
Methods: Electronic medical record data were extracted from encounters for all HIV clinic patients seen from December, 2014 to June, 2016. Baseline anal pap smear rate was below expectation. An HIV inter-professional team including infectious disease and public health physicians developed and implemented an electronic tool for anal cancer risk assessment and screening. Anal pap smear technique was reviewed with all HIV clinic providers. Anal pap smear rate was again analyzed three months post- electronic tool implementation. Electronic reminder tool usage was also evaluated with binary logistic regression.
Results: Data from 403 active HIV clinic patients (97.2% male) were included in pre-implementation analysis. Anal pap smear rate was 1.3/100-patient-years. Three months post-implementation, anal pap smear rate increased more than eight-fold to 10.6/100-patients year. 263 patients were seen during post-implementation period. Of these, 188 (71.5%) had the anal cancer risk assessment performed; 160 of whom (85%) had no anal cancer risk factors.
Risk factors for the remaining 28 included 22 reporting man who has sex with men (MSM), 15 reporting receptive anal intercourse (RAI), 9 with history of ano-genital condyloma, and 1 with a history of abnormal pap smear.
Anal cancer risk assessment varied significantly among providers in multivariate analysis. In adjusted analysis, a significant difference was seen between providers who were inter-professional team members versus those who were not (OR 3.3; 95% CI 1.3-8.3; p-vaue 0.0128). Neither patient socio-demographics nor recent CD4 count were associated with likelihood of provider electronic tool usage.
Conclusions: An electronic tool to screen improves anal cancer risk factor identification and anal pap smear rate. Adjusted analysis suggests that including providers in the development and implementation of electronic medical tools enhances appropriate tool usage.

MOPED1088

Primary Health Care (PHC) clinical placement improve services offered to people living with HIV and TB in Lesotho

S.H. Phafoli[1], J. Uysal[2], S.C. Stender[3], A. Christensen[4], S. Reinhardt[5], V. Kikaya[6], N. Lebaka[7]
[1]*Jhpiego Lesotho, Senior Nursing and Midwifery Technical Advisor, Maseru, Lesotho,* [2]*Uni, MPH, Los Angeles, United States,* [3]*Jhpiego, Senior Technical Advisor HIV/TB/ID, Cape Town, South Africa,* [4]*Jhpiego, Regional HIV and TB Advisor, Dar es Salaam, Tanzania, United Republic of,* [5]*Jhpiego, Senior Program Officer, Baltimore, United States,* [6]*Jhpiego, Country Office, Maseru, Lesotho,* [7]*Ministry of Health, Nursing Services, Maseru, Lesotho*
Presenting author email: semakaleng.phafoli@jhpiego.org

Background: Lesotho has one of the highest burdens of HIV and TB in the world, with 25% of adults living with HIV and 75% of TB patients co-infected with HIV. The country also has severe shortage of human resources for health. Nurses and midwives are the first, and often the only healthcare access point especially for more than 75% Basotho living in rural areas. It is therefore important that their pre-service education equip them with the necessary skills to manage TB and HIV/AIDS. However, nurses and midwives receive most of their clinical education at late stage, when they are assigned to work at hospital level. To bridge this clinical education gap, Jhpiego supported nursing schools to implement PHC clinical placements for students to acquire key skills including those related to TB and HIV care, treatment and support.
Methods: We conducted an assessment to determine the effect of including PHC clinical placements on student competence and confidence. HIV related tasks were identified and tracked from the clinical placements' logbooks for students that were placed in PHC settings during the academic year 2015-2016. Seventeen tasks related to TB and HIV were tracked for nursing and nine tasks for midwifery students. Analysis of data was done using Epi Info 7.
Results: A total of 226 students (179 nursing and 47 midwives) from six training institutions were placed for PHC clinical rotations throughout the country. The following HIV and TB related skills were performed at least once by 92% (N=165) of the nursing students: HIV counseling and testing, WHO HIV clinical staging, and TB screening. Tasks conducted frequently by midwives were: screening for symptoms of TB (91%, N=43) and HIV testing services (83%, N=39).
Conclusions: The evaluation concludes that PHC clinical placements significantly expose students to the range of TB and HIV skills they have to practice and master before their graduation. Pre-service education of nurses and midwives should include varied experiences to ensure students gain skills in all areas relative to deployment. In addition, students during PHC rotations assisted with service delivery in settings where there are inadequate human resources for health.

MOPED1089

Adaptation of effective models to build capacity of health workers to increase disclosure of HIV to infected children, Dar es Salaam Tanzania: a quality improvement project

A. Minja[1], H. Siril[2,3], A. Kaale[4], M. Makuchilo[2], M. Somba[4], A. Sariah[2], S. Kaaya[5], D. Urassa[2], A.P. Mhalu[2], J. Kamala[4], Z. Aloyce[4]
[1]*African Academy for Public Health, Programs, Dar es Salaam, Tanzania, United Republic of,* [2]*Management and Development for Health, Dar es Salaam, Tanzania, United Republic of,* [3]*MDH, Dar es Salaam, Tanzania, United Republic of,* [4]*African Academy for Public Health, Dar es Salaam, Tanzania, United Republic of,* [5]*Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of*
Presenting author email: agape_minja@yahoo.com

Background: Delays or not disclosing a HIV positive status to the infected child can cause depression, suicidal behavior, and refusal of ARVs, and poor school performances if a child finds out accidentally or much later in life. Evidence shows that making decisions to disclose a HIV positive status to the infected child still remains a dilemma for both health care workers and guardians/parents.
In Tanzania, the National guidelines requires child disclosure to be completed by age of 10 years, however, there are still many HIV infected children who do not know their status by the age 10 years thus increasing chances for accidental disclosures and the associated negative consequences.
We report a quality improvement project implemented from 2015-2016 in Tanzania to address this gap.
Methods: In-depth interviews with 20 health workers (HW), chart reviews for 450 HIV infected children and clinic flow observations were done. Based on this information child disclosure training curriculum for HW was modified and piloted among 52 HW for 3 months. Pre and post training tests were done, mean test scores were calculated and compared using student t-tests. Proportion of children supported for disclosure was compared before and after the intervention; chi square test was used to detect differences.

Results: The mean age was 41years (SD=8.9), 85% were females, doctors (21%), nurses (52%), and others (27%). Mean scores of disclosure knowledge among HW were 37% and 79% for pre and post-tests respectively (P <0.0001). Doctors' scored higher compared to other HW (P <0.001).
At baseline only 48 (22%) children had support for disclosure. At the end of 3 months 262 guardians/ parents were supported; 112 (43%) children were fully disclosed of their HIV positive status; 99 (38%) were partially disclosure and only 36 (14%) remained undisclosed, (P <0.0001).
Conclusions: Using simple quality improvement approach to address gaps on disclosure knowledge and practice of HW improved support and disclosure of HIV positive status to the infected children. Scaling up this approach to similar sites and expanding to address other gaps that guardians/parents and children may be facing on disclosure could improve the health of HIV infected children.

MOPED1090

State AIDS Clinical Expert Panel (SACEP): a mechanism to ensure rationale switch and clinical mentoring

M. Bamrotiya[1], R.S. Gupta[1], B. Rewari[2], V. Purohit[3], A. Sinha[1], R. Rana[4], M. Mhtre[4]
[1]National AIDS Control Organization, New Delhi, India, [2]SEARO-WHO, New Delhi, India, [3]Independant Public Health Consultant, New Delhi, India, [4]Former National AIDS Control Organization, New Delhi, India
Presenting author email: bamrotiya.manish@gmail.com

Background: India's ART programme which started in 2004, introduced second line treatment in 2008. With introduction of newer regimens in National programme, a major concern remained ensuring rationale switch as well as regular clinical mentoring of peripheral facilities. SACEP mechanism was established with aim to systemize and institutionalize early identification and treatment for failures and hence prevent emergence of drug resistance.
Methods: Selected Institutes with required capacity were identified and a panel was formed with specialist with varied expertize including program managers. This panel is trained specifically for management of treatment failure, difficult case scenarios and need based clinical mentoring. The panel regularly conducts meetings and examine patient's referred from linked center and assess them for treatment failure. The number of SACEP panels were scaled up as lessons from program implementation were learnt.
Results: SACEP mechanism has scaled from less then 10 in 2008 to 106 centers in 2016. Currently India has 106 centers with functional and trained SACEP covering 528 ART centers. Till May 2015, 27027 PLHIV have been assessed by this panel which were suspected for treatment failure at ART centers, out of which only 16159 (59%) were found eligible for second line and 15097 (93%) were initiated on ART. Though suspected as immunological or clinical failure by ART centers, 31% PLHIV did not meet the criteria for failure or had sub optimal adherence.
The SACEP mechanism prevented undue exposure to second line in significant number of patients and also ensure high uptake of second line among those who required it.
Conclusions: With comparatively limited options for treatment it is essential that judicial use of regimens be ensured. At the same time early detection and switch is crucial for treatment failure cases to improve survival and avoid emergence of drug resistance. SACEP serves an effective mechanism and should be scaled up so that the benefits are maximized and patient travels are minimized.

MOPED1091

Community perspectives on supporting the ethical scale-up HIV services among transgender women in Argentina in the context of treatment as prevention

V. Zalazar[1], N. Cardozo[1,2,3], M.E. Socías[1,4], I. Arístegui[1,5], C. Frola[1], C. Antonini[1], H. Beylis[1], M. Romero[2,3], O. Sued[1], P. Cahn[1], J. Montaner[4], K. Shannon[4], P. Duff[4]
[1]Fundacion Huesped, Clinical Research, Buenos Aires, Argentina, [2]Asociación de Travestis, Transexuales y Transgéneros de Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [3]REDLACTRANS, Buenos Aires, Argentina, [4]British Columbia Centre for Excellence in HIV/AIDS, St. Paul's Hospital, Vancouver, Canada, [5]Universidad de Palermo, Buenos Aires, Argentina
Presenting author email: virginia.zalazar@huesped.org.ar

Background: Transgender women (TGW) are the most affected group by HIV epidemic in Argentina and continue to have limited access to HIV services. Globally, the TGW community has expressed ethics-related concerns regarding targeted HIV scale-up strategies, the potential impact of discrimination by healthcare providers, and the need to tailor HIV services based on TGWs' needs. This qualitative study aimed to understand TGW's experiences and perspectives on ethical issues related to HIV services.
Methods: This community-based study explored the following ethical issues: autonomy, informed consent, beneficence and equity across all stages of the HIV cascade, as well as knowledge and attitudes regarding the secondary prevention benefit of ART (i.e., treatment as prevention [TasP]). Interviews were conducted by a trained TGW peer research associated (PRA) and were on average 1 hour in duration. After obtaining informed consent, interviews were audio-recorded, transcribed verbatim and analyzed using participatory coding techniques.
Results: Twenty-five TGW living with HIV were interviewed. We found that TGW lacked adequate information about HIV before being tested, and some did not recall an appropriate informed consent process. Regarding treatment, TGW felt disregarded by health workers, who failed to explain even basic HIV concepts (e.g., the meaning of CD4 T cell, viral load, how ART works). Many participants suggested a peer-navigator within healthcare settings would help improving access and comfort with HIV services. None of the TGW interviewed were aware of the potential prevention benefit of ART, but after explaining the TasP concept, all agreed on the potential of this strategy.
Conclusions: Our study offers several community-driven suggestions to support patient rights and the ethical scale-up of HIV services needed to improve treatment outcomes. Given the communication barriers and lack of adequate information received by patients along each step of the HIV cascade, patient education and the use of peer navigators are recommended to help improve TGWs' access and experiences with HIV services. In line with UNAIDS guidelines towards achieving the 90-90-90 targets, specialized training for healthcare workers focused on respectful communication skills, ethics, gender-based stigma and discrimination is an essential step towards achieving comprehensive care for TGW and the 90-90-90 targets.

MOPED1092

Reducing HIV-related stigma in healthcare settings through the development of an evidence-informed guideline

G.T. Feyissa[1], C. Lockwood[2], Z. Munn[2], M. Woldie[3]
[1]Jimma University, Department of Health Education and Behavioral Sciences, Jimma, Ethiopia, [2]The University of Adelaide, School of Public Health, North Adelaide, Australia, [3]Jimma University, Jimma, Ethiopia
Presenting author email: garummatolu@yahoo.com

Background: HIV-related stigma has been an obstacle against the achievement of the global health priority targets by negatively impacting adherence to, and uptake of services. As an effort to improve the practice and service in HIV and related areas, this project sought to develop an evidence-informed guideline to reduce HIV-related stigma.
Methods: We used a mixture of guideline de novo and adaptation technique to develop the guideline drawing upon the Knowledge to Action Model. First, we conducted a systematic literature search for guidelines and systematic reviews. The units of evidence were then critically appraised. A content analyses of the units of evidences was then carried out to generate the list of working recommendations. Summaries of findings table were produced using Gradepro software package. Consensus was finally established through two rounds Delphi panel survey and two consensus meetings. Then, the feasibility and appropriateness of the recommendations were assessed through external panel review and seven in-depth interviews with health professionals and health managers.
Results: The literature search yielded a total of 1532 records. Based our inclusion criteria and the results of critical appraisal, we included 11 records (5 systematic reviews and 6 guidelines). Initially, 26 recommendations were drafted from the content analyses of the documents included. The recommendations were evaluated using a survey of Delphi panel and external experts. Based on these evaluations, 10 recommendations were retained in the final draft. The Delphi panel, external reviewers and the key informants suggested that the guideline be introduced through training, workshops, availing hard copies, through a multidisciplinary team meeting of experts working on care and treatment of clients living with HIV and through HIV mentorship program. It was also suggested that the indicators be integrated into the hospital performance indicators. Participants reported that the guideline would help not only to achieve HIV-related goals, but also other health facility initiatives such as compassionate and respective care (CRC) and clean and safe health facility (CASH).
Conclusions: The current project has keep rigor and applicability of the evidence into current initiatives and practices. The current guideline can be integrated into new and existing health facility initiatives such as CRC and CASH.

MOPED1093

Setting research priorities for the intersection of alcohol and HIV/AIDS in low and middle income countries

S. Gordon[1], M. Tomlinson[1], S. Skeen[1], C. Parry[2], K. Bryant[3], M.J. Rotheram-Borus[4]
[1]Stellenbosch University, Department of Psychology, Stellenbosch, South Africa, [2]Medical Research Council, Alcohol, Tobacco and Other Drug Research Unit, Cape Town, South Africa, [3]National Institute on Alcohol Abuse and Alcoholism, HIV/AIDS & Alcohol Research Program, Bethesda, United States, [4]University of California, Los Angeles, UCLA Global Center for Children & Families, Los Angeles, United States
Presenting author email: sarahg@sun.ac.za

Background: The harmful use of alcohol is a component cause for more than 200 diseases. The association between alcohol consumption, risk taking behavior and a range of infectious diseases such as HIV/AIDS is well established. The prevalence of HIV/AIDS as well as harmful alcohol use in low and middle income countries is high. Alcohol has been identified as a modifiable risk factor in the prevention and treatment of HIV/AIDS. The objective of this paper is to define research priorities for the interaction of alcohol and HIV/AIDS in low and middle income countries.
Methods: The Child Health and Nutrition Research Initiative (CHNRI) priority setting methodology was applied in order to assess research priorities of the interaction of alcohol and HIV/AIDS. A group of 171 global and local experts in the field of alcohol and or HIV/AIDS related research were identified and invited to generate research questions. This resulted in 205 research questions which have been categorized and refined by senior researchers into 48 research questions to be evaluated using five criteria: answerability, effectiveness, feasibility, applicability and impact, as well as equity.
Results: The 48 research questions will be sent out during the course of February 2017 for independent evaluation and scoring. Each competing research question will receive a score on each of the five criteria ranging from 0 to 100%. The scores will represent a shared opinion of the experts independent scoring. Results following scoring of research questions expected May 2017.
Conclusions: Recent research has shown the causal link between alcohol consumption and the incidence of HIV/AIDS including a better understanding of the pathways through which alcohol use affects ARV adherence (and other medications to treat opportunistic infections) and CD4 counts. This paper will present potential research priorities relating to HIV/AIDS prevention, treatment, care and or support. These research priorities have implications for international funding organizations and policy makers.

MOPED1094

Mapping and size estimation of key populations in Kosovo

D. Gexha Bunjaku[1], E. Deva[2], L. Gashi[1], P. Kaçaniku Gunga[1], F. Emmanuel[3]
[1]National Institute of Public Health, Prishtina, Kosovo, [2]Community Development Fund, Prishtina, Kosovo, [3]University of Manitoba, Winnipeg, Canada
Presenting author email: dafinagexha@gmail.com

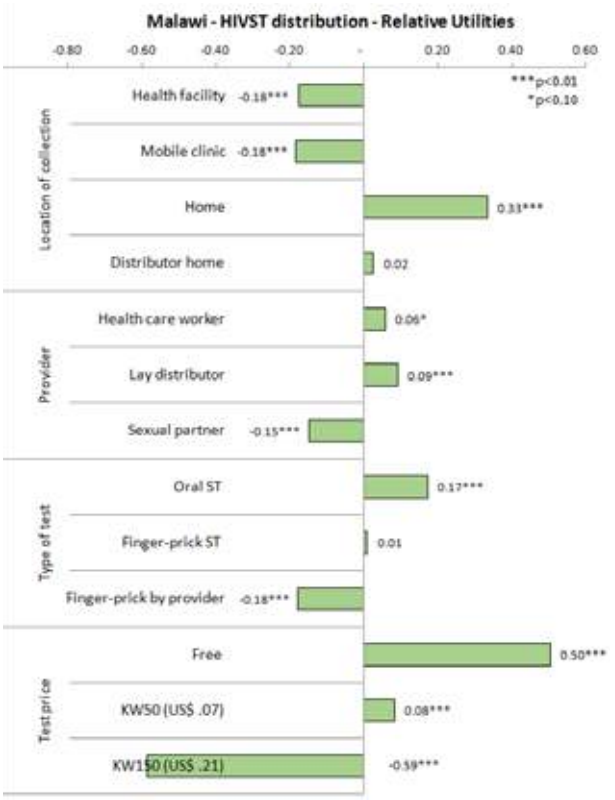
Background: This is the first study of this nature in Kosovo. The objective of the research was to conduct population size estimate at granular and national level, distribution, settings and typologies of Female Sex Workers (FSWs), Men who have Sex with Men (MSM) and People Who Inject Drugs (PWID) in order to provide a sound platform to improve service delivery and suggest ways to scale up the response.
Methods: Cross sectional survey in 26 municipalities of Kosovo, Feb-April 2016 through two sequential steps: systematic information-gathering from secondary key informants within each zone and validating each spot through primary key informants. In addition internet sites and mobile apps were mapped for MSM in the similar way. KP size estimates were calculated for each spot and rolled up into municipality estimates then aggregated into national estimates.
Results: Men who have sex with men is the largest key population identified with a total number of 6814 (range 6445 to 7117). MSM congregate at 141 geographical spots across six types of spots including geo and virtual mapping, with an overall national rate of 12 MSM per 1000 adult men. Fewer MSM operate at geographic spots, due to social norms MSM keep their activities hidden and mostly operate through internet and cell phones. An estimated number of FSW was 5037 (4213 to 5860) with national rate of 8.9 FSWs per 1000 adult females. The study identified 790 geographical spot with eight different spot typologies. An estimated 1/5th of the FSWs do not operate on geographical spots, while approximately 10% of FSW in Kosovo use websites to connect with clients. A total of 5819 (4777 to 6860) PWID were calculated with rates of 10.2 PWID per 1000 adult men spread over 847 geographical spots with five spot typologies. No female PWID were identified at geographic spots.
Conclusions: These are size estimates which were calculated through involvement of key populations and finalized with their agreement. The information on the operational structures and networks gathered through this study could be used to develop targeted public health interventions.

MOPED1095

Informing targeted HIV self-testing service delivery in Malawi and Zambia: a multi-country discrete choice experiment

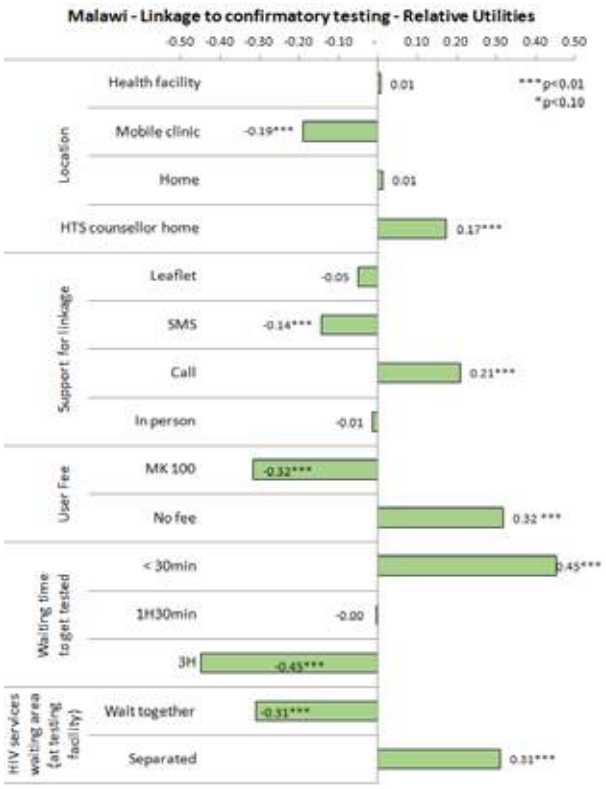
M. d'Elbée[1], P. Indravudh[2], L. Mwenge[3], B. Hensen[1], M. Neuman[1], A. Choko[2], A. Muzumara[3], M. Simwinga[3], H. Ayles[3], C. Johnson[4], K. Hatzold[5], L. Corbett[1,2], F. Terris-Prestholt[1]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Zambart, Lusaka, Zambia, [4]World Health Organization, Geneva, Switzerland, [5]Population Services International, Harare, Zimbabwe
Presenting author email: marc.delbee@lshtm.ac.uk

Background: Adult HIV prevalence remains high in Southern Africa. HIV self-testing (HIVST) is a new approach with potential to improve coverage. To inform HIVST implementation, we elicited user preferences to quantify the strength of preferences for alternative HIVST distribution and linkage options using discrete choice experiments (DCEs).
Methods: Four DCEs were implemented within representative household surveys in Malawi and Zambia. Adults (≥16 years) were randomly allocated to DCE on: HIVST distribution or linkage to confirmatory testing and care. We explored preference heterogeneity by country, age, gender and HIV testing experience.
Results: For distribution (n=1116), participants preferred to receive HIVST at home or at a distributor's home to mobile clinics (and drugstores in Zambia only). Oral fluid tests were preferred to provider-administered or self-administered blood-based tests. HIVST distribution via sexual partner was viewed less favourably, especially among men. HIVST price had a strong negative impact on uptake.



[Figure 1 - HIVST distribution DCE - Malawi]

For linkage to care (n=843), phone call was preferred to SMS, a personal visit or no follow-up. The home of the HIV testing services (HTS) provider was preferred for confirmatory testing after a reactive self-test in Malawi only. Facility user fee and waiting time for confirmatory testing were strong disincentives.



[Figure 2 - Linkage to care DCE - Malawi]

Conclusions: The DCE results were consistent across these countries with similar HIV context and suggest community-based distribution and linkage are critical aspects of HIVST delivery. A next step is to explore preferences of populations among whom HTS uptake and linkage to care are known to be low, such as men, youth and key populations.

MOPED1096

Building a telehealth intervention to facilitate engagement in HIV and related health services by transgender women of color in Washington, DC, U.S.A

M. Magnus[1], E. Edwards[1], A. Dright[1], A. Brown[1], L. Gilliam[1], V. Criss[1], M. Levy[1], N. Sikka[1], M. Siegel[1], E. Machtinger[2], C.C. Watson[3], I. Kuo[1]
[1]George Washington University, Washington, United States, [2]University of California, San Francisco, San Francisco, United States, [3]George Washington University (at Time of this Work), Washington, United States
Presenting author email: manyadm@gwu.edu

Background: Transgender women of color (TWC) are an underserved population who often experience HIV and barriers to healthcare including stigma, violence, and trauma. Few mobile health applications or interventions are customized to serve TWC. The purpose of this study was to conduct qualitative research to inform development of a TWC-specific telehealth intervention to increase access to care and HIV services.
Methods: TWC ≥18 years with at least one structural barrier to care, and clinicians who provide care to TWC (N=22), were recruited through peer referral and professional contacts, respectively. Two focus groups of TWC (both living with HIV and at risk for HIV) were also convened. Semi-structured interviews asked how telehealth can be implemented to serve TWC with structural barriers. Transcripts were analyzed using thematic coding and content analysis and barriers for TWC were categorized into individual, organizational, and environmental levels, sublevels. Upon completion of data collection, several day-long meetings with the study team and key TWC stakeholders were convened to discuss the findings and propose the intervention and instrumentation.
Results: Saturation was reached on barriers to be addressed by the intervention for it to be effective. These included survival and instability, temporal discounting, and prioritizing hormone therapy over health care, HIV prevention or treatment as individual level barriers to services. Type of services needed versus those provided, congruence between providers and patients, pessimism about services and provider, and lack of provider cultural competency were identified as key organizational and environmental barriers. Illustrative text is shown in Table 1.

Theme: Individual-level barriers
Summary: The telehealth intervention must not only focus on HIV-related services but must first address elements of survival which necessarily take priority over prevention. Where providers are unaware of patient prioritization of needs, the intervention can bridge a gap by supporting TWC to communicate needs to providers and/or identify priority care simultaneous with HIV-related care
Sub-Theme: Survival and general instability: "Because that's really the issue when you're homeless to the streets you're in the shelters and sometimes you just forget [to take medications]." "The HIV I'm not too much worried about it's the disease of addiction that I'm worried about that will kill me before anything else."
Sub-Theme: Temporal discounting "Some [transwomen] have a preconceived notion that they have short life spans anyway so what's the point in running to the doctor? Uh and they also fall prey to the ideology of ,I feel fine so nothing can't be wrong.' "
Sub-Theme: Prioritization of HIV care: "Their top needs were, say 1-5, and we're talking about they're homeless. You would be amazed - and we've done this before that you would be amazed to know that you would think that because a person's HIV positive, they got mental health, and they homeless that those would be the top three. But it's not. The top one is hormone therapy. And that's what they seek for, the hormone therapy and number two would be housing, and then the health care would come in there as far as primary medical and all that and then the mental health, the mental health falls to the bucket and we're talking people that's sometimes severe mental health."
Theme: Organizational and environmental-level barriers
Summary: The telehealth intervention must support TWC to identify service locations where providers are culturally-competent and available. Providers can then better address differences in priorities while ensuring all needs are being met, those both patient-identified and health-related. Referral to providers who have experience with transgender communities is needed so that stigma and insensitive practices are avoided.
Sub-Theme: Availability of services: "They [the clinics] schedule people so close to each other right I don't feel as though I get my full medical care because here I am. I'm a transgender who has um, several illness, and even past HIV it's like "you'll have to come back for that," "we'll Schedule an appointment for that." I got chronic bone disease, I got congestive heart failure and it's like everything that I need, when I have to wait 90 days to see my doctor - my appointments are like every 90 days- and when get in with her after 15 minutes it's like okay well your time is up, you know, whatever you don't get within 15 minutes we'll reschedule."
Sub-Theme: Discordance in provider / patient priorities: "Where you're worried about their cholesterol they may be worried about hormone management. Where you're worried about their blood pressure, they may be worried about um, you know um, laser hair removal." [provider]
Sub-Theme: Provider lack of cultural competency / transgender specific knowledge: "Oh, Mr. [name], this is [clinic] calling to remind you of your appointment on so and so so and so, that hurts. I mean I'm a seasoned transgender woman, if I say seasoned because I'm 55 years of age, I'm seasoned so you can imagine if I'm hurt, imagine the kid that's 16, 17, those young transgenders. They can't cope with that. But I manage to because I know how important health care is."

[Illustrative Domains and Quotes]

Conclusions: These data enabled development of a telehealth intervention customized for TWC that was piloted in another study and found to be acceptable, feasible, and associated with improvements in routine, HIV service utilization and intention to seek care. This intervention, developed through a participatory process, offers an innovative solution to improve health outcomes for TWC.

MOPED1097

Availability of antiretroviral medicines and characteristics of stock-outs in public facilities in Kinshasa, Democratic Republic of Congo

T. Gils[1], C. Bossard[1], A. Acma[2], A. Mbala Seki[2], M. Mashako[2], F. Biayi[3], I. Casteels[2], G. Van Cutsem[1], S. Spiers[4]
[1]Medecins Sans Frontieres, Southern Africa Medical Unit, Cape Town, South Africa, [2]Medecins Sans Frontieres, Kinshasa, Congo, Democratic Republic of the, [3]Programme National d'Approvisionnement de Médicaments, Kinshasa, Congo, Democratic Republic of the, [4]Projet SIDA Médecins Sans Frontières, Kinshasa, Congo, Democratic Republic of the
Presenting author email: msfocb-kinshasa-sida-pmr@brussels.msf.org

Background: Stock-outs of antiretroviral medicines (ARVs) are early warning indicators for HIV resistance. This study aimed at analyzing the availability of ARVs in public pharmacies and characterizing the stock-outs in Kinshasa, Democratic Republic of Congo.
Methods: Data for this cross-sectional study were collected on a questionnaire during physical visits to antiretroviral treatment (ART) facilities and warehouses in Kinshasa between October and December 2016. All facilities in charge of over 200 patients on ARVs were selected, as well as one facility with 100 to 200 and one with less than 100 patients per health zone. All warehouses in the corresponding health zones were selected. Stock-outs of ARVs were determined by physical verification during the visit and through verification on stock cards for a three-month period before the visit. For those items for which a stock card was available, the stock-

out duration was collected. For four ARVs, stock cards were compared with physical stocks and considered as correct if the difference between the quantities was less than 10%. For all ARVs stock-outs, the pharmacy responsible reported coping mechanisms used.
Results: The survey included 94 facilities, covering 73% of people on ART in Kinshasa. Among facilities visited, there were 107 stock-outs of ARVs counted on day of visit and 92 reported in the preceding three-month period, of which 36% were not recorded on a stock card (33 facilities). Stock cards were correct for less than 75% of facilities and less than 50% of zonal warehouses; 50% of facilities had stock-outs of at least one ARV on visit day, with a median duration of 61 days [IQR = 23-82]. Second line and pediatric ARVs were most frequently out of stock. In 31% of stock-out cases on visit day and in 38% of stock-outs in the previous three months patients had been sent away without ART. In 44% of stock-outs on visit day and 72% of stock-outs in the previous three months, the ARVs were available in the zonal warehouse in the same period.
Conclusions: This study shows that urgent action is needed to reduce stock-outs, focusing on the last mile delivery and on specific ART regimens.

MOPED1098

Motivations of young Thai men who have sex with men to access HIV testing, 2015-2016

C. Ungsedhapand[1], W. Wimonsate[1], K. Pancharoen[1], A. Sriporn[1], P. Leuchai[1], S. Winaitham[1], S. Yafant[1], P. Sirivongrangson[2], T. Holtz[1,3], E. Dunne[1,3]
[1]Thailand Ministry of Public Health - U.S. Centers for Disease Control and Prevention Collaboration, HIV/STD Research Program, Nonthaburi, Thailand, [2]Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand, [3]Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, United States
Presenting author email: tkh3@cdc.gov

Background: Young men who have sex with men (MSM) are a vulnerable population who need access to regular HIV testing. Since December 2014, Thailand has had policies supporting HIV testing for minors without parental consent. We investigated the reasons adolescents and young adults aged 15-24 years old attended HIV voluntary counseling and testing (VCT) at Silom Community Clinic (SCC), Bangkok, from January 2015- June 2016.
Methods: During the initial VCT visit, we recorded the reasons reported by clients for the visit. For this analysis, we selected 322 cases (161 clients aged 15-17 years and a random selection of 161 clients aged 18-24 years) for medical record extraction and qualitative review. We grouped the primary reason for the visit into two categories: self-motivation (to check or confirm HIV and STI status, to address symptoms of STI or need for treatment, to access post or pre-exposure prophylaxis [PEP/PrEP]) or peer-motivation (suggested or requested by provider, partner, friend, parents, community based-organization, or employer). We used Chi-Square test to evaluate the association between motivation for the visit and client characteristics.
Results: From January 2015-June 2016, 2528 new clients attended VCT; 166 (6.6%) were aged ≤18 years and 585 (23.1%) were aged 18-24 years. Among the 322 clients evaluated, 296 (89%) self-identified as MSM, 222 (67%) were students, and 191 (58%) had never been tested for HIV. Self-motivation was reported by 212 (64%); the primary reason was to check or confirm HIV and STI status (n=107, 33%). Among the 322 clients, 71 (21%) had HIV infection and 54 (16%) had an RPR titer ≥1:8. The motivation for the visit did not differ by age group. Self-motivation was higher among those who had a history of HIV testing (77% versus 54%, p< 0.001), those found with HIV infection (82% versus 59%, p< 0.001) and those found with RPR titer ≥1:8 (80% versus 61%, p=0.008).
Conclusions: Motivations for young Thai MSM attending a clinical setting for testing suggest high self-perceived risk for HIV and STIs. In order to reach more young clients for HIV and syphilis testing, evaluation of motivation for testing can enable outreach efforts.

MOPED1099

Strengthening the "last mile" distribution system of HIV-related commodities in two DRC provinces to improve product availability in support of the 90-90-90 goal

R. Tuala Tuala[1], S. Saleeb[2], M. Basua[3], R. Mulongo[3]
[1]Management Science for Health (MSH), Pharmaceutical and Health Technology, Kinshasa, Congo, Democratic Republic of the, [2]Management Science for Health, Pharmaceutical and Health Technology, Arlington, United States, [3]Management Sciences for Health, Pharmaceutical and Health Technology, Kinshasa, Congo, Democratic Republic of the
Presenting author email: tualadavid@gmail.com

Background: Organizing an effective supply chain in DRC, where basic infrastructure is lacking, is challenging. Regional distribution centers (CDRs) cannot deliver antiretrovirals (ARVs) and related commodities to end-user facilities/communities. CDRs deliver these products to lower health zones (HZs), which often lack the resources and logistical support to distribute ARVs to end-user facilities. This makes the "last mile" the most challenge for the supply chain in DRC. ARVs languish in HZ stores while end-user facilities/communities experience stock-outs and shortages. A lack of qualified staff to quantify orders and manage inventory and no adequate information system further aggravate the problem.
The US Agency for International Development-funded Systems for Improved Access to Pharmaceuticals and Services (SIAPS) Program implemented an intervention package in DRC's Haut-Katanga and Lualaba provinces, and this study assessed the impact of that intervention by comparing baseline and postintervention data.
Methods: A rapid situation analysis identified factors that contribute to stock-outs. Based on the findings and in collaboration with HZ management teams, the last-mile distribution strategy was modified so that ARVs are delivered directly to end-user facilities/communities. In addition, pharmaceutical management trainings were conducted for health workers involved in ARV management, and stock-management software was updated for use in CDRs to promote efficiency. The impact of this interventional package was assessed.
Results: A total of 184 health workers were trained on stock management for ARVs and other commodities. ARVs are now delivered to the end-user facilities/communities using the modified "last-mile" distribution strategy, and under and overstocking rates have improved significantly: before the intervention, only 30% of facilities had an optimum level of ARV stock compare to 80% after the intervention—an improvement of 167% from December 2015 to September 2016. This resulted in improved patient care and health outcomes.
Conclusions: The study shows how the modified "last-mile" distribution strategy, staff capacity building, and an enhanced information system have improved the availability of and access to ARVs by patients in the Haut-Katanga and Lualaba provinces.
The replication of this intervention in similar environments has the benefit of bringing about results that can positively contribute to the Joint United Nations Programme on HIV/AIDS' 90-90-90 goal.

MOPED1100

Perceptions of introducing HIVST and peer-led delivery model amongst female sex workers in rural and urban districts in Southern Malawi

W. Lora[1,2], M. Sambo[3], M. Kumwenda[2], L. Kayira[2], W. Sibande[2], M. Teagtmeyer[4], E. Corbett[2,5], N. Desmond[2,4]
[1]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom, [2]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [3]Malawi Liverpool Wellcome, Blantyre, Malawi, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom
Presenting author email: wezzielora86@gmail.com

Background: Female sex workers (FSWs) are amongst the high-risk groups for HIV in Malawi. HIV prevalence amongst FSWs is estimated at 25% which is higher than in women of the general population (12.9%). Uptake of HIV testing among FSWs remains low. HIV self-testing (HIVST) is being promoted as private and convenient in the general population but there is a gap in knowledge in relation to development of HIVST interventions that can address HIV testing needs amongst FSWs. This study aimed to explore perceived benefits and harms of introducing of HIVST, and peer-led delivery model amongst female sex workers in Malawi.
Methods: A Rapid Ethnographic Assessment (REA) was employed amongst FSWs who are based at home, street or venue, and venue owners in two rural and one urban districts in Southern Malawi for a three-month period. Participant observations were conducted in bars, rest houses and clubs where FSWs hang out or reside for a period of one month in each district. 34 FSWs and 101 venue owners were involved in-depth interviews. Data analysis was done manually using a thematic framework simultaneous with data collection.

Results: FSWs and venue owners believed HIVST could provide convenience and increase opportunity for regular testing for HIV, however, lack of immediate support after HIV positive diagnosis was identified as a potential social harm. Peer-led delivery model was perceived as an option for HIVST delivery to target the hard to reach FSWs but mistrust and storage of HIVST kits were observed as barriers to implementation of this model. FSWs and venue owners, therefore, suggested that health providers and venues owners should be incorporated in the model. FSWs also wanted the model to recognize and accommodate different types of sex work.
Conclusions: The benefits and harms of HIVST were consistent with those that have been established in the general population in Malawi. A multi-pronged approach of HIVST delivery amongst FSWs was perceived as an ideal strategy. REA was an important method of informing HIVST delivery model amongst sex workers in this setting.

MOPED1101

Building Quality Improvement (QI) capacity to achieve the 90:90:90 goals in sub-Saharan Africa: four years' experience with a multi-country QI course

M. Rabkin[1,2], G. Dougherty[1], A. George[1], L. Walker[1], M. Panya[3], I. Rondinelli[1]
[1]ICAP at Columbia University, New York, United States, [2]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States, [3]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of
Presenting author email: mr84@columbia.edu

Background: The global scale-up of HIV programs has been remarkably successful, but reaching the global 90:90:90 targets is challenging for many countries. Although the use of quality improvement (QI) methods can be an effective way to bridge the "know/do gap" between the identification of effective health interventions and their successful implementation, a needs assessment conducted in 2013 indicated that Ministry of Health (MOH) and US government (USG) staff in many PEPFAR focus countries lacked robust QI capacity. In response, ICAP at Columbia University (ICAP) and the US Centers for Disease Control and Prevention (CDC) designed an Introduction to Quality and Quality Improvement course for USG staff and their MOH counterparts.
Methods: Using the "backwards design" approach to curriculum development, we developed a three-phase course emphasizing practical skills, hands-on learning, and south-to-south exchange. Phase 1 is a five-day foundational workshop, in which country teams composed of MOH and USG staff learn key elements of the Model for Improvement and begin to design a QI project aligned with national priorities and the 90:90:90 targets. These activities continue in Phase 2, via webinars and email consultation. In Phase 3, teams present their project proposals for feedback, while continuing to learn QI methods and skills.
Results: 230 participants from 18 countries took the course from 2014-2016. Using Kirkpatrick's four-level evaluation model, we assessed participant Reaction via surveys during and after the course; each year, at least 93% of participants rated the course as very good or excellent and at least 76% agreed that they had achieved all course learning objectives. Learning was assessed via pre- and post-tests, which consistently showed improvement. Behavior and Results were assessed via surveys given to alumni at 6, 19, and 27 months following the course; although response rates have been low, respondents indicate that they have continued to use the skills they learned during the course to further QI activities within PEPFAR programs.
Conclusions: The Introduction to Quality and QI course has served as PEPFAR's flagship QI course, building QI competencies and fostering a south-to-south community of practice designed to improve the coverage, quality and impact of HIV services for sustainable epidemic control.

MOPED1102

Strategies to improve Kaposi sarcoma outcomes in Zimbabwe: a community-based clinical trial of a training intervention for improved primary care of AIDS-KS (the SIKO study)

M.Z. Borok[1], S. Mawhinney[2], E. Simoes[3], M. Matimba[4], M. Mulvahill[5], C. Moore[6], S. Fiorillo[7], F. Jaji[8], I. Gudza[1], T. Campbell[7]
[1]University of Zimbabwe College of Health Sciences, Medicine, Harare, Zimbabwe, [2]Colorado School of Public Health Denver, Biostatistics, Denver, United States, [3]University of Colorado Denver, Paediatrics, Denver, United States, [4]University of Zimbabwe, Clinical Research Centre, Harare, Zimbabwe, [5]University of Colorado School of Medicine, Paediatrics, Denver, United States, [6]University of Colorado, Biosttistics and Bioinformatics, Denver, United States, [7]University of Colorado School of Medicine, Infectious Diseases, Denver, United States, [8]University of Zimbabwe, Clinical Research Centre, Harare, United States

Background: Zimbabwe is a predominantly rural country with approximately 80% of the population accessing medical care through a tiered system of local health centres. Over the past 5 years, antiretroviral therapy has been decentralized to primary care clinics staffed by generalist doctors and nurses. Little is known about how to improve Kaposi's sarcoma (KS) treatment outcomes in these settings.
Methods: A package of interventions designed to improve KS care in primary care settings by early detection and improved clinical management was evaluated in a randomized step-wedge cluster design. The package included a standardized clinical evaluation tool, palliative care integration, standardized KS treatment, and improved consultative services for rural clinicians. The interventions were implemented at 8 primary care sites (4 rural/4 urban) in Zimbabwe. All persons with suspected KS were eligible. Training modules incorporating KS recognition, particularly early KS, diagnosis and treatment, symptom control and palliative care were delivered during the intervention period at each site by a team of trained nurses and doctors experienced in KS patient care. The primary endpoint was the proportion with early stage (T0) KS pre- and post-intervention.
Results: Between February 2013 and January 2016, 1102 subjects (96% HIV+) with suspected KS were enrolled: 47%, 20% and 33% had incident, prevalent and false KS diagnoses, respectively, with 60%, 62% and 44% male; and 34%, 27% and 25% rural. For incident KS, median age (IQR) was 37 (32, 43). Incident KS One-year mortality (95% CI) was 37% (32%, 42%), over twice the previously observed rate (16%) in the university-affiliated tertiary referral KS clinic. Adjusted odds (aOR) of early diagnosis among incident cases, within clinic, before and after the SIKO intervention, were 1.48 (0.63, 3.49; P=0.37); for false diagnosis aOR was 1.83 (1.16, 2.88; P=0.0096). Adjusted hazard ratio for time to death was 1.36 (0.85, 2.20; P=0.20).
Conclusions: The SIKO package of interventions increased false positive KS diagnosis rate with no significant change in the proportion of early KS diagnosis. KS mortality in decentralized primary care clinics in Zimbabwe was higher than expected and was not affected by the SIKO intervention.

MOPED1103

Extending perinatal care for mothers living with HIV (MLH) and their children through paraprofessional home visiting: RCT results over 5 years

M.J. Rotheram[1], M. Tomlinson[2], I. Le Roux[3], T. Weichle[1], A. Wynn[1]
[1]University of California, Psychiatry, Los Angeles, United States, [2]Stellenbosch University, Psychology, Stellenbosch, South Africa, [3]Philani Nutrition Centers, Cape Town, South Africa
Presenting author email: mrotheram@mednet.ucla.edu

Background: Uptake is high of ARV in pregnancy, but MLH do not maintain the multiple tasks required to maintain their own health and that of their children over time. Extending results from 18 months post-birth, the impact of perinatal home visiting to all community mothers and MLH was evaluated over 60 months post-birth.
Methods: In 2009-2010, a RCT was mounted in 24 neighbourhoods of Cape Town townships. Matched neighbourhoods were randomized to standard clinic care (n=596 mothers; 12 neighbourhoods) or to receiving perinatal home visiting over time (n=644 mothers, 12 neighbourhoods), with visits declining substantially at 6 months post-birth. Maternal and child outcomes, including MLH, were monitored during pregnancy, at 2 weeks post-birth, 6, 18, 36, and 60 months post birth, with follow-up rates from 83%-96%. The 354 MLH and their children (5.6% positive) were also monitored over time. Over 5 years, 9.9% of mother-child dyads had one death.
Results: All mothers, including MLH, who received home visiting, were significantly less likely to be depressed at 36 months and to use alcohol or have problematic drinking at 60 months. Children of MLH were more likely to be shorter at 36 months and underweight at 60 months than children of uninfected mothers

- however, there was no intervention difference. While less than a third of MLH had been consistently linked to care from 6 months to 36 months, 87% of MLH were linked to care by 60 months; 79% were receiving ARV and 88% were adherent to ARV - similar across conditions. Children were similar in cognitive, behavioral, and social behaviors between intervention and control. However, children of MLH and HIV uninfected mothers scored almost 3 points lower on the Kaufman assessment at 60 months.
Conclusions: Perinatal visits must be extended over time in low and middle-income countries in order to sustain substantial gains observed early. MLH do not sustain consistent HIV care over time. Yet, benefits remain both to all community mothers, MLH, and to their children.

MOPED1104

A quantitative study of workforce patterns and the PMTCT Option B cascade in Côte d'Ivoire

B. Huffstetler Rowan[1], A. Granato[1], J. Hughes[2], E. Squires[2], J. Robinson[1], S. Kouyaté[1], B. Doroux Aristide[1], V. Kourai[3], S. Gloyd[1]
[1]Health Alliance International, Seattle, United States, [2]University of Washington, Seattle, United States, [3]Health Alliance International, Abidjan, Cote D'Ivoire
Presenting author email: valerie.kourai@healthallianceinternational.org

Background: Côte d'Ivoire continues to face regionally high rates of mother-to-child transmission of HIV despite implementation of a national program to prevent transmission (PMTCT). The aim of this study was to assess the impact of workforce factors (density, distribution and training of physicians, midwives, nurses, pharmacists, community health workers and other staff) on PMTCT program success.
Methods: Primary and secondary data were collected from a nationally representative sample of 50 PMTCT sites between June 2015 and February 2016. Assessment of the association between workforce factors and PMTCT outcomes (testing, treatment and retention) were assessed using multivariate logistic regression with generalized estimating equations.
Results: Statistically significant positive associations were found between HIV testing and the following workforce densities (odds ratios presented are for a difference of 1 healthcare worker per 1000 new antenatal care patients): total healthcare worker density (OR = 1.01, 95% CI 1.01-1.01), physician density (OR = 1.03, 95% CI 1.01-1.05), density of trained staff (OR = 1.09, 95% CI 1.08-1.10) and midwife density (OR = 1.10, 95% CI 1.08-1.12). Negative associations were found between pharmacist density and testing and treatment (OR = 0.91 [0.86-0.96] and 0.83 [0.69-0.99] respectively) and between community health worker density and testing (OR = 0.96, 95% CI 0.95-0.97). No associations were found between workforce indicators and retention in care.
Conclusions: While this study showed some statistically significant associations between workforce patterns and PMTCT service delivery, the effect size of these associations was small. For an average site, the largest positive association (OR of 1.10) equates to increased testing for only 7.7 patients per year per additional midwife per 1000 patients. The study's complex results suggest that even in settings with a limited healthcare workforce, a greater density of healthcare workers does not necessarily correlate with better PMTCT outcomes. This highlights the need for additional research aimed at understanding more complex workforce factors, as well as non-workforce factors, impact PMTCT success.

MOPED1105

Lay provider HIV testing: a promising strategy to accelerate 90-90-90 in Vietnam

B. Vu Ngoc[1], K. Green[1], H. Phan Thi Thu[2], M. Tran Hung[3], S. Vo Hai[2], H. Ngo Van[1], A. Doan Hong[1], L. Dang Hong[3]
[1]PATH, Mekong Regional Program, Hanoi, Vietnam, [2]VAAC, Hanoi, Vietnam, [3]CCIHP, Hanoi, Vietnam

Background: The HIV epidemic in Vietnam is concentrated among key populations (KP), including people who inject drugs (PWID), men who have sex with men (MSM), and female sex workers (FSW). Although conventional testing services are available at all levels, annual KP uptake of HIV testing is low (~30%). In 2015 Vietnam Ministry of Health (MOH) adopted the WHO recommended lay provider HIV testing strategy to accelerate the committed UN 90-90-90 targets. USAID/PATH Healthy Markets project partnered with the MOH to pilot community-based HIV testing through KP-led community-based organizations (CBO) and village health worker networks (VHW) in four provinces (Ho Chi Minh City, Hanoi, Nghe An and Dien Bien).
Methods: Operations research was designed to evaluate the acceptability, feasibility, and effectiveness of the models for increasing HIV testing, diagnosis and treatment among KP. We observed HIV testing using rapid diagnostic test kit (Determine HIV-1/2 Antibody) performed by 153 lay providers (78 CBO and 75 VHW) through two rounds (3 clients per person each), interviewed with 918 clients before and after testing, and reviewed routine monitoring data on HIV testing from December 2015 to December 2016.
Results: Lay providers identified a higher proportion of positive cases (5% overall and 6.9% in urban areas, with false positive of 0.9%) than conventional HIV testing (0.9% according to national data). Among confirmed HIV cases, 93% were enrolled in treatment. Lay providers successfully reached and tested KP and sex partners (SP) who had never been tested for HIV before (72%), or tested infrequently (>12 months): 49%. Reasons for choosing lay providers for HIV testing included confidentiality (66%), receiving a rapid result (51%), and convenience (40%). Clients were highly satisfied with HIV testing by lay providers (91%), and would recommend this testing option to others (96%).
Conclusions: This study confirms that lay providers in Vietnam are capable of providing quality and satisfactory HIV testing services. Lay provider HIV testing is an effective approach to reach KP and their sex partners who otherwise would not test, or not as frequently. The MOH is supporting for scaling up this promising approach to reach 90-90-90 in Vietnam.

MOPED1106

Innovating to improve health worker continuous professional development (CPD): challenges in evaluating utilisation of interactive online resources in Uganda

R. Kikonyogo[1], J.W. Arinaitwe[1], L. Namara[1], U. Ssekabira[1], P. Buyego[1], S. Okware[1], R. Parkes Ratanshi[2]
[1]Infectious Diseases Institute, Training and Capacity Development, Kampala, Uganda, [2]Cambridge Institute of Public Health, University of Cambridge, Cambridge, United Kingdom
Presenting author email: rkikonyogo@idi.co.ug

Background: Capacity building of health workers (HW) in Africa has traditionally relied on face-to-face training which is labor intensive and takes HW away from their workplaces for extended periods. E-Learning however is gaining popularity as an alternative means of training HWs in resource limited-settings, since it reaches more HW, is cheaper and causes less disruption of work. The Infectious Diseases Institute (IDI) was accredited by the Ministry of health to provide CPD for HW. Since 2002, IDI offered short classroom courses to over 23,680 health workers across 39 countries. We are now innovating with cost effective models to increase our reach and impact.
Methods: IDI launched the Ugandan Academy for Health Innovation and Impact program in 2015 aimed at improving outcomes in HIV and TB care through design and implementation of innovative projects. Through this, we established an open access clinical training website for development of HW capacity. The website is based on Moodle; a free online learning management system. The website presents real life patient complex cases from the IDI HIV clinic. These are converted into interactive presentations. Consent is sought from the patients but no identifying features are used. IDI is using Google analytics to track the number of HW who have accessed the website since its launch in May 2016.
Results: 2,638 sessions were downloaded and 16,984 had viewed the e-Learning page from 10 countries. User feedback requested a mobile phone based platform as well as computer interface and also certification for CPD.
Conclusions: Lessons-learnt and way forward: Google analytics captures internet protocol (IP) addresses unique to each computer. However this doesn't capture individual users, and in some health centers, particularly rural, many HW use the same computer. We would also like to evaluate the impact of the training on practice of HW. We are establishing user accounts to track individual use to enable award of CPD points and e-certificates upon completion following a knowledge assessment. We aim to assess change in practice with questionnaires 6 months after completion of the online sessions. IDI aims to be the first training institute to provide online CPD to HW in Uganda.

MOPED1108

Development and assessment of a tablet-based clinical training approach for nurses providing Option B+ services in Mozambique

S. Gimbel[1], J.L. Manuel[2], F. Floriano[3], G. Castro[2], M. Pinho[4], J. Zucule[4], K. Sherr[5], C. Soi[5], J. Pfeiffer[5], K. Asbjornsdottir[5], C. Inguane[6]
[1]University of Washington, Family and Child Nursing/ Global Health, Seattle, United States, [2]National Institute of Health, Beira Operations Research Center, Beira, Mozambique, [3]Health Alliance International, Beira, Mozambique, [4]Ministry of Health, Sofala Provincial Health Department, Beira, Mozambique, [5]University of Washington, Global Health, Seattle, United States, [6]University of Washington, Anthropology, Seattle, United States
Presenting author email: kasbjorn@uw.edu

Background: Introduction of Option B+, which has rapidly expanded in many sub-Saharan countries with high HIV burden and limited resources, including Mozambique, requires targeted strengthening of nurse clinical competencies to ensure adequate care and management of HIV-infected pregnant women. A tablet-based training approach building core clinical competencies of nurses introducing Option B+ in pregnancy was designed and evaluated to strengthen routine supervision by nurse managers.
Methods: A standardized assessment tool measured nurse competency at baseline, endline and post 3 months across 30 health facilities (20 intervention, 10 control) to 90 nurses by six district nursing supervisors. Focus group discussions assessing acceptability were conducted at 3 clinics following implementation.
Results: From baseline to endline, nurses who received the intervention experienced a three to four-fold greater improvement in Option B+ knowledge and skills assessment scores, compared to nurses at control facilities (10.2% vs 2.9%; p<0.014). In subgroup analyses, nurse managers at intervention facilities had on average a 14.5% improvement in assessment scores, while no change was noted in nurse managers at control facilities (p<0.025). During implementation, the tablet-based training intervention was integrated into routine supervision, and was perceived by MCH nurses to be easy to use, contextually appropriate, engaging, and with level-appropriate content.
Conclusions: Results demonstrated the feasibility and acceptability of this tablet-based training approach in resource limited settings, and significant improvements in nurses' knowledge and skills to implement Option B+. The study demonstrated that instructional videos and accompanying assessments can be built into tablet-based modules, through Open Data Kit (ODK) (https://opendatakit.org/), to capture results centrally and be rapidly used to identify low-performing facilities. Ensuring maternal and child health nurses are adequately trained and supported to provide quality care is a priority to maximize the potential impact of this approach.

MOPED1109

Perceived cost advantages and disadvantages of purchasing HIV self-testing kits (HIVST) among Tanzanian men: a qualitative analysis to inform demand generation

L. Jennings[1], D.F. Conserve[2], J. Merrill[1], L. Kajula[3], J. Iwelunmor[4], S. Linnemayr[5], S. Maman[6]
[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]University of South Carolina, Arnold School of Public Health, Department of Health Promotion, Education, and Behavior, Columbia, United States, [3]Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of, [4]Uni, Department of Kinesiology and Community Health, Champaign, Tanzania, United Republic of, [5]RAND Corporation, Santa Monica, United States, [6]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, United States
Presenting author email: dxc341@gmail.com

Background: Impoverished men have lower rates of HIV testing and higher unknown HIV-positive status than women. Low socio-economic status can hinder demand generation of testing services. Yet, few studies have investigated men's financial views regarding the benefits or drawbacks of HIVST. Economic theory suggests that individuals will obtain an HIV test if anticipated benefits are greater than anticipated costs. Therefore, we examined how poor men's perceptions of the cost advantages and disadvantages of HIVST may influence demand.
Methods: Twenty-three interviews were conducted to qualitatively assess perceived costs saved and incurred from use of HIVST kits in infrequently- or never-tested Tanzanian men. All men were shown an HIVST kit and video. They were then asked about the costs associated with provider-led HIV testing, financial benefits and concerns of HIVST, and willingness to pay for HIVST. Data were coded and analyzed using inductive content analyses. We then grouped codes into perceived cost advantages and disadvantages and tabulated the range of prices men were willing to pay for a self-test kit.
Results: Perceived cost advantages of HIVST were avoidance of spending money to test in facilities, omission of follow-up fees, affordability relative to private clinics, and increased time for earning income and other activities. Men also discussed the imbalance of the financial benefit of accessing free, public HIV testing with the resources spent for transport, purchasing meals away from home, and long wait lines. Perceived cost disadvantages of HIVST were prohibitive kit costs, required prior savings to purchase kits, expenditures relating to death, and preferences for free provider-performed testing. Men were also concerned about the psychological costs of inaccurate results. HIVST demand was moderate with varied willingness to pay.
Conclusions: Men's decisions to self-test for HIV takes into account expected financial gains and losses. Demand generation for HIVST among men should consider use of low fees or free HIVST, while emphasizing potential savings from reduced travel, clinical costs, or time way from work. Efforts are also needed to address anticipated emotional costs of HIVST, such as anxiety from kit errors, purchasing "death", or testing alone, which for some men was a substantial barrier.

MOPED1110

Innovative, targeted, evidence-based demand creation approaches for voluntary medical male circumcision (VMMC): a 3-month pilot in Zambia

A. Machinda[1,2], B. Thurston[1], G. Sishekanu[2], S. Ellis[1,2], M. Sundaram[3], N. Chintu[1,2]
[1]Population Services International (PSI), Washington, United States, [2]Society for Family Health (SFH), Lusaka, Zambia, [3]Bill and Melinda Gates Foundation, Seattle, United States
Presenting author email: albertmachinda@gmail.com

Background: Although Zambia has seen an increase in VMMC since 2009, targets have not been achieved hence need for innovative demand creation methodologies including use of market research and human centred design (HCD). These methods should target the most impactful ages (15-29 years) and shorten the journey to circumcision. Utilizing findings from a 2014 journey mapping study conducted in Zambia, Society for Family Health (SFH) employed HCD strategies to analyse and translate findings into demand creation solutions. The process prioritized four of seven identified segments of men, created robust archetypes, and uncovered insights used to inform tailored messages and prototypes for new VMMC demand creation tools to be piloted for effectiveness, efficiency and usability.
Methods: A non-randomized implementation pilot was conducted in eight SFH supported public facilities in four districts. Twenty-three Community Health Workers (CHWs) (13 male, 10 female) and eight supervising CHWs were selected and trained on new messaging and tools. A similar number of CHWs continued to utilize standard demand creation methods in the same facilities.
CHWs conducted door-to-door mobilization activities using new tools and potential clients were classified into a specific segment, exposed to tailored messaging and tools, and recorded in the daily activity report (DAR). Clients interested in getting

circumcised were scheduled for an appointment and provided with a referral card. Clients who missed appointments were followed-up a maximum of three times by the CHW.

Results: Overall conversion rate (circumcisions/appointments) was 43% (1,461/3,421) during pilot compared to 35% (884/2,532) for standard methods. Conversion rate was higher amongst priority segments at 45% compared to 39% in non-priority segments. 68% of those circumcised were aged 15-29 years in both methods. On average, men took 42 days from first contact to circumcision. Younger CHWs were more effective whilst female CHWs' conversion rate was 47% compared to 38% for male CHWs.

Conclusions: The use of segmentation to provide tailored messages and tools is as effective as established demand creation methods and has potential to improve and revolutionize approaches to demand creation for VMMC. Emphasis should be placed on mapping the cascade to VMMC and shortening a man's journey to circumcision.

Optimising uptake of HIV testing among young people: a mixed-methods study on HIV self-testing preferences in Zimbabwe and Malawi

P. Indravudh[1], E. Sibanda[2], M. d'Elbee[3], M. Kumwenda[1], G. Maringwa[2], M. Simwinga[4], L. Nyirenda[5], C. Johnson[6], C. Lopez[7], K. Hatzold[8], F. Terris-Prestholt[3], M. Taegtmeyer[5], UNITAID/PSI Self-Testing Africa (STAR)
[1]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Zambart, Lusaka, Zambia, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]World Health Organization, Geneva, Switzerland, [7]Population Services International, Harare, Zimbabwe, [8]Population Services International (PSI) Zimbabwe, Harare, Zimbabwe
Presenting author email: peach.indravudh@gmail.com

Background: HIV self-testing (HIVST) is a promising method for reaching young people underserved by standard HIV testing and unaware of their status. This study uses mixed methods to examine young people's preferences for HIVST distribution and inform scale-up of youth-targeted HIVST services in southern Africa.

Methods: This study is nested within large-scale distribution of oral HIVST kits in Malawi and Zimbabwe (STAR). Twelve focus groups (n=107) and 15 interviews were undertaken with purposively sampled youth (16 to 25 years) exposed to distribution. Discrete choice experiments (DCE) on HIVST delivery were administered to randomly sampled household members. Multinomial logit models were used to identify preference strength and heterogeneity among young people in Malawi (n=245) and Zimbabwe (n=96).

Results: There was strong concordance between the two methods and countries. HIVST was highly accepted by young people, particularly young men. Self-testing was seen to address youth-specific barriers around conventional HIV testing, including stigma of testing outside of marriage. Distribution of HIVST kits at home was the biggest driver of demand and valued as time and cost-saving. Alternative locations, such as mobile clinics and health facilities, were disliked. Compared to adults 26 years and older, batch distribution to the household was less preferred by young people, who reported decreased decision-making autonomy when offered in the presence of family members. Lay distributors were valued over HTC counsellors and intimate partners as HIVST providers, with qualitative participants also liking peer distribution.

Free tests were important to young people, with small fees ($0.07-$1) acting as disincentives. First-time testers expressed a desire for support before and after testing, including by helpline or in person. The qualitative findings were mixed in terms of preferred testing methods, though DCE respondents highly valued oral fluid-based HIVST. Untested young people had similar utilities for oral and blood-based HIVST, reflecting indifference for sample collection method and overall value for self-testing.

Conclusions: HIVST appealed to young people whom might not have otherwise tested. Young people are not a homogenous group and our findings supported proactive and low-cost distribution by lay providers, with more support needed for first-time testers. Concordance of results by method will also be presented.

MOPED1112

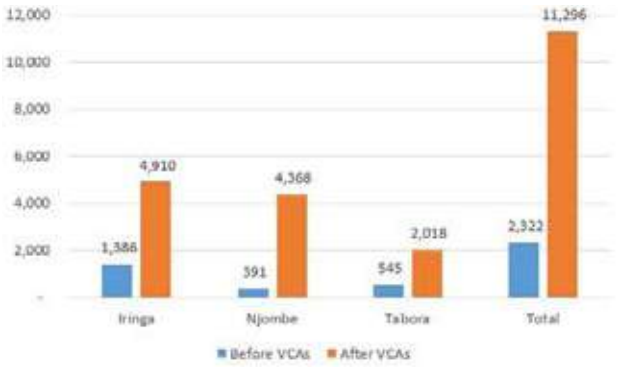
Leveraging local intelligence: use of Volunteer Community Advocates (VCAs) leads to a five-fold increase in number of VMMCs in routine services in Tanzania

M. Makokha[1], A. Christensen[1], A. Hellar[1], S. Mkungume[1], K. Curran[2], Z. Mwandi[3], E. Njeuhmeli[4], V. Kiggundu[4], E. Mlanga[5], G. Lija[6], G. Msalale[7], P. Luvanda[8], E.C. Kessy[9]
[1]Jhpiego, AIDSFree, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Washington, United States, [3]Jhpiego, AIDSFree, Nairobi, Kenya, [4]USAID, Washington, United States, [5]USAID, Dar es Salaam, Tanzania, United Republic of, [6]MoHCDGEC Tanzania, National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of, [7]MoHCDGEC Tanzania, Tabora RHMT, Tabora, Tanzania, United Republic of, [8]MoHCDGEC Tanzania, Iringa RHMT, Iringa, Tanzania, United Republic of, [9]MoHCDGEC Tanzania, Njombe RHMT, Njombe, Tanzania, United Republic of
Presenting author email: maende.makokha@jhpiego.org

Background: Tanzania has been implementing VMMC services for HIV prevention since 2009. With PEPFAR and USAID support, AIDSFree through Jhpiego has supported the Ministry of Health to implement VMMC services in 27 routine sites providing service in the Iringa, Njombe, and Tabora regions. A variety of strategies have been employed to sensitize and recruit clients. Between October 2015 and March 2016, demand creation was led by a team of non-local Community Health Promoters (CHPs). Based on formative research findings, in April 2016 CHPs were replaced by Volunteer Community Advocates (VCAs) who are early VMMC adopters and live within the catchment area of the sites offering VMMC services. VCAs receive a 2-day training on VMMC and ongoing on-the-job support.

Methods: We conducted a retrospective review of the Jhpiego VMMC database, comparing the number of VMMCs conducted during routine services before VCAs were introduced (October 2015-March 2016) and after (April-September 2016). No new routine VMMC sites were introduced during this time period. Statistical tests were used to analyze significance of the differences observed.

Results: A total of 13,618 clients were circumcised in the 27 static sites during the review period (October 2015-September 2016). Overall, there was a five-fold increase in VMMCs conducted across all static sites compared to the previous 6 months from 2,322 to 11,296 VMMCs (Fig 1). The observed increase in the number of clients seen in the routine VMMC sites before and after VCAs were introduced was statistically significant (chi-square = 404.45, p-value <0.00001).



[Fig. 1: Impact of VCAs on Number of VMMCs]

Conclusions: The introduction of VCAs led to a significant increase of clients seen in VMMC routine sites across the three supported regions within the six month period. This demonstrates the important role that volunteers from the communities they serve play in educating and advocating for services and translating this to new VMMC clients.

MOPED1113

Spending to alleviate demand constraints lowers unit costs: a cost-effectiveness analysis of voluntary medical male circumcision to prevent HIV in Tanzania

S. Torres-Rueda[1], H.A. Weiss[1], M. Wambura[2], H. Mahler[3], K. Kripke[4], J. Chilongani[2], E. Kuringe[2], R.J. Hayes[1], M. Plotkin[3], M. Makokha[3], A. Hellar[3], C. Schutte[5], G. Mshana[2], N. Larke[1], G. Lija[6], J. Changalucha[2], J.M. Grund[7], F. Terris-Prestholt[1]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [3]Jhpiego, Baltimore, United States, [4]Avenir Health, Washington, United States, [5]Strategic Development Consultants, Durban, South Africa, [6]Ministry of Health and Social Welfare, Dar es Salaam, Tanzania, United Republic of, [7]Centers for Disease Control and Prevention (CDC), Atlanta, United States
Presenting author email: fern.terris-prestholt@lshtm.ac.uk

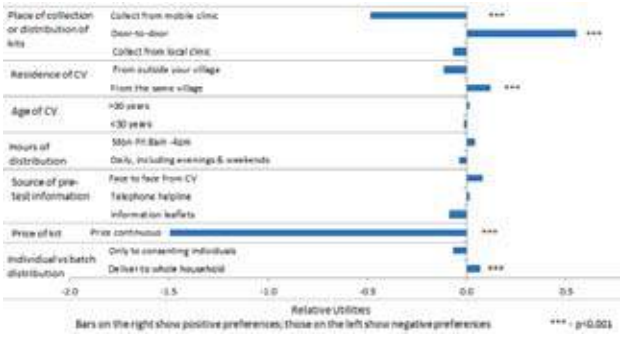
Background: Although voluntary medical male circumcision (VMMC) reduces HIV acquisition and is widely considered cost effective, demand side constraints result in sub-optimal efficiency in service provision: campaign-style VMMC programmes have site-specific fixed costs, and uptake among men with the highest HIV incidence (20-34 years), is low. A cluster randomised controlled trial was conducted to assess the effectiveness of a locally-adapted demand creation intervention in increasing uptake of campaign-delivered VMMC among men aged 20-34 in Tabora and Njombe regions. The intervention included messages targeting older men, use of peer promoters, age group-specific waiting areas, and information sessions for female partners.
Methods: Cost data were collected on surgical, demand-creation and supervisory activities across all clusters in both trial arms. The DMPPT 2.1 was used to estimate the number of HIV infections averted and related cost savings given the number of VMMCs per cluster. DALYs were calculated and used to estimate incremental cost-effectiveness ratios (ICERs).
Results: The intervention resulted in large increases in VMMC uptake. Client load varied across clusters and was higher in the intervention arms (480-1187 in Tabora; 218-500 in Njombe) than in the control arms (272-951 and 102-268, respectively). Despite the additional costs of tailored demand creation, demand increased more than proportionally: mean costs per VMMC in the intervention arms were $61 in Tabora and $130 in Njombe, and in the control arm $70 and $193, respectively. Sites with higher uptake had lower unit costs, suggesting economies of scale. More HIV infections were averted in Njombe (likely due to higher HIV incidence), in both control and intervention arms (102 and 164, respectively) than in Tabora (67 and 123, respectively). Once averted treatment costs were considered, greater cost-savings were observed in Njombe. Consequently, the intervention was more cost-effective in Njombe (-$427/DALY) than in Tabora (-$331/DALY).
Conclusions: The number of clients in Tabora was 2.5 times higher, leading to lower unit costs. The achievement of cost savings attributable to spending more to address local preferences successfully reduced demand constraints. However, in the case of Njombe, it was still worth spending more on increasing demand among hard-to-reach men due to their higher HIV acquisition risk.

MOPED1114

Preferences for models of HIV self-test kit distribution: results from a qualitative study and choice experiment in a rural Zimbabwean community

E.L. Sibanda[1], G. Maringwa[1], N. Ruhode[1], C. Madanhire[1], M. Tumushime[1], C. Watadzaushe[1], M. d'Elbée[2], P. Indravudh[3], C. Johnson[4], K. Hatzold[5], M. Taegtmeyer[6], E.L. Corbett[2,3], F.M. Cowan[1,6], F. Terris-Prestholt[2]
[1]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [4]World Health Organization, Geneva, Switzerland, [5]Population Services International, Harare, Zimbabwe, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom
Presenting author email: euphemiasibanda@yahoo.co.uk

Background: New HIV testing models are needed to reach the UN's 90-90-90 testing target. HIV self-testing (HIVST) has potential to improve testing uptake, but optimal models of distribution are uncertain. We conducted a qualitative study and discrete choice experiment (DCE) to explore preferences for models of HIVST kit distribution in rural Zimbabwe.
Methods: Following door-to-door distribution of HIVST kits by community volunteers (CV) in Mazowe district, focus group discussions (FGDs) were held to explore views on distribution models. FGDs were analysed thematically and used to identify distribution attributes that might be important for HIVST scale-up. After piloting the pictorial and paper-based questionnaire, a DCE was used to estimate relative preferences for each attribute. Analysis used multinomial logit modelling.
Results: Between Apr-May 2016, we ran 8 gender-specific FGDs (n=81, 39 female). Participants favoured household HIVST distribution by CV because it reduced travel and time costs. Distribution by nurses or community health workers was viewed less favourably because they were thought to be too busy. In contrast to other testing models, CVs from the same village were preferred, being considered more likely to relate well to locals and able to support all households. Participants valued the confidentiality that is offered by HIVST. Most emphasized kits should not be sold because people would not afford them.
296 participants were surveyed in the DCE. The figure shows presented attributes and their relative preference.



[Relative Utilities for HIVST Program Characteristics]

An optimum HIVST model is one where local CVs distribute kits door-to-door to whole households. Participants were strongly against selling of kits; even a small increase in price could offset some of the highly favoured attributes.
Conclusions: Door-to-door HIVST kit distribution is acceptable in rural communities. The mixed methods study allowed us to anticipate which service-delivery attributes were important and the reasons thereof. The relative strength of preferences can also guide planning and implementation priorities.

MOPED1115

Multi-disease community health campaigns: responding to community health priorities and reducing stigma for HIV testing in the SEARCH Study

N. Sang[1], D. Kwarisiima[2], J. Kabami[3], K. Kadede[1], M. Atukunda[4], K. Snyman[2], R. Burger[5], T. Clark[5], C. Camlin[5], E. Charlebois[5], M. Petersen[6], E. Bukusi[7], C. Cohen[5], M. Kamya[8], D. Havlir[5], G. Chamie[5], SEARCH Collaboration
[1]Kenya Medical Research Institute, Suba, Kenya, [2]Makerere University - University of California San Francisco Research Collaboration, Kampala, Uganda, [3]Makerere University - University of California San Francisco Research Collaboration, Mbarara, Uganda, [4]Makerere University - University of California San Francisco Research Collaboration, Mbale, Uganda, [5]University of California, San Francisco, San Francisco, United States, [6]University of California, Berkeley, Berkeley, United States, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Makerere University, Kampala, Uganda
Presenting author email: nortonsang@gmail.com

Background: Achieving the first 90-90-90 goal of >90% HIV-infected persons tested requires innovative approaches that address known barriers to HIV testing. The SEARCH trial (NCT:1864603) reached 97% testing coverage of stable adult residents after two years with an approach that aimed to incentivize participation by offering multi-disease services with HIV testing, and reduce stigma associated with accessing HIV testing alone, at community health campaigns (CHC). We sought to assess demand for non-HIV services and evaluative community attitudes towards this approach.
Methods: We advertised and offered multi-disease services (Table), at 2-week CHCs that provided HIV testing in Uganda and Kenya annually. We used finger-prick for testing requiring blood draws. New diagnoses made were either treated on-site (e.g. malaria), or linked to care (often same-day; e.g. TB). We shared our findings with the Ministries of Health. We measured demand via service uptake by residents at three annual CHCs. We assessed attitudes via in-depth interviews and focus-group discussions with CHC participants and community leaders.
Results: Overall, 120,312 (76%) of 159,179 stable residents attended a CHC at least once over three annual campaigns. Among adults, 84% were screened for hypertension and 79% for diabetes. In eastern Uganda, 89% of adults underwent TB screening. Fever/malaria screening was performed in 84% of adults, and 92% of children, and 22% of adults accessed urgent care services. With high CHC participation, local organizations partnered with SEARCH to provide medical male circumcision, cervical cancer screening, family planning and antenatal care, when available. Qualitative data showed CHC participants were drawn in by non-HIV services, and CHCs attracted individuals who reported prior reluctance to access HIV testing, and provided concealment for those seeking HIV testing.

Service	Method	Population accessing services	Demand: population uptake (%)	Demand: Population uptake % women vs. % men
Hypertension screening	Blood pressure once; with repeated measures x 2 if elevated	≥18 year olds	56911/68118 (84%)	88% vs. 78%
Diabetes screening	Random blood glucose	≥15 year olds	61,258/77,784 (79%)	83% vs. 74%
Malaria screening	If fever present, offer rapid diagnostic testing	All residents	≥15: 65,475/77,784 (84%) <15: 74,864/81,395 (92%)	≥15: 88% vs. 79%
TB screening	If cough >2 weeks, offer sputum fluorescence microscopy x 2	≥15 year olds; Eastern Uganda region only	22,269/25,126 (89%)	90% vs. 86%
Urgent Care	On-site clinician to address urgent complaints (e.g. skin complaints, musculoskeletal pain, etc.)	All residents	17,058/77,784 (22%)	25% vs. 18%
Men's Health Tent	Group discussion & individual counseling for men's health complaints	≥15 year old men, Eastern Uganda & Kenya regions only	7,274/21,251 (34%)	N/A

[Multi-disease services & population uptake at CHCs]

Conclusions: Demand was high for integration of multi-disease services into population-wide HIV testing, and inclusion of these services may have reduced stigma associated with HIV testing. A multi-disease approach to HIV testing is one way to achieve the 90% testing goal.

MOPED1116

Knowns and unknowns: a review and mapping of existing, ongoing and planned research on adolescent girls and young women in sub-Saharan Africa as end users of HIV prevention products

E. Donaldson, A. Gomez, E. Gardiner, I. Halldorsdottir, R. Loar,
HIV Prevention Market Manager
AVAC, New York, United States
Presenting author email: edonaldson@avac.org

Background: Adolescent girls and young women (AGYW) 15-24 account for 20 percent of all new HIV infections globally.[1] To address the disproportionate number of new infections in this population, a variety of HIV prevention products are needed and need to be introduced to the market in a manner that supports use. Studies have shown oral pre-exposure prophylaxis (PrEP) is effective in preventing HIV; however, uptake and adherence pose potential limitations to use among AGYW. The HIV Prevention Market Manager analyzed completed, ongoing and planned work on AGYW in sub-Saharan Africa as the end users of HIV prevention products to assist prevention product introduction and marketing efforts. [1] UNAIDS, 2015
Methods: Focusing on AGYW ages 15-28 in sub-Saharan Africa three types of inquiry were used: 1) systematic review of existing literature, 2) landscape mapping of ongoing and planned research from 2010 to 2016 and 3) an analysis of the review and mapping. The review utilized key terms to screen relevant articles and the Ability-Motivation-Opportunity framework, combined with marketing's four Ps—product, price, place, promotion—as the inquiry framework. The mapping, informed by structured interviews with stakeholders and surveys, tracked research by study type, location, study size and intent. The analysis looked at stages of product adoption and mapped information against each stage.
Results: The mapping identified 34 organizations working on 53 end-user projects primarily in South Africa, Kenya and Zimbabwe, with acceptability and adherence the primary study areas and oral PrEP the primary product under study. The review of almost 80 articles identified factors which may influence AGYW's acceptance, uptake and adherence to prevention products. Among other findings, literature shows cultural norms against adolescents' sexual activity limit AGYW's ability to negotiate HIV prevention. The analysis identified key gaps in research, including understanding an AGYW's journey from awareness to the decision to use, and to adhere, to a prevention product.
Conclusions: While this is a crowded space, there are significant gaps in in research towards understanding how AGYW's think, act and are influenced along the prevention journey. The review, mapping and analysis provide a solid foundation for future research, marketing or intervention design.

MOPED1117

Rapid scale-up of PMTCT program through public-private partnerships in 14 states/ UTs in India

L. Ramakrishnan[1], K.S. Sachdeva[2], J. Meloot[1], A. Hegde[2], M.K. Suryadevara[1], J. Niranjan[1], S. Yadav[1], K. Suma[1], K. Vaikundanathan[1], S. Ebenezer[1], P. Mohanty[1], S.K. Angappan[3], L. Ramakrishnan[3], S.S. Raghavan[1], Project Svetana Implementing Team Members from 14 States / Union Terirories of India
[1]*SAATHII, Svetana Program, Chennai, India,* [2]*National AIDS Control Organization, Ministry of Health and Family Welfare, Government of India, New Delhi, India,* [3]*SAATHII, Chennai, India*
Presenting author email: lakshmir@saathii.org

Background: Twenty percent of 27 million deliveries (annual) take place in the private sector, yet the coverage of PMTCT services is limited. The National AIDS Control Organization (NACO), in partnership with GFATM and SAATHII, initiated Project Svetana to increase HIV counseling and testing of pregnant women in the private sector, and to link those diagnosed positive to care and treatment services.
Methods: The project was rolled out in 231 districts from 14 states that contribute to 90% of the estimated positive pregnant women in the private sector. The project employed a public-private partnership strategy, whereby the government, private facilities, and SAATHII shared resources and responsibilities. Private facilities were engaged through implementation (PPP) or referral site (RS) models. PPP sites entered into formal agreements, provided PMTCT services and maintained and shared data, whereas referral sites referred identified positive pregnant women for care and treatment services and shared data. District-level Interventions included: (i) compilation of lists of facilities; (ii) facility assessment of infrastructure, human resources and client load; (iii) sensitization of private providers in partnership with professional medical associations (PMAs); (iv) enrollment and sensitization of consenting sites; and (v) technical assistance for establishing PMTCT services and reporting.
Results: Between October 2015 and December 2016, 23,739 facilities were mapped, 54% of these were enrolled (2791 as PPP and 9946 as referral sites) and 63% were functional. In addition, 4389 private providers were oriented on the national guidelines. The program reached 2.16 million pregnant women with testing services, accounting for 46% of estimated deliveries in the private sector. Among these 1,481 were positive, 91% (1352) received treatment, 147 opted for medical termination of pregnancy, 891 delivered and 854 were live births. 68% (554) of the 820 eligible infants underwent early infant diagnosis (six months) and 4 found to be positive (1%).
Conclusions: Strong government ownership, Public-Private Partnership models and technical assistance by interface agency enabled rapid scale-up. Diverse models of intervention facilitated engagement of over 50% of mapped facilities. Intensified involvement of PMAs and policy changes requiring mandatory reporting from the private sector are critical for elimination of pediatric HIV.

Integration of HIV Services with Other Programmes

MOPED1118

Uptake of HIV testing and counselling (HTC) among acutely malnourished children in rural and urban Blantyre, Southern Malawi: a retrospective comparative review

L.R. Kalumbi, F. Kamanga
University of Malawi - The Polytechnic, Department of Environmental Health, Blantyre, Malawi
Presenting author email: lkalumbi@poly.ac.mw

Background: Human Immunodeficiency Virus (HIV) is understood to contribute substantially to the increased burden of malnutrition-related morbidity and mortality in sub Saharan Africa. Fittingly, integration of HTC in Community Management of Acute Malnutrition (CMAM) services is envisioned to facilitate prompt identification and referral into care.
However, there is limited evidence to establish HTC uptake and location-specific variations which may exist in CMAM programmes. We aimed at assessing the uptake of HTC in CMAM programme in Blantyre and compare these findings in rural and urban settings.
Methods: We conducted a retrospective review of CMAM monthly reports for 2014 and 2015 from 6 urban and 12 rural health facilities. The population comprised acutely malnourished children aged 6 months to 12 years. A pre-tested data abstraction tool was used to extract data on location, new admissions, HTC referral, and HIV sero status. We used descriptive statistics, univariate and bivariate analysis to assess the associations between HTC referral/testing and covariables, expressed as odds ratio with 95% CI.

Results: Of the total 4527 children newly admitted/enrolled in CMAM programme, 2411 (53.5%) were referred for HTC. HIV test was done in 913 (92%) and 1346 (95%) children at urban and rural health facilities respectively. HIV prevalence was 23.7% and 17.3%, respectively, corresponding with a 49% (95%CI 21-83%) higher level in urban relative to rural Blantyre. Level of HTC referral did not differ between rural and urban facilities (OR=1.09, 95%CI 0.97-1.23). Rural facilities were 68% more likely to test referred children compared to urban facilities (OR=1.68, 95%CI 1.21-2.34).
Conclusions: While HTC referral rates were similar across settings, urban facilities were less likely to test referred children for HIV and had higher HIV prevalence, compared to rural facilities. Interventions to increase CMAM HTC uptake should contextualise location. Future research ought to target factors leading to location-specific variations in HIV testing and prevalence. Use of retrospective secondary data was a limitation in terms of level of analysis since CMAM reporting is grouped and not per child.

MOPED1119

Successful results from TB/HIV integrated pilot model leading to national TB/HIV integration initiatives in Vietnam

H. Mai[1], N. Nguyen[1], P. Phan[1], H. Pham[1], N. Nguyen[2], C. Pham[2], P. Nguyen[2], D. Bui[3], H. Nguyen[3], N. Nguyen[4], M. Pham[4], S. Nguyen[5], L. Nguyen[6]
[1]FHI 360 Vietnam, Hanoi, Vietnam, [2]Vietnam National Tuberculosis Control Program (NTP), Hanoi, Vietnam, [3]Vietnam Administration for HIV/AIDS Control (VAAC), Hanoi, Vietnam, [4]USAID Vietnam, Hanoi, Vietnam, [5]Nho Quan District Hospital, Ninh Binh, Vietnam, [6]Hung Ha District Hospital, Thai Binh, Vietnam
Presenting author email: thuhien@fhi360.org

Background: Tuberculosis (TB) is a leading cause of death among people living with HIV/AIDS (PLHIV), including in Vietnam where fragmented TB and HIV systems enable high attrition, mortality, and service inefficiencies. In July 2014, the USAID SMART TA project, implemented by FHI 360, and Vietnam Ministry of Health (MoH) began piloting an integrated TB/HIV service model in Nho Quan and Hung Ha District Hospitals in Thai Binh and Ninh Binh provinces. The pilot incorporated HIV services into two TB sites to deliver TB and HIV services by one healthcare team.
Methods: Two years (July 2014-June 2016) of service and staffing data for integrated sites were reviewed and compared to those of standalone facilities.
Results: The integrated model reduced the number of room and staff required to deliver HIV and TB services from seven staffs and five rooms to three staffs and two rooms. The sites integrated TB and HIV services into hospital examination procedures and secured health insurance reimbursements for services. The model reduced the number of visits required to diagnose TB in HIV patients from three to one, and waiting time for diagnostic results from seven to two days.
Integrated sites outperformed standalone facilities within the same provinces in proportion of (1) TB patients tested for HIV (Thai Binh: 100% vs. 95%; Ninh Binh: 100% vs. 94%); (2) new HIV patients on IPT (100% vs. 75% in Thai Binh); and (3) AFB-positive new TB patients cured (Thai Binh: 95% vs. 94%; Ninh Binh: 100% vs. 91%). ART quality was comparable across sites, with similar proportions of on-schedule patient re-examination, adherence assessment, and ART initiation.
Pilot sites delivered services to 216 HIV and 404 TB patients, of whom 12 (12 male, 0 female) were TB/HIV co-infected and treated for both TB and HIV. Eight of these completed treatment for and recovered from TB during the pilot. No new active TB cases were identified among HIV patients.
Conclusions: Although a modest sample size, the pilot yielded positive results. This prompted the MoH to expand the integrated model to 12 provinces, with plans for 18 others, to improve treatment outcomes and sustainability as external funding declines.

MOPED1120

Willingness to donate organs for transplants among persons living with HIV

A. Nguyen, S. Anjum, S. Halpern, K. Kumar, S. Rasmussen, A. Massie, A. Tobian, D. Segev, J. Sugarman, C. Durand
Johns Hopkins University School of Medicine, Baltimore, United States
Presenting author email: anguye44@jhmi.edu

Background: The HIV Organ Policy Equity (HOPE) Act was recently enacted and now permits persons living with HIV to donate organs in the US. HIV+ to HIV+ organ transplantation could shorten waitlist times among both HIV-infected and uninfected individuals. However, it is unknown whether people living with HIV (PLWH) are willing to donate organs.
Methods: We conducted a survey of willingness to donate among PLWH at an HIV clinic in an urban academic research hospital. Fisher's exact and chi-squared tests were used to compare participants who were willing vs unwilling to donate.
Results: Among 114 survey participants, median age was 55 (IQR=49-58), median duration of HIV infection was 20 years (IQR=12-25), 52.2% were men, 96.4% were African American, 99.1% had government insurance, and 54.4% were hepatitis C-coinfected. Participants reported broad willingness to donate: 79.8% as deceased donors and 62.3% as living donors. Twenty one percent were registered organ donors.
Participants unwilling to be deceased donors were more likely to report concerns about trusting the medical system (47.8% vs 7.7%, p <0.001) and whether HIV infection would affect organ function in recipients (60.9% vs 20.9%, p <0.001) (Table 1). Participants unwilling to be living donors were more likely to express concerns about going through surgery (46.5% vs 23.9%, p <0.01), worsened health post-donation (55.8% vs 21.1%, p <0.001), changes in their HIV treatment (41.9% vs 18.3%, p <0.01), and poor health due to HIV (55.8% vs 21.1%, p <0.001) (Table 2).

Concerns with (%)	Willing to donate (N=92)	Not willing to donate (N=22)	P-value
Financial burden	4.4	8.7	0.6
Trusting the medical system	7.7	47.8	<0.001
Adequate organ function despite donor's medical history	20.9	60.9	<0.001
Organs taken before death	25.3	17.4	0.6
Body disfigured before funeral	9.9	21.7	0.1

[Table 1. Concerns with being a deceased donor]

Concerns with (%)	Willing to donate (N=71)	Not willing to donate (N=43)	P-value
Undergoing surgery	23.9	46.5	0.01
Worse health post-donation	21.1	55.8	<0.001
Changing HIV treatment	18.3	41.9	<0.01
Poor health post-donation because of HIV	21.1	55.8	<0.001

[Table 2. Concerns with being a living donor]

Conclusions: A majority of PLWH surveyed expressed willingness to be deceased and/or living organ donors. This supports the feasibility of implementing HIV+ to HIV+ transplants, which can have a public health benefit. However, few PLWH were registered as organ donors indicating an opportunity for further education and outreach.

MOPED1121

Therapeutic outcomes of TB-HIV co-infected patients in the Lualaba mining province in the DRC

D. Kashosi[1], E. Mulowayi[2]
[1]Management Sciences for Health, Kinshasa, Congo, Democratic Republic of the, [2]Management Sciences for Health (MSH), Integrated Health Project Plus, Medford, Congo, Democratic Republic of the
Presenting author email: emulowayi@msh.org

Background: The Democratic Republic of Congo's (DRC) limited infrastructure and weak health system help make it among the countries most deeply affected by TB-HIV co-infection globally. While the therapeutic success rate of HIV-negative TB patients is 85% in the DRC, there is little published research documenting the therapeutic success rate for TB/HIV co-infected patients. The objective of this retrospective study is to present the therapeutic outcome of TB in TB-HIV co-infected patients in a southern DRC province characterized by high HIV prevalence (3.2%).
Methods: This study was conducted in the mining town of Kolwezi, in the Lualaba province of southern DRC, under the USAID-funded Integrated Health Project Plus (IHPplus). Co-infected patients from 23 HIV care sites were included in the study, and all health care providers were trained in the management of patients co-infected with TB-HIV. IHPplus provided TB commodities and tools for data collection and transmission.
Data were collected retrospectively from routine programmatic data, patient medical records, and HIV testing registers for the period of October 2015 to September 2016.
Results: Of 1,484 tuberculosis patients, 1,379 were counseled and tested (93%) during the study period. Of these, 324 were co-infected with TB-HIV (23.5%), and 314 of them were placed on TB treatment and ART (98.7%). 125 patients completed their TB treatment and were evaluated with the following outcomes: 60 patients were declared cured of TB (48%); 44 reported treatment completed for TB (35.2%); 11 were unevaluated at the end of their treatment (8.9%); 9 were reported to have died during treatment (7.2%); 1 was reported lost to follow-up (0.8%); and there were no cases of treatment failure. The therapeutic success rate was 104 out of 125 (83.2%), and mortality was 9 out of 125 (7.2%).

Conclusions: The study results demonstrate that trained providers, regular monthly follow-up, and a steady supply of TB and HIV commodities improve therapeutic success for TB-HIV co-infected patients in underserved settings, although TB-HIV co-infection negatively affects the outcome of TB treatment.

MOPED1122

Measuring integration of HIV and other primary care services in South African clinics: the challenges of using routine data

N. Lince-Deroche, S. Kgowedi, R. Mohamed, L. Long
Health Economics and Epidemiology Research Office, Johannesburg, South Africa
Presenting author email: nlince-deroche@heroza.org

Background: South Africa has the world's largest HIV epidemic. The South African National Department of Health favors an integrated approach for provision of primary healthcare services. HIV and other healthcare needs must be addressed holistically. However, there is limited effort to track integration in the country. Our aim was to assess whether facility-based registers used for routine data collection could be used to track integrated service provision.
Methods: We conducted a retrospective review of patient registers and electronic aggregate records at three primary healthcare clinics (PHCs) in Johannesburg. We identified all paper registers used in the PHCs. From February-August 2016, trained study staff transcribed service data representing one month (November 2015) from the registers into an Excel workbook. Then we attempted to match patients across service registers using their name, age, gender, and national identification number. Services found to have been provided to the same individual on the same day-although noted in different registers-was a priori identified as a proxy for integration.
Results: According to publicly available electronic data a total of 13,780 patients (4,602, 4,605 and 4,573 per clinic) visited the three clinics during the month of November 2015. One register, called the "Comprehensive Tick Register" (CTR), was designed to allow for documentation of multiple services per individual patient. According to the CTR, 25.5%-37.5% of all patients obtained more than one healthcare service on a given day; 1.7%-10.0% received HIV testing plus another primary care service.
The clinics also maintained several other, individual service registers. Unfortunately, it was impossible to match patients across these registers. Patient identifiers were not consistently and adequately recorded. Where patients were required to be listed in two or more registers, there were errors and missing information. Comparing electronic statistics derived from facility reports to the paper registers, including the CTR, there was over- and underreporting.
Conclusions: Data reviewed in the CTR and other registers in the study PHCs were inconsistent and incomplete. Plans for moving to an entirely electronic record keeping system may help; however, staff likely requires support and guidance regarding the importance and usefulness of high quality service data.

MOPED1123

Increasing antiretroviral therapy initiation rates among people who inject opioids in Tanzania: the integration of methadone and antiretroviral therapy (IMAT) strategy

S. Hassan[1], A. Cooke[2], D. Mushi[3], J. Mbwambo[3], B. Lambdin[1]
[1]RTI International, Behavioral and Urban Health Program, San Francisco, United States, [2]Fielding School of Public Health, University of California, Community Health Sciences, Los Angeles, United States, [3]School of Medicine Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of
Presenting author email: saria.hassan@gmail.com

Background: The prevalence of HIV among the population of people who inject opioids (PWIO) in Dar es Salaam is 42%, compared to 7% in the general population of the city. Beginning in 2011, an opioid treatment program (OTP), using methadone, was established in Tanzania to reduce the risk and transmission of HIV. Enrollment of PWIO into the OTP program surged, but linking HIV-positive, eligible OTP patients into anti-retroviral therapy faced many obstacles. To address these challenges, we engaged the community of OTP patients and providers to design an integrated methadone and anti-retroviral therapy (IMAT) program.
Methods: We conducted in-depth interviews with patients (n=20) and providers (n=12) and a cross-sectional survey (n=140) with HIV-positive OTP patients to understand perceived challenges and recommendations. Findings were presented and discussed at community engagement meetings with patients, providers and government stakeholders to further refine IMAT. In October 2015, IMAT implementation began. Using routine, programmatic data, binomial regression was used to compare the probability of ART initiation before verses after IMAT, adjusting for eligibility status.
Results: Results showed that 93% of OTP patients thought integration would improve their satisfaction with services, but 34% were concerned that ART co-dispensed with methadone would disclose their HIV status to their peers. Providers were concerned about the potential increased workload. To accommodate these concerns, the IMAT strategy allowed for a private room for consultations, 3 ART dispensing options chosen by the patient and flexible scheduling at the discretion of the HIV provider.
After IMAT implementation, all 126 HIV-positive OTP patients received HIV care. ART initiation rates increased 38% (95% CI: 2-88%; p< 0.001) from 71% pre-IMAT to 97% post IMAT, adjusting for eligibility status. ART was dispensed as follows: 4% at pharmacy window with methadone, 18% directly observed therapy in a private room and 78% monthly supply from an OTP nurse.
Conclusions: We successfully integrated HIV care and treatment into an OTP program in Dar-Es-Salaam, Tanzania with increased rates of ART initiation. IMAT's success was driven by the early consideration of perceived challenges by OTP patients and providers. Future work will address the ongoing concerns about stigma and scale-up without overburdening OTP clinics.

MOPED1124

Mistimed and unwanted pregnancy among female sex workers in India: a potential marker of reproductive and HIV risk

B. Mahapatra[1], S. Schensul[2], S. Patel[3], N. Saggurti[4], D. Ganju[1]
[1]Population Council, New Delhi, India, [2]University of Connecticut Health Center, Farmington, United States, [3]Population Council, Senior Program Officer, New Delhi, India, [4]Population Council, Country Office, New Delhi, India
Presenting author email: bbmahapatra@gmail.com

Background: While a number of studies of female sex workers (FSWs) have focused on HIV and other sexually transmitted infections, there has been less emphasis on reproductive health issues. Research from India shows a large proportion of FSWs getting pregnant with limited use of family planning methods. However, it is not known whether these births were planned on unintended and to what degree unintended pregnancies are evidence of risky sex. In this context, the current study examines the level of mistimed/unwanted pregnancy and explores the factors linked to wanted, mistimed and unwanted pregnancy among FSWs.
Methods: Data was collected using a two-stage sampling design from 4098 FSWs across five Indian states (Andhra Pradesh, Telangana, Karnataka, Maharashtra and Tamil Nadu) in 2015. FSWs were asked a series of questions related to pregnancy and their intent for last pregnancy. FSWs who indicated that they did not want their last pregnancy were classified as "unwanted"; those who wanted but not at that time were categorized as "mistimed" and rest were considered as "wanted". We fitted a multinomial logistic regression to estimate predictors of mistimed and unwanted pregnancy among FSWs.
Results: About 62% of FSWs surveyed were ever pregnant; 8% of these identified their last pregnancy as mistimed, 40% as unwanted and 52% wanted. The relative risk ratio (RR) of mistimed pregnancy as compared FSWs who wanted pregnancy was higher among those who were literate (RR:1.46, P=0.019), mobile for sex work (RR:1.81, P< 0.001), currently married (RR:2.08, P< 0.001) and those having poor negotiation skills on condom use (RR:1.97, P=0.029). Similarly, RR of unwanted pregnancy was higher among FSWs who were 30 years or older, not-formerly married, having occupation other than sex work, street based, mobile for sex work, and diagnosed as HIV positive.
Conclusions: Unwanted and mistimed pregnancy is prevalent among FSWs and can be an indicator of HIV risk, MTCT as well as the risk of bringing an unwanted child into a precarious living situation. These results indicate that reproductive health and HIV risk reduction program should not be looked in isolation; an integrated and comprehensive curriculum for FSWs is necessary to comprehensively reduce reproductive risks.

MOPED1125

Cervical cancer screening outcomes among safer conception service clients, Johannesburg, South Africa

N.E.C.G. Davies[1], N. Naidoo[1], D. Pillay[1], N. Sikhosana[1], S. Mullick[1], S. Schwartz[1,2]
[1]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States
Presenting author email: ndavies@wrhi.ac.za

Background: Cervical cancer is a leading cause of mortality amongst reproductive-aged women. Despite effective antiretroviral therapy (ART), cervical cancer incidence remains significantly higher amongst HIV-infected women. Integrating cervical cancer screening into HIV prevention and treatment programmes may address unmet prevention and diagnostic needs. We report cervical cancer screening outcomes for safer conception clients in Johannesburg, South Africa.

Methods: HIV-affected couples desiring pregnancy accessed an integrated safer conception service including HIV testing, ART and STI management, pre-conception risk reduction counselling, PrEP for HIV-uninfected partners and cervical cancer screening. Females were eligible for a Papanikolaou smear if HIV-infected and last pap was >1 year ago, had unknown results or had never been done or if HIV-uninfected, >30 years old and no pap smear in the last ten years. Clinical records and laboratory results were reviewed for smears done between June 2015-January 2017.
Results: 361 females enrolled (median age 33yrs, IQR 30-37yrs). Pap smear coverage was 82% with 221 of 271 eligible clients accessing a pap smear. Twenty-four eligible women were not offered, 18 declined the offer whilst eight conceived before a pap was performed.
Of 221 smears performed, 15% of women required colposcopy, including 22 with high grade squamous intraepithelial lesions (HGSIL), eight atypia where HGSIL could not be excluded and four persistent atypia. Follow-up for abnormalities was indicated for a further 42% of women including 19 with atypical squamous cells of unknown significance and 71 low grade squamous intraepithelial lesions; 41% (90) were reported negative for intraepithelial lesions or malignancy, 2% had inadequate samples. Shift in flora suggestive of bacterial vaginosis was reported in 79 (36%) cases and seven had trichomonas vaginalis infection. Both infections may increase HIV transmission and miscarriage risks.
Conclusions: Women accessing cervical cancer screening via a safer conception service had high rates of cervical pathology requiring further management. This highlights the importance of improved sexual and reproductive health and HIV service integration to ensure WLH, including those already on ART, are routinely offered cervical cancer screening to reduce cervical cancer incidence. Women presenting for preconception care require screening to ensure timely management of cervical pathology and infections before pregnancy is achieved.

MOPED1126

Perceptions of living organ donation among people living with HIV

S. Van Pilsum Rasmussen, S. Seaman, M. Henderson, J. Sugarman, D. Segev, C. Durand
Johns Hopkins University, Baltimore, United States
Presenting author email: christinedurand@jhmi.edu

Background: The HIV Organ Policy Equity (HOPE) Act, passed with broad HIV community support, lifted the United States prohibition on transplanting HIV+ organs into HIV+ recipients. However, using organs from HIV+ living donors remains controversial as the risks of living donation (LD) among people living with HIV (PLWH) is unknown. Although the HOPE Act requires protecting donors' rights and interests, doing so requires information about the motivations and concerns of potential HIV+ donors.
Methods: We conducted semi-structured interviews with PLWH to assess their motivations for donating and perceived risks and benefits of LD. Ten participants who reported they would "definitely" be willing to be an LD in a quantitative survey were interviewed. Interviews were recorded, transcribed, coded, and reconciled by two coders using NVivo.

Theme	Representative Quote
HIV-specific Motivations for Donation	
Solidarity with other PLWH	"Those of us who are long term survivors, like my buddy, we help each other out... I think that's a little more unique to the whole HIV thing"
Stigma of HIV	"Cause the stigma with HIV still, and a lot of people don't wanna help people with HIV so it's an important way to raise awareness about HIV and raise awareness about [people] who need an organ transplant"
HIV-specific Benefits of Living Donation	
Feeling "normal"	"Even though you sick yourself you can help somebody else, sure that's a major benefit, it'd make your feel normal"
HIV-specific Concerns about Living Donation	
Concerns about self (donor):	
Risks of compromised immune system	"Just the recovery period, our immune system is a little bit weaker, and it may take longer to recover... You know what I mean, just to have to worry about infections and stuff"
Other health problems (related to HIV)	"... they probably have other health problems to deal with"
Concerns about recipient:	
Superinfection	"I think the biggest thing for some people might be, what's the different strains... what's your strain, what's the strain of the other person that you're givin' it to"

[Table 1. HIV-specific motivations for as well as perceived benefits and risks of HIV+ Living Organ Donation]

Results: Several themes emerged, including general and HIV-specific motivations and concerns about LD (Table 1). Most participants were motivated by a desire to save someone's life. HIV-specific motivations for LD included solidarity with other PLWH and the stigma of HIV. Most participants described helping someone as a general benefit of LD; some participants identified "feeling normal" as an HIV-specific benefit. Participants identified general and HIV-specific concerns about the risks of LD both for themselves and for the recipients, including the donor's compromised immune system, the donor's HIV-related health problems, and risk of HIV donor-to-recipient super-infection.
Conclusions: Some motivations, benefits and concerns raised by PLWH interested in LD were consistent with attitudes of HIV-uninfected LD in other studies. However, unique HIV-specific motivations and benefits included demonstrating solidarity among PLWH and overcoming stigma to confer a sense of normalcy. Participants were concerned about potential risks for both donor and recipient. HIV+ LD education should address these HIV-specific issues. The actualization of these expectations should be monitored as HIV+ LD is performed.

MOPED1127

A comparative analysis between a community-based and a hospital-based model of HIV care for men who have sex with men in the city of Chicago

M.O. Brito, S. Khosla, A. Lubrano, L. Santana, J. Davila, T. Martinez, A. Eugeni, R.M. Novak
University of Illinois, Medicine, Chicago, United States
Presenting author email: mbrito@uic.edu

Background: Men who have sex with men (MSM) are disproportionately affected by HIV in Chicago. MSM who use drugs or are homeless are harder to retain in medical care. The University of Illinois Health Community Clinic Network (UCCN) operates 6 HIV storefront clinics throughout Chicago. These clinics are co-located with a University of Illinois (UIC) program that provides street outreach and harm reduction interventions to drug users.
The purpose of this study was to compare the effectiveness of this community based model to the traditional hospital based model (HBM) for providing HIV care to MSM in Chicago.
Methods: This was a retrospective cohort study of HIV infected MSM treated at storefront clinics and at the UIC hospital in Chicago, Illinois, USA, from January 1, 2010 to December 31, 2014. Data were extracted from electronic medical records. We generated descriptive statistics and calculated Chi squares and t tests to compare variables. Main outcomes of interest were: aggregate time during which the HIV viral load was undetectable and proportion of AIDS related illnesses during the study period.
Results: A total of 290 men were included in the study. Half received care at UCCN (49%). Most of the clinics were staffed by nurses. Mean age was 39 (±12) years. UCCN served a higher proportion of uninsured or publicly insured (75% vs. 54%, p< 0.01), active drug users (38% vs. 24%, p=0.01) and homeless patients (16% vs. 0%, p=< 0.01). UCCN patients missed more clinic visits (Median= 7 vs. 2.5, p=< 0.01) and were more likely to interrupt antiretroviral therapy (39% vs. 19%, p=< 0.01); however, there was no difference in the aggregate time in which the viral load was undetectable (1.3 yrs. vs. 1.3 yrs., p=0.88) or in the proportion of AIDS related illnesses (UCCN: 7% vs. HBM: 12%, p=0.15) during the study period.
Conclusions: Despite serving a more marginalized population and being staffed by mid-level providers our community clinic model is as effective as a hospital based clinic in providing care to HIV infected MSM. Sexual orientation- and drug abuse-affirming services, intensive street outreach and targeted case management likely contributed to the success of this model.

MOPED1128

Community-based integrated cervical cancer screening and HIV testing: experience from demand creation and community mobilization in rural Tanzania

D. Chalambo[1], B. Kamala[1,2], E. Musa[1], L. Semanyesa[1], D. Kisaka[1]
[1]T-MARC Tanzania, Dar es Salaam, Tanzania, United Republic of, [2]Stavanger University, Health Sciences, Stavanger, Norway
Presenting author email: dchalambo@tmarc.or.tz

Background: In Tanzania, cervical cancer is the leading cause of cancer-related deaths in women, representing 38.4% of new cancer cases. Evidence show links between cervical cancer, Human Papilloma Virus (HPV) and HIV infections. T-MARC Tanzania conducted integrated community mobilization and demand creation to increase HIV and cervical cancer testing and screening respectively. We aim to describe VIA positivity rate in relation to HIV and age.

Methods: A prospective cross section approach was used. Project activities were implemented in Iringa region through a network of trained team of 61 community volunteers and 33 village health workers. Mass screening was conducted across seven health facilities in three predominantly rural districts. Data on HIV testing, cervical cancer screening status by Visual Inspection with Acetic acid (VIA) and treatment offered were collected by trained personnel. Descriptive statistics and 95% CI were calculated.
Results: A total of 2,869 women responded to sensitization across seven facilities. All of them (100%) were screened for cervical cancer and 85% were tested for HIV. Overall HIV prevalence and VIA positivity rate were 17.27% (95%; 95% CI: 15.8%-18.8%) and 7.3% (95% CI: 6.1%-8.3%) respectively. VIA positivity rate was significantly higher among HIV positive women (11.2%; 95% CI: 9.1%-15.3%) than HIV negative (6.2%; 95% CI: 5.2%-7.3%) and unknown status (8.1%; 95% CI: 5.9-11.1%). By age groups, the VIA positivity rate was higher among 20-29 years (10.7%; 95% CI: 8.5%-15.5%) compared to the rest of the groups i.e. < 20 years at 6.4%; (95% CI: 2.5%-15.4%), 30-39 years at 8.7% (95% CI: 7.2%-10.6%), 40-49 years at 5.3% (95% CI: 3.9%-7.2%) and 50 years and above at 2.1% (95% CI: 1.2%-3.8%).
Conclusions: VIA positivity rate was higher amongst HIV positive women irrespective of age. VIA positivity rate was higher amongst 20-29 years old women irrespective of their HIV status. The integration of cervical cancer screening services within existing PMTCT, HIV care and treatment, and other reproductive health programs will ensure that those most vulnerable to the disease are accessed cost effectively with a more comprehensive continuum of health care package.

MOPED1129

Rapid scale-up of reflexed cryptococcal antigen (CrAg) screening across a CD4 laboratory network in South Africa

L.-M. Coetzee[1,2], N. Cassim[1,2], N. Govender[3,4], S. Carmona[2], D.K. Glencross[1,2]
[1]National Health Laboratory Service (NHLS), National Priority Programme, Johannesburg, South Africa, [2]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [3]National Institute of Communicable Diseases, Mycology, Johannesburg, South Africa, [4]University of the Witwatersrand (WITS), Johannesburg, South Africa
Presenting author email: naseem.cassim@nhls.ac.za

Background: Cryptococcal meningitis (CM) is a major cause of HIV-related morbidity and mortality preventable by early detection of cryptococcal antigenaemia (CrAg) using the lateral flow assay (LFA) followed by fluconazole treatment. In South Africa, a pilot study for reflexed CrAg detection against confirmed CD4 samples with a count < 100 cells/µl was initiated in 2013 to include selected clinics from eight CD4 testing laboratories. A national reflexed CrAg screening program was introduced across the remainder of the CD4 laboratory network of the National Health Laboratory Service (NHLS) from July 2016. This study reports the implementation scale up of reflexed CrAg testing and its impact on test volumes.
Methods: Retrospective data analysis was performed on CD4 and CrAg data from January to October 2016 to assess monthly CrAg test volumes, coverage and positivity rates. Data collected from January to June 2016 represents the pilot laboratories (n=8) serving pre-selected health facilities only. July to October data reflects implementation scale up across an additional 41 CD4 testing facilities to include all referring health facilities.Coverage is reported as the percentage of CrAg tests done divided by the total number of CD4 samples < 100 cells/µl. Statistical analyses were done using Excel and Stata software. Percentage CrAg positivity is also reported.
Results: Monthly CrAg volumes for the pilot period ranged from 4.5k-6.5k, representing coverage of 15.6 to 23.6% (Jan to June 2016). After implementation of national CrAg screening between July and October 2016, monthly CrAg test volumes increased from 11.5k to 29.6k respectively. This represents a 6-fold increase in CrAg test volumes by October.Coverage increased from 39.5 (July) to 98.2% in October. Positivity rates did not change significantly between pilot and implementation periods, at 5-6% of CD4< 100cells/µl.
Conclusions: This study demonstrates the rapid scale up of reflexed CrAg screening across the national CD4 laboratory network in South Africa over a four month implementation period made possible through the existing CD4 central support system. It is anticipated that reflexed CrAg screening would save lives base on published cost-effectiveness study results.

MOPED1130

Piloting the integration of routine maternal HIV screening in Malawi's immunisation programme

C. Stillson[1], J. Joseph[2], L. Berman[1], G. Nyirenda[1], C. Banda[1], M. Matchaya[3], M. Murowa[4], F. Chimbwandira[5], G.Z. Chirwa[6], R. Mwenda[7], M. Eliya[5], A. Gunda[1]
[1]Clinton Health Access Initiative, Lilongwe, Malawi, [2]Clinton Health Access Initiative, Boston, United States, [3]Blantyre District Health Office, Blantyre, Malawi, [4]Thyolo District Health Office, Thyolo, Malawi, [5]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [6]Ministry of Health, EPI, Lilongwe, Malawi, [7]Ministry of Health, Health Technical Support Services, Lilongwe, Malawi
Presenting author email: cstillson@clintonhealthaccess.org

Background: There is a high risk of HIV seroconversion during pregnancy and postpartum in the sub-Saharan African setting. While most pregnant women in Malawi are screened for HIV during antenatal care, there is no current requirement for maternal retesting postpartum. Given the risk of mother-to-child transmission via breastfeeding, it is critical to evaluate additional HIV screening points for mothers postpartum. Additionally, a persistently low uptake of follow up HIV testing for known HIV exposed infants (HEIs) throughout breastfeeding has led to delays in initiation of antiretroviral therapy. To evaluate the viability of integrating maternal postpartum and HEI HIV screening at an existing highly-utilized health service, a pilot was conducted to screen mothers and infants attending clinics for routine infant immunisations.
Methods: A cross-sectional, non-experimental implementation pilot was conducted in 15 randomly selected health centres in two districts between June and November 2016. Mothers with an unknown HIV status, a previous HIV-negative result greater than 3 months prior to their visit, or a known HEI that had missed a scheduled HIV test were eligible for enrolment. Following routine immunisation services, eligible and consenting mothers were offered on-site referral for HIV testing and counselling for themselves and/or their infants.
Results: 3675 mothers were screened during immunisation visits at 15 health centres. Of these women, 1977 were eligible and 1400 enrolled in the pilot. Most mothers reported having a previous HIV test (94%), with a median time from last test of 6 months and median time since delivery of 3.3 months. Of those enrolled, 96% received HIV testing and counselling, yielding 0.30% positive, 99% negative, and 0.37% indeterminate results. 54 eligible HEIs were identified and referred for testing, yielding 5.5% positive, 76% negative, and 18.5% unknown results.
Conclusions: While the testing yield for mothers with a previous HIV-negative or unknown status was less than expected, the high uptake of HIV testing among eligible women suggests that routine postpartum HIV screening at immunisation visits is both acceptable to mothers and feasible for health centres. Additionally, screening at this entry point for HEIs missing a testing milestone could be a viable supplement to existing PMTCT programs.

WHO clinical care recommendations to respond to children and adolescents who have been sexually abused including for preventing HIV and sexually transmitted infections (STIs)

A. Amin[1], M. Reijnders[1], C. Garcia-Moreno[1], K. Scott[2], Z. Shubber[3], N. Ford[4], P. Mayaud[5], J. McTavish[6], B. Matthews[7]
[1]WHO, Reproductive Health and Research, Geneva, Switzerland, [2]Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, United States, [3]Imperial College, London, United Kingdom, [4]WHO, HIV and AIDS, Geneva, Switzerland, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]McMaster University, Toronto, Canada, [7]Queensland University of Technology, Brisbane, Australia
Presenting author email: amina@who.int

Background: Globally, 20% of girls and 8% of boys are estimated to have experienced child sexual abuse (CSA). Such violence can lead to adverse mental health outcomes, STI and HIV acquisition, unwanted pregnancies and injuries. It is also associated with increased HIV risk-behaviours such as substance and alcohol use, engagement in sex work, and having multiple concurrent sexual partners later in life. Therefore, integrating interventions to address CSA including PEP and STI prophylaxis in primary or emergency care, sexual and reproductive health, HIV, child and adolescent health services is critical. We present evidence-based recommendations to provide clinical care to children and adolescents who have been sexually abused including for STI and HIV prevention.
Methods: The recommendations are based on the methods laid out for developing WHO guidelines and include evidence retrieval through systematic reviews and qualitative reviews, synthesis and quality appraisal for the following topics: provision of first-line support; PEP adherence support; STI prophylaxis; mental health support; and addressing police reporting obligations. Five reviews were conducted to address these topics, which were discussed by an international expert group to formulate recommendations. Other topics are addressed through existing guidelines.

Results: A review of barriers to PEP adherence highlighted common factors to be: fear of HIV, forgetfulness, traumatic associations and stigma linked with the assault and mental health problems. The review on STI treatment highlighted that few sexual assault survivors come back for treatment. Reviews of mental health interventions highlighted the need to address post-traumatic stress disorder. Qualitative studies indicated that children and adolescents want care that is non-judgmental, respects their preferences, assures them confidentiality and is timely. Requirements to report child sexual abuse to the police deterred care seeking and obtaining timely care.
Conclusions: Clinical care for sexual abuse of children and adolescents needs to be provided in a manner that supports their psychosocial wellbeing, respects their rights and addresses their physical health care needs, including for HIV, STI and pregnancy prevention. Barriers to PEP adherence and STI treatment follow up need to be addressed. Psychological interventions should ideally be part of the package of care.

MOPED1132

Successful decentralisation and integration of cervical cancer screening and treatment in rural Swaziland

L. Pasipamire[1], C. Edwards[1], B. Kerschberger[1], S. Sibanda[1], G. Sibanda[1], M. Pasipamire[2], N. Staderini[3], S. Kabore[1], B. Rusch[3], N. Lukhele[2], I. Ciglenecki[3], Z. Fakudze[1]
[1]Medecins Sans Frontieres, Mbabane, Swaziland, [2]Swaziland National AIDS Program (SNAP), Ministry of Health, Mbabane, Swaziland, [3]Medecins Sans Frontieres, Geneva, Switzerland
Presenting author email: drnomthi@gmail.com

Background: Cervical cancer is one of the leading causes of cancer deaths in women in resource limited settings. Cervical cancer screening aimed at detecting and treating precancerous lesions is now recommended by the World Health Organisation (WHO) in both HIV negative and positive women to limit the burden of invasive cervical cancer.
However, access to cervical cancer screening is limited in low to middle income countries due to programmatic constrains such as logistics and human resources for health. We aimed to introduce and decentralise cervical cancer screening in the public health sector in order to decrease morbidity and mortality from cervical cancer.
Methods: Medecins Sans Frontieres in collaboration with the Ministry of Health established a mobile screen and treat programme using visual inspection with acetic acid (VIA).Trainings were conducted for the mobile screening teams between July and August 2016. Since September 2016 the mobile teams visited 26 predominantly rural primary and secondary health care facilities to perform cervical cancer screening to sexually active women. If found positive, clients received onsite treatment for cervical pre-cancerous lesions using cryotherapy. Those with advanced or extended lesion and suspicion of invasive cervical cancer were referred to the gynaecologist at the regional hospital.
We used frequencies and proportions to describe the women who were screened and reported their outcomes.
Results: A total of 647 clients were screened using VIA method with a median age of 33 (IQR: 27- 42) and a median parity of 3 (IQR: 1-4). Of those screened 317 (49%) were HIV positive. One hundred and twenty (18.5%) had positive VIA and of these 55 (45.8%) were HIV positive. The prevalence of pre-cancerous lesions among the HIV positive was 17.4% compared to 19.7% in HIV negative women (p=0.33). Among those VIA positive, 84 (70.0%) received onsite cryotherapy and 10 (8.3%) were suspicious of invasive cervical cancer and were referred to gynaecologist for further treatment with 1 (10.0%) undergoing the loop electrosurgical excision procedure (LEEP) therapy.
Conclusions: Decentralisation of cancer screening is feasible in resource limited countries and offers the opportunity to detect and treat precancerous cervical lesions thereby reducing the burden of cervical cancer in these settings.

MOPED1133

Prevalence of diabetes and hyper- cholesterolemia among adults on ART for more than 10 years in Malawi

S.C. Mathabire[1,2], A. Tayea[2], J. Bitilinyu-Bangoh[3], E. Bermudez[2], L. Salumu[4], I. Amoros Quiles[5], E. Szumilin[4], Z. Chirwa[6], F. Rick[2], D. Maman[1]
[1]Epicentre, Clinical Research Department, Paris, France, [2]Medecins Sans Frontieres, Chiradzulu, Malawi, [3]Queen Elizabeth Central Hospital, Laboratory, Blantyre, Malawi, [4]Medecins Sans Frontieres, Paris, France, [5]Medecins Sans Frontieres, Lilongwe, Malawi, [6]Ministry of Health, HIV and AIDS Department, Lilongwe, Malawi
Presenting author email: cmathabire@yahoo.com

Background: Data on cardio-vascular disease (CVD) risk among patients receiving long term ART are critically needed in sub-Saharan Africa. We assessed prevalence of diabetes, hypercholesterolemia and evaluated Framingham Risk Score (FRS) among those on ART for more than 10 years in Chiradzulu, Malawi.
Methods: HIV positive patients receiving ART for more than 10 years (patients) and HIV-negative people living around the selected health centers (controls) were invited to participate. Following informed consent, a standardized questionnaire, clinical, and laboratory exams (HbA1c, and LDL Cholesterol) were performed and the Framingham Risk Score (FRS) calculated for each participant. Two multivariate logistic regressions were used to assess the association between high HBA1C level (≥6%) or hyperlipidemia and ART status.
Results: A total of 379 ART patients and 356 controls were included in the study. Median age was 48 years [IQR 42-57] and 73.2% (95%CI 69.9-76.3) were female. The median time on ART for patients was 11.6 years [IQR 10.6-12.4].
The prevalence of HbA1c ≥6.0% in the 30-44, 45-59, and ≥60 year's age groups was 5.0%, 6.4%, and 13.2% among patients, and 3.4%, 4.2%, and 1.7% among controls respectively. Using the multivariate model with variables; HIV status, age group, gender, education, and BMI; patients were more likely than controls to have an HbA1c ≥6.0% (aOR 1.9; 95%CI 1.1-3.2, p=0.02). Prevalence of LDL Cholesterol >130mg/dl in the 30-44, 45-59, and ≥60 year's age groups was 8.0%, 15.4% and 23.7% among patients and 1.8%, 12.5% and 11.8% among controls respectively. Using the multivariate model with same variables as above, difference of having LDL >130mg/dl between patients and controls was only marginally significant (aOR 1.6; 95%CI 0.9-2.7; p=0.1).
FRS increased with age and male gender, up to 41.2% and 53.9% of male patients and controls age≥60 years having a FRS≥20%, respectively. However, no significant differences in FRS were identified between patients and controls.
Conclusions: The prevalence of diabetes and hypercholesterolemia were significantly higher for patients on ART >10 years compared to controls. However, FRS was high for elder HIV-negative controls, suggesting that an approach focusing on decreasing CVD risk should target both HIV-positive and HIV negative at high risk.

MOPED1134

High magnitude of under nutrition among HIV-infected adults who have not started ART in Tanzania: a call to include nutrition care and treatment in the test and treat model

B. Fokas Sunguya[1], N. Ulenga[2], H. Sirili[2], E. Mtisi[3], S. Puryear[4], E. Aris[2], E. Tarimo[5], D. Urassa[1], W. Fawzi[6], F. Mugusi[7]

Presenting author email: sunguya@gmail.com

Background: Undernutrition among people living with HIV (PLHIV) can be ameliorated if nutrition specific and sensitive interventions are integrated into their HIV care and treatment centers (CTC). Integrated care is lacking despite expansion of antiretroviral therapy (ART) coverage, representing a substantial missed opportunity. This research aims to examine nutrition status and associated risk factors among HIV-positive adults prior to ART initiation in Tanzania in order to characterize existing gaps and inform early integration of nutrition care into CTC.
Methods: We analyzed data from 3,993 pre-ART adult PLHIV enrolled in CTCs within the Trial of Vitamin (TOV3) and progress of HIV study in Dar es salaam, Tanzania.. Baseline data included demographics, feeding characteristics, clinical, psychological, and biological variables. The primary outcome for this analysis was nutrition status, measured as body mass index (BMI) below 18.5 kg/m^2. We conducted descriptive analyses of baseline characteristics and utilized multiple logistic regression to determine independent factors associated with pre-ART undernutrition.

Results: Undernutrition was prevalent in about 27.7% of pre-ART adults, with a significantly higher magnitude among males compared to females (30% vs. 26.6%, p <0.025). Severe undernutrition (BMI <16.0kg/m^2) was prevalent in one in four persons, with a trend toward higher magnitudes among females (26.2% vs. 21.1% p=0.123). Undernutrition was also more prevalent among younger adults (p <0.001), those with lower wealth quintiles (p=0.003), and those with advanced HIV clinical stage (p <0.001) compared to their respective counterparts. Pre-ART adults presented with poor feeding practices, hallmarked by low dietary diversity scores and infrequent consumption of proteins, vegetables, and fruits. After adjusting for confounders and important co-variates, pre-ART undernutrition was associated with younger age, low wealth indices, advanced clinical stage, and low dietary diversity.
Conclusions: One in every four pre-ART PLHIV presented with undernutrition in Dar es salaam, Tanzania. Risk factors for undernourishment included younger age, lower household income, advanced HIV clinical stage, and lower dietary diversity score. Knowledge of the prevalence and prevailing risk factors for undernutrition among pre-ART PLHIV should guide targeted, early integration of nutrition interventions into routine HIV care and treatment in high-prevalence, low-income settings such as Tanzania.

Key lessons from a low threshold, results-oriented medically assisted programme along Kenya´s coastline

S. Abdallah[1], A. Baghazal[2], F. Ibrahim[3], M. Kirimo[4], M. Hassan[5], F. Sulliman[6], E. Mwamburi[7], M. Sirengo[8], K. Shikely[2], S. Bertrand[9], S. Patta[10], S. Swaleh[2]
[1]United Nations Office on Drugs and Crime, ROEA, Health, Nairobi, Kenya, [2]County Government of Mombasa, Dept of Health Services, Mombasa, Kenya, [3]Kilifi County, Health, Kilifi, Kenya, [4]Malindi Sub-County Hospital, MAT Clinic, Malindi, Kenya, [5]Kisauni Health Centre, MAT Clinic, Mombasa, Kenya, [6]UNODC ROEA, Health, Nairobi, Kenya, [7]USAID Kenya, Nairobi, Kenya, [8]Ministry of Health, National AIDS and STI Control Programme, Nairobi, Kenya, [9]United Nations Office on Drugs and Crime (UNODC), Regional Office East Africa, Nairobi, Kenya, [10]County Government of Mombasa, Health services, Mombasa, Kenya
Presenting author email: docbaghazal@gmail.com

Background: HIV prevalence among people who inject drugs (PWID) in Kenya is 18.3% versus 5.6% for general adult population. Since 2014 Kenya's Ministry of health and its partners has strived to scale up Medically Assisted Therapy (MAT- alias Opioid Substitution Therapy) to achieve national strategic goal of universal access to HIV prevention, treatment and care for all by 2030. UNODC with USAID/ PEPFAR, supported national and county health authorities and CSOs partners to establish 3 MAT clinics in Kilifi and Mombasa Counties.
Methods: Retrospective records review performed to assess implementation process and results of GOK-UNODC-USAID Coast MAT Programme. Findings appraised against national guidelines and best practices.
Results: Total 1,020 opioid dependent persons enrolled for MAT from February 2015, females 12.5%, median age of females 30 (IQR 26.5-34) versus males 37(IQR 32-42) years. 75% not in union, 70% primary level education, 55% unemployed, 40% lived alone. Average duration heroin use 12.2 years from median age 20 years (IQR 18 to 25). 63% ever injected heroin average 7.3 years from heroin initiation. 14% HIV infected (females 35% versus males 11%), 8% HCV infected. 50% ever incarcerated, 20% previous 30 days.
After 22 months, 85% MAT clients retained, 9% lost to follow up, 1% died (half in hospitals) from HIV/TB, meningitis, jaundice/liver failure; Dengue, Immunosuppressant Syndrome, overdose. Urine drug toxicology confirms decline in heroin use (12%) compared to cannabis (>40%) at 12 months. 5 MAT clients successfully weaned off due to economic migration, feel recovered, treatment fatigue. Another 8% voluntarily tapering down, primarily males without co-morbidities. Improved behavior of MAT Clients and decline in community criminality increasing community demand.
Conclusions: Within 2 years Kenya's MAT program revealed notable impact at individual, family and community levels. MAT providers acquiring expertise with individualized results-oriented treatment approach, with optimal dosage, concurrent management of co-morbidities, and structured psychosocial support. Decentralization and integration of MAT services within primary health care vital for scale up. However, MAT coverage remains low - 10% PWID reached due to: scarcity of MAT sites, health worker shortages, distance/transport costs, misconceptions, limited family support and livelihood assistance.

MOPED1136

High prevalence of postpartum suicidal ideation among women living with HIV in rural Zimbabwe

E.S. Comrie-Thomson[1,2,3], Z. Kapamurandu[4], P. Wata[4], B. Madzima[5], J. Davis[1,2], M.-A. Nicholas[1], D. Patel[4], S. Luchters[1,2,6], K. Webb[4]
[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [3]Ghent University, Department of Obstetrics and Gynecology, Ghent, Belgium, [4]Organisation for Public Health Interventions and Development, Harare, Zimbabwe, [5]Ministry of Health and Child Care, Family Health, Harare, Zimbabwe, [6]International Centre for Reproductive Health (ICRH), Ghent University, Department of Obstetrics and Gynecology, Ghent, Zimbabwe
Presenting author email: liz.comriethomson@burnet.edu.au

Background: Available research indicates postpartum depression is widespread in low- and middle-income countries (LMICs), and suicide accounts for approximately 20% of postpartum deaths worldwide. Psychosocial stressors of initial HIV+ diagnosis and living with HIV, together with shared social determinants of HIV+ status and depression, indicate postpartum mental morbidity is likely an important health concern for women living with HIV. Mental morbidities can constrain capacity to adhere to HIV treatment, yet mental health is rarely addressed in routine service delivery in LMICs. Prevalence data from rural Zimbabwe is used to assess the importance of this gap in service delivery.
Methods: A cross-sectional baseline survey was conducted June-August 2016 for a community-based health program in rural Mutasa District, Zimbabwe. Trained non-clinical female enumerators administered the survey in eight health facility catchment areas with women who had given birth in the previous six months. The questionnaire included a Shona-language version of the Edinburgh Postnatal Depression Scale (EPDS), previously validated in Zimbabwe. Survey data was analysed with Stata 13.0, adjusted for clustering effects.
Results: A sample of 452 women was achieved, 12.4% of whom identified as HIV+. Mean age was 25.5 years, mean number of children 2.4, and mean age at first marriage 19.1 years. Using the validated EPDS cutoff of 11, symptoms of clinically significant depression and anxiety were common across all women, with no significant difference between HIV+ and HIV- women. Suicidal ideation as captured by EPDS was high in the total sample, but significantly more common among women living with HIV.

Scale	Prevalence, 95% CI(%) N=452	Prevalence among HIV+ women, 95% CI (%) N=56	OR HIV+ vs HIV-, 95% CI
EPDS ≥ 11	31.86, 28.08-35.90	35.71, 27.05-45.43	1.24, 0.74-2.08
Suicidal ideation	18.58, 14.42-23.62	32.14, 23.67-41.97	2.37, 1.25-4.48

[Mental health outcomes]

Conclusions: These findings affirm growing evidence of the high burden of postpartum mental morbidity in LMICs, and indicate substantially increased suicidal ideation among postpartum women living with HIV. Low-cost community and clinic-based interventions for women with postpartum mental morbidity have been proved effective and feasible. For the safety and care of HIV+ women and their newborns, including improved adherence to HIV treatment, the integration of mental health screening and referral with maternal-child health and HIV services across the continuum of care is a priority, particularly in high prevalence settings.

MOPED1137

Managing HIV TB co-infection at HIV treatment centers: six months experience

R. S. Gupta[1], N. Kadyan[1], V. Purohit[2], M. Bamrotiya[1], A. Sinha[1]
[1]National AIDS Control Organisation, Ministry of Health & Family Welfare, Delhi, India, [2]World Health Organisation, New Delhi, India
Presenting author email: nishakadyan@gmail.com

Background: HIV-TB Co-infection ranks high among the major public health challenges. Addressing dual burden has been a key priority for the National AIDS Control Organisation (NACO) and Central TB division (CTD). The joint aim of NACO and CTD is to reduce the HIV-TB burden as well as to reduce the morbidity and mortality associated with the dual infection. All PLHIV under care are routinely screened for TB at each visit as part of program guidelines.
Methods: Program records and reports between April-Nov 2016 were reviewed on the reported HIV TB co-infection. Data reported in monthly report as well as specifically collected from all states was compiled and analysed for the same period. Analysis of referrals from HIV to TB program as well as initiation on ART was undertaken for the year 2016-17(April 2016-November 2016).
Results: 12,28,295 PLHIV were in active care and were getting HIV care services at 528 Centers across India and were screened for TB. 54,489 (4% of visits to ARTCs) PLHIVs were TB suspects and were referred for confirmation of diagnosis.

22,261 PLHIV were found to be confirmed HIV-TB positive. Amongst these, 34% were sputum positive, 34% sputum negative and 32% had extra pulmonary TB. Of the PLHIVs diagnosed with HIV-TB co infections 9819(44%) were already taking ART. Of the remaining 12471(56%) in Pre-ART Care, 8144(65%) were initiated on ART within one month of diagnosis and further 3457(28%) between one to two months of diagnosis while 1295(10%) did not start ART. Overall, 19187(91%) of the PLHIV with co-infection were started on ATT and 20607(93%) were initiated on CPT.
Conclusions: HIV-TB programmatic coordination at ART centers has yielded very good results with improved and timely initiation of treatment for both diseases and prophylaxis with co-trimoxazole. However, further efforts are needed to cover the last leg of co-infected individuals. Same cohort should be followed for treatment outcomes.

MOPED1138

Integration of WASH service into HIV/AIDS care and treatment package for PLWHA: an effective way to improve HIV treatment outcomes

G. Kinaalwa[1], R. Anguzu[2], J. Arinaitwe[3]
[1]Mityana Uganda Charity, Operations/Administration, Kampala, Uganda, [2]Mityana Uganda Charity, WASH and Health, Kampala, Uganda, [3]Mityana Uganda Charity, Monitoring and Evaluation Department, Kampala, Uganda
Presenting author email: kinaalwajeff@gmail.com

Background: Globally, efforts to scale-up HIV care and treatment services doubled. However, access to improved water and sanitation is still suboptimal. Many life threatening opportunistic infections are caused by inadequate access to safe drinking water, sanitation and hygiene (WASH). This paper presents strategies and key lessons from an integrated WASH and HIV/ADS service package to improve ART response in resource limited settings.
Methods: Mityana Uganda Charity (MUC) started implementing WASH project in 2015 to improve access to reliable sources of clean water and adequate sanitation facilities in Mityana district. Priority was given to areas or households infected and affected by HIV. Individuals trained and given information on HIV prevention and treatment, safer behavioral practices, water purification and simple technology water filtering systems. Water springs were protected and boreholes drilled in the project area. Model homes which comprised of HIV positive children were established which also acted as community reference points and water management committees were established and trained for project sustainability and each committee had representation of PHA
Results:
· A total of 538 Households with 4,476 individuals benefited from the project to access clean and safe water, of which 32% were HIV infected persons.
· 20 Water management committees with 190 members (70% women) were established and trained on safe water management of water purification systems
· 10 model homes with specific focus to families with children living with HIV were established with adherence levels monitored to have increased to 90% from 60% at project inception.
· 20 water sites (10 springs, 10 boreholes) were developed and protected to provide safe water the community
· Increasing access to safe water can result into improved nutritional status infected and affected people and reduce susceptibility to HIV.
· Development partners can contribute to a comprehensive response to HIV prevention and care through by increasing access to safe water and adequate sanitation facilities as a human right. A community participatory approach is important for ownership and sustainability.
Conclusions: HIV and poverty eradication programs need to design integrated interventions that account for social-economic and equity aspects to achieve better HIV treatment outcomes in resource limited settings.

MOPED1139

Integrating pediatric HIV diagnosis with relevant health programs for optimal pediatric HIV uptake

D. Midiani[1], E. Saka[2], R. Bhairavabhotla[3], J. Sherman[4], I.L. Zungu[5]
[1]Malawi Ministry of Health, HIV Department, Lilongwe, Malawi, [2]UNICEF, HIV and AIDS Department, Lilongwe, Malawi, [3]UNICEF, New York, United States, [4]UNICEF, HIV & AIDS Department, Lilongwe, Malawi, [5]Ministry of Health, Diagnostics Department, Lilongwe, Malawi
Presenting author email: dalomidiani@gmail.com

Background: In Malawi, in 2015 an estimated 150,000 new pediatric infections occurred and 110,000 children living with HIV aged 0-14 years died from HIV-related causes. In 2016, 65% of children were on ART as compared to 68% of the adult population. Identifying optimal HIV integration points with other child health service points may demonstrate the benefits of targeted case finding.
Methods: An analysis of HIV data from studies and program was conducted. The analysis included 2016 HIV Early Infant Diagnosis (EID) data generated using Point of Care (POC) devices placed in pediatric wards (Inpatient and outpatient) and ART/PMTCT/Mother Infant Pair (MIP) clinics in 8 health facilities over the period of 8 months, an analysis of 2016 Nutrition Rehabilitation Unit (NRU) data, and an analysis of the 2015 national laboratory management system (LMIS) data for HIV EID. Chi square and Fisher's exact tests were used to determine if there were significant differences in HIV positivity at various service points of health centers.
Results: 76% of 6,570 children admitted in NRU were tested for HIV and 14% of total tested were found to be infected with HIV. When, 857 HIV exposed children, aged 6 weeks to 11.9 months, were tested using EID POC devices at various service delivery points, HIV positivity rates were 46% for the inpatient pediatric ward and 2% for ART/PMTCT clinics. Analysis of the LMIS data for HIV EID revealed that 45% of children tested in the pediatric ward were infected with HIV compared to 30% of children tested through NRUs and 4% in ART/PMTCT/MIP clinics. A Chi-square test of significance showed that HIV positivity varies between entry points at 5% level of significance.
Conclusions: Integrating HIV testing at Pediatric wards and NRU yielded the highest HIV positivity in children as compared to HIV testing at ART, PMTCT or MIP service delivery points. Integrating HIV EID and rapid HIV testing in these settings is strategic and optimum for identifying HIV-infected children and initiating life-saving treatment at the earliest.

MOPED1140

Expanding access to early infant diagnosis through integration of services at immunization service points in Rwenzori region, Uganda

H. Bitimwine[1], F. Musiime[2], A.S. Lutaaya[2], P. Nahirya-Ntege[2], P. Ajuna[2], A. Kekitiinwa[2]
[1]Baylor College of Medicine Children's Foundation, Medical & Psychosocial, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda
Presenting author email: bitimwine@gmail.com

Background: Coverage for early infant diagnosis (EID) remains low in Uganda with many HIV exposed infants receiving their first DNA PCR test beyond the second month of life. The EID coverage at 2 months i.e. percentage of the expected HIV exposed infants accessing a first DNA PCR test at 2 months is low(35%) and yet the immunization coverage for DPT_1 is high (99%). Infants receive DPT_1 vaccine at six weeks of age, coinciding with the time for the first DNA PCR test.
Therefore, the high DPT_1 coverage presents an opportunity to improve EID coverage at 2 months.
Against this background, Baylor-Uganda implemented interventions to integrate EID into existing immunization services in four districts of Rwenzori region in an effort to improve EID coverage at 2 months.
Methods: The following interventions were implemented:
1) Training of immunization workers and HIV testing services(HTS) providers at immunization service points on pro-active identification of HIV exposed infants (started July 2016)
2) Rolling out of the ,appointment' stickers (started October 2016). The stickers were placed on the child health cards at immunization service points to alert health workers of infants' HIV exposure status.
They also prompted health workers to determine HIV exposure status of the infants in the event that it had not been determined earlier. We abstracted consolidated data from the District Health Information system and summarized the EID coverage at 2 months in proportions for the period before and through the intervention.
Results: EID coverage at 2 months has steadily increased from the time of the interventions from 33% to 48% (see figure 1).

[Figure 1]

Conclusions: Training of immunization workers and HTS providers at immunization service points and use of stickers enhanced EID coverage by 2 months in Rwenzori region. These interventions are recommended in low EID coverage areas with good DPT1 coverage.

MOPED1141

Cost of integrating non-communicable disease (NCD) care into Ugandan HIV/medical clinics in the SEARCH study

S.B. Shade[1], T. Osmand[1], A. Luo[2], S. Maddali[3], B. Mwebaza[4], R. Mwesigye[4], E. Kwisera[4], H. Imukeka[4], D. Kwarisiima[4], F. Mwanga[4], J. Ayieko[5], A. Owaraganise[4], E.A. Bukusi[5], C.R. Cohen[6], E.D. Charlebois[1], T.D. Clark[3], M.L. Petersen[7], M.R. Kamya[8], D.V. Havlir[3], V. Jain[3]
[1]*University of California, San Francisco, Division of Prevention Science, Department of Medicine, San Francisco, United States,* [2]*University of California, San Francisco, Department of Epidemiology & Biostatistics, San Francisco, United States,* [3]*University of California, San Francisco, Division of HIV, Infectious Disease & Global Medicine, San Francisco, United States,* [4]*Infectious Disease Research Collaboration, Mbarare, Uganda,* [5]*Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya,* [6]*University of California, San Francisco, Department of Obstetrics, Gynecology and Reproductive Services, San Francisco, United States,* [7]*University of California, Berkeley, School of Public Health, Berkeley, United States,* [8]*Makere University College of Health Sciences, School of Medicine, Kampala, Uganda*
Presenting author email: starley.shade@ucsf.edu

Background: Changes in body weight, nutrition, exercise, smoking and aging in Sub-Saharan Africa have led to rising rates of non-communicable diseases (NCDs), including diabetes (DM) and hypertension (HTN). The SEARCH Study (NCT:01864603)—an HIV test-and-treat community-randomized trial—includes community censuses, community health campaigns (CHCs), and immediate linkage to care. NCD screening (for DM/HTN) was included in CHCs to reduce stigma associated with HIV testing, and to improve NCD outcomes. We previously estimated costs of HIV care in SEARCH communities at $275/patient/year. Here, we sought to estimate the incremental cost of adding NCD care for both HIV-positive and HIV-negative community members.
Methods: DM/HTN care was integrated into 10 Ugandan medical clinics serving SEARCH intervention communities from 08/2015-05/2016. Clinics provided NCD care for HIV-positive patients during HIV-related visits and for HIV-negative patients on one focus day/week. Quarterly visits included blood glucose/BP management and medication dispensation. We estimated the incremental cost/year/patient with DM/HTN. We calculated costs using standard micro-costing techniques, time-and-motion studies, interviews with management staff, and review of administrative/clinical records. Cost categories included staff salaries, fixed costs (e.g., facilities and equipment), recurring goods (e.g., medications) and services (e.g., laboratory tests).
Results: Overall, 107 HIV-positive patients and 2324 HIV-negative patients received NCD care an average of 3.4 and 2.9 times, respectively, during the first year of implementation. Average incremental cost of NCD care was $11.34 per HIV-positive patient/year (a 4% marginal increase over HIV care), and $14.74 per HIV-negative patient/year (5% of the cost of HIV care). Key incremental costs for HIV-positive patients included medications ($9.66/patient/year; 85%) and laboratory testing ($1.68/patient/year; 15%). Key costs for HIV-negative patients included medications ($8.24/patient/year; 56%) and clinic staff salaries ($3.09/patient/year; 21%), while minor costs included laboratory testing ($1.43/patient/year; 10%), fixed ($1.55/patient/year; 11%) and other recurring costs ($0.43/patient/year; 3%).
Conclusions: For only 4-5% in additional costs, NCD care was added to HIV care, and also expanded to all HIV-negative patients in prototypic Sub-Saharan African clinics, demonstrating substantial cost synergy. These results should encourage accelerated scale-up of NCD care in existing clinics to inexpensively improve management of DM/HTN, reduce stigma from HIV testing and care, and improve community health.

An example of integration with health system in India: screening for HIV at primary health centre

S. Swarankar[1], A. Hegde[2], P. Sujith[1], T. Mulik[1], M. Ansari[1], R. Sindhu[1], K. Sachdeva[1]
[1]*National AIDS Control Organisation, Basic Services, Delhi, India,* [2]*National AIDS Control Organisation, Basic Services, Thane, India*
Presenting author email: drashahegde@gmail.com

Background: In India, the adult HIV prevalence is 0.27 and estimated number of people living with HIV (PLHIV) is around 2.1 Million. For early detection of HIV positive individuals, it is essential to s prioritize the population who need to be screened viz. High Risk Group, Pregnant Women, patients with TB, STI/RTI infection etc. To screen the majority of these population for HIV, the Facility Integrated Counselling & Testing Centres (FICTC) have been established in Government as well as Private Health Institutions. In facility Integrated Counselling centers, the existing health staff identified is trained to conduct HIV counselling and HIV screening through point of care testing kit. Individuals who found reactive to HIV through Point of care Test Kits are linked to Stand Alone ICTC for confirmation of HIV with three test strategy.
Methods: In year 2015, a total of 13,698 FICTCs have been established, which increased to 16,458 in year 2016. Out of these, 13,092 (80%) are located at Government health facilities at Primary Health Centers & Community Health Centers and 3,366 (20%) in private institutions. In year 2015, 2.17 & 3.98 Million Individuals & pregnant women respectively have been tested at FICTC, which is 14 & 34% of total tested. This increased to 2.54 individuals & & 5.65 million pregnant women in the year 2016, which is 14.3 & 39% of total tested. The Individuals who found reactive to HIV are linked to SA ICTC with triplicate referral form.
Results: In year 2016, there is 20% increase in establishment of FICTC, which in turn increase in the HIV screening at FICTC, which is 17 & 42 % higher in general individuals & pregnant women respectively as compare to year 2015.
Conclusions: To screen the priority population for HIV in concentrated epidemic, it is essential to establish FICTC as screening centre at all Public Health service delivery points in the country. It will contribute towards achieving the target of elimination of Mother to Child Transmission of HIV and 90% (PLHIV who know their HIV status) of 90:90:90.

MOPED1143

Can STI screening be suitably integrated into community-based HIV testing services for men in Cape Town, South Africa?

M. van Niekerk, H. Draper, S.-A. Meehan
Stellenbosch University, Desmond Tutu TB Centre, Pediatrics, Faculty of Medicine & Health Sciences, Cape Town, South Africa
Presenting author email: mbunting@sun.ac.za

Background: In sub-Saharan Africa, a 59% increase in new cases of curable STIs has been reported. Having an STI increases the chances of acquiring HIV infection. Men do not typically get screened for STIs because they do not access health services.
Community-based HIV testing (CBHTS) services for HIV and other integrated services (STI; Condom promotion) offer early case detection and linkage to care for populations who do not typically access health services.
This study describes the proportion of clients (HIV infected & uninfected) with STI symptoms dis-aggregated by males and females.
Methods: Five CBHTS centres were established in HIV prevalent communities around Cape Town. Clients self-referred for HTS at either fixed sites/on a mobile basis; services were provided from a mobile van and tents set up at main thoroughfares in the community. HIV rapid testing was conducted according to national guidelines. All clients were screened for STI symptoms, presentation of 1 or more symptoms would result in referral to a STI health facility. Data was collected between August 2013-August 2016 and entered into a Microsoft Access database & validated.
Results: Overall, 68 877 clients tested for HIV, 34 688(50.3%) were male.2 662 (4%) were HIV+. Median CD4 POC test result was lower for males versus females (268-499vs 301-634). 6% of HIV+ females reported STI symptoms, 4% of HIV+ male clients reported STI symptoms. A higher proportion of HIV negative men reported STI symptoms compared to HIV negative females (91%vs84%). HIV negative clients were more likely to link to a health facility for STI services compared to HIV+ clients (50%;47%vs 19%;10%).HIV+ men were more likely to link to a health facility for STI services compared to females (p< 0.001; 19%vs10%).
Conclusions: An integrated HIV and STI service within the community can identify men with STI symptoms and refer them to diagnostic services. Screening HIV negative male clients for STIs can identify those clients who still practice high-risk sexual behaviour. This data identifies the urgent need for the re-prioritisation of condom promotion and programs.

MOPED1144

"We need incentives!" Health care professionals' reluctance to propose systematically HIV testing during general consultation in Cote d'Ivoire

S. Carillon[1], A. Bekelynck[2], N. Assoumou[3], A. Kouadio[3], H. Ouantchi[3], C. Danel[4], J. Larmarange[1], DOD-CI ANRS 12323
[1]Ceped UMR 196 (Paris Descartes IRD), SageSud ERL Inserm 1244, IRD, Paris, France, [2]Pro, Abidjan, Cote D'Ivoire, [3]Institut d'Ethno-Sociologie (IES), Abidjan, Cote D'Ivoire, [4]INSERM 1219, Bordeaux, France
Presenting author email: severine.carillon@ceped.org

Background: To increase access to HIV testing, WHO recommended in 2007 provider-initiated HIV testing using a simplified but still exceptional approach in terms of pre-test counseling and consent. Cote d'Ivoire implemented in 2009 systematic HIV testing proposal in all medical consultations, irrespective of reasons. What are health care professionals (HCPs) perceptions and experiences related to testing proposal?
Methods: An ethnographic multi-site study was conducted in 3 general medical services (urban, semi-urban, rural) in 2 Ivorian health districts: 37 in-depth interviews with HCPs and 200 observed medical consultations (general medicine). A thematic analysis was performed on HCPs' practices and discourses.
Results: The proportion of patients offered an HIV test was low (around 20%), due to HCPs' reluctance to propose an HIV test in the absence of clinical suspicion. When offered, HIV test was more often prescribed than proposed. The analysis revealed 4 types of explanations in HCPs discourses.
(1) Due to stigma associated to HIV, HCPs feared a negative reaction from their patients: refusal, offence, distrust, loss of patients.
(2) Time-consuming specificity of HIV testing in terms of counseling, consent and administrative procedure (separate record and dedicated prescription) is perceived by HCPs as not useful and inducing a work overload that should be financially compensated or realized by dedicated providers, as it was before 2009.
(3) In the absence of clinical suspicion, they considered that proposing an HIV test during a general consultation is not medically justified and not their priority.
(4) Finally, HCPs felt that they are not sufficiently trained.
Conclusions: HCPs experiences and perceptions are negatively affected by the legacy of the successive HIV policies implemented since the beginning of the epidemy. Some complex procedures, historically implemented due to confidentiality and stigma issues, could maybe be simplified today. Integrating HIV testing in routine is a challenge considering that these activities were previously implemented with dedicated incentives, training and human resources. In a context of limited resources and mixed epidemic, how to prioritize and reorganize HIV testing in general consultations while motivating HCPs and being efficient in terms of public health?

MOPED1145

Low immunization coverage of the expanded immunization program in HIV-infected children initiated on ART and its determinants in Abidjan and Ouagadougou, Project MONOD ANRS 12206, 2011-2013

S. Atsé[1], D. Dahourou[2,3], C. Amani-Bosse[4], C. Diméglio[1], M. Amorissani-Folquet[5], C. Yonaba[6], K. Malateste[7], D. Yé[8], M. Timité-Konan[9], S. Desmonde[1], I. Ahoba[10], V. Leroy[1], MONOD ANRS 12206 Study Group
[1]INSERM U 1027, University Toulouse 3, Toulouse, France, [2]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [3]INSERM U 1219, Bordeaux, France, [4]Programme PACCi, Abidjan, Cote D'Ivoire, [5]Service de Pédiatrie, CHU de Cocody, Abidjan, Cote D'Ivoire, [6]Service de Pédiatrie, CHU Yalgado Ouédraogo, Ouagadougou, Burkina Faso, [7]INSERM U 1219, Bordeaux University, Bordeaux, France, [8]CHU Charles de Gaulle, Ouagadougou, Burkina Faso, [9]CHU de Cocody, Abidjan, Cote D'Ivoire, [10]Programme National de Lutte contre le SIDA, Abidjan, Cote D'Ivoire
Presenting author email: valeriane.leroy@isped.u-bordeaux2.fr

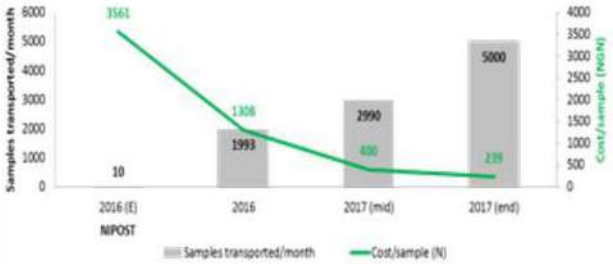
Background: Thank to the access to antiretroviral treatment (ART), HIV-infected children survive, but their vulnerability to residual infectious diseases remains, justifying the National Expanded Program on Immunization (EPI) recommendations in this population. We assessed the vaccine coverage and its associated factors in HIV-infected children included in a research project in Abidjan, Côte d'Ivoire and Ouagadougou, Burkina Faso.
Methods: All confirmed HIV-infected children, less than two years of age, and whose parents have given their written consent were included from 2011 to 2013 in the ANRS 12206 MONOD therapeutic cohort to receive a lopinavir-based ART for 12 months. At inclusion, all EPI immunizations planned at birth for BCG, at 6, 10, and 14 weeks for diphtheria-tetanus-pertussis -polio-Hib-HBV, and at 9 months for yellow fever measles, and its relative dates were recorded. Those, with incomplete vaccine program had catching-up doses. At baseline, the EPI immunization coverage was measured, and its associated factors studied using a logistic regression.
Results: Between 05/2011 and 01/2013, 161 children were initiated on ART at median age of 13.7 months. At inclusion, vaccination coverages were: BCG: 85% (95% Confidence Interval [CI]: 78% -90%); Oral polio vaccine coverage was 52% (CI: 41% -61%) in Abidjan and 81% (CI: 69% -90%) in Ouagadougou; 3-dose diphtheria-tetanus-pertussis-polio: 70% (95%CI: 63% -77%), 3-dose Hepatitis B: 58% (95%CI: 50% -66%); 3-dose Haemophilus influenzae b: 56% (95CI: 48% -64%); yellow fever: 62% (95%CI: 52% -71%) and measles: 61% (95%CI: 51% -70%). Mother in charge of the child, living in a single dwelling rather than a common living-place, living in Abidjan rather than Ouagadougou and child´s mother having no mobile phone, were variables independently associated with the absence of immunization.
Conclusions: This study showed insufficient immunization coverage among HIV infected children compared to the national recommendations. Strengthening both the EPI coverage and early initiation of antiretroviral therapy among HIV-infected children remains a priority to improve their survival in West-Africa.

MOPED1146

Increasing efficiency in sample logistics: integrated sample transportation and results delivery of HIV and TB samples in the Federal Capital Territory (FCT), Nigeria

J. Kama[1], J. Odogwu[1], O. Ofili[1], A. Akinrin[1], B. Onemola[1], A. Osbourne[2], B. Urik[2], S. Denamps[2], N. Bansal[1], J. Jiboye[1], F. Lufadeju[1], O. Wiwa[1]
[1]Clinton Health Access Initiative, Abuja, Nigeria, [2]Clinton Health Access Initiative, Boston, United States
Presenting author email: jjiboye@clintonhealthaccess.org

Background: Transportation of HIV and TB diagnostic samples to testing facilities is a major challenge across Nigeria and has proven to be uncoordinated, inefficient, and costly, leading to long turn-around-times (TAT) for results delivery and delays in initiation of treatment for clients.
Methods: Poor sample collection and storage practices have been major barriers particularly in scaling up the number of diagnosed clients and initiating them on treatment in the HIV and TB space as the cold chain logistics of sputum and plasma samples are specific and the associated costs, prohibitive. In 2015, the Clinton Health Access Initiative (CHAI) Nigeria in collaboration with the Federal Ministry of Health, designed an integrated sample transportation and results delivery (iST) model to mitigate sample transportation challenges and reduce TAT to patients receiving test results. Key objective was to pilot an efficient and cost-effective iST system at 278 health facilities across 6 area councils in Abuja, Nigeria.
Results: As of 2016 December, 15,000 samples had been transported. 100% of facilities recorded a reduced TAT, with 65% of these facilities recording TAT within 30 days. In addition, 88% of CD4 and TB sputum sample results were returned within 14 days. Cost projections comparisons achieved 63% cost savings when compared to baseline.
Conclusions: Overall, the pilot has increased efficiencies in terms of frequency, reliability and TAT of sample collection and results reporting; however, addressing pre-existing fragmentation of systems, funding and incentives structures may be necessary to ensure continued success.



[Figue 1 - Cost Projections]

Implementation effectiveness: qualitative analysis of the integrated methadone and antiretroviral therapy (IMAT) strategy

A. Cooke[1], S. Hassan[2], D. Mushi[3], J. Mbwambo[3], B. Lambdin[2]
[1]*University of California, Los Angeles, Los Angeles, United States,* [2]*RTI International, Oakland, United States,* [3]*Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of*
Presenting author email: blambdin@rti.org

Background: HIV prevalence in Dar es Salaam, Tanzania is approximately 7%, research indicates prevalence is higher among people who inject drugs (PWID) with approximately 42% of PWID being HIV-positive. Given high HIV prevalence among PWID, integrating ART with opioid treatment programs can capitalize on treatment and prevention benefits. In 2015, an integrated methadone and antiretroviral therapy (IMAT) program was established at Muhimbili National Hospital in Dar es Salaam. Understanding how implementation of care integration is carried out is critical for future implementation efforts. We explore the connection between implementation context, intervention characteristics and implementation using the Consolidated Framework for Implementation Research (CFIR).
Methods: In-depth interviews were conducted with HIV-positive OTP patients (n=35) and their providers (n=8), 6-months after IMAT implementation. Provider interviews were assessed using CFIR's implementation constructs to assess implementation effectiveness. Patient interviews were analyzed using thematic content analysis, to understand experiences with the implementation process and perceptions of care integration.
Results: Providers felt the ability of the intervention to incorporate patient needs, fit into clinic procedures, and evidence for the effectiveness of the intervention had a positive influence on implementation effectiveness. Strong positive influences included adaptability, and perceptions of the advantage of implementing IMAT compared to alternative solutions. Resources dedicated to intervention such as physical space and time presented a challenge to implementation effectiveness.
OTP patients felt the ability to receive ARVs in the clinic made it easier for them to receive care. Patients identified challenges to implementation, such as clinic resources, consistent access to nutrition, and concerns about stigma from their fellow OTP patients. OTP patients enrolled in IMAT felt positively about the program overall, indicating that IMAT improved care receipt, and streamlined the care process.
Conclusions: This research uses qualitative data and CFIR constructs to assess the effectiveness of an implementation strategy that integrates HIV care into an OTP program in Dar es Salaam Tanzania. This work allows us to understand the key contributors to the success of the project; while at the same time recognizing the challenges that are being faced. These are important considerations when looking to expand the strategy to other OTP programs in the region.

MOPED1148

The prevalence of HIV, hepatitis B & C in a South African emergency department

BB. Hansoti[1], D. Stead[2], N. Mvandaba[3], A. Eisenberg[4], A. Parrish[3], M. Whalen[1], S. Reynolds[1,5], A. Redd[1,5], S. Dandorf[1], R. Rothman[1], T. Quinn[1,5]
[1]*Johns Hopkins University, Baltimore, United States,* [2]*Frere Hospital, East London, South Africa,* [3]*Walter Sisulu University, East London, South Africa,* [4]*National Institute of Allergy and Infectious Diseases, NIH, Division of Intramural Research, Bethesda, United States,* [5]*National Institute of Health (NIH), Bethesda, United States*

Background: Emergency departments (ED) are recognized as a high yield venue for HIV testing worldwide. In many resource-rich countries routine HIV and hepatitis screening has allowed for the early recognition and treatment of asymptomatic, previously undiagnosed infection. In this study we sought to define the scope of HIV and hepatitis infection in a South African emergency care context where screening is not routinely implemented.
Methods: This study utilized an identity-unlinked methodology to determine the point-prevalence of HIV, Hepatitis B, and Hepatitis C infection in the Frere Hospital ED, in the Eastern Cape from September 1st to November 30, 2016. All patients who had blood drawn in the Adult ED during the study period were enrolled. After clinically collected samples had been stored for one week in the onsite laboratory, excess sera was de-identified (except age and sex) and tested for HIV Ag/Ab, Hepatitis B surface Ag, Hepatitis B core IgM, and Hepatitis C antibody. Data were compared using T-test and chi-square tests for statistical analysis.
Results: Over the 3-month period 1246 patients had routine laboratory testing with sufficient excess sera for further analysis. In this unbiased sample, the HIV prevalence was 27.6%. HIV positive individuals were significantly younger (mean age 37.9 years versus 42.4 years, p<0.0001) and more likely to be female (59.3%, p<0.0001) compared to their HIV negative counterparts. The HIV positive patients had a significantly higher proportion of Hepatitis B and/or Hepatitis C co-infection (Table 1).

	All Participants (n-1246)	HIV positive (n=344)	HIV negative (n=902)	p-value
Age, mean in years (95% CI)	41.2 (40.7-41.8)	37.9 (36.6-39.2)	42.4 (41.0 - 43.9)	p<0.0001
Male Sex	635 (50.9)	140 (40.7)	495 (54.9)	p<0.0001
Female Sex	611 (49.1)	204 (59.3)	407 (45.1)	p<0.0001
Hep B Surface Ag positive	65	27	38	p<0.0001
Hep B Core IgM positive	12	4	8	p<0.0001
Hep C Total Ab positive	14	8	6	p<0.0001

[Charecteristics of Participants by HIV status]

Conclusions: The HIV prevalence in this ED setting is more than double the nationally estimated prevalence of 12.2%. This likely reflects the burden of HIV related disease presenting to the ED, and is evidence for the ED being a high yield setting for routine HIV testing. Of interest, the prevalence of Hepatitis B (5.6%) and Hepatitis C (1.1%) viral infections were lower than anticipated, but higher in the HIV positive population compared to HIV negatives.

MOPED1149

Uncovering the burden of HIV infection in South African emergency departments

B. Hansoti[1], D. Stead[2,3], N. Mvandaba[4], A. Parrish[4], S. Reynolds[1,5], A. Redd[1,5], R. Rothman[1], T. Quinn[1,5]
[1]*Johns Hopkins University, Baltimore, United States,* [2]*Frere Hospital, Division of Infectious diseases, Department of medicine, East London, South Africa,* [3]*Walter Sisulu University, Medicine, East London, South Africa,* [4]*Walter Sisulu University, East London, South Africa,* [5]*National Institute of Health (NIH), Bethesda, United States*
Presenting author email: dfstead@gmail.com

Background: South Africa has the highest HIV burden in the world (6.8 million people), but almost half of these are undiagnosed or not engaged in care. Extending HIV testing strategies to unreached population groups is essential. Routine HIV testing is mandated in all government health facilities, but seldom offered in emergency departments (ED)'s. ED's provide transient care to large numbers of patients, with a generally younger patient profile, making it a potentially useful HIV testing setting. In this exploratory study we sought to implement and evaluate the 2015 National South African counselor initiated HIV Counseling and Testing (HCT) strategy within one large ED in the Eastern Cape of South Africa.
Methods: We performed a point prevalence survey and implemented a HCT strategy with 24-hour coverage at Frere Hospital ED (volume approximately 3,000 patients per month) in the Eastern Cape from September 1st to November 30, 2016. All adult patients (≥ 18 years) that presented for care in the ED during the study period, were clinically stable (i.e., South African Triage level 2-5), and fully conscious (i.e., able to provide informed consent) were offered rapid point-of-care HCT and clinical data collection by trained HIV counselors.
Results: Our study enrolled 2181 patients, of which 66.9% (n=1461) consented to a rapid POC HIV test. The prevalence of HIV infection in these patients was 17.3% (n=377). This is significantly higher than the national estimate for adults of 12.2% (p <0.001). Furthermore 72.1% (n=272) of patients with a positive HIV test were previously unaware of their HIV positive status. The majority of new diagnoses (over 74.3%) were made between 7pm and 7am, in young males presenting with traumatic injuries.
Conclusions: This study provides evidence that EDs should be utilized as a testing venue to combat the HIV epidemic in SA and to reach an under-tested population. Unfortunately, the HCT strategy implemented was only able to enroll a fraction of the patients that presented for care. Further research is required on how best to optimize testing in this setting and the provision of linkage to care from the emergency department.

MOPED1150

Chronic hepatitis C among intravenous drug users in Tanzania: assessment of the liver disease and utility of HCV core antigen detection and quantification

Z. Mohamed[1], J. Mbwambo[2], Y. Shimakawa[3], L. Poiteau[4], S. Chevaliez[4], J.-M. Pawlotsky[4], J. Rwegasha[5], S. Bhagani[6], S. Taylor-Robinson[1], J. Makani[7], M. Thursz[1], M. Lemoine[1]
[1]Imperial College London, Liver and Antiviral Unit, London, United Kingdom, [2]Muhimbili University of Health and Allied Science, Psychiatry, Dar es Salaam, Tanzania, United Republic of, [3]Institut Pasteur, Unité d'Épidémiologie des Maladies Émergentes, Paris, France, [4]French National Reference Center for Viral Hepatitis B, C and delta, Virology, Paris, France, [5]Muhimbili National Hospital, Gastroenterology, Dar es Salaam, Tanzania, United Republic of, [6]Royal Free Hospital, Infectious Diseases and HIV Medicine, London, United Kingdom, [7]Muhimbili University of Health and Allied Science, Haematology, Dar es Salaam, Tanzania, United Republic of
Presenting author email: zameer.mohamed@imperial.nhs.uk

Background: The World Health Organisation (WHO) has recently called for hepatitis C virus (HCV) elimination and has identified injecting drug users (IDUs) as a key population. This study aimed to assess 1) the prevalence and severity of chronic hepatitis C among IDUs in Dar-es-Salaam, Tanzania, and 2) the validity of a HCVcAg detection and quantification using serum and dry blood spots (DBS) for identification of viraemic subjects in the sub-Saharan Africa resource-constrained setting as compared to the standard HCV quantitative PCR.
Methods: Between May and July 2015, consecutive HCV-seropositive patients enrolled in the local opioid substitution treatment (OST) centre were invited to participate in the study. All completed an epidemiological questionnaire and were offered comprehensive liver evaluation including liver stiffness measurement (LSM). HCV RNA detection (CAP/CTM HCV version 2.0, Roche Molecular Systems, Pleasanton, CA), genotyping (NS5B gene phylogenetic analysis) and HCVcAg on blood samples and DBS (Architect assay; Abbott Diagnostics) were also performed.
Results: Of the 1,011 IDUs registered in the OST clinic, 731 (72%) underwent anti-HCV antibody testing and 388 (53%) had a positive result. 153 patients from the positive group were enrolled: 141 (92%) were male, median age was 38 years (IQR 34-41), and 65 (42%) were co-infected with HIV. The median LSM was 5.3 kPa (IQR 4.4-6.5): 21 (17%) had clinically significant fibrosis (≥F2) and 6 (5%) had cirrhosis (F4). 116 patients (76%) had a detectable and quantifiable HCV RNA (median value: 5.3 Log IU/mL (IQR 4.0-6.3)). Only genotypes 1a (68%) and 4a (32%) were identified. Sensitivity of HCVcAg to identify patients with positive HCV RNA was 99% using sera and 77% using DBS. HCVcAg levels were linearly correlated with HCV RNA levels both in sera (r=0.80 p< 0.0001) and DBS r=0.75 p< 0.001).
Conclusions: In order to comply with the HCV global elimination goal, an increased focus on chronic hepatitis C screening and treatment in IDUs in East Africa is critical. The HCVcAg offers an interesting practical alternative to overcoming the diagnostic barrier in Africa. However its utility in DBS remains sub-optimal.

MOPED1151

Predictors of HCV seroconversion in people who inject drugs in 5 regions of Ukraine

A. Meteliuk[1], A. Mazhnaya[2], S. Filippovych[3], F.L. Altice[4]
[1]ICF Alliance for Public Health, Kyiv, Ukraine, [2]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior and Society, Baltimore, United States, [3]ICF Alliance for Public Health in Ukraine, Kyiv, Ukraine, [4]Yale University School of Medicine, Section of Infectious Diseases, AIDS Program, New Haven, United States
Presenting author email: meteliuk@gmail.com

Background: While there were 39,664 PWID officially registered with drug addiction clinics in 2016, WHO estimates 310,000 PWID in Ukraine. Even though the harm reduction services for PWID were introduced in Ukraine in 2001, national 2015 surveillance showed 55.9% prevalence of Hepatitis C Virus (HCV) in PWID reaching 90% in some areas. The objective of this analysis was to assess HCV seroconversion in PWID in Ukraine and its predictors.
Methods: The data were collected in 2014-2015 within the research project implemented in partnership with Yale School of Medicine on access to opioid antagonist treatment (OAT). Respondent-driven sampling was used to recruit current PWID (n=521) and random sampling was used to recruit OAT patients (n=434) in 5 regions of Ukraine. Interviews were followed by rapid HCV testing. Seroconversion was defined as present if respondent stated he had been tested HCV-negative before and was tested HCV-positive after the interview. Predictive model using logistic regression was built with HCV seroconversion as the outcome. Potential confounders included demographics, risky sexual behavior, risky injecting behavior, length and frequency of injecting, alcohol intake, HIV status, and history of incarceration.
Results: Mean age of participants was 37.3 years (s.d.8.2); most of respondents were male (73.8%); mean length of injecting was 22.2 years (s.d.9.1). HCV prevalence in the sample was 64.1%. The prevalence of HCV seroconversion was 11.6% (n=111). The mean interval for HCV seroconversion 2.8 years (s.d.3.2; range:1-19). The logistic regression showed that OAT had a protective effect against HCV (OR=0.52; 95%CI=0.37-0.88) seroconversion. Surprisingly, neither risky injecting behavior nor length/frequency of injecting were statistically significant.
Conclusions: Despite large coverage of PWID with harm reduction services countrywide, the prevalence of HCV seroconversion in this key population remains very high. The results of our study show that OAT programs are an effective means of HCV prevention in PWID that is why there is an urgent need in the country for scaling up OAT programs as well as expanding access to HCV treatment on a national level.

MOPED1152

Eliminating HCV/HIV coinfection through enhanced treatment: HCV treatment in primary care is feasible and highly effective

A.L. Bowring[1], J.S. Doyle[1,2], J. Roney[2], D. Iser[3], J. Sasadeusz[2,4], M. O'Reilly[5], C. Fairley[6], E. Gane[7], H. Jennifer[2], G.V. Matthews[8], N. Medland[6], R. Moore[9], M. Prins[10,11], M. Stoové[1], B.-K. Tee[12], M. Hellard E[1,2]
[1]Burnet Institute, Melbourne, Australia, [2]The Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, [3]St Vincent's Hospital, Department of Gastroenterology, Melbourne, Australia, [4]Doherty Institute, Victorian Infectious Diseases Service, Melbourne, Australia, [5]Prahran Market Clinic, Melbourne, Australia, [6]Alfred Health, Melbourne Sexual Health Clinic, Melbourne, Australia, [7]University of Auckland, Auckland City Hospital, Auckland, New Zealand, [8]Kirby Institute, University of New South Wales, Sydney, Australia, [9]Northside Clinic, Melbourne, Australia, [10]University of Amsterdam, Faculty of Medicine, Amsterdam, Netherlands, [11]Public Health Service of Amsterdam, Amsterdam, Netherlands, [12]Centre Clinic, Melbourne, Australia
Presenting author email: anna.bowring@burnet.edu.au

Background: Gay and bisexual men (GBM) are the key population affected by HIV and hepatitis C (HCV) coinfection in Australia. Access to HCV direct-acting antivirals (DAA) for all in Australia provides an opportunity to dramatically increase treatment access. The co-EC Study supports general practitioners to initiate treatment in primary care settings, aiming to provide proof-of-concept that treatment scale-up can eliminate HCV in coinfected GBM. We report on the feasibility of this model-of-care based on preliminary treatment outcomes.
Methods: The co-EC Study is an ongoing (March 2016-) clinician-directed, non-randomised trial of DAA among people with HIV/chronic HCV coinfection. HCV testing and treatment are delivered by specialists or general practitioners with nursing support at tertiary (n=2) and primary care (n=4) sites in Melbourne, Australia. Nurses deliver education, treatment support and coordinate visits.
Enrolment involves routine clinical data (haematological, biochemical, fibrosis assessment), which may prompt a specialist to be consulted for advice or referral prior to treatment initiation, and participants complete a self-reported behavioural survey. The primary outcomes of this preliminary analysis are treatment uptake and sustained virological response (SVR12).
Results: To date, 160 participants have enrolled (99% male; median age 48), including 106(66%) seen in primary care. Of these, based on clinic data 40(38%) could commence treatment immediately, 25(24%) required specialist advice, 17(16%) required specialist referral, and 22(21%) had incomplete data. Overall, 136(85%) participants have commenced treatment (sofosbuvir/daclatasvir-50%; sofosbuvir/ledipasvir-47%) with no difference in uptake between primary and tertiary sites. The majority have been treated for HCV genotype 1 (70%) or 3 (24%).
High-risk behaviours were commonly reported at enrolment, including: ever injecting drugs (62%) and of those, ever injecting with a used needle/syringe (33%); past month recreational drug use (50%); and in the previous six months, group sex (27%) and inconsistent condom use among those with casual male sex partners (79%).
Fifty-six participants have been assessed 12-weeks post-treatment. Where HCV RNA was available (n=50), 100% achieved SVR12.
Conclusions: This model-of-care has successfully reached HIV/HCV coinfected men with high-risk sexual and drug-use behaviour. Treatment in primary care settings is feasible, highly effective and may lead to sustained increases in treatment uptake and HCV elimination in HIV-coinfected GBM.

MOPED1153

Role of PLHIV networks in facilitating hepatitis C cascade of care in South and South East Asia

O. Syarif
Asia Pacific Network of People Living with HIV/AIDS, Capacity Development, Bangkok, Thailand
Presenting author email: octoberomaro@gmail.com

Background: Greater access to ART significantly improved PLHIV health. However, HCV co-infection remains major cause of morbidity and mortality. A study from WHO estimated 285,600 (221,100 - 406,500) co-infected individuals in South and South East, which contributes 13% in global estimation of HIV - HCV co-infection[1]. Absence of HCV services threat PLHIV life quality despite successful anti retroviral therapy.
[1] Prevalence and burden of HCV co-infection in people living with HIV: a global systematic review and meta-analysis Lucy Platt, Philippa Easterbrook, Erin Gower, Bethan McDonald, Keith Sabin, Catherine McGowan, Irini Yanny, Homie Razavi, Peter Vickerman WHO 2015. Published by Elsevier Ltd/Inc/BV
Methods: In 2014, APN+ started HCV treatment literacy for PLHIV and advocacy program towards availability of integrated HIV - HCV program in 7 south and south east Asia countries, include India, Indonesia, Myanmar, Nepal, Pakistan, Thailand and Vietnam. Treatment literacy materials developed and trainings conducted with local PLHIV groups. At regional level APN+ established regional advocacy platform to address patent and other intellectual property barriers to access for medicines. New website www.hepcasia.com developed to reach broader community.
Results: Significant price reduction of DAA drugs resulted from advocacy led by community in India, brought down the price as low as 500 USD per treatment course, followed with approval of generic version DAAs to be marketed in Indonesia and Myanmar and leads to insertion of hepatitis C program in National AIDS strategic plan in those two countries. In December 2016 Indonesian MoH announced procurement bid for DAA drugs to treat 6,000 co-infected patients in the following years. While at the same time Myanmar started preparation of HIV-HCV integrated pilot program for PWID community. In addition APN+ helps IAC, local partner in Indonesia to set up buyers club, which by December 2016 has allowed 120 patients accessed treatment with DAAs drugs under trained physicians.
Conclusions: Providing HCV treatment literacy to PLHIV groups enabled them to self organized and creates pressure towards government to improve its AIDS program and address HCV co-infection. Community initiated buyers club can get patients treated, but presence of integrated HIV-HCV program is instrumental to reach desired impact.

MOPED1154

Evaluation of implementing integrated HIV services with other development programs: the case of Ethiopian Electric Utility and Power Companies

A.B. Guraro[1], P.P. Gile[2]
[1]Ethiopian Electric Utility, HIV/AIDS Prevention and Control Office, Addis Ababa, Ethiopia, [2]Higher Education Institutions' Partnership sub-Forum against HIV/AIDS in Ethiopia, Addis Ababa, Ethiopia
Presenting author email: adullahb@gmail.com

Background: HIV&AIDS is a global development problem. Its drastic effects are much higher among productive work forces in large scale hydropower construction projects and electric service workplaces. These workplaces are located in hotspots with commercial sex workers and internally displaced youth driving them to HIV risks hence this calls for execution of integrated HIV services with development programs. This study aims to evaluate the integration of HIV services with development programs and workplaces of Ethiopian Electric Utility (EEU) and Ethiopian Electric Power (EEP).
Methods: This is a cross sectional study conducted between February 12 and July 30 20016.Both quantitative and qualitative methods were employed. Multi-stage sampling techniques were used to select the study settings (5 regions & 2 project sites) and sample respondents. Primary data was gathered through questionnaire survey from 600 respondents, key informants, focus groups, in-depth interviews. Project documents, strategic and operational plans, annual reports of the two companies were reviewed. Triangulation was made to ensure validity and reliability of data.
Results: Almost all respondents declared that HIV services were implemented in the companies while the majority (68%) of them reported inadequate level of integration of the services with the development programs. 79.5% of them reported that HIV service was adequately integrated with clinical care and treatment. 62.9% respondents declared that HIV services in hotspot project areas were integrated with commercial sex worker targeted projects with whom the young displaced migrant workers have a high client relationships. However, less than 20% of the respondents utilized VCT within a year with significant variations ($p < 0.05$) among regions and project sites.. ¾ of PLHIV participants reported that the level of integration is not adequate hence they confront stigma and discrimination. 73.4% of respondents reported accessibility of condom is high. Data from document review and qualitative methods also confirmed the findings.
Conclusions: The majority of respondents knows and appreciates the integration of HIV services with development programs of the companies. However, the findings show that there are needs for improving adequacy and comprehensiveness of integrating HIV services to all the development projects and strengthening the efforts in all work places of the companies.

MOPED1155

Integration of HIV services: the case of the Kenya Police Service recruits training

S. Ochola[1], P. Mwanzo[2], F. Muinde[3]
[1]National AIDS Control Council, Coordination and Support, Nairobi, Kenya, [2]Kenya Police Service, AIDS Control Unit, Nairobi, Kenya, [3]National AIDS Control Council, Nairobi, Kenya
Presenting author email: sallyochola@gmail.com

Background: HIV prevalence in Kenya is 5.9%. 51% of the 77,647 adult new infections in 2015 were adolescents and young people aged 15-24 years. Out of the 1.5 million people living with HIV, 268,586 are adolescents and young people aged 15-24 years. The Kenya Police Service recruits new staff aged 18-30 years from among the general population. Some of these young people do not know their HIV status and their knowledge level is below 70% with HIV stigma level estimated at 45%. It is therefore critical for the newly recruited police officer to acquire HIV and AIDS competency inorder to prevent new infections, reduce mortality and morbidity and reduce stigma and discrimination among themselves and their clients.
Methods: The Kenya Police intergrates HIV services into the newly recruited police officers training every year using the Evidence-based Combination HIV and AIDS Prevention interventions. The AIDS Control Unit works together with partners to provide HIV, AIDS and human rights information, HIV services, co-morbidities screening and referrals provided in line with the existing government guidelines with meaningful participation of young PLHIV as mobilisers, peer educators, facilitators and service providers.A total of 6000 recruits were targeted for this intervention.
Results: The integration of HIV services into recruits training yielded the following results:
1. 5981 young people were reached with comprehensive HIV information
2. 5858 young people were tested for HIV
3. 11 young people receiving positive HIV results referred for further care
3. 5858 young people were screened for TB and STIs
4. 659 of clients with signs of TB were tested for TB and tested negative
5. 6 of young people with signs of STI were tested for STI and none tested positive
6. 10 young men were referred for VMMC and received VMMC services
7. 5981 of the recruits demonstrated a clear understanding of the HIV prevention, treatment, care and support needs themselves, clients and key populations
Conclusions: 97.4% demand for services and 100% demand for information was catalysed through MIPA and high level support. Integration of HIV services, therefore, is cost effective, sustainable, complements facility based service provision and contributes to "Getting to Zero".

MOPED1156

Integration of economic empowerment into combination prevention for out-of-school adolescent girls and female sex workers in Tanzania

T. Kipingili[1], C. Casalini[2], J. Ngabani[2], N. Lugumira[2], N. Rutabanzibwa[2], J. Zoungrana[2], E. Mlanga[3], H. Ameir[4], A. Komba[2], C. Chipere[1], T. Lennemann[2]
[1]PACT Tanzania, Sauti Project, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego Tanzania, Sauti Project, Dar es Salaam, Tanzania, United Republic of, [3]United States Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [4]Tanzania Commission for AIDS, Dar es Salaam, Tanzania, United Republic of
Presenting author email: tkipingili@pactworld.org

Background: In the USAID-funded Sauti program, out-of-school adolescent girls and young women (AGYW) aged 15-24 and female sex workers (FSW) are offered an economic strengthening savings and loans (WORTH) platform that provides a unique combination of curriculum-based financial literacy, community banking, microbusiness development and behavioral change communication, "WORTH+ includes biomedical services such as HIV testing and linkage to care and family planning (FP).
Methods: Data were collected from a representative sample of 9,034 AGYW and 1,452 FSW in 28 wards of five regions in Tanzania selected through multi-stage random sampling in April 2016 using mobile data collection. Univariate analyses were conducted using Chi-square test.

Results: While 56% considered FP their responsibility with no significant difference between AGYW and FSW, condom use was low (45%), and 36% of participants considered anal sex to be an acceptable FP method. Compared to AGYW, FSW were less literate (77% vs. 65%, p=0.001), but more likely to own a micro-enterprise prior to joining WORTH+ (68% vs. 47%, p<0.001). FSW were also committed to higher mandatory and voluntary savings, with 40% of FSW saving >2 USD against 54% of AGYW saving < 1 USD per week (p<0.001).
Irrespective of the beneficiary groups, savings amounts differed significantly by region of the country and marital status (p<0.001), but not by micro-enterprise ownership.
Conclusions: The high proportion of microenterprises already owned by the target populations suggest great potential for interventions that develop feasible economic alternatives to commercial or transactional sex for populations at elevated risk of HIV. However, AGYW and FSW differ by their baseline financial literacy, economic status, and ability to save, therefore economic empowerment interventions need to be tailored to their group-specific dynamics.

MOPED1157

Harm reduction through Medically Assisted Therapy (MAT): a new paradigm to curb human immunodeficiency virus (HIV) transmission among people who use drugs in Malindi, Kenya

P. Ochieng[1], J. Njau[1], M. Kirimo[2], F. Ibrahim[3], R. Musyoki[3], S. Abdallah[4], F. Sulliman[4]
[1]Malindi Sub-County Hospital, Health, Pharmacy Unit, Malindi, Kenya, [2]Malindi Sub-County Hospital, Health, MAT Clinic, Malindi, Kenya, [3]Kilifi County Government, Health, Kilifi, Kenya, [4]United Nations Office on Drugs and Crime, Mombasa, Kenya
Presenting author email: paul.ochieng70@gmail.com

Background: The Kenya Modes of Transmission (KMoT) 2008 study attributed 3.8% of new adult HIV infections to injecting drug use. The positive impact of MAT on opioid-dependent individuals with respect to harm reduction is well documented. Various studies confirm longer retention in MAT (≥ 1 year) yields better treatment outcomes. As Kenya strives to curb the dual HIV and drug use epidemic through MAT, there is urgent need to evaluate treatment retention and establish risks for attrition.
Methods: A retrospective MAT record review of clients enrolled by April 2015 using longitudinal Excel-based attendance, clinical and pharmacy registers. Variables analyzed co-morbidities, socio-demographic characteristics, daily methadone pick-up and monthly treatment status. Time-points for 6, 12 and 18 months were September 2015, April and September 2016. All data disaggregated by age and gender at baseline. Treatment retention defined as being active on MAT each month of selected time frame, without treatment interruptions.
Results: A total 271, 145 and 138 clients regularly accessed MAT for 6, 12 and 18 months respectively. About 95% of them injected drugs; males comprised 85%. 91 clients (80% males) had communicable co-morbidities; with 57, 17, 13 and 23 clients positive for HIV, Tuberculosis, Hepatitis B and Hepatitis C viruses respectively (males comprising 79%, 94%, 85% and 87% respectively). The modal age cohort with co-morbidities was between 35 to 45 years. Median duration on MAT for 6, 12 and 18 months cohorts was 4.8, 9.6 and 14.2 respectively. By end of 18 months, MAT retention rate of 37% was recorded, compared to 89% (81/91 clients, 64 males) for co-morbid population.
Conclusions: MAT program in Malindi achieved an average of 63% retention after 12 months, surpassing the 50% average retention for developing countries (PubMed: 23859638). Drug use is a predisposing factor to contracting HIV and other sexually transmitted infections that require multidisciplinary intervention. Regular psychosocial support for males is paramount to improve treatment outcomes.

MOPED1158

Tit integration of HIV testing and prevention services among men who have sex with men (MSM) in the government owned health facilities in Western Kenya

P. Olang'o[1], P. Mwimali[1], R. Karuga[2], M. Seii[1]
[1]LVCT Health, Services, Kisumu, Kenya, [2]LVCT Health, Services, Nairobi, Kenya
Presenting author email: pshukuru@lvcthealth.org

Background: HIV prevalence (18.2%) and incidence (35%) among men who have sex with men (MSM) in Kenya are disproportionately high, compared to the rest of the population. Risky sexual behavior and poor health seeking among MSM (especially in government facilities) exacerbate their HIV epidemiological burden. There is little evidence on the feasibility of integrating MSM focused HIV prevention services in government health facilities. To generate this evidence, LVCT Health partnered with government health facilities and a regional MSM health organization to mobilize MSM for HIV prevention, care and treatment services.
Methods: In this implementation research, we analyzed service delivery data in 11 government facilities in Western Kenya between November 2015 and September 2016. We collected quantitative data to assess the integration of MSM focused services (testing, Sexually Transmitted Infections (STI) screening, linkage to care and treatment in routine health services, uptake, viral suppression and retention). Qualitative data on perception of services by MSM were collected through 11 informal interviews. Data on HIV Testing Services, STI Screening and Care and Treatment was abstracted from service delivery records. Quantitative data was analyzed using descriptive methods and qualitative data was analyzed using content analysis method.
Results: In total, 5,290 MSM were reached with HIV prevention messages, and 85% (n=4497) screened for STI. STI prevalence was recorded at 3% and uptake of STI treatment services at 100%. 5,132 were tested for HIV with a HIV positivity rate of 4% (n=188) recorded. 78% (n=146) were linked to care and treatment and 94% (n=146) were initiated on ART. Retention in care was 84%; viral load uptake (87%) and viral suppression was achieved in 78% of MSM clients.
The consistency in the services from the static site has been a motivating factor for the clients to seek service for instance "...walking to a MOH facility and getting a friendly provider motivates you to go to the clinic..."
Conclusions: This partnership between civil society and government facilities improved the HIV cascade of care - towards the 90:90:90 targets. This study provides a benchmark for the integration of MSM services in government facilities.

MOPED1159

Exploring the psychosocial well-being of HIV-positive children and youths orphaned by HIV

E. Okonji[1], C. Gaillard[2]
[1]Regional Psychosocial Support Initiative (REPSSI), Research, Johannesburg, South Africa, [2]Regional Psychosocial Support Initiative (REPSSI), APSI, Johannesburg, South Africa
Presenting author email: emeka.okonji@repssi.org

Background: One major challenge in the successful implementation of retention and adherence intervention programmes in sub-Saharan Africa is limited interventions that address the psychosocial needs of HIV positive children orphaned by AIDS. Few available studies have shown that children orphaned by AIDS reported higher depression, peer problems, PTSD, conduct problems and delinquency than the non-orphans or orphans due to other causes. Therefore, this study seeks to assess the psychosocial changes that take place amongst adolescents living with HIV. The Regional Psychosocial Support Initiative (REPSSI) is an NGO that specialises in the provision of psychosocial support services to infants, children, and youths through her partners including government, and other NGOs and CBOs in 13 Southern and Eastern African countries.
Methods: An intervention involving twenty support groups operating in Harare was developed using a concept of supporting grief in children and adolescents. HIV+ adolescents and their caregivers played an active role in the development of the curriculum intervention. This approach assures contextualization and is both innovative and sustainable. Baseline, and follow-up in a randomised control trial approach was conducted in which qualitative and quantitative data was collected from adolescents exposed to the curriculum and those who are not exposed. Ethical approval was obtained from the Zimbabwe Research Ethics Committee.
Results: Overall, 242 children and youth in the age group 10-24 years participated in the baseline survey. Of which 55% of the participants are girls. Furthermore, 76% of participants have lost both parents, (61%) father only, and 54% mother only. Of those who lost father 67% reported that their father was the bread winner. More than half of the participants who lost either one or both parents reported that life was too tough, failed to sleep, and felt run down. There was no significant difference between type of orphan hood and the key psychosocial indicators measured, as well as, gender, and age.
Conclusions: Interventions addressing the psychosocial needs of HIV positive children and youth orphaned by HIV is crucial in programming as this will improve their psychosocial well-being which in turn improves their adherence and retention to treatment, care and support.

Background: Elimination of pediatric AIDS requires not only the elimination of mother-to-child transmission of HIV, but also better treatment adherence for HIV+ children. The WHO recommends viral load testing every six months to monitor health and assess treatment adherence for children 6 months to 13 years old. In Côte d'Ivoire, no study has yet been conducted to describe the HIV+ pediatric population with relation to their viral loads, nor assessed whether viral load levels are correlated with reported treatment adherence. This study seeks to measure adherence levels of pediatric patients with high viral loads compared to low viral loads in a university teaching hospital of Bouaké, Côte d'Ivoire.
Methods: This is a retrospective, descriptive study among all children (0-14 years) on ARV treatment for at least 6 months who received viral load analyses at the study site from July 2015 - December 2016. Viral load, ARV treatment, and pharmacy registries were cross referenced to determine viral load, reported adherence (as described by parents and caregivers), and other demographic indicators. Descriptive and statistical analyses were done to assess correlation between reported observance and viral load level, both in the aggregate and disaggregated by age.
Results: Preliminary descriptive results show that, among the 101 patient charts analyzed, 59% had viral loads of less than 1000 copies/ml ("low") while 42% had greater than 1000 copies/ml ("high"). More younger children (0-8 years) had lower viral loads (62%), while older children were almost evenly split between low (51%) and high (49%) viral loads. Among reported adherent patients, 71% had low viral loads, while only 32% of non-adherent patients had low viral loads. Further statistical analyses are being undertaken to determine whether factors such as sex, further disaggregated age, or other health conditions are associated with viral load levels or reported adherence.
Conclusions: Though monitoring of pediatric viral loads is essential to ensuring the management of HIV in children, especially in resource-poor settings, challenges remain in adherence to and suppression of viral load. Further research should measure associated factors to adherence as well as to understand to what level viral load is a result of non-adherence or treatment failure.

Implementation of a health information system to improve uptake of early infant diagnosis in HIV-exposed infants and birth immunization coverage in HBV-exposed infants in Abidjan, Cote d'Ivoire: the DEPISTNEO project

S. Desmonde[1], M. Amorissani-Folquet[2,3], C. Amani-Bosse[2], D. Glohi[4], S. Lenaud[2], S. Karcher[5], M.-J. Lohoues-Kouacou[6], A. Inwoley[7], I. Ahoba[4], V. Leroy[1], DEPISTNEO Working Group

Presenting author email: sophie.desmonde@isped.u-bordeaux2.fr

Background: Early infant diagnosis (EID) coverage is insufficient in Abidjan, estimated 33% in 2015, partially due to poor linkage between birth and 6-week EID. We implemented a novel routine screening strategy that combines rapid diagnostic testing for both maternal HIV and HBV exposure in newborns at time of birth linked to a computer-based health information system (HIS) that tracks from birth HIV/HBV-exposed mother-infant pairs through the continuum of postnatal care in Abidjan, Côte d'Ivoire.
Methods: All mother-infant pairs who give maternal consent in the five participating maternity clinics are included. At birth, all mothers are tested and those infected who are unaware of their status are offered a second opportunity to be enrolled in care. All those HIV-infected receive PMTCT. Additionally, rapid HBV-testing is offered; HBs-Ag-exposed children receive immunization at birth. All livebirths are recorded in the HIS; HIV and/or HBV-exposed children are tracked through the continuum of care. Each step of the EID and immunization cascades (6-10-14W) is recorded in the HIS. Weekly reports alert social workers in case of a missed visit, who then contact families to re-schedule. Children are followed-up until definite diagnosis after breastfeeding cessation.
Results: Between August-December 2016, 3209 births were recorded. HIV testing coverage at time of birth was 99%: maternal prevalence of HIV was 3.7% (95%Confidence Interval (95%CI): 3.1-4.4). Of those HIV-infected, 56% were already on combined ART. Among the 111 HIV-exposed live-born infants, 63 had reached follow-up >6 weeks: 44% (95%CI:32-56) had a DBS for virological testing. After HIS alerts, 6-week virological testing coverage reached 56% (95%CI:43-68); overall 6-week immunization coverage in HIV-exposed infants was estimated 48% (95%CI:36-61). Acceptability of maternal HBV testing reached 95%: prevalence of HBV was 7.0% (95%CI: 6.1-7.9). Among the 219 HBV-exposed children, 99% were immunized at birth. Of these children, 128 had reached a follow-up>6 weeks: their 6-week immunization coverage was 65% (95%CI:57-73).
Conclusions: Maternal HIV and HBV rapid diagnostic testing at birth is both feasible and acceptable. While immunization at 6 weeks and EID coverage remain low, HBV immunization coverage at birth is high. Compared to Ivorian national reports, the HIS improved EID uptake.

Presenting author email: drsachdevak@gmail.com

Background: Indian Early infant Diagnosis (EID) for HIV program began in 2010. Under Indias' EID algorithm infants are called for testing at 6 weeks, 6 months, 12 months and 18 months of age, unless found positive and linked to care. Any infant arriving at age greater than 6 months is administered an antibody test at the sample collection centre, and a Dried Blood spot (DBS) sample is sent for PCR testing at laboratory only if antibody test is found positive. This paper seeks to quantify antibody negativity at different ages and linkage losses between stages of testing.
Methods: A retrospective analysis was conducted on program data comprised of 4,294 infants presenting for testing from May 2013-October 2016 in Maharashtra. The following metrics were evaluated - (a) Antibody negativity at different ages and (b) Loss to follow up (LFU) between 1) antibody positivity and collection of DBS sample, 2) DBS detected and collection of confirmatory sample and 3) between confirmatory diagnosis and treatment linkage. Analysis was done for Financial Years (FY), starting with April and ending with March.
Results: Median age at first, second, third and fourth visit were 2.2, 6.9, 13 and 18.5 months. The proportion of patients registering within ages 0-2 months increased from 26% in FY 14-15 to 56% in FY 15-16. 85% of antibody tests were unreactive for infants within ages 6-9 months. DBS sample weren't collected for 27% of those detected on antibody test. 34% of those detected on DBS screening test didn't return for a confirmatory test. 54% of those found detected on confirmatory test weren't linked to treatment.
Conclusions: The decreasing median age at first visit indicates that the programme has been successful in reaching infants earlier but LFU at various stages necessitates focused strategies to reduce linkage loss. Infants found negative on antibody are not administered a PCR test, making high antibody test negativity a concerning finding due to possibility of false negativity and missing out infected infants. Further research in this area is required.

MOPED1163

Analysis of HIV testing trends among HIV-exposed infants in Malawi using an electronic laboratory system, 2012-2016

J. Sexton[1,2], D. Phiri[1], G. Chipungu[1], A. Kim[3], R. Mwenda[4], D. Singer[1]
[1]*U.S. Centers for Disease Control and Prevention, Lilongwe, Malawi,* [2]*ASPPH/CDC Allan Rosenfield Global Epidemiology Fellowship, Washington, United States,* [3]*U.S. Centers for Disease Control and Prevention, Atlanta, United States,* [4]*Malawi Ministry of Health, Lilongwe, Malawi*
Presenting author email: kzj9@cdc.gov

Background: In 2016, 5.5% of HIV-exposed infants (HEI) aged 1-6 months were diagnosed with HIV infection in Malawi. Since 2011, Malawi has expanded testing to align with WHO guidance on testing of HEI between the ages of 4-6 weeks. We describe the impact of infant virologic testing (IVT) scale-up activities on the number of infants tested, diagnosed, and on treatment using clinical, laboratory, and M&E data sources.

Methods: An analysis was performed utilizing nationally representative IVT data collected from 2012-2016 from 9 reference laboratories and entered into a centralized laboratory management system (LIMS) with nationally reported aggregated statistics of HEIs from Malawi Ministry of Health (MOH) Integrated HIV Program Quarterly Reports, 2012-2016. Using these two data sources, we reported change in HEI care and IVT overt time.
Results: In 2012-2016, 170,543 IVT results were entered into LIMS, including 12,344 (7%) positive IVT from 636 health facilities in the Northern (8%), Central (28%), and Southern (64%) regions. The distribution of IVT by district was consistent with population distribution, with most tests reported in Lilongwe (12%) and Blantyre (10%) Districts. According to MOH data, of the total number of infants born, 160,236 (7%) infants discharged alive from maternity were known to be HIV-exposed; 148,398 (92%) of these infants received anti-retroviral (ARV) prophylaxis; and 114,162 (70%) were enrolled in HEI follow-up before 2 months of age. The data also showed an increase in total testing volume by 55% and a 53% increase in the number of facilities utilizing LIMS laboratories. Most notably, the number of HEI linked to care following a positive HIV test increased progressively from 47% to 96%.
Conclusions: By synthesizing LIMS data on IVT with routine program monitoring clinical and laboratory data for HEIs, we were able to demonstrate an increase in number of IVT performed on HEIs, an improvement in the number of HEIs enrolled in follow-up care, and a sustained percentage of HEIs receiving ARVs after a positive EID test. The study also demonstrates electronic LIMS data as an important source of information that complements routine sources for monitoring HIV programmatic activities in Malawi.

MOPED1164

An assessment of the effectiveness of reaching untested HIV-exposed infants through community-based mobile outreach clinics in Lesotho

K. Sindelar[1], J. Joseph[2]
[1]Clinton Health Access Initiative, Lesotho - Pediatric HIV, Maseru, Lesotho, [2]Clinton Health Access Initiative, Applied Analytics, Denver, United States
Presenting author email: ksindelar@clintonhealthaccess.org

Background: In 2014, only 56% of HIV-exposed infants (HEIs) in Lesotho received an Early Infant Diagnosis (EID) test within two months of birth. Mortality rates for HIV+ infants peaks between 6-8 weeks of life, and before the age of two, half of all untreated babies will die. Thus, detection and initiation on treatment at the earliest possible stage is crucial in saving these lives. An evaluation was conducted in Lesotho to measure the effectiveness of reaching previously untested HEIs through community-based mobile outreach clinics (MOCs).
Methods: From December 2015-December 2016, seven public-private MOCs operated four days a week, visiting a different site once per month. The MOCs were located in remote areas and offered a range of clinical services with a focus on HIV testing for children, including collection of dried blood spots. A mobile application was designed for real-time data collection at point-of-care for healthcare workers to capture data on HEIs; including residence, gender, age, and testing history.
Results: Out of 1,336 MOCs, 164 HEIs were identified, averaging 0.12 identifications per MOC, with near equal male-to-female distribution. Overall, only 34.1% were known to have been previously tested (EID or rapid). There was a negative correlation between age and volume identified, with 32.9% of infants between 0-1 months old, 31.7% 2-4 months old, 25% 5-11 months old, and 10.4% 12-24 months old. Previous testing had been conducted on infants aged 0-1 month (3.7%), 2-4 months (42.3%), 5-11 months (58.5%) and 12-24 months (47.1%).
Conclusions: While the number of identifications per MOC was low, they were effective at finding young HEIs (< 6 weeks) and those with no known previous testing. The MOCs also found a surprisingly high proportion of untested HEIs between 12-24 months old. This suggests that in addition to the geographical barriers faced in remote communities, caregiver reluctance to receive facility-based testing was a factor in preventing HEIs from being tested until a community option was available. It is therefore recommended to increase community EID as a supplement to facility-based EID, with prioritization in regions with underserved communities in remote locations, as well as places where HIV stigma remains prevalent.

MOPED1165

Uptake of birth testing for early infant diagnosis of HIV among HIV exposed infants at Livingstone Central Hospital: 2008 to 2016

J.N. Mutanga[1,2], S. Mutembo[2,3], D. Sialondwe[1], C. Kanene[4], R. Fubisha[1], J. Chiyonga[5], C. Whalen[2]
[1]Livingstone Central Hospital, Pediatrics and Child Health, Livingstone, Zambia, [2]University of Georgia, Epidemiology and Biostatistics, Athens, United States, [3]Ministry of Health Zambia, Clinical Care, Choma, Zambia, [4]CDC, Zambia, Prevention, Choma, Zambia, [5]Ministry of Health, Clinical Care, Choma, Zambia
Presenting author email: jane.mutanga@gmail.com

Background: In 2014, only 37% of HIV exposed infants in Zambia had an HIV DNA-PCR test for HIV diagnosis within the first two months of life. Limited laboratory services led to poor uptake of Early Infant Diagnosis (EID) among other things. The aim of our study is to evaluate the effectiveness of HIV testing at birth or within the first 6 weeks of life under programmatic conditions in a setting with a high prevalence of HIV.
Methods: Using a retrospective cohort study design, we abstracted data from inpatient and outpatient records in the department of pediatrics. We performed descriptive analysis and estimated HIV testing and positivity rates at different time intervals. We evaluated the proportion of infants who tested positive for HIV within the first 6 weeks of life. We include only the first test for each child in this analysis.
Results: We enrolled 2,452 children who tested for HIV with DNA-PCR below 2 years of age. Of these, 850 (37%) tested within the first 2 months of life. Of those that tested within 2 months, 197 (23%) tested within the first 6 days of life. At least 5% of all the tests done within the first 6 days of life confirmed HIV infection while 5% of all tests done from 1 week to 4 weeks of age and 6% of all tests done from 5 to 8 weeks of age confirmed HIV infection.
Overall, 51% of those tested were female. Although infant HIV testing numbers did not increase substantially during this period, the proportion of mothers who knew their HIV status during pregnancy increased (5% in 2008 to 72% in 2015). Sixty five percent (65%) of infants tested within the first 6 weeks of life completed follow-up to at least 2 years.
Conclusions: In this cohort of HIV exposed babies, HIV testing within the first 6 days of life had similar results with testing from 1 to 4 weeks and 5 to 8 weeks of age. This finding supports HIV testing for HIV-exposed infants using nucleic acid tests at birth and during the first 6 days of life in resource limited settings.

MOPED1166

Viral load monitoring with SAMBA-1, a semi-quantitative nearly point-of-care method in Arua, a rural district in Uganda

S. Nicholas[1], B. Schramm[1], E. Poulet[1], E. Ajule[2], H. Candiru[2], P. Adroa[2], M. Gueguen[3], S. Balkan[3]
[1]Epicentre, Paris, France, [2]Medecins Sans Frontieres, Arua, Uganda, [3]Medecins Sans Frontieres, Paris, France

Background: Point-of-care (POC) systems for viral load (VL) monitoring have considerable potential but evidence from ‚real-life' use is limited. In September 2013, Médecins sans frontières, with UNITAID funding implemented SAMBA-1, a semi-quantitative (1000 copies threshold) nearly point-of-care VL test system in the Regional Referral Hospital of Arua, a rural district, Uganda. The objective was to provide access to routine VL testing to approximately 7000 ART patients followed by Ministry of Health (MOH). We describe the VL cascade to highlight successes and challenges in the first 3 years of implementation.
Methods: We performed a retrospective observational cohort analysis using routine patient monitoring data. We describe the sequence of VL tests performed between September 2013 and November 2016 for patients followed with at least 6 months on ART (eligible for VL), and outcomes up-to 1 year after an initial VL≥1000 copies/ml.
Results: Over the study period, 9,305 patients were eligible for VL and coverage was 78.1%. Of the patients tested, 1748 (24.1%) had a VL ≥1000 copies/ml, and of these, 1221 (69.9%) received a repeat VL test. Median time to repeat VL was 6 months (following MOH protocol), at which 457 (37.5%) suppressed, 763 (62.5%) remained with a VL≥1000 copies/ml. Of the 763 patients with two consecutive VLs ≥1000 copies/ml, 59 (7.7%) were switched to the next ARV line. Clinical review was same day for 92% of tests. National VL testing protocol was incomplete for 3265 (35.1%) eligible patients, of whom 45.3% were lost-to-follow-up, 1.5% died and 13.2% transferred-out by date analysis censorship.
Conclusions: POC VL testing achieved good VL-testing coverage, permitted same-day clinical review of results and timely follow-up. However, ensuring every patient gets their VL test remains a challenge in a dynamic cohort. Close program monitoring and support to staff is essential to identify and address gaps in the VL monitoring cascade. Very few treatment failures switched regimen. Key constraint is reluctance, by clinicians to switch patients based on semi-quantitative results and

by some patients even after failure confirmation. The issue could be overcome by improving clinicians' knowledge on the validity of the 1000-threshold, patients' education and psychosocial support.

MOPED1167

HIV self-testing in Zambia: User ability to follow the manufacturer's instructions for use

C.I. Gotsche[1,2], M. Simwinga[2], A. Muzumara[2], K.N. Kapaku[2], L. Sigande[2], M. Neuman[1], M. Taegtmeyer[3], E. Corbett[1], C. Johnson[4], A. Schaap[1,2], A. Mwinga[2], K. Hatzold[5], H. Ayles[1,2]

[1]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [2]Zambart Project, University of Zambia, Lusaka, Zambia, [3]Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, United Kingdom, [4]World Health Organisation, Geneva, Switzerland, [5]Population Services International, Harare, Zimbabwe

Presenting author email: caroline.gotsche1@alumni.lshtm.ac.uk

Background: HIV self-testing (HIVST) is a new approach to increase testing uptake. Although evidence demonstrates that supervised users can accurately perform HIVST, the ability of unsupervised users to do so, using manufacturer's instruction for use (IFU) requires further investigation. The Clinical Performance study (CPS) within the PSI/ UNITAID STAR Project provided participants with the OraQuick® HIV rapid self-test (OFT) and IFU, and asked them to perform the test. In the pilot phase of the CPS (June 2016), participants were provided IFU only. Video recording showed low levels of comprehension and poor sensitivity and specificity were obtained. Hence, additional step-by-step demonstrations by health workers were provided before the participant initiated the HIVST. This study investigated intended user ability to understand and follow the IFU.

Methods: Cognitive interviews were conducted with 17 purposely selected adults and adolescents to assess understanding of the IFU. Video recordings of 17 participants conducting unsupervised HIVST (76.5% males, 88% rural) were analysed descriptively and scored using a predetermined standardised checklist.

Results: Cognitive interviewing revealed that participants struggled to open the test kit easily. The most difficult instructions to understand were those related to the collection of oral fluid by swabbing the gums. Adolescents were more likely to swab accurately and to rely on both images and written instruction compared to adults. Understanding and interpreting images and particular terms (pouch, press firmly e.g.) was perceived challenging.

Video analysis showed that only 8/17 participants read the IFU before the test, despite explicit instructions to do so. There was a significant association ($p< 0.05$) between participants who read the instructions and their ability to correctly collect oral fluid sample. Only 4/17 participants were able to conduct all steps correctly. Women were 2.5 times more likely to perform all steps of the test correctly.

Conclusions: The OraQuick® HIV rapid test, though validated under ideal conditions, is shown to be challenging to use under real life conditions even after step-by-step demonstrations. Further improvements of pictorial/written IFU and the way the HIVST kits are designed is required to decrease user errors and to enable people to follow the IFU reliably.

MOPED1169

Clinical evaluation of a smartphone-based electronic reader of two dual rapid diagnostic tests for HIV and syphilis

L.-T. Allan-Blitz[1,2], S.K. Vargas[3], K.A. Konda[3,4], S. Herbst de Cortina[5], C.F. Caceres[3], J.D. Klausner[4,6]

Presenting author email: carlos.caceres@upch.pe

Background: Combination assays for HIV and syphilis are becoming increasingly available. Handheld automated readers that read and quantify lateral flow-based rapid tests provide a novel approach to diagnostics and a centralized data system for epidemiologic research.

Methods: We enrolled MSM and transgender women ≥18 years of age seeking medical services at an STD clinic in Lima between October 2016 and January 2017. Venous blood was tested using two rapid dual HIV and syphilis tests (SD BIOLINE HIV/Syphilis Duo, Hagal-dong, Republic of Korea and First Response HIV 1+2/ Syphilis Combo, Nani Daman, India). HIV infection was confirmed with 4th generation EIA tests, while syphilis infection was confirmed with RPR, TPPA, and TPHA titers. Clinic staff visually inspected dual-test results, after which, the dual-tests results were read by the Cellmic HRDR-200 automated reader (Cellmic, LLC. Los Angeles, USA), an opto-mechanical smartphone attachment. Automated reader results were compared with visual inspection results. To assess how well the automated reader results correlate with visual inspection results, we calculated negative and positive percent agreement, concordance, and kappa statistic.

Results: On confirmatory testing of the 172 participants, 29% were HIV-infected, and 50% had treponemal antibodies (71% of whom had reactive RPR titers). The comparison of reader results with the results of visual inspection for both rapid assays can be found in Table 1.

Syphilis Antibody		No. Positive Tests	No. Negative Tests	% Positive Agreement (95% CI)	% Negative Agreement (95% CI)	Concordance	Kappa Statistic
First Response	Reader	57	100	98.3 (90.6 - 100)	98.0 (93.0 - 100)	0.98 (0.95 - 1.00)	0.96 (0.91 - 1.00)
	Operator	58	99	96.6 (88.1 - 99.6)	99.0 (94.5 - 100)		
SD BIOLINE	Reader	56	101	98.2 (90.5 - 100)	98.0 (93.02 - 99.8)	0.98 (0.95 - 1.00)	0.96 (0.91 - 1.00)
	Operator	57	100	96.5 (87.9 - 99.6)	99.0 (94.6 - 100)		
HIV Antibody		No. Positive Tests	No. Negative Tests	% Positive Agreement (95% CI)	% Negative Agreement (95% CI)	Concordance	Kappa Statistic
First Response	Reader	47	110	97.9 (88.7 - 100)	97.3 (92.2 - 99.4)	0.98 (0.94 - 0.99)	0.94 (0.88 - 1.00)
	Operator	49	108	93.9 (83.1 - 98.7)	99.1 (95.0 - 100)		
SD BIOLINE	Reader	50	107	98.0 (89.4 - 100)	100 (96.6 - 100)	0.99 (0.97 - 1.00)	0.99 (0.96 - 1.00)
	Operator	49	108	100 (92.8 - 100)	99.1 (95.0 - 100)		

[Table 1]

Conclusions: Our results show that the performance of the automated reader correlated well with visual inspection. Given that high correlation, further implementation of the automated reader is warranted to investigate its utility in areas without technicians trained in visual inspection of rapid tests, as well as for the purposes of epidemiologic monitoring and surveillance.

MOPED1170

Performance of the point of care Cepheid GeneXpert HIV qual for early infant diagnosis: field experience in Kenya

V. Sarah Opollo[1], A. Nikuze[2], E. Anyango[3], F. Humwa[3], B. Oyaro[3], S. Wanjala[4], W. Omwoyo[5], M. Majiwa[3], D. Maman[6]
[1]Kenya Medical Research Institute/Centres for Disease Control, HIV Research, Kisumu, Kenya, [2]Medecins Sans Frontieres, HIV Research, Kisumu, Kenya, [3]KEMRI/CDC, HIV Research, Kisumu, Kenya, [4]MSF-Epicentre, Nairobi, Kenya, [5]Ministry of Health, Government, Kisumu, Kenya, [6]MSF-Epicentre, HIV Research, Cape Town, South Africa
Presenting author email: david.maman@epicentre.msf.org

Background: Access to testing services at the patient clinic can reduce loss to follow-up and result turn-around times hence minimizing barriers to early linkage to care and treatment among HIV infected children. Currently samples for HIV diagnosis are sent to centralized testing facilities which are located only at specific regions in Kenya. However, there are Point of Care (POC) early infant diagnosis (EID) technologies elsewhere, but none has been evaluated in Kenya despite the urgent need for data to inform policy formulation regarding EID. The Cepheid Xpert technology for POC EID, offers a great opportunity to minimize the HIV associated high morbidity and mortality rates through decentralization of early HIV testing. This technology also allows for same-day results thus facilitating prompt linkage to care. We evaluated the GeneXpert HIV Qual EID POC in Homabay County, Kenya against the standard of care platform, Roche CAP/CTM HIV-1 qualitative PCR, using dried blood spots (DBS).
Methods: Between January - July 2016, DBS samples were collected from HIV exposed children < 18 months of age enrolled in a cross-sectional study. Samples were collected by qualified nurse counselors, and were tested by trained technicians using field based GeneXpert and conventional laboratory based Roche CAP/CTM HIV-1 qualitative PCR. Sensitivity and specificity were determined.
Results: 3814 mother/baby pairs were included in the study, out of which 968 babies were HIV exposed as per the mothers' HIV status. A total of 34 (3.5%) children were concordantly positive using both platforms. GeneXpert yielded a sensitivity of 97.1% and specificity of 100% with an overall error rate of 0.9%. The PPV and NPV were 100% and 99.9% respectively.
Conclusions: Our findings show that the POC GeneXpert performs comparable to the conventional CAP/CTM using DBS, suggesting that this technology may be adopted in the laboratory near POC and used in quick diagnosis of HIV and its result used to inform linkage to care of children who are found to be HIV exposed at the same time supplementing the progress of EID in the region.

Presenting author email: drsoethiha.sgg@gmail.com

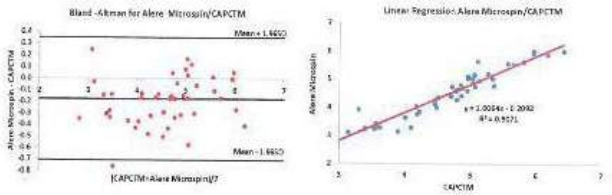
Background: World Health Organization recommended Early Infant Diagnosis (EID) using polymerase chain reaction (PCR) technology since 2010. Integrated HIV care program in Myanmar implemented EID of HIV exposed babies in March 2012 across its 10 antiretroviral therapy (ART) centers. Blood samples from the ART centers were sent using public transport to a centralized PCR facility at public health laboratory (PHL), Mandalay. We aimed to determine the uptake of EID services, turnaround time (TAT) to result receipt by mother from sample collection and factors associated with delayed (≥8 weeks of age)/no EID uptake and long TAT (≥7 weeks)/non-receipt of result by mother among HIV exposed babies < 9 months at enrollment between 2013 and 2015.
Methods: Retrospective cohort study involving record review.
Results: Of 1349 babies, uptake of EID (< 8 weeks) was 47% (633/1349), sample collection was delayed (≥8 weeks) in 27% (367/1349) and not done in 26% (349/1349) babies. Among 1000 babies' sample collected, long TAT or non-receipt of results by mother was seen in 680 (68%). After adjusting for confounders, mothers neither on ART or PMTCT before pregnancy when compared to mothers on ART before pregnancy [aRR (0.95 CI): 1.8 (1.5, 2.2)] and distance of ART center from PCR facility ≥128 km when compared to < 128 km [RR (0.95 CI): 2.2 (1.8, 2.7)] were risk factors for delayed or no sample collection. Babies with mother's CD4 count of 100-350 cells/mm^3 at enrollment [aRR (0.95 CI): 0.8 (0.7, 0.9)] had 20% lower risk of long TAT or non-receipt of results when compared to ≥350 cells/mm^3. Distance between ART centers and PHL ≥105 km [aRR (0.95 CI): 1.2 (1.1, 1.4)], when compared to < 105 km, had 20% higher risk of long TAT or non-receipt of results, respectively.
Conclusions: Uptake of EID was low and turnaround times were prolonged. This study supports the implementation of universal ,test and treat' recommendation among people living with HIV at field level in Myanmar which has the potential to improve the uptake of EID. Innovative interventions like point of care EID testing and/or systematic use of mobile technology to communicate results are urgently needed.

MOPED1172

Point-of-care HIV viral load testing: suitable performance with Alere™q 50µl plasma cartridge

L. Hans[1,2], N. Ndungane[1], A. Mayne[3], S. Carmona[1,2]
[1]National Health Laboratory Services, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Molecular Medicine and Haematology, Johannesburg, South Africa, [3]University of South Africa, Department of Life Sciences, Pretoria, South Africa
Presenting author email: lucia.hans@nhls.ac.za

Background: Universal HIV viral load (HIVVL) scale-up is urgently needed if the 90-90-90 target of 90% viral load suppression is to be reached by 2020. HIVVL testing in Southern Africa is provided by central laboratories, with some areas still recurring improved coverage. Point-of-care (POC) assays can assist in increasing access to HIVVL in remote locations. Plasma remains the gold standard sample type for HIVVL, but centrifugation for sample separation remains a challenge in facilities. We evaluated the performance of the new Alere q 50ul plasma cartridge against the Roche (CAPCTM) HIV-1 V.2 assay using standard and alternative methods of plasma separation.
Methods: Parallel testing of routine 147 samples was performed between Alere™q and Roche assay (1000µL input volume). Viral load >1000 cp was considered virological failure. The lower limit of detection (LLOD) of the assay was determined by probit analysis of 30 repeats at 5 concentrations. Fifty samples were tested using three methods of plasma separation viz.: standard centrifugation, 1 hour of standing (leucodepletion) and 1 minute of microspinning.
Results: The Alere™q assay had a sensitivity of 98.1% and specificity of 96.8%. The LLOD was 734 copies/mL. 95% confidence intervals (CI) at mean ± 1.96SD were set for the Bland-Altman graph and linear regressions were performed (Figure 1); 6 of the 147 sample values (4,8%) lay outside the CIs. Regression model fit is as follows: CAPCTM / Alere standard centrifugation (R^2= 0.95), CAPCTM / Alere leucodepletion (R^2=0.83) and CAPCTM / Alere microspin (R^2=0.91), Alere leucodepletion / Alere centrifugation (R^2 =0.83) and Alere microspin / Alere centrifugation (R^2=0.91).



[Figure 1. The Bland-Altman and linear regression graphs for Alere™q assay using one minute of microspinning for plasma separation.]

Conclusions: The 50µL Alere cartridge with its adequate LLOD and comparable performance to the reference, with no compromise in sensitivity or sensitivity favours POC testing. Plasma separation can be simplified to suit POC HIVVL as a short microspin appears sufficient to remove leucocytes.

MOPED1173

HIV rapid test external quality assessment: Brazil´s experience

P.C. Gaspar[1], A. Bigolin[2], H.M. Machado[2], A.F. Pires[1,3], M. Franchini[1], A.S. Benzaken[1], M.L. Bazzo[2]
[1]Department of Surveillance, Prevention and Control of Sexually Transmitted Infections, HIV/AIDS and Viral Hepatitis / Ministry of Health, Brasília, Brazil, [2]Federal University of Santa Catarina, Florianópolis, Brazil, [3]Postgraduate Program in Collective Health of University of Brasília, Brasília, Brazil
Presenting author email: ana.pires@aids.gov.br

Background: Policies promoting access to HIV diagnosis have led to the widespread use of rapid tests (RT) in health facilities of different complexities throughout Brazil. To monitor the quality of the testing procedures, the Ministry of Health introduced the National Program of External Quality Assessment for RT (EQA-RT). This involves healthcare professionals registering on an online platform to receive a panel with four dried tube specimens with unknown reactivity for HIV. The respondents should test the samples as if it they were from their own patients and follow the algorithms recommended by Ministerial Directive of HIV diagnoses. The results are then submitted online for subsequent analysis.
Methods: We analyzed reports from eight EQA-RT rounds conducted in 2014-2016. The quality of the professionals´ performance was assessed by examining the degree of concordance between the results from the panel samples that were expected and those actually reported, and the agreement of their conduct with the Brazilian guidelines. Certificate of approval is issued in the event of 70% accuracy. Any professional receiving less than 70% approval rating is sent a report suggesting possible causes and solutions for issues that might have been responsible to prevent the quality of testing.
Results: The average number of participants per round was 843 (545 in 2014, 909 in 2015 and 1,075 in 2016) distributed in 347 mainly primary healthcare units. It was interesting to note that many higher complexity services, despite registering in the program, failed to report the results (e.g. a 55% abstention rate in one of the rounds). Regarding the performance on EQA-RT, an average of 94% of respondents was approved per round, with 61% achieving 100% accuracy. The most common failures identified so far have been the lack of knowledge of Brazilian guideline with erroneous algorithms executionfor HIV diagnosis.
Conclusions: The majority of healthcare professionals currently participating in Brazil´s EQA-RT program are maintaining a high level of RT quality. While the number of participants doubled in 2014-2016, there is still a need for education work to encourage more adherence to the Program aimed at ensuring the reliability and credibility of the TR results.

MOPED1174

Dried blood spots for viral load: evaluating the use of DBS in order to increase access to viral load monitoring

E. Auma
Kemri/CDC, HIV Research Laboratory, Kisumu, Kenya
Presenting author email: aumaerick@gmail.com

Background: Access to viral load based on HIV RNA level quantification in plasma remains limited in resource-constrained settings. Measurement of HIV viral load using DBS could facilitate the expansion of treatment monitoring to support viral load suppression in these settings. We assessed the performance of a newly modified RNA elution protocol (FVE) for DBS compared to the predicate testing with plasma on the COBAS® AmpliPrep/ COBAS® TaqMan® HIV-1 v2.0 Test.
Methods: 435 parallel EDTA plasma and whole blood (DBS) samples were collected from adult patients referred for routine viral load monitoring at the Charlotte Maxeke Johannesburg Academic Hospital (n=281) and KEMRI/CDC Kisumu, Kenya (n=154). DBS were processed using the modified FVE protocol that required elusion of DBS in 1X phosphate buffered saline; both plasma and DBS were tested on the COBAS® AmpliPrep/ COBAS® TaqMan® HIV-1 v2.0 Test and the results.
Results: Plasma VL ranged from < 20 copies/mL to >100,000 copies/mL. Of the 155 plasma >= 1000 copies/mL, 128 DBS were also >= 1000 copies/mL for a sensitivity of 82.6%. Of the 228 plasma < 1000 copies/mL, 224 DBS were also < 1000 copies/mL for a specificity of 98.2%. There was strong correlation between DBS and plasma across all stratifications (concordance = 0.92). There were no statistical differences between DBS and plasma VL up through 42 days after collection when using a 1000 copy/mL threshold.
Conclusions: DBS can be used for monitoring viral load up to 42 days after collection and should be considered for increasing access of viral load monitoring resource limited settings.

MOPED1175

Marker-assisted HIV-1 viral load pooling deconvolution improves monitoring capacity

T. Liu[1], J. Hogan[1,2], M. Daniels[3], M. Coetzer[1], Y. Xu[1], G. Bove[1], A. Delong[1], M. Orido[2], L. Diero[2,4], R. Kantor[1]
[1]Brown University, Providence, United States, [2]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [3]University of Texas at Austin, Austin, United States, [4]Moi University, Eldoret, Kenya
Presenting author email: tliu@stat.brown.edu

Background: The World Health Organization (WHO) recommends global routine viral load (VL) testing for antiretroviral therapy monitoring. VL testing in many resource-limited settings (RLS) is constrained by cost and technology. To increase VL monitoring capacity, we hypothesized that VL pooling, which reduces VL assays needed, can be further improved by incorporating in its deconvolution process information from low-cost, routinely-collected clinical markers (RCMs; e.g. CD4 count).
Methods: We developed mMPA (marker-assisted mini-pooling with algorithm), a new VL pooling deconvolution strategy that utilizes available RCMs to determine an efficient order of sequential individual VL testing in positive pools, and dictates when the sequential testing can be stopped. Using data from 918 study participants at the Academic Model Providing Access to Healthcare (AMPATH) in Eldoret, Kenya, we simulated our method's implementation; evaluated the impact of pool size, prevalence of virological failure, VL measurement error and assay detection cutoffs; and compared our method with individual VL testing and existing pooling deconvolution algorithms.
Results: Using a pool size of 5 and incorporating CD4 count as a RCM to assist deconvolution, mMPA can significantly reduce the number of VL assays by 52% (Confidence Interval (CI)=48-57%) compared with individual testing, and by 19% (CI=14-22%) compared with existing VL pooling algorithms. Incorporating additional RCMs in addition to or instead of CD4 (e.g. time on therapy, WHO staging) in mMPA can further reduce the number of assays needed. mMPA also improves sensitivity (82% vs 74%), negative predictive value (97% vs 95%), and positive predictive value (98% vs 96%) over an existing pooling algorithm, with a comparable high specificity (>99%). mMPA depends on the pool size, virological failure prevalence, and RCMs used for deconvolution, but is relatively insensitive to the impact of assay detection cutoffs and assay measurement errors.
Conclusions: mMPA can substantially increase the capacity of VL monitoring. By using information from RCMs, mMPA can deconvolute pools more rapidly and with higher diagnostic accuracy than existing methods, resulting in less VL tests needed. Particularly relevant for RLS, mMPA has potential to provide comprehensive VL monitoring to more HIV-infected people receiving treatment.

MOPED1176

Effect of routine viral load testing on turnaround time and availability of results among target patients receiving antiretroviral therapy in Kenya

P.K. Mwaura[1], S. Nakitare[1], A. Agweyu[2], C. Njigua[1], K. Owuor[3]
[1]Christian Health Association of Kenya, Health Services, Nairobi, Kenya, [2]Health Strat, Health Services, Nairobi, Kenya, [3]Kenya Medical Research Institute, Monitoring and Evaluation, Nairobi, Kenya
Presenting author email: pkmwaura@gmail.com

Background: The Kenya national guidelines on viral load (VL) monitoring changed from targeted to routine testing in June 2014. While scaling-up VL testing may improve the standard of monitoring for all patients on antiretroviral therapy, these new guidelines may shift focus away from target populations. This study aimed to determine the effect of the new guidelines before and after implementation on turn-around time and availability of results.
Methods: We conducted a retrospective cohort study of routine program data from 42 health facilities under the Christian Health Association of Kenya HIV program and the National AIDS and STI Control Program (NASCOP) website database. Target patient populations comprised of pregnant women, children, confirmatory and drug-switch patients.
We compared the time period prior to (January to June 2014) and after (January to June 2015) implementation of the new Kenya national guidelines. Median turnaround time (TAT) from the time of sample collection to dispatch of results periods was calculated.
Results: VL results were available for 5115 patients over the routine period, compared to 971 during the targeted period. Approximately half of the confirmatory VL results (154/286) were available during the targeted period compared to 47/505 (9.3%), p< 0.001 during the routine period. Single drug substitutions in the targeted period had 101/971 (10.4%) VL results and pregnant women 64/672(9.5%) results available versus 294/5115 (5.7%) and 158/3532 (4.8%), p<0.0001 in the routine period respectively.

Overall, median TAT was 13 days in the targeted period, increasing to 32 days (p<0.001) for the routine period. TAT for venous dry blood spot samples increased by 3 days compared to 31 days for frozen plasma.
Conclusions: Introduction of routine viral loads increased available VL results for patients on ART but reduced the proportion available to priority patients and prolonged their TAT. The effect of the new guidelines on TAT was more pronounced for frozen plasma than venous dry blood spot samples. Careful planning is essential prior to VL scale-up to minimize negative effects on target patient populations.

MOPED1177

Evaluation of routine viral load monitoring during pregnancy at antenatal clinics in South Africa

M. Lesosky[1], N.-Y. Hsiao[2,3], E. Mukonda[1], T. Glass[1], L. Myer[4,5]
[1]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [2]National Health Laboratory Services, Cape Town, South Africa, [3]University of Cape Town, Division of Medical Virology, Cape Town, South Africa, [4]University of Cape Town, Division of Epidemiology & Biostatistics, School of Public Health & Family Medicine, Cape Town, South Africa, [5]University of Cape Town, Centre for Infectious Disease Epidemiology & Research, Cape Town, South Africa

Background: Global targets for antiretroviral therapy (ART) programmes call for ≥ 90% of patients on ART with VL < 1000cps/mL. However there are few insights into progress towards this goal among pregnant women despite the importance of viral control for PMTCT and maternal health. We examined levels of VL < 1000cps/mL among pregnant women on ART attending public sector antenatal clinics (ANC) in the Western Cape province of South Africa.
Methods: Routinely collected public sector VL monitoring data from the South African National Health Laboratory Service were examined from 8 primary care ANC clinics from 2009-2015. In this setting VL monitoring is routinely conducted in women at their first ANC visit (for women on ART prior to pregnancy) or 12-16 weeks after ART initiation (for women initiating during pregnancy). Analyses examined time trends in the proportion of women with VL< 1000cps/mL by patient age and ART status (initiation prior to versus during pregnancy).
Results: Among 6017 women (7529 VL tests) the median (IQR) age was 30 (26-34) years. The proportion of women initiating ART prior to pregnancy increased from 11% in 2009-2010 to 42% in 2014-2015. The number of VL tests/month increased from < 100 in 2009 to >300 in 2015. After excluding repeat tests, the aggregate rate of VL< 1000cps/mL was 84.7%, and was slightly lower in women initiating ART in pregnancy (83.3%) versus women initiating prior to pregnancy (86.2%). For both ART status groups, younger women had significantly lower levels of VL < 1000cps/mL (Figure; p< 0.001).
Conclusions: Against a background of rapid scale-up of VL monitoring during pregnancy in this setting, levels of viral control in pregnant women appear below global targets, raising concerns for MTCT and maternal health. In particular, young women initiating ART in pregnancy are at persistently increased risk for elevated VL and may require special programmatic consideration.

MOPED1178

Progress towards achievement of the UNAIDS 3rd 90 in Zimbabwe: capacity and functionality of viral load monitoring in 22 districts

T. Maphosa[1], K. Webb[1], V. Chitiyo[1], S. Page[1], J. Murungu[2], B. Engelsmann[1], P. Nesara[1], D. Patel[1]
[1]Organisation for Public Health Interventions and Development, Harare, Zimbabwe, [2]Ministry of Health and Child Care, AIDS and TB Program, Harare, Zimbabwe
Presenting author email: tmaphosa@ophid.co.zw

Background: Zimbabwe is one of the 22 high burden countries that adopted the UNAIDS targets, and launched a viral laod (VL) scale up plan in 2015. The plan provides a road map to scale up VL monitoring from 3% in 2015 to 70% by the end of 2017 and 90% by 2018. To aid the Ministry of Health and Child Care in its efforts, the Organization of Public Health Interventions and Development (OPHID) conducted an assessment establishing existing capacity and functionality of VL monitoring in Zimbabwe.
Methods: In May 2016 data on the current availability of VL monitoring, functionality of equipment human resource capacity and existing bottlenecks was collected in 22 purposively sampled districts. Stata V12 was used to conduct the descriptive analysis.
Results: At time of survey, 50% (11/22) of districts were not collecting samples for VL monitoring. High variability across districts was observed in VL sample transportation and result notification systems, mostly being partner dependent. None of the districts implementing VL had standard operating procedures on who can interpret VL results and initiate switch to second line regimens. Less than 5% of the health workers in post were trained in VL sample collection and result interpretation. No district indicated health care workers are "confident at interpretation of VL results". Only 18% (4/22) districts and 33% (1/3) of the labs surveyed were aware of their annual viral load target.
Conclusions: Our assessment revealed limited availability and capacity to conduct VL monitoring in 22 districts serving 367,399 people on ART. There is an urgent need to support MOHCC to make VL testing available, accessible and affordable for PLHIV on ART to reach the 3rd 90 in Zimbabwe. Standardization of VL sample transportation must be prioritized. We recommend viral load machine capacity utilization analysis be conducted to improve optimization. Improved communication of national policies and targets to provincial, district and site level is needed to achieve VL scale up. Expansion of VL monitoring and capacity building health workers should be simultaneously.

MOPED1179

Performance characteristics of a new commercial assay for HCV RNA viral load quantification in plasma: preliminary results in Cambodia

J. Nouhin[1], S. Prak[1], S. Heng[2], A. Kerleguer[2], F. Rouet[1]
[1]Pasteur Institute in Cambodia, HIV/Hepatitis Unit, Phnom Penh, Cambodia, [2]Pasteur Institute in Cambodia, Clinical Biology Laboratory, Phnom Penh, Cambodia
Presenting author email: njanin@pasteur-kh.org

Background: Since 2016, direct-acting antivirals (DAA)-based treatments for hepatitis C are available in Cambodia. Therefore, there is an urgent need for low-cost hepatitis C virus (HCV) RNA viral load (VL) assays for identifying subjects with active HCV infection and for monitoring of treatment efficacy. Here we report the performance in Cambodia of the OMUNIS PUMA HCV kit (Omunis, Clapiers, France), a new commercial HCV RNA VL test using an open real-time PCR machine, on plasma harboring mainly HCV genotype 6.
Methods: The evaluation was conducted on 101 plasma specimens collected and stored at -80°C between 2015 and 2016 at Pasteur Institute in Cambodia. After a manual Qiagen extraction (QIAamp Viral RNA Mini kit) with 140 ml of plasma, the real-time OMUNIS HCV RNA PCR amplification was done by targeting the 5' UTR region of the HCV genome. The lower limit of quantification of the test was 70 IU/mL. Results of the OMUNIS test were compared with those obtained using the fully automated closed Roche platform (Roche Cobas AmpliPrep/Cobas TaqMan HCV Test, v2.0) used as gold standard. HCV genotyping was performed from the same Qiagen extracts in the NS5B region for samples with detectable HCV RNA VL.
Results: All 76 (100%) plasma samples that had detectable HCV RNA VL with the Roche TaqMan HCV kit showed detectable VL results with the Omunis PUMA HCV assay. Results were highly correlated (correlation coefficient R = 0.87) between the two techniques, with a median difference of -0.4 log IU/mL. HCV genotype distribution was as follows: genotype 6 (55%, mostly subtype 6e), genotype 1b (31%), genotype 2a (12%), and genotype 1a (2%). Of 25 plasma samples that were undetectable with the Roche test, 25 (100%) were also undetectable with the OMUNIS assay.

Conclusions: This new low-cost (around 25-30 USD per test) HCV RNA assay should be further evaluated/used in resource-limited countries where the prohibitive cost for HCV RNA VL measurement is currently a barrier for monitoring viremic HCV-infected patients treated with DAA.

MOPED1180

Plasma IP-10 levels as a surrogate of virological failure in treated HIV-patients

L. Pastor[1,2,3], A. Casellas[1], M. Rupérez[1,4], J. Carrillo[1,2], L. Luis[4], E. Macete[4], R. Paredes[2,5,6], J. Blanco[2,3,5], D. Naniche[1]
[1]ISGlobal, Barcelona Centre for International Health Research (CRESIB), Hospital Clínic-Universitat de Barcelona, Barcelona, Spain, [2]AIDS Research Institute-IrsiCaixa, Hospital Germans Trias i Pujol, Badalona, Spain, [3]Institut Germans Trias i Pujol (IGTP), Hospital Germans Trias i Pujol, Universitat Autonoma de Barcelona, Badalona, Spain, [4]Centro de Investigação em Saúde da Manhiça (CISM), Maputo, Mozambique, [5]Universitat de Vic - Universitat Central de Catalunya, Barcelona, Spain, [6]Llu, Badalona, Spain
Presenting author email: lucia.pastor@isglobal.org

Background: As anti-retroviral treatment (ART) coverage continues to increase, achieving effective first-line ART monitoring is a key determinant to optimize HIV management, reduce further transmissions and achieve the global target of 90% viral suppression. The gold standard for detecting virological failure is plasma viral load (VL) determination; however its availability is very limited in low-income countries. We hypothesized that because of its association with VL, IP-10 levels could be a surrogate marker of potential virological failure in ART-treated individuals, representing an affordable tool in low-income countries.
Methods: HIV-1-infected adults on first-line ART for at least 1 year attending routine visits in the Manhiça District Hospital, Mozambique, were evaluated for virological failure in a cross-sectional study conducted in 2013. Plasma levels of IP-10 were quantified by ELISA. From the total sample, 80% was used for model construction and 20% for validation. Logistic regression with penalized likelihood was used to build a prediction model able to identify the cases, defined as individuals with VL>150 copies/mL. Receiver operating curves (ROC) from univariate and adjusted-multivariate models were compared for the best prediction.
Results: From the 319 ART-treated individuals analysed, 106 had detectable VL (33%) of which 81 (76%) had VL>1000copies/mL. Mean age was 41 years, 70% were females, median CD4 T-cell count was 441 (IQR 273-614) and median time on ART was 3.2 years (IQR 2.0-5.2). IP-10 levels were significantly different among patients with detectable (104.4pg/mL) and undetectable VL (39.2pg/mL) [d2] (U-test p< 0.0001). IP-10 levels demonstrated high accuracy for discrimination of cases in both the univariate and the multivariate model adjusted by CD4 T-cell count and days on ART (AUC>0.80). Both models showed substantial agreement of classification (kappa=0.68) so for practical use the univariate IP-10 model was considered. A cut-off value of IP-10≥43.6pg/mL provided the best classification performance, showing a sensitivity of 91.0% (95%CI 83.1-96.0) and specificity of 56.0% (95%CI 48.1-63.7) for detection of virological failure, which was confirmed in the validation set.
Conclusions: IP-10 is an affordable and easily quantifiable biomarker that can be used to pre-screen individuals on ART for treatment failure, reducing the number of VL determinations required to monitor ART in low-income countries.

MOPED1181

HIV viral load monitoring in four West and Central African countries: how is virological failure managed by caregivers in the OPP-ERA project ?

G. Breton[1], J. Ndawinz[1], P. Nimbona[2], O. Sylla[3], J.-J. Akamba[4], M. Mbangue[5], S. Doukou[6], A. Minga[7], H. Guidigbi[8], E. Nerrienet[9], M.S. Diallo[10], M. Cisse[10], A. Jousset[1], C. Rouzioux[11]

Presenting author email: jacques.ndawinz@solthis.org

Background: Since 2013, WHO recommends HIV viral load testing (VLT) as the preferred marker to monitor efficacy of antiretroviral therapy (ART). WHO recommendations include that patients with VL above 1000 copies/mL should be counselled to reinforce ART adherence and VL be retested after 3/6 months. Patients with a second VL remaining above 1000 copies/mL need a switch to a second line of ART. The OPP-ERA project supported the increased access of VLT in four West and Central African countries (Burundi, Cameroun, Guinea, Ivory Coast) with the aim to implement VLT and apply WHO VL guidelines for patient follow up, including for those with virological failure.
Methods: Patients data from 6 OPP-ERA laboratories, from August 2014 to March 2016 were analyzed using Stata 11.1. Chi square test were used for group comparison.
Results: A total of 31,286 patients have benefited from at least one VLT after a median ART duration time of 4 years (2-7). Most of them (89.7%) were on first line ART. For 6687 patients (21%), the first VL was >1000 cp/mL (that means virological success at 79%). Among them, 695 (10,4%) benefited from a second VLT; 1.1%, 2.9% and 6.4% had a second VLT < 3 months, 3 to 6 months and >6 months respectively. Among 620 (9.3%) patients (range 0 to 49% between health facilities, p<0,001) who have benefited from a second VLT more than 3 months after the initial VLT, virological failure was confirmed in 45% of cases (range 22% to 67% between health facilities, p< 0,001).
Conclusions: Despite good results of 79% virological success within the OPP-ERA project, management of patients with virological failure by caregivers remains challenging. Despite disparity between facilities., less than 1/10 of patients with virological failure has benefited from a VL control according to WHO recommendation. Furthermore, our data suggest that with the implementation of VLT and proper appropriation by caregivers, a high number of patients requiring a second line ART is likely to be identified. Therefore strengthening of caregivers skills is recommended for VL scale up, better HIV care management and adequate planning of second line ART needs.

Presenting author email: jacques.ndawinz@solthis.org

Background: Shortening the time to viral load (VL) undetectable threshold at 1000 copies/ml has positive implications in decreasing the risk of HIV morbidity, mortality and transmission. The aim of this study is to estimate the probability to achieve VL undetectability among ART patients who had first detectable VL at enrollment, within the OPP-ERA project.
Methods: Data of antiretroviral treatment (ART) patients collected during the first 20 months in six OPP (open polyvalent platforms) laboratories located in Guinea, Cameroon, Burundi and Ivory Coast were examined. The analysis were restricted to patients with first VL measurement detectable at enrollment in OPP-ERA and having benefited from at least two VL. Kaplan Meir method was used to estimate the duration and probability to achieve VL undetectability and to compare these indicators between groups.
Results: About 35,000 VLT were performed for 31,300 patients with a median duration of 4 years on ART. Among them, 695 were included in the study for a total of 1538 VL. At enrollment, median age was 36 years (IQR: 27-45), 66% were women, median VL was 43,815 copies/ml (IQR: 7,155-276,093), 90% were on ART. Median time between two consecutives VL was shorter among patients initiating ART during OPP-ERA than before (5 versus 7 months, p< 0.001). The proportion of patients achieving VL undetectability within 6, 12 and 18 months after enrollment was, respectively, 14, 41 and 83%. The median time to achieving undetectable VL was 13 months. This median was shorter among patients initiating ART during OPP-ERA than before (8 versus 14 months, p< 0.0001). Probability to achieve VL undetectability was lower among patients with a VL >50,000 copies/ml at enrollment, compared to patient with < 50,000 copies/ml (p< 0.0001).
Conclusions: Time to achieve VL undetectability is longer than expected among these patients who are on ART since several years. However, patients who initiated ART during OPP-ERA achieve VL undetectability more rapidly, suggesting that earlier access to VL allows a closer virological monitoring that helps reinforcing adherence to ART and reduce risk of ART resistance.

Improving access to quality-assured HIV-related in vitro diagnostic medical devices through the transparency and strategic partnership of the Global Diagnostics Working Group

A. Sands[1], L. Vojnov[2], Global Diagnostics Working Group
[1]*World Health Organization, Essential Medicines and Health Products, Geneva, Switzerland,* [2]*World Health Organization, Geneva, Switzerland*
Presenting author email: vojnovl@who.int

Background: In the wake of a large product failure for a widely used HIV rapid diagnostic test (RDT) in 2012, the lack of communication between implementing partners and procurers severely limited the response required by national testing programmes. When such uncoordinated actions are taken in response to product complaints, and when delays occur in quality assessments of IVDs, the impact on public health is immense. The GDWG consists of ASLM, US CDC, CHAI, Global Fund, MSF, UNICEF, UNITAID, USAID and WHO.
Methods: In order to respond swiftly to quality and regulatory issues, several members of the GDWG responsible for procurement or quality assurance of HIV-related IVDs are supporting a joint quality strategy with the aim of improving access to affordable, quality-assured HIV-related IVDs, while also creating a forum to cultivate transparency around the conditions and quality concerns of these products. WHO and USAID, along with the US CDC agreed to establish a joint quality assessment mechanism for HIV-related IVDs. Furthermore, GDWG members have agreed to establish a taskforce on post-market surveillance for IVDs. Lastly, GDWG members meet face-to-face twice per year, and by teleconference if matters of urgency permit.
Results: From January 2015 through to December 2016, three joint assessments have been successfully conducted (Aquios CL flow cytometer, Alere™ q HIV-1/2 Detect, Xpert® HIV-1 Qual Assay). These assessments were completed in half the time compared to the average time for WHO prequalification assessment in 2016. This method of joint assessment will ultimately lead to a common list of product approved for use by GDWG members. The GDWG has also been successful in identifying discrepancies in quality assurance policies among agencies, suggesting there is room for further collaboration in this area
Conclusions: The formation of the GDWG for HIV-related IVDs has enhanced collaborating, collective knowledge and transparency on changes to products already approved for procurement, as well as acted as a platform to exchange information and coordinate when product concerns arise. As new diagnostics come to market and the trend towards decentralization continues, transparency and strategic partnership will be critical to ensure quality IVDs reach the people who need them most.

Presenting author email: fern.terris-prestholt@lshtm.ac.uk

Background: Decentralised early infant diagnosis (EID) of HIV using point-of-care testing (POCT) has the potential to narrow current testing gaps, which ranges from 13% to 58% across Kenya, South Africa, Uganda and Zimbabwe. However, without external quality assurance (EQA) systems, POCT can lead to potentially high mis-diagnosis rates. EQA programmes aim to assess the provider proficiency in performing POCT and identify critical gaps in the laboratory systems. Problems identified are addressed through corrective actions. We are the first to model the cost-effectiveness of EQA programmes, with application to POCT EID in these countries, representing varying HIV epidemics and health systems.
Methods: Countries were brought together to develop a national EQA programme and estimated costs related to implementing these programmes using a bottom-up costing approach, including start-up and recurrent costs. Optimal POCT performance was estimated using published data on sensitivity (98.5%) and specificity (99.9%), while a suboptimal programme without EQA was conservatively modelled using lower confidence bounds (sensitivity 91.7% and specificity 99.3%). Assuming EQA improves programmes to optimal performance, $/DALY averted was modelled. Potential for a 1-year EQA programme to avert missed HIV infections, false positive diagnoses and unnecessary treatment costs over 20-years was modelled from observed clinical EID POCT performance from published studies.
Results: The national annual incremental cost of EQA, including corrective action ranged from US$100,000 in Kenya to $365,000 in Zimbabwe. Even in optimal testing scenarios, misdiagnosis rates are estimated around 0.3%. Without EQA, the misdiagnosis in the deteriorated programme ranged from 1.4% in Uganda to 1.7% in Zimbabwe, or 179 to 555 infants misdiagnosed annually in Kenya and South Africa, respectively. Adding EQA to POCT EID is cost-saving across all countries, i.e. the costs saved by averting unnecessary treatment exceeds the EQA programme costs.
Conclusions: Though EQA would initially require increased funding, it rapidly provides a positive return on investment by averting the costs of treating HIV-negative infants (potentially for life), and save lives by correctly identifying HIV-positive infants needing treatment. This study is the first to demonstrate the value of funding EQA programmes.

Background: Previous studies have shown that the emergence and proliferation of antigen-specific CD8+ T cells during early stages of HIV infection is associated with persistent antigenemia. Early initiation of combination antiretroviral therapy (cART) confers clinical benefit to HIV infected persons but the impact of cART on HIV-specific immune responses and the potential for recall or boosting of these responses is unknown. In this study, we evaluated the maintenance of CD8+ T cell responses longitudinally in early treated individuals with hyperacute HIV-1 subtype C infection.
Methods: Samples of young females identified with acute HIV-1 infection (HIV PCR positive, antibody negative) who initiated cART very early and untreated patients were used. The magnitude, breadth and maintenance of HIV-1 specific CD8+ T cell responses were defined using IFN-gamma ex vivo ELISPOT and cultured ELISPOT. Also, the phenotype (HLA-DR, CD38, CD127) and functional (IFN-gamma) characteristics of tetramer specific CD8+ T cells were investigated using MHC class I tetramers and intracellular cytokine staining (ICS).
Results: Early treated patients with hyperacute infection induced initial CD8+ T cell responses that coincided with a sharp drop in viremia and an increase in CD4 counts. These early induced CD8+ T cell responses were however low in magnitude (144.3 SFC/million PBMC) when compared to untreated patients [316.6 SFC/million PBMC (p=0. 009)]. Interestingly, compared to untreated patients, CD8+ T cells in early treated patients were less activated and had a high expression of CD127; thus suggesting a potential for long term survival of these responses. Additionally, memory responses specific to HIV-1 measured at later stages (six months onwards) of infection were maintained in these treated patients as indicated by cultured ELISPOT assays.
Conclusions: Summarily, our results demonstrate that early initiation of cART led to an induction of CD8+ T cell responses that were less activated and had higher potential for long term survival. These responses were also maintained as memory responses which may be recalled rapidly upon re-stimulation with HIV-1 antigens. This data may offer insight in implementing novel therapeutic strategies in order to enhance protective immunity and promote control of viral replication post treatment interruption.

Presenting author email: cpereira@pasteur.fr

Background: Natural control of infection has been associated with efficient HIV/SIV-specific CD8+T-cell responses. However, the determinants leading to the development of such responses and the role of protective HLA alleles are still unclear.
Methods: We monitored for 18 months 16 Mauritius Cynomolgus macaques (CM) after infection with SIVmac251 and studied immunological and virological events leading to durable control of infection. CM receiving a low viral dose (nonH6 $5AID_{50}$, n=4) or carrying the protective H6 MHC haplotype (H6 50AID50, n=6), both conditions leading frequently to control of viremia, were compared to H6-negative CM exposed to the higher dose of the virus (nonH6 50AID50, n=6).
Results: Twelve CM spontaneously controlled plasma viremia (VL) below 400 SIV-RNA copies at 6 months p.i. No differences were found in VL or SIV-DNA in blood at the VL peak (day 15 p.i.) between SIV controllers (SIC) and non-controllers, but these levels correlated with levels during the chronic phase, and controllers had a faster viral decline to set point. SIC had lower levels of SIV-DNA in lymph nodes at day 15 and in all tissues analyzed at the end of the study. SIC and non-controllers had a different cytokine profile during the follow up. All animals developed SIV-specific CD8 T-cell responses (measured by ICS) coinciding with the start of VL decline at primary infection, however no differences could be found between SIC and non-controllers. In contrast, an efficient capacity of CD8 T-cells to eliminate infected CD4 T-cells was developed preferentially in SIC (both H6 and nonH6) and its magnitude increased overtime coinciding with the establishment of elite control. Moreover, SIV-suppressive capacity of CD8+ T-cells at day 15 and 70 p.i. negatively correlated with VL at day 15 (in the first case) and at the end of the study (in both cases). This activity was stronger in SIC at the end of the study in all tissues.
Conclusions: We provide here unprecedented insight into the dynamic development of effective CD8 T-cell responses against SIV. Initial enhanced capacities of CD8 T-cells to suppress SIV infection shaped viral levels during primary infection and increased over time until reaching levels allowing viral control.

Background: How CD8+ T-cells control virus during HIV infection is not understood. We hypothesized that the main effect of CD8+ T-cells occurs before viral integration, due to minimal direct viral cytopathic effects. We developed a model of viral dynamics with pre- and post-integration stages to study the effect of CD8+ T-cell depletion. Model predictions were tested in SIV-infected rhesus macaques (RMs) receiving integrase inhibitor raltegravir (RAL) monotherapy with or without CD8+ T cells.
Methods: Sixteen SIVmac251-infected RMs were treated with both RAL and CD8-depleting antibody M-T807R1 (RD), or just RAL (R) and followed, with RAL treatment interrupted after 23 days. Plasma viral loads (VLs) were measured by qRT-PCR. T-cell counts and immune activation were monitored flow-cytometrically. We analyzed the VLs during the first ~12 days following RAL initiation using a viral dynamics model including infected cells pre- and post-viral DNA integration. We fitted the model to the data using a nonlinear mixed effect model to estimate the death rate of infected cells pre- and post-virus integration and the efficacy of RAL.
Results: CD8+ T-cell depletion was profound and lasted throughout RAL therapy. Depletion of CD8+ T-cells led to an increase in VL prior to the start of therapy. Macaques receiving just RAL treatment had much greater decays in VL than those treated with RAL and the CD8-depleting antibody. The latter group had small decays or rebounded early during RAL therapy. From the fits of the model, we estimated the efficacy of RAL in blocking integration at 96.3%, the half-life of virus-producing cells at ~13h, and a different loss rate of infected cells pre-integration in the two groups (0.0016/day vs. 0.19/day, for DR and R groups respectively). A model allowing for these different loss rates was better than a model with a common loss rate for both groups (p=0.0001).
Conclusions: Use of RAL monotherapy revealed that the turnover of infected cells pre-integration has a half-life of about 3.6 days. However, in the absence of CD8+ T-cells, this half-life reaches >100 days. These results suggest that CD8+ T-cells have a strong cytolytic effect on infected cells before viral integration.

TUAA0104

Memory-like NK cells exploit innate priming and alternative signaling mechanisms to enhance function and mobilize at HIV/SIV mucosal portals of entry

S. Shah, C. Manickam, A. Jimenez, R.K. Reeves

Presenting author email: roger_reeves@hms.harvard.edu

Background: Burgeoning evidence indicates a broader functional repertoire for NK cells beyond innate immunity including memory and other memory-like functions. One recent example is memory-like NK cells identified by lack of the FcR intracellular γ-signaling chain (FcRΔg-NK cells) which still require antibody to grant antigen-specificity, but are pre-sensitized and capable of rapid mobilization and more robust responses against viral antigens. Interestingly, FcRΔg-NK cells are initially expanded by huCMV infection as part of innate-priming, but can execute memory-like killing against other pathogens through incompletely understood mechanisms.
Methods: Sixty rhesus macaques were used in this study: twenty-one specific pathogen-free, rhCMV-; 10 rhCMV+ but otherwise experimentally naïve; and 22 chronically SIVmac-infected macaques. Samples were analyzed from 10 naïve and 10 untreated HIV-infected human subjects. NK cell analyses were performed using polychromatic and phospho- flow cytometric phenotypic and functional assays.
Results: FcRΔg-NK cells were systemically distributed in mucosal and secondary lymphoid organs, but, correlating with viral load, increased two- and four-fold in CMV+ and HIV/SIV-infected individuals, including the GI tract. CD16 and α4β7 were concomitantly upregulated in infection suggesting innate memory-like priming is required for both antibody-dependent functional potency and mucosal homing. FcRΔg-NK cells displayed little difference in binding affinity to virus-antibody immunocomplexes compared to traditional NK cells, but exhibit two-fold more robust IFN-γ secretion and cytotoxicity, suggesting disparate signaling or activation could account for improved function. To that end, FcRΔg-NK cells showed significantly reduced expression of Helios and Eomes — indicative of a broader functional repertoire and/or epigenetic modification, and clustered independently from traditional NK cells in 20-parameter analyses via multidimensional t-SNE. The γ-chain adaptor, Syk, was reduced or inactively dephosphorylated in FcRΔg-NK cells, but expression of ζ-chain, which is phosphorylated by adaptor Zap70, was significantly upregulated, suggesting these cells may exploit the ζ-chain/Zap70 pathway in the absence of γ-chain/Syk to achieve greater functional potency.
Conclusions: Collectively, our work presents the first description of a combinatorial mechanism of innate-priming and alternative signaling cascade to explain the functional potency of memory-like phenomena of NK cells mobilizing in the mucosae against HIV/ SIV. Future studies harnessing memory-like NK cells could create exciting modalities for both vaccine and curative therapies.

The human penis is an immunologically active tissue: a preliminary study on the development of an HIV vaccine

A. Sennepin[1,2,3], F. Real[1,2,3], M. Duvivier[1,2,3], Y. Ganor[1,2,3], S. Henry[1,2,3], D. Damotte[4], M. Revol[5], S. Cristofari[5], M. Bomsel[1,2,3]
[1]Cochin Institute, INSERM U1016, Department of Mucosal Entry of HIV-1 and Mucosal Immunity, Cell Biology, and Host Pathogen Interactions, Paris, France, [2]CNRS, UMR 8104, Paris, France, [3]Paris Descartes University, Sorbonne Paris Cite, Paris, France, [4]GH Cochin-Saint Vincent de Paul, Anatomy and Pathological Cytology Service, Paris, France, [5]Saint Louis Hospital, Plastic Surgery Service, Paris, France
Presenting author email: alexis.sennepin@inserm.fr

Background: HIV-1 is primarily sexually transmitted. We have shown that the human penis, including the foreskin but also the urethra, fossa navicularis and glans, is one of the main portal of entry for the virus. Unlike other mucosa, the penile immune system and mechanisms that induce a penile immune response remain unclear, most likely due to the difficulty to access human tissues. Our previous studies demonstrated that the male urethra contains macrophages, the main targets of HIV-1, as well as memory T cells. These studies relied on morphologic analyses, and thus failed to provide a comprehensive phenotype. To asses the role of these mucosal immune cells, that are a prerequisite to the elaboration of efficient preventive strategies against HIV-1, we therefore characterize extensively the immune profile of immune cells of the different penile regions.
Methods: Single cell suspensions were prepared for each region of 32 penile tissues collected from individuals undergoing transgender surgery and analyzed by multi-parametric flow cytometry. The expression patterns of memory, activating and homing receptors of B and T lymphocytes were evaluated as well as that of NK cells. In complement, the tissue distribution of each of these immune populations in the different penile compartments was also studied morphologically.
Results: In all penile compartments, CD3-/CD19+ B cells represent around 2% of CD45+ cells and >50% B cells display CD27 and FcRL4 receptors thus harbor a memory phenotype. However, < 5 % are IgG+ or IgA+ and thus able to secrete antibodies in the lamina propria. TCD4+ and TCD8+ lymphocytes represent the major populations of CD45+ cells, with 90% with a CD38-/HLADR-/CCR7-/CD45RA- resting effector memory phenotype (T_{EM}). These resting T_{EM} cells reside in all penile region epithelium and lamina propria but lack CD103+ resident phenotype. Furthermore, all penile compartments contain low numbers of CD3-/ CD56+ NK cells capable of antibody-dependent cell-cytotoxicity and surface-expressing the NKp44 receptor indicative of activation.
Conclusions: Altogether, the human penis is an immunologically active tissue including the cellular machinery required to induce/produce a specific and effective immune response against mucosal pathogen. This must be taken considered when elaborating efficient vaccine strategies against HIV-1.

TUAB01 Antiretroviral Therapy - ART: Season Two

TUAB0101

Efficacy and safety of switching from boosted-protease inhibitor plus emtricitabine/tenofovir disoproxil fumarate regimens to the single-tablet regimen of darunavir/cobicistat/emtricitabine/tenofovir alafenamide (D/C/F/TAF) in virologically-suppressed, HIV-1-infected adults through 24 weeks: EMERALD study

J.-M. Molina[1], J. Gallant[2], C. Orkin[3], E. Negredo[4], L. Bhatti[5], J. Gathe[6], E. Van Landuyt[7], E. Lathouwers[7], V. Hufkens[7], S. Vanveggel[7], M. Opsomer[7]
[1]University of Paris 7, Denis Diderot, Paris, France, [2]Southwest CARE Center, Santa Fe, United States, [3]Barts and Health NHS Trust, London, United Kingdom, [4]Germans Trias i Pujol University Hospital, Badalona, Spain, [5]AIDS Healthcare Foundation, Beverly Hills, United States, [6]Therapeutic Concepts, Houston, United States, [7]Janssen Pharmaceuticals NV, Beerse, Belgium
Presenting author email: jean-michel.molina@aphp.fr

Background: D/C/F/TAF, a once-daily, single-tablet regimen containing darunavir (D 800mg), cobicistat (C 150mg), emtricitabine (F 200mg) and tenofovir alafenamide (TAF 10mg), is undergoing investigation in two Phase 3 studies, EMERALD (NCT02269917) and AMBER (NCT02431247).
Methods: EMERALD, a randomized (2:1), open-label, international, multicenter, parallel-group, non-inferiority, 48-week study, is evaluating the efficacy and safety of switching to D/C/F/TAF vs continuing a boosted protease inhibitor plus emtricitabine/TDF (control) in patients who are virologically suppressed [viral load (VL)< 50c/mL] for ≥2 months. FDA-stipulated primary endpoint is proportion with cumulative virologic rebound (confirmed VL≥50c/mL or premature discontinuations, with last VL≥50c/mL) through Week 48 (non-inferiority margin=4%). Pre-planned Week 24 interim results are presented.
Results: 1141 patients were randomized and treated (N=763 D/C/F/TAF vs N=378 control). Baseline characteristics: median age 46; 18% women; 25% non-white (21% black); 10% CD4+< 350 cells/mm^3; 71%, 22%, and 8% on darunavir, atazanavir and lopinavir, respectively (15% on cobicistat). Cumulative virologic rebound was 1.8% (n=14 D/C/F/TAF) vs 2.1% (n=8 control), of which 10/14 and 5/8 respectively, resuppressed (< 50c/mL) by Week 24; there were no confirmed rebounds ≥200c/mL. At Week 24, FDA snapshot analysis showed virologic suppression (VL< 50c/mL) was 96.3% (D/C/F/TAF) and 95.5% (control), and virologic failure occurred in 0.5% and 0.8%, respectively, with no discontinuations for virologic failure and no detected resistance to any study drug.
Safety was similar between arms through 24 weeks, with low incidences of Grade 3-4 adverse events (AEs) (D/C/F/TAF 4.5% vs control 4.5%), serious AEs (2.6% vs 3.2%), and treatment discontinuations (overall, 2.9% vs 2.9%; due to AEs, 1.4% vs 1.1%). The most common AEs (≥5% both arms) were: nasopharyngitis (7.6% vs 6.6%), URI (6.3% vs 6.3%), vitamin D deficiency (5.5% vs 5%). There were no deaths. Total cholesterol/HDL-cholesterol ratios were similar between arms, with minimal changes from baseline. Changes from baseline in renal safety parameters were consistent with known profiles of the individual D/C/F/TAF components; Mean ΔeGFR (cystatin-C clearance by CKD-EPI): +0.3mL/min/1.73m^2 (D/C/F/TAF) vs. -1.0mL/min/1.73m^2 (control).
Conclusions: In virologically suppressed adults, switching to once-daily D/C/F/TAF was well tolerated, resulted in a low cumulative virologic rebound rate, and a high virologic suppression rate through 24 weeks.

TUAB0102

Switching from a boosted protease inhibitor (PI/r) based regimen to a dolutegravir regimen in virologically suppressed patients with high cardiovascular risk or age ≥50 years is non-inferior and decreases lipids

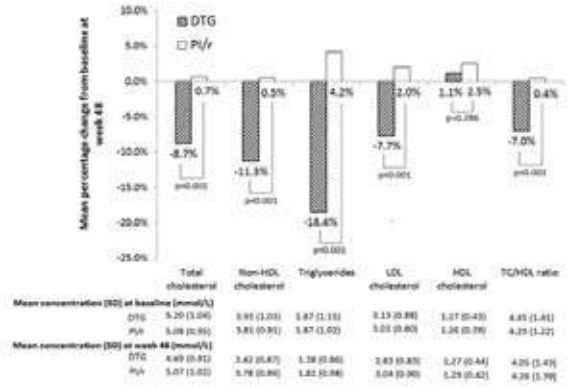
Background: Switching from a PI/r to dolutegravir (DTG) may improve convenience and lipid profile.
Methods: NEAT022-NCT02098837 is a European, open label, randomized, non-inferiority trial. HIV-infected adults ≥ 50 years or with a Framingham score ≥10% were eligible if HIV RNA <50 copies/mL for at least 24 weeks while on a PI/r regimen. Patients were randomized (1:1) to switch to DTG or to remain on PI/r. Primary end-points were: proportion of patients with HIV RNA <50 copies/ml at week 48 and a non-inferiority margin of -10% and percentage change of total plasma cholesterol. Secondary end-points included changes in other plasma lipid fractions, and adverse events.
Results: 415 patients were randomized: 205 to DTG and 210 to continue PI/r. 89% were men, 87 % were ≥50 years, 74 % had a Framingham score >10%, and suppressed viremia for a median of 5 years. At week 48, in the ITT analysis, treatment success rate was 93% in DTG arm and 95% in PI/r arm (difference -2.0%, 95%CI -6.5 to 2.6, non-inferiority demonstrated). There were 4 virological failures with DTG (from 58 to 130 copies) and 1 with PI/r (3,373 copies) without selection of resistance. There was no significant difference in terms of grade 3 or 4 AE´s or treatment modifying AE´s (7 in DTG arm -of whom 6 due to mood disturbances or insomnia- and 3 PI/r arm). Total cholesterol and other lipid fractions (except HDL) significantly (p<0.001) improved in the DTG arm overall



[Fig 1. Changes in lipid fractions at 48 weeks]

and in all baseline PI/r strata. About 30 % were on lipid lowering agents at weeks 0 and 48 in each arm.
Conclusions: Switching from a PI/r based regimen to a DTG regimen in virologically suppressed HIV patients ≥ 50 years old or with a Framingham score ≥10% was non-inferior, well tolerated and improved the lipid profile.

TUAB0103

Efficacy of dual therapy with protease inhibitors plus lamivudine as maintenance treatment in HIV-positive patients on second-line in Africa: the ANRS 12286/MOBIDIP trial 96 weeks results

Background: In the MOBIDIP trial, dual therapy with boosted protease inhibitors (bPI) plus lamivudine showed superiority to bPI monotherapy in maintenance of virologically controlled HIV positive patients on second line antiretroviral treatment (ART) at 48 weeks. At week 48, the monotherapy arm was interrupted on DSMB advice and patients on dual therapy continued their follow up until week 96. Here we present the results of the dual therapy arm at 96 weeks.
Methods: This open label trial, conducted in Cameroon, Senegal and Burkina Faso, randomized 265 patients on stable PI plus NRTIs second line ART with HIV1 RNA (VL) < 200 copies/ml, CD4>100 cell/mm3 and adherence >90%, to receive ongoing ritonavir-boosted PI (darunavir or lopinavir) or on going bPI plus lamivudine. The main outcome was failure rate at 96 weeks in the intention to treat (ITT) population. Failure was defined as 1) a confirmed VL above 500 copies/ml (VF), 2) reintroduction of the NRTI backbone or 3) interruption of bPI.
Results: At inclusion, the 132 patients in the dual arm were mainly women (70%), median CD4 was 472 (IQR 360-621) cell/mm3, 83% had VL <50 copies/ml, median time on second line was 38 (IQR 30-47) months, PI was darunavir (one third) or lopinavir (two third). At first line failure, 97% had the M184V mutation.
At 96 weeks, in ITT analysis, 8.3% (IC95% 4.2-14.4%) patients failed in the dual arm (8 VF, 1 death, 2 lost to follow-up). Median delay to failure was 60 weeks. Three/4 patients who reintroduced tenofovir had VL <200 copies/ml in a median time of 13 weeks.
At 96 weeks, 79% and 91% of patients had VL below 50 and 200 copies/ml respectively.
Median increase in CD4 was 62 cell/mm3. We registered 28 severe adverse events, 1 in relation with study drugs. No significant changes in metabolic parameters were observed.
Conclusions: After viral suppression with bPI plus NRTIs in second line therapy, maintenance with bPI plus lamivudine is associated with a high rate of long-term success despite the presence of M184V mutation.

TUAC01 Updates from PrEP Clinical Trials

Presenting author email: s.mccormack@ucl.ac.uk

Background: The PROUD trial clearly demonstrated the clinical effectiveness of TDF/FTC in the first year of use. The continued follow-up of participants on PrEP (range 2-4 years), which included regular testing for HIV and other STIS, allows assessment on whether effectiveness is maintained in the longer term and the extent of potential exposure to HIV.
Methods: PROUD was a pragmatic trial in which MSM were randomised to receive daily TDF/FTC either immediately (IMM) or after a deferral (DEF) period of 12 months. Main efficacy findings were based on follow-up during the deferred phase when IMM had access to PrEP and DEF did not. Since Nov 14, when all participants were offered PrEP, the trial has entered a post-deferred phase. We compare incidence rates of HIV and selective STIs during the deferred and post-deferred phases.
Results: 524(269 IMM, 255 DEF) and 449(244 IMM, 205 DEF) participants contributed to the deferred and post-deferred phases. Of 368 who attended a clinic in the last 6 months of follow-up, 327(89%) had at least one PrEP prescription. HIV and rectal gonorrhoea(rGC)/chlamydia(rCT) incidence in each phase is shown by group in the table.

	Deferred Phase		Post-deferred Phase	
Infection	**IMM**	**DEF**	**IMM**	**DEF**
HIV	1.6 (4/254)	9.4 (21/223)	1.2 (5/423)	0.3 (1/353)
Rectal GC	35.3 (81/229)	33.1 (67/203)	31.4 (129/411)	32.7 (116/355)
Rectal CT	33.6 (77/229)	21.2 (43/203)	33.1 (136/411)	29.9 (106/355)

[HIV and STI incidence (per 100 PY)]

There was no difference in HIV incidence between the groups in the post-deferred phase (p=0.18), but a significant decrease in the DEF group once they had access to PrEP (p< 0.0001). The rate in the IMM group remained similar in the two phases (p=0.66). The incidence of rectal infections was high in both groups and phases. rCT was lowest in the DEF group during the deferred phase, and this was driven by those who did not report rCT in the year before enrolment.
Conclusions: The reduction in HIV incidence in the DEF group confirms the remarkable effectiveness of TDF/FTC. The relatively stable incidence in the IMM group indicates this effect is durable. High ongoing incidence of rCT/rGC shows that participants remained at high risk of HIV and this needs to be taken into account when planning PrEP provision in public health programmes.

On-demand PrEP with TDF/FTC remains highly effective among MSM with infrequent sexual intercourse: a sub-study of the ANRS IPERGAY trial

Presenting author email: guillemette.antoni@inserm.fr

Background: The ANRS IPERGAY trial demonstrated among MSM a 86% relative reduction of HIV-1 incidence with on demand PrEP in the TDF/FTC arm (2 infections, 219 person-years (py) of follow-up (FU), incidence: 0.91/100 py) as compared to the placebo arm (14 infections, 212 py of FU, incidence: 6.60/100 py). Participants in this trial used a median of 15 pills /month and had a median of 10 sexual intercourse /month. We wished to investigate whether on demand PrEP remained effective among participants having less frequent sexual intercourse and using fewer pills.
Methods: Assuming that participants with less frequent sexual intercourse would use fewer pills, and because individual patterns of pill use showed large intra-participant variability over time, we focused our analysis on person-time between 2 consecutive visits when participants used ≤15 pills /month and PrEP was used "systematically or often" during sexual intercourse, and not "from time to time or never". We then cumulated in each arm FU time spent with this pattern of pill use. A 4th generation HIV-1/2 ELISA assay was performed at each visit allowing to date the time of HIV-infection. Incidence rates of HIV-infection/100 py in both arms were then compared using mid-p exact test.
Results: Six HIV-1 infections occurred during FU among participants using ≤15 pills/month taken "systematically or often" during sexual intercourse: 6 in the placebo arm (incidence: 9.3/100 py, total FU time: 64.8 py) and 0 in the TDF/FTC arm (incidence: 0/100 py, total FU time: 68.9 py, p=0.013). The relative reduction of HIV incidence was 100% (95% CI: 20-100). During these follow-up periods, a median of 5 (IQR: 2-10) sexual intercourse/month were reported and a median of 9.5 (IQR: 6-13) pills/month were used. Restricting the analysis to periods when participants reported at least one condomless sexual act yielded similar results with HIV incidence of 12.3/100 py in the placebo arm (6 infections, 48.8 py of FU) and 0/100 py in the TDF/FTC arm (0 infection, 54.3 py of FU, p=0.011).
Conclusions: On-demand PrEP with TDF/FTC remains highly effective in MSM having infrequent sexual intercourse.

Presenting author email: imcgowan@pitt.edu

Background: Long-acting (LA) injectable formulations of antiretroviral agents are being developed for HIV-1 prevention. The MWRI-01 Phase 1 study was undertaken to characterize the safety, acceptability, pharmacokinetic (PK), and pharmacodynamic (PD) profile of LA rilpivirine (RPV). Single dose (SD) data have previously been reported (McGowan I et al. Lancet HIV 2016). We now present data on the multiple dose (MD) phase of the study.
Methods: HIV-1 uninfected participants received three intramuscular doses of 1200 mg LA RPV at 2 month intervals. We collected plasma, genital/rectal fluids, and tissue (rectal (RT), cervical (CT), and vaginal (VT)) before and after exposure to LA RPV for assessment of PK and PD (ex vivo biopsy challenge with HIV-1). Clade B (HIV-1_{BaL}) and Clade C (G147-1) viruses were used separately in the explant

challenge model. The primary study objective was to characterize product safety and the analysis included all enrolled participants.
Results: We enrolled 8 women and 4 men. There were 195 adverse events reported, of which 193 (99%) were Grade 1 (71%) or Grade 2 (28%) and the majority were related to injection site discomfort. Table 1 provides the PK values (geometric mean; 90% CI) for each compartment 56 days after dosing.

	Plasma		RT		VT	CT
	Women	Men	Women	Men	Women	Women
Dose 1	39 (33-45)	29 (17-40)	46 (34-53)	29 (17-40)	22 (14-29)	28 (23-33)
Dose 3	59 (45-73)	40 (30-51)	61(52-70)	40 (30-51)	40 (28-52)	44 (22-66)

[Table 1: PK Data 56 Days After Injection (ng/mL)]

We found significant suppression of viral replication in RT for both Clade B ($p<0.05$) and Clade C ($p<0{\cdot}0001$) viruses at all time points in RT. In contrast, viral suppression was only seen in CT at Day 56 after the first dose of LA-RPV and at no time point for VT.
Conclusions: : MD administration of LA RPV was safe and well tolerated. As with our previous SD data, we saw prolonged suppression of viral replication in RT following exposure to LA RPV. Interestingly, despite modest accumulation of plasma RPV over time, there was minimal evidence of viral suppression in CT or VT.

TUAC0104

Impact of microbiota on female genital tissue and plasma concentrations of dapivirine

S. Hillier[1,2], L. Meyn[1], K. Bunge[1], M. Austin[2], B. Moncla[1,2], C. Dezzutti[1,2], B. Devlin[3], M. Marzinke[4], C. Hendrix[4], L. Rohan[2,5]
[1]University of Pittsburgh, Obstetrics, Gynecology and Reproductive Sciences, Pittsburgh, United States, [2]Magee-Womens Research Institute, Pittsburgh, United States, [3]International Partnership for Microbicides, Silver Spring, United States, [4]Johns Hopkins University, Baltimore, United States, [5]University of Pittsburgh, Pharmaceutical Science, Pittsburgh, United States
Presenting author email: hillsl@mwri.magee.edu

Background: Women having a non-Lactobacillus dominant vaginal microbiota enrolled in CAPRISA 004 had lower detection of tenofovir (TFV) in cervicovaginal lavage (CVL) fluid than women having a Lactobacillus dominant microbiota. In FAME-04, decreased concentrations of TFV diphosphate in genital tissues and TFV in the plasma were highly correlated to higher Nugent score and increased vaginal concentrations of Gardnerella vaginalis and Atopobium vaginae. Vaginal rings containing dapivirine, a nonnucleoside reverse transcriptase inhibitor, have been shown to reduce incident HIV. The objective of this secondary analysis was to evaluate whether vaginal microbiota associated with bacterial vaginosis similarly impacted dapivirine concentrations in genital tract tissues and plasma following vaginal application.
Methods: 24 healthy HIV negative women (mean age 27, 58% white) used either dapivirine 0.05% gel (1.25 mg) or films (1.25 mg) for 6 days at home. On the 7th day, women inserted the final dose in the clinic with confirmation of correct product placement. Two hours later, cervical and vaginal biopsies along with CVL and plasma were obtained for dapivirine quantification using a validated liquid chromatography tandem mass spectrometry assay. Vaginal samples for diagnosis of bacterial vaginosis using the Nugent criteria and quantitative polymerase chain reaction (qPCR) detection of G. vaginalis and A. vaginae were collected prior to product use. The relationship between vaginal microbiota and dapivirine levels was assessed using linear regression models.
Results: There was no association between increasing concentrations of G. vaginalis in the vagina detected by qPCR and dapivirine concentrations in vaginal tissue, cervical tissue, CVL, or plasma ($p=0.45, 0.93, 0.51, 0.99$ respectively). Similarly, vaginal concentrations of A. vaginae were not associated with dapivirine concentrations in CVL, vaginal and cervical tissues or plasma ($p\geq0.31$). Nugent criteria associated with bacterial vaginosis were not associated with lower CVL, tissue or plasma concentrations of dapivirine ($p\geq0.19$).
Conclusions: In contrast to tenofovir, genital and plasma concentrations of dapivirine, were not impacted by increasing concentrations of vaginal bacteria associated with bacterial vaginosis. While replication of these results is needed, these data suggest that the levels of dapivirine following vaginal application should not be impacted by the microbiota associated with bacterial vaginosis.

TUAC0105

Experiences and perceptions of PrEP among gay and other men who sex with men (MSM) using PrEP in the PROUD study in England

M. Gafos[1], W. Nutland[2], S. Wayal[3], G. Bell[4], M. Rayment[5], C. Rae[5], S. McCormack[1], R. Horne[6]
[1]MRC Clinical Trials Unit at UCL, Institute of Clinical Trials & Methodology, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]UCL, London, United Kingdom, [4]She, Sheffield, United Kingdom, [5]Chelsea and Westminster Hospital NHS Foundation Trust, Directorate of HIV/GU Medicine, London, United Kingdom, [6]UCL, School of Pharmacy, London, United Kingdom
Presenting author email: m.gafos@ucl.ac.uk

Background: There are concerns that PrEP could increase risk compensation, especially reducing condom use. The PROUD study (Nov12-Nov16) reported an 86% reduction in HIV and no increase in STIs. We explore PROUD participants' experiences and perceptions of PrEP in relation to other risk reduction strategies.
Methods: We conducted semi-structured in-depth-interviews with 41 HIV-negative MSM, purposively selected based on self-reported high/low PrEP adherence and increased/same risk behaviour. Interviews were digitally recorded, transcribed and analysed using framework analysis.
Results: The majority of participants reported risk reduction strategies including occasional condom use, strategic positioning, or sero-sorting. Participants applied rules to their sexual behaviour, such as using condoms "if it was a one night stand", or not being receptive "outside of a relationship". Typically, PrEP was added to the existing set of ‚rules'. For some participants, PrEP allowed a relaxing of the rules, for example about strategic positioning: "I have definitely experienced more as a bottom", or about condomless sex: "I have had more unprotected sex than before… it doesn't mean that I only have unprotected sex". Other participants insisted PrEP had not changed their rules: "I haven't changed the way I think because I am taking this pill". Participants described PrEP as a "security blanket", an added "defence mechanism" and used analogies such as wearing a "crash helmet… on my bicycle". PrEP was described as affording "more intimacy", "reassurance", and giving "added control". By using PrEP, many participants with HIV-positive partners sought to reduce their partner's anxiety about the risk of transmission. The benefits of PrEP were described within the social context of risk environments in cities like London, the chemsex scene, and the digitization of sexual contact. PrEP use was viewed as time-limited: "clearly it is a period, a moment… it is not going to be a lifetime".
Conclusions: These data suggest that PrEP was added to a range of ‚rules' already used to mitigate risk, rather than replacing them. PrEP impacted on the boundaries of the rules for some people but not all. In social contexts of high-risk behaviour, PrEP offers added protection and psycho-social benefits that increase individual choice in the mitigation of risk.

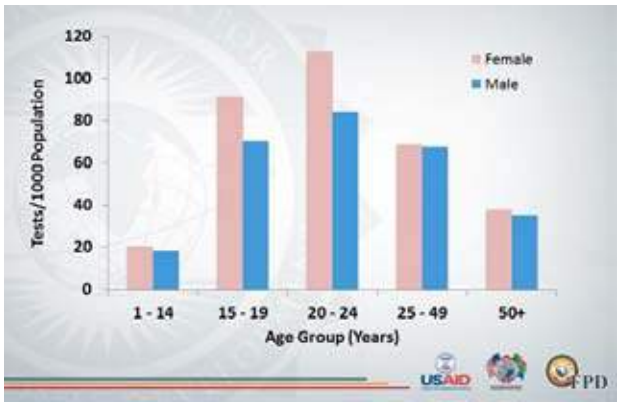
High uptake of community-based HIV testing by adolescent girls and young women aged 15-24: implications and synergies for PrEP roll out?

A. Medina-Marino[1,2], A. Mumbauer[3], T. Farirai[4], L.-G. Bekker[5], S. Johnson[6], N. Nkhwashu[4]
[1]Foundation for Professional Development, Research Unit, Pretoria, South Africa, [2]University of Pretoria, School of Health Systems and Public Health, Pretoria, South Africa, [3]Foundation for Professional Development, Strategic Information Department, Pretoria, South Africa, [4]Foundation for Professional Development, HIV Prevention Department, Pretoria, South Africa, [5]University of Cape Town, The Desmond Tutu HIV Centre (DTHC), Cape Town, South Africa, [6]Foundation for Professional Development, Technical Assistance Cluster, Pretoria, South Africa
Presenting author email: andrewm@foundation.co.za

Background: HIV incidence among female youth aged 15-24 in South Africa is four times higher than their male counterparts. Recent HIV prevention trials in South Africa documented incidence of 5-6% per year in 15-24 year old adolescent girls and young women (AGYW). HIV counselling and testing is the entry point for treatment and prevention services, and is key to implementing effective HIV prevention strategies. Community-based HIV counselling and testing (CBCT) has the potential to increase testing among key populations. We present interim findings of our at-scale CBCT program targeting high transmission areas in 13 high HIV burden districts in South Africa.
Methods: Routine programmatic data from October 2015 - September 2016 were used. Descriptive statistics were performed. HIV positivity and testing uptakes rates were calculated and stratified by age group, gender, and district.

Results: A total of 660,351 individuals were tested (positivity= 6.6%; uptake= 54.9/1000 population). The largest number of testers were individuals age 25-49 (n= 309,323; uptake= 68.2/1000 population). The highest testing uptake was by individuals age 15-24 (uptake= 90.6/1000 population).
Further disaggregation into 15-19 and 20-24 year old age groups reveal that adolescent girls age 15-19 (uptake= 91.6/1000 population) and young women age 20-24 (uptake= 112.8/1000 population) had the highest testing uptake of any age groups of either gender (Figure 1). These finding persist when uptake was disaggregated by district.
Conclusions: Implementation of our CBCT program has been extremely successful. Though the largest number of tests were performed on those aged 25-49 years, AGYW had the highest testing uptake. If access to PrEP by AGYW is to be scaled up, innovative supply-side interventions and service delivery platforms must be identified. Stakeholders involved in PrEP implementation should consider the synergies that CBCT programs may provide for identifying and delivering PrEP services to AGYW.



[Testing Uptake by Age Group and Gender]

TUAC0202

Finding the right target population for PrEP: the cost-effectiveness of pre-exposure prophylaxis provision to female and male adolescents and young women in South Africa

G. Meyer-Rath[1,2], L. Jamieson[2], L. Johnson[3]
[1]Boston University, Center for Global Health and Development, Boston, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa

Background: The South African government is in the process of identifying a suitable roll-out strategy for providing oral PrEP to young people at risk of acquiring HIV. We were tasked to evaluate the cost-effectiveness of providing PrEP to young women (20-24 years) vs male or female adolescents (15-19 years), both when covering everyone in these groups or only those self-identifying as being at high risk.
Methods: We used Thembisa, an existing HIV transmission model, and cost input from the first PrEP demonstration projects to model the impact of PrEP provision on new HIV infections and cost per HIV infection averted over 20 years, over a baseline of the current HIV programme, including potential cost savings due to reduced treatment need.
We compared provision to all young people in a sub-population to targeting via self-selection by high-risk individuals. Target coverage was set to 18% of either population and varied in sensitivity analysis.
Results: PrEP provision to adolescents of both genders is the most cost-effective option, being more effective and less costly than provision to young women (see Table). Provision to female adolescents is slightly more effective and cost effective than provision to male adolescents. At 18% coverage of either all young people in the target population or only those at high risk, the impact on HIV infections averted is similar, but self-selection by high-risk individuals results in much smaller populations on PrEP.
As a result, targeted provision is much more cost effective. PrEP is however not cost saving at any of the coverage rates tested (1-99%) for any of the populations, with or without successful targetting to high-risk sub-populations.

	Base-line	Young women (20-24)		Adolescents; both genders (15-19)		Adolescents; females (15-19)		Adolescents; males (15-19)	
Risk group		All	High risk	All	High risk	All	High risk	All	High risk
Number of person years on PrEP [millions]	-	8.7	1.4	10.7	3.7	5.9	1.6	4.7	2.1
Total cost [billions USD]	43.86	45.43	44.10	45.67	44.38	44.86	44.06	44.69	44.21
Incremental cost [billions USD] (% change)	-	1.53 (3.5%)	0.20 (0.5%)	1.76 (4.0%)	0.48 (1.1%)	0.96 (2.2%)	0.16 (0.4%)	0.79 (1.8%)	0.31 (0.7%)
Total new HIV infections [millions]	4.63	4.54	4.56	4.38	4.39	4.47	4.49	4.52	4.53
HIV infections averted [thousands] (% change)	-	82.4 (1.8%)	65.61 (1.5%)	250.0 (6.1%)	230.3 (5.5%)	153.4 (3.6%)	140.1 (3.2%)	106.4 (2.4%)	98.7 (2.2%)
Incremental cost-effectiveness ratio [USD/HIV infection averted]	-	$18,511	$3,013	$7,058	$2,099	$6,264	$1,164	$7,438	$3,144

[Results by sub-population]

Conclusions: Provision of PrEP to female adolescents is more cost effective than to male adolescents or young women. PrEP, although expensive, can be made more cost effective if high-risk sub-populations successfully self-select for PrEP.

TUAC0203

State-level school-based sex education policies on sexual orientation are associated with changes in teaching about HIV prevention

A. Grosso, D. Bermudez, M.A. Chiasson
Public Health Solutions, Research and Evaluation, New York, United States
Presenting author email: grossoas@gmail.com

Background: The Sexuality Information and Education Council of the United States (SIECUS) reported in 2015 that 11 states had state-level laws or policies regarding school-based sex education that were discriminatory toward lesbian, gay, bisexual, and/or transgender (LGBT) individuals or stated that homosexuality must not be promoted or addressed as a socially acceptable alternative. This was an 83% increase from the number of states in 2014. The implementation of these policies may limit the HIV education available to LGBT students and their heterosexual peers.
Methods: We constructed a panel dataset for even numbered years from 2006-2014. The independent variable was an indicator from SIECUS State Profiles about whether states´ sex education laws were LGBT-stigmatizing. The three dependent variables were from the Centers for Disease Control and Prevention (CDC) School Health Profiles system. Based on self-administered questionnaires from the principal and the lead health education teacher in a sample of high schools, the CDC reported for each state the percentage of schools that tried to increase students' knowledge about HIV prevention, human sexuality, and sexually transmitted disease (STD) prevention. We conducted ordinary least squares regression analysis in Stata/SE 14 with state and year fixed effects to control for unobserved time-invariant state-level confounders and state-invariant time-varying confounders.
Results: In the regression models, having a state sex education policy that was anti-LGBT was associated with a 17.4%, 21.7%, and 16.3% decrease in the percentage of schools that tried to increase student knowledge about HIV prevention, human sexuality, and STD prevention, respectively ($p<0.05$).

Year →	2006	2008	2010	2012	2014	State sex education law is negatively LGBT-biased (combined states and years) ↓	
% (n/N) of states with negatively LGBT-biased sex education laws →	21.6% (11/51)	13.7% (7/51)	13.7% (7/51)	11.8% (6/51)	11.8% (6/51)	No	Yes
% of schools that tried to increase student knowledge about HIV prevention	81.4%	88.9%	88.4%	86.9%	85.9%	87.4%	81.4%
% of schools that tried to increase student knowledge about human sexuality	73.7%	84.6%	84.2%	82.4%	80.5%	82.4%	75.6%
% of schools that tried to increase student knowledge about STD prevention	77.5%	86.4%	86.7%	85.7%	84.9%	85.4%	79.4%

[Sex education implementation by LGBT policy]

Conclusions: State sex education laws that are negatively biased toward LGBT people may increase reluctance of teachers to try to increase student knowledge about sex education topics in general, including those that are not related to sexual orientation or gender identity. Given the increase in these laws in the past year, we expect that additional teens will be denied instruction on these topics. Further research is necessary to assess how this may affect youth risk behaviors and sexual health outcomes.

TUAC0204

Potential for HIV transmission among adolescents and young adults receiving antiretroviral therapy

S. Wood[1,2], N. Dowshen[1,2], C. Gowda[3], S. Lee[4], S. Ratcliffe[5], R. Gross[6,7]
[1]Children's Hospital of Philadelphia, Division of Adolescent Medicine, Philadelphia, United States, [2]University of Pennsylvania, Perelman School of Medicine, Department of Pediatrics, Philadelphia, United States, [3]Ohio State University College of Medicine, Infectious Diseases, Columbus, United States, [4]Children's Hospital of Philadelphia, Craig Dalsimer Division of Adolescent Medicine, Philadelphia, United States, [5]University of Pennsylvania Perelman School of Medicine, Department of Biostatistics, Epidemiology, and Informativs, Philadelphia, United States, [6]University of Pennsylvania, Perelman School of Medicine, Departments of Medicine and Epidemiology, Philadelphia, United States, [7]University of Pennsylvania, Center for Clinical Epidemiology and Biostatistics, Philadelphia, United States
Presenting author email: woodsa@email.chop.edu

Background: Adolescents and young adults (AYA) living with HIV have lower rates of virologic suppression and higher rates of sexually transmitted infections (STIs) than older adults, which increases HIV transmission potential. We aimed to identify the proportion of participants with, and risk factors for, high HIV transmission potential within a cohort of HIV-positive AYA.
Methods: Retrospective cohort study of HIV-positive, antiretroviral therapy (ART)-treated, AYA, ages 13-24, at a U.S. adolescent HIV clinic from 2002-2015. We included all visits with viral load (VL) measurement after ART initiation. High transmission potential was defined as incident STI (Neisseria gonorrhea, Chlamydia trachomatis or Treponema palladium) with concurrent VL >1500 copies/ml. Generalized estimating equations (GEE) were used to calculate odds ratios (ORs) and 95% confidence intervals (CI) for hypothesized risk factors for high transmission potential, including age, gender, insurance status, sexual orientation, race and history of STI at entry to care.
Results: Participants (n=251) were followed for a median of 3.2 years (IQR 1.5-5.3), contributing 2,860 visits. Participants were 87% African-American (n=218), and 73% men and transgender women who have sex with men (n=182) and 48% (n=120) had a history of STI at entry to care. The median visit age was 21 years (IQR 19-23). Incident STI was detected in 68% (n=166) of participants comprising 15% (n=299) of visits. Participants were viremic (VL >1500 copies/ml) at 27% (n=640) of visits. High transmission potential occurred at least once in 16% (n=39) of participants and 3% of visits. In the final GEE model, history of STI at or before entry to HIV care conferred a nearly four-fold increased odds of high transmission potential (OR 3.8, 95% CI: 2.0-7.1, p< 0.001). There was no significant association between age, gender, sexual orientation, race, or insurance status and high HIV transmission potential.
Conclusions: In this conservative model of transmission potential, 16% of ART-treated AYA in care were episodically at high risk of HIV transmission, demonstrating the limits of treatment as prevention in this setting. A baseline history of STI conferred higher risk of transmitting HIV, emphasizing the need for secondary prevention interventions targeting both ART adherence and sexual risk reduction for HIV-positive youth.

TUAC0205

HIV and HSV-2 risk among young women in age-disparate partnerships: evidence from KwaZulu-Natal, South Africa

B. Maughan-Brown[1], G. George[2], S. Beckett[2], M. Evans[3], C. Cawood[4], D. Khanyile[4], L. Lewis[5], A. Kharsany[5]
[1]Southern Africa Labour and Development Research Unit (SALDRU), University of Cape Town, Cape Town, South Africa, [2]Health Economics and HIV and AIDS Research Division (HEARD), University of KwaZulu-Natal, Durban, South Africa, [3]Department of Anthropology, York University, Toronto, Canada, [4]Epicentre AIDs Risk Management (Pty) Limited, Cape Town, South Africa, [5]Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Durban, South Africa
Presenting author email: brendan.maughanbrown@gmail.com

Background: Young women in sub-Saharan Africa continue to exhibit high HIV prevalence and incidence rates. We explored the role age-disparate partnerships play in HIV-infection risk among 15-24 year old women in an endemic setting in South Africa.
Methods: During June 2014-June 2015, a cross-sectional household survey was conducted in KwaZulu-Natal Province, South Africa comprising 9812 individuals aged 15 to 49 years. Venous blood samples were collected for HIV antibody and viral load tests, and herpes simplex virus type 2 (HSV-2) antibody tests. A partnership was defined as age-disparate if the age-difference between partners was five years or more. Multiple logistic regression analyses were first used to assess the associations between age-disparate partnerships and both HIV and HSV-2 status - HSV-2 may increase a young women's risk of HIV-infection - among 15-24 year old women who reported at least one sexual partner (n=1557).
The second set of analyses used partnership data reported by men - restricted to on-going partnerships with 15-24 year old women (n=1078) - to assess whether age-disparate partners of young women were more likely to be HIV-positive with a detectable viral load (≥20 copies/ml), and therefore pose a greater level of risk, than age-similar partners.
Results: Women who reported any age-disparate partnerships were more likely to test positive for HIV (37% vs 22%, p<0.01) and HSV-2 (65% vs 46%, p<0.01). After controlling for, inter alia, age and number of lifetime sexual partners the odds of young women having HIV (aOR:1.56, p<0.01,95%CI:1.13-2.17) and HSV-2 (aOR:1.85, p<0.01,95%CI:1.41-2.44) were greater for those who reported age-disparate partnerships. Men in age-disparate partnerships with young women were also more likely to be HIV-positive (5-9 year age-difference: aOR 2.12, p<0.01,95%CI:1.26-3.57; 10+ year age-difference: aOR 4.93, p<0.01,95%CI:2.67-9.12) and be HIV-positive with a detectable viral load (5-9 year age-difference: aOR 2.30, p<0.01,95%CI:1.36-3.87; 10+ year age-difference: aOR:2.57, p<0.01,95%CI:1.34-4.92) compared to men in age-similar partnerships with young women.
Conclusions: Results suggest a positive association between age-disparate partnerships and young women's HIV risk. Expanding treatment and combination prevention, including targeted interventions addressing risk from age-disparate sexual partnering, is vital to reducing HIV incidence amongst young women.

TUAC03 Hitting the First 90 Target: Lessons from Population-Based Surveys

TUAC0301

Findings from the 2016 Zambia Population-based HIV Impact Assessment (ZAMPHIA): HIV prevalence, incidence and progress towards the 90-90-90 goals

D.T. Barradas[1], S. Gupta[1], C. Moyo[2], K. Sachathep[3], K. Dzekedzeke[4], T. Nkumbula[4], D.B. Williams[5], H. Patel[5], T. Dobbs[5], C. Nakazwe[6], W. Kasongo[7], H. Cai[1], S. Kamocha[1], C.B. Ndongmo[1], K. Hageman[1], M.A. Riggs[1], ZAMPHIA Study Team
[1]Centers for Disease Control and Prevention, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia, [3]ICAP, Mailman School of Public Health, Columbia University, New York, United States, [4]ICAP, Lusaka, Zambia, [5]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [6]Central Statistics Office, Lusaka, Zambia, [7]Tropical Disease Research Centre, Ndola, Zambia

Background: Based on modeled estimates, 13% of people in Zambia were living with HIV in 2014. The 2016 Zambia Population-based HIV Impact Assessment (ZAMPHIA) is the first national survey to directly assess the status of Zambia's HIV epidemic by measuring HIV incidence. Findings from ZAMPHIA and progress toward meeting the UNAIDS 90-90-90 targets, including viral load suppression (VLS), are presented.
Methods: A nationally representative household-based sample of 12,310 eligible households was selected in 511 enumeration areas; analyses account for study design. Consenting participants provided demographic and clinical information and blood samples for household HIV testing per national guidelines. HIV-seropositive results were confirmed using the Geenius supplemental assay; viral load and limiting antigen (LAg) avidity EIA testing were performed at a central lab on all HIV-seropositive samples. HIV incidence estimates were based on World Health Organization criteria for recent infection (LAg <1.5 OD units and HIV RNA >1000 c/ml). VLS was defined as HIV RNA <1000 c/ml.
Results: In total, 19,029 adults and 7,959 children provided interviews and blood samples (response rate: 68%). Participation by eligible adults was higher for women than men (71% vs 63%, P< 0.0001). HIV prevalence estimates among adults aged 15-59 and children aged 0-14 were 12.3% and 1.3%, respectively. Adult HIV incidence was 0.66% (female 1.00%, male 0.33%); mean VLS prevalence among all HIV-seropositive adults was 59.8%. An estimated 67.3% of persons living with HIV (PLHIV) knew their HIV status (1st 90), 85.4% of PLHIV who reported knowing their status also reported receiving ART (2nd 90), and 89.2% of these PLHIV who reported receiving ART were virally suppressed (3rd 90).

Conclusions: Zambia has achieved progress towards meeting the UNAIDS 90-90-90 goals. HIV prevalence is stabilizing; HIV incidence is low; and prevalence of VLS is high. Identification of gaps in testing, ART, and viral load suppression is needed to better target expansion of HIV treatment services in Zambia.

Indicator	Males	Females	Total
HIV prevalence among adults, % [95% CI]	9.5 [8.8, 10.3]	14.9 [14.0, 15.8]	12.3 [11.6, 12.9]
HIV prevalence among children, % [95% CI]	--	--	1.3 [1.0, 1.6]
HIV incidence among adults % [95% CI]	0.33 [0.11, 0.56]	1.00 [0.65, 1.36]	0.66 [0.45, 0.88]
Viral load suppression (VLS) prevalence among HIV+ adults, % [95% CI]	57.4 [53.4, 61.5]	61.3 [58.7, 63.8]	59.8 [57.4, 62.2]
Prevalence of HIV+ adults who report knowing their HIV status, % [95% CI]	62.8 [58.7, 66.8]	70.0 [67.5, 72.5]	67.3 [64.8, 69.7]
Self-reported ART prevalence among HIV+ adults who report knowing their HIV status, % [95% CI]	86.2 [83.1, 89.4]	84.9 [82.5,87.4]	85.4 [83.4, 87.4]
VLS prevalence among HIV+ adults who report ART and knowing their HIV status, % [95% CI]	88.2 [85.1, 91.4]	89.7 [87.7, 91.8]	89.2 [87.4, 91.0]

Correlates of being outside the 90-90-90 cascade among adults ages 15-64 years in Zimbabwe

A. Hakim[1], E. Radin[2], L. Ruangtragool[3], A. Herman-Roloff[4], N. Ahmed[2], G. Musuka[5], H. Dube[5], M. Mhangara[6], L. Gwanzura[7], S. Munyati[7], E. Gonese[8], A. Nwankwo-Igomu[8], H. Patel[1], K. Sleeman[1], S. Kinchen[1], J. Justman[2], B.A. Tippett-Barr[8], ZIMPHIA Survey Group

[1]US Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [2]ICAP at Columbia University, New York, United States, [3]ASPPH/CDC Allan Rosenfield Global Health Fellow, U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe, [4]US Centers for Disease Control and Prevention, Pretoria, South Africa, [5]ICAP at Columbia University, Harare, Zimbabwe, [6]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [7]Biomedical Research Training Institute, Harare, Zimbabwe, [8]US Centers for Disease Control and Prevention, Harare, Zimbabwe

Presenting author email: hxv8@cdc.gov

Background: Zimbabwe has made great strides in combatting HIV, partially through increasing testing and treatment. To reach the UNAIDS 90-90-90 targets it is necessary to know who is unaware of their HIV infection, who is not on treatment, and who is not virally suppressed in order to engage or re-engage them in HIV services. We identify correlates of being outside this cascade.

Methods: The 2015-2016 Zimbabwe Population-based HIV Impact Assessment was a cluster-based nationally-representative household survey. Face-to-face interviews were conducted with 22,496 adults aged 15-64 years, and blood specimens collected from 20,572 of them for HIV testing following the national serial rapid testing algorithm of Determine, First Response and Stat-Pak. Treatment status was self-reported and viral load testing was conducted using Roche Taqman 96. Weighted analysis was conducted in SAS. Variables associated with being outside the 90-90-90 cascade at p<0.1 in bivariate analysis were included in the multivariate model.

Results: HIV prevalence was 14.6% among 15-64 year olds. Among HIV-infected participants, 25.8% were unaware of their infection. Among those aware of their infection, 13.2% were not on treatment. Of those on treatment, 13.5% were not virally suppressed. In multivariate analysis, males were more likely than females to be unware of their HIV infection (AOR: 1.74, 95% CI: 1.43-2.10) as were those aged 15-24 years (AOR: 4.59, 95% CI: 3.13-6.72) and aged 25-34 (AOR: 2.43, 95% CI: 1.73-3.41) compared to those aged 55-64 years. Compared to those ages 55-64 years, those aged 15-24 and 25-34 years were least likely to be on treatment (AOR: 3.88, 95% CI: 1.93-7.80 and AOR: 5.03, 95% CI: 2.85-8.89, respectively). Being on treatment and virally unsuppressed was associated with being male (AOR: 1.57, 95% CI: 1.17-2.09) and being aged 15-24 and 25-34 years compared to 55-64 years (AOR: 2.99, 95% CI: 1.50-6.11, and AOR: 3.82, 95% CI: 2.09-7.01, respectively). Neither province nor urban residence were associated with being outside any step of the cascade. Sex was not associated with being aware and not on treatment.

Conclusions: People < 35 years and men should be further targeted for HIV testing and additional support for linkage to and retention on treatment.

TUAC0303

90-90-90 targets in HIV-positive women using results from MPHIA: a Malawi success story

N. Wadonda-Kabondo[1], C. West[1], R. Nyirenda[2], F. Chimbwandira[1], S. Nkoka[3], A. Voetsch[4], T. Dobbs[4], G. Chipungu[1], I. Chirwa[5], M. Blackson[6], G. Sundeep[1], E. Radin[7], MPHIA Study Team

[1]CDC, Lilongwe, Malawi, [2]Malawi Ministry of Health, Lilongwe, Malawi, [3]ICAP at Columbia University, Lilongwe, Malawi, [4]CDC, Atlanta, United States, [5]National Statistical Office of Malawi, Lilongwe, Malawi, [6]Malawi National AIDS Commission, Lilongwe, Malawi, [7]ICAP at Columbia University, New York, United States

Presenting author email: vzn7@cdc.gov

Background: While women in Malawi continue to experience a high burden of HIV infection, implementation of Option B+ since 2011 has led to substantial improvement in increasing access to antiretroviral therapy (ART) for HIV-positive women. This study aimed at describing the progress in women towards achieving the UNAIDS 90-90-90 targets in Malawi.

Methods: The Malawi Population-Based HIV Impact Assessment (MPHIA) was a two-stage cluster survey of randomly selected households in Malawi. Data collection occurred from November 2015 to August 2016. Participants answered a questionnaire involving reproductive history, PMTCT/option B+, and HIV testing and care. The survey involved collection of blood samples, home-based counseling and testing (HBCT) using the national rapid HIV test algorithm followed by laboratory-based confirmation using Geenius™. Incidence was measured using the Lag-Avidity EIA. Viral load suppression (VLS) was defined as <1,000 HIV RNA copies/mL. Descriptive analyses were conducted to examine progress towards 90-90-90 parameters in women and accounted for the study design.

Results: Of 12,231 eligible women ages 15 to 64 years, 9,956 (81.4%), women were interviewed and tested. Seventy-six percent (76.3%, 95% Confidence Interval (CI):74.2-78.9) of women reported knowledge of their HIV+ status. Of the women who knew their HIV+ status, 90.0% (95%CI:87.1-92.9) reported being on ART. Of the women who reported ART use, 92.3% (95%CI:90.4-94.2) had achieved VLS. Progress towards 90-90-90 targets also varied by age, see Table. At population level (irrespective of knowledge of HIV and ART status), prevalence of VLS among HIV+ women 15-64 years was 72.9% (95%CI:69.9-75.9); highest among older women but much lower in young women. HIV incidence among women was 0.48% (95%CI:0.20-0.76), which was about 50% greater in women than men (0.25%, 95%CI:0.05-0.46).

Age Group	Diagnosed	On Treatment	Virally Suppressed
	% (95% CI)	% (95% CI)	% (95% CI)
15-24 years	58.7 (48.4-69.0)	76.9 (59.0-94.7)	79.3 (68.4-90.2)
25-34 years	72.6 (67.5-77.8)	88.0 (82.0-94.1)	94.5 (92.0-97.0)
35-44 years	84.8 (81.0-88.5)	91.7 (88.5-94.9)	91.7 (88.3-95.1)
45-54 years	76.4 (68.8-84.0)	95.3 (92.3-98.2)	93.6 (89.4-97.7)
55-64 years	85.1 (76.7-93.5)	94.7 (89.3-100.0)	95.3 (88.7-100.0)

[90-90-90 Targets by Age Group among Women]

Conclusions: Although women are at greater risk of HIV infection in the reproductive age group, they seem to get into treatment, stay on treatment, and achieve VLS. However, the first 90 was not reached, suggesting that a reasonable number of women are not accessing Malawi's PMTCT program and further efforts are needed to diagnose and treat these cases; and prevent new infections.

TUAC0304

Children living with HIV in Malawi: first survey-based measurement of national pediatric HIV prevalence and viral suppression

S. Jonnalagadda[1], G. Bello[2], S. Suzue[3], J. Burnett[4], E. Radin[3], K. Brown[1], J. Cuervo-Rojas[5], F. Ogollah[5], E. Kim[6], D. Payne[6], H. Patel[1], K. Sleeman[1], S. Hrapcak[1], A. Voetsch[1], Malawi Population-based HIV Impact Assessment Study Group

[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]Malawi Ministry of Health, Lilongwe, Malawi, [3]ICAP at Columbia University, New York, United States, [4]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [5]ICAP at Columbia University, Lilongwe, Malawi, [6]Centers for Disease Control and Prevention, Division of Global HIV and TB, Lilongwe, Malawi

Presenting author email: wau4@cdc.gov

Background: To date, national pediatric HIV burden estimates in Malawi were derived from modeling using clinic-based data. In 2015, an estimated 84,000 children 0-14 years old were living with HIV in Malawi. The Malawi Population-based

HIV Impact Assessment (MPHIA), a national household survey conducted from 2015 - 2016, provides the first direct measurement of national HIV prevalence and viral suppression (VS) prevalence among children 0-14 years.
Methods: MPHIA tested children in every other surveyed household (n=13,234) using the national HIV rapid test (RT) algorithm consisting of Determine™ (screening RT) and UniGold™ (confirmatory RT). Children >18 months who tested positive by both RTs were confirmed by laboratory-based testing using Geenius™ HIV 1/2 Confirmatory Assay (Bio-Rad). Children ≤18 months screening reactive on Determine underwent DNA PCR testing for HIV diagnosis. HIV RNA viral load suppression was defined as < 1,000 copies/mL. Weighted national pediatric HIV prevalence and VS prevalence were measured using SI-CHAID weights. Jackknife Replication method was used to calculate 95% confidence interval (CI). Number of children living with HIV was estimated using population projections from the Malawi National Statistics Office (NSO).
Results: Of 9,952 eligible children, 6,143 (61.7%) provided blood for HIV testing. Of those tested, 99 children were HIV positive; 2 were DNA PCR positive. Overall prevalence was 1.6% (95% CI: 1.2% - 2.0%), equivalent to 122,721 children living with HIV (95% CI: 90,868 - 154,573). Among those infected, VS prevalence was 42.9% (95% CI: 30.5% - 55.4%). HIV prevalence was greater in urban compared to rural areas; VS was considerably low among children< 5 years, and those residing in urban areas.

Variable	Unweighted number of children who tested HIV positive/ Number tested	prevalence (%)	95% CI	Weighted number of children living with HIV	95% CI	Number of children (NSO projection)	Viral suppression (%)	95% CI
0-4 years	20/1,854	1.2	0.6 - 1.8	30,541	14,492 - 46,591	2,583,791	21.9	3.6 - 40.4
5-9 years	37/2,197	1.6	0.9 - 2.3	49,271	27,076 - 71,466	3,063,666	49.1	31.2 - 67.0
10-14 years	42/2,092	2.0	1.3 - 2.7	42,909	27,069 - 58,749	2,143,287	50.3	29.7 - 70.9
Urban residence	37/1,911	2.3	1.4 - 3.1	26,826	13,621 - 40,032	1,181,940	28.9	12.2 - 45.5
Rural residence	62/6,143	1.5	1.0 - 1.9	95,894	65,917 - 125,872	6,608,804	47.0	32.2 - 61.9

[HIV prevalence and viral suppression in children]

Conclusions: The MPHIA estimate of the number of children living with HIV is 46% greater than the current estimate which is currently being used for planning of pediatric HIV interventions. Low rates of viral suppression seen in children indicate the need for uptake of effective HIV treatment and adherence interventions to achieve the UNAIDS target of 73% viral suppression among children.

TUAC0305

Estimating HIV incidence and the undiagnosed HIV population in the European Union / European economic area

A. van Sighem[1], A. Pharris[2], C. Quinten[2], T. Noori[2], A.J. Amato-Gauci[2], and the ECDC HIV/AIDS Surveillance and Dublin Declaration Networks
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden
Presenting author email: a.i.vansighem@amc.uva.nl

Background: Each year, about 30,000 people are newly diagnosed with HIV in the 31 countries of the European Union/European Economic Area (EU/EEA). We aimed to estimate the number of people living with undiagnosed HIV in the entire EU/EEA and in four sub-regions.
Methods: Annual data on HIV diagnoses in 2003-2015 were retrieved from a database for HIV/AIDS within The European Surveillance System (TESSy). HIV diagnoses were adjusted for reporting delay and stratified by the presence of an AIDS-defining event within 3 months of HIV diagnosis, and, for individuals without AIDS, by CD4 cell count (≥500, 350-499, 200-349, < 200 cells/mm^3) at the time of diagnosis. Countries were grouped in sub-regions as defined by United Nations. A back-calculation method based on the ECDC HIV Modelling Tool was used to estimate annual numbers of newly acquired HIV infections, the distribution of time between infection and diagnosis by calendar year, and the number of people still undiagnosed by the end of 2015.
Results: In 2003-2015, there were 403,169 HIV diagnoses: 142,010 (35%) in Western, 121,624 (30%) in Northern, 27,662 (7%) in Eastern, and 111,873 (28%) in Southern Europe. In the entire EU/EEA, 120,100 (95% CI:113,000-127,800) people were estimated to be living with undiagnosed HIV by the end to 2015, of whom 47% had a CD4 count ≥500 cells/mm^3 and 31% <350 cells/mm^3, with 28,000 (95% CI: 24,700-31,700) new infections in 2015. The estimated number of undiagnosed HIV infections was highest in Southern Europe, while infection rates were highest and time to diagnosis shortest in Northern and Western Europe (Table).

Sub-region	Undiagnosed, total	Undiagnosed, CD4 ≥500		Undiagnosed, CD4 <350		Infection rate [/100,000 population]	Time to diagnosis (years)
Western	36,000 32,500-39,600	18,700 16,700-20,800	52%	9,800 9,200-10,700	27%	5.8 5.0-6.8	2.5 [1.2-4.6]
Northern	27,800 25,700-30,700	14,200 12,900-15,900	51%	7,800 7,300-8,400	28%	9.4 8.5-10.8	2.3 [1.1-4.3]

Undiagnosed population and infection rate with 95% confidence intervals, and median time to diagnosis [interquartile range] in 2015.

[Undiagnosed population and infection rates]

Conclusions: A substantial number of people in the EU/EEA are living with undiagnosed HIV. Although the estimated CD4 distribution suggests that approximately half of them are in an early stage of infection, a significant proportion are estimated to have late stage infection, suggesting more efforts are needed to test and diagnose these people.

TUAC04 Prevention: It's Not Just about PrEP

The effect of a conditional cash transfer for HIV prevention on the experience of partner violence for young women: evidence from a randomized experiment in South Africa HPTN 068

K. Kilburn[1], A. Pettifor[2,3], J. Edwards[2], A. Selin[2], S. Delong[2], R. Twine[3], J. Hughes[4], J. Wang[4], X. Gomez-Olive[3], C. MacPhail[3,5], K. Kahn[3]
[1]University of North Carolina at Chapel Hill, Global Health and Infectious Diseases, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [3]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [4]Statistical Center for HIV/AIDS Research and Prevention (SCHARP), Seattle, United States, [5]University of New England, Armindale, Australia
Presenting author email: kkilburn@unc.edu

Background: Evidence has shown that the experience of violence by a partner has important influences on women's risk of HIV acquisition. Conditional cash transfers (CCTs) targeted to young women in sub-Saharan Africa have been advocated as an intervention to reduce the risk of HIV-infection, but the success of such interventions may be conditional upon changes in gendered power inequalities. Using a randomized experiment in northeast South Africa, we find that a CCT targeted to poor girls in high school reduced the risk of intimate partner violence (IPV) by 34%. The purpose of this study is to understand the pathways through which the CCT affects IPV.
Methods: Our study is a phase 3, randomized controlled trial (HPTN 068) in a rural area in Mpumalanga province, South Africa. Eligible young women (aged 13-20) and their parents or guardians were randomly assigned (1:1) to receive a monthly cash transfer conditional on school attendance versus no cash transfer. Participants (N=2,448) were interviewed at baseline, then at annual follow-up visits at 12, 24, and 36 months. We estimate the primary outcome, physical IPV in the past 12 months, using a GEE log-binomial regression model. We examined mediation of direct effects through intermediate pathways using methods designed for nonlinear models under the counterfactual framework. Mediators include sexual behaviors, empowerment, and economic well-being measures.
Results: We find evidence that the CCT works through delaying sexual debut or reducing the likelihood of having a sexual partner. The intervention interacts with these mediators leading to a larger reduction in IPV risk. Compared to the direct effect of the CCT on any physical IPV [RR 0.66, CI(95%):0.59-0.74], the risk of IPV is further reduced when we set the controlled direct effect to either no sexual debut [RR 0.53, CI(95%):0.45-0.63] or to no sexual partners [RR 0.56, CI(95%):0.48-0.63].
Conclusions: Results indicate that a CCT for adolescent school girls has protective effects on girls' experience of violence in part because the intervention reduces the likelihood of debut or having a sexual partner, thereby reducing the opportunity for IPV. Since these behaviors also protect against HIV acquisition, this evidence strengthens the case for CCTs for HIV prevention.

TUAC0402

The effect of school attendance and school drop out on incident HIV and HSV-2 among young women in rural South Africa enrolled in HPTN 068

M.C.D. Stoner[1], J.K. Edwards[1], W.C. Miller[1,2], A.E. Aiello[1], C.T. Halpern[1], A. Julien[1], A. Selin[1], R. Twine[3], J. Hughes[4,5], J. Wang[5], F.X. Gomez-Olive[3], R.W. Wagner[3], C. MacPhail[6], O. Laeyendecker[7], Y. Agyei[7], S.M. Tollman[3,8], K. Kahn[3,8], A. Pettifor[1], HPTN 068

Presenting author email: stonerm@email.unc.edu

Background: Education may protect against sexual transmitted infections but has primarily been studied as educational attainment in adults or using measures of prevalent rather than incident infection. Few studies have explored schooling as a measure of time spent in a structured school environment. We hypothesize that low versus high attendance in school and school drop out versus staying in school are associated with a higher risk of incident HIV and HSV-2 infection among young women
Methods: We used longitudinal data from the HPTN 068 randomized trial in Agincourt, South Africa to determine if percentage of school days attended between annual surveys and school dropout affect incident HIV and HSV-2 in young women aged 13-23. We examined inverse probability of exposure weighted survival curves and used them to calculate 1, 2 and 3-year risk differences and risk ratios for the effect of school attendance on incident HIV and HSV-2, accounting for confounding. A marginal structural cox model was then used to estimate the hazard ratios for the effect of school attendance and school drop out on incident HIV and HSV-2.
Results: Over the study period, 107 incident HIV cases occurred among the 2328 women without HIV at baseline, and 208 HSV-2 incident cases occurred among the 2238 women without prevalent HSV-2 at baseline. Risk of HIV and HSV-2 increased over time and was lower for young women who had high attendance (>=80% school days) versus low attendance (< 80%) at all time points. After accounting for relevant confounders, young women with low attendance were more likely to develop HIV (HR: 2.97; 95% CI: 1.62, 5.45) and HSV-2 (HR: 2.47; 95% CI: 1.46,4.17) over the follow up period than young women with high attendance. Similarly, young women who dropped out of school had a higher weighted hazard of both HIV (HR 3.25 95% CI: 1.67,6.32) and HSV-2 (HR 2.70; 95% CI 1.59,4.59).
Conclusions: Young women who attend more school and stay in school have a lower risk of incident HIV and HSV-2 infection. Interventions to prevent infections should continue to encourage young women to attend school more frequently and to avoid drop outs.

TUAC0403

Increasing HIV test uptake and case finding through assisted HIV partner notification services: a systematic review and meta-analysis

S. Dalal[1], C. Johnson[1], V. Fonner[2], C. Kennedy[3], N. Siegfried[4], C. Figueroa[1], R. Baggaley[1]
[1]World Health Organization, HIV/AIDS, Geneva, Switzerland, [2]Medical University of South Carolina, Charleston, United States, [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States, [4]Independent Clinical Epidemiologist, Cape Town, South Africa
Presenting author email: dalals@who.int

Background: Despite the expansion of HIV testing services (HTS), an estimated 40% of people with HIV infection remain undiagnosed. New approaches are needed enhance HTS efficiency in order to reach the first UN 90-90-90 goal to diagnose 90% of people with HIV infection by 2020. We conducted a systematic review on the effectiveness of assisted partner notification in improving HIV test uptake and diagnosis, and the occurrence of adverse events, to inform the development of WHO normative guidelines.
Methods: We systematically searched five electronic databases through June 2016. We also contacted experts in the field and authors for additional information where needed. Eligible studies compared assisted HIV partner notification services to passive or no notification, and measured one of the following outcomes: HIV test uptake, proportion of partners tested and diagnosed HIV-positive, CD4 or viral load, linkage to clinical assessment or antiretroviral therapy, linkage to prevention for HIV-negative partners, and any social harm among HIV-positive patients or their partners. We used the Cochrane Collaboration's tool to assess risk of bias and GRADE to evaluate the quality of the evidence. Where appropriate, random-effects meta-analysis was conducted.
Results: Of 1742 citations identified, four randomized controlled trials (RCT) and six observational studies totalling 5150 index patients from eight countries were included. Meta-analysis of three individually-randomised trials provided moderate quality evidence that assisted partner notification services increased HTS uptake among partners 1.5 times compared to passive referral (Relative Risk [RR]=1.46; 95% CI: 1.22-1.75; I^2=0%). Overall, studies reported 13-72% of partners were HIV positive, and between 12-66% of partners were newly diagnosed. The proportion of HIV-positive partners was 1.5 times higher with assisted partner notification than with passive referral (RR=1.47; 95% CI: 1.12-1.92; I^2=0%; moderate quality evidence). Few instances of violence or harm were reported.
Conclusions: Assisted partner notification improved partner testing and increased diagnosis of people with HIV infection, with few reports of harm. WHO strongly recommends offering voluntary assisted HIV partner notification services as part of a comprehensive package of testing to all newly diagnosed persons, and periodically to all HIV positive persons throughout their care and treatment.

Association between HIV and sexually transmitted infections and partner circumcision among women in uMgungundlovu District, South Africa: a cross-sectional analysis of HIPSS baseline data

S. Davis[1], C. Toledo[2], L. Lewis[3], C. Cawood[3], A. Bere[4], M. Glenshaw[4], A. Kharsany[3]
[1]US Centers for Disease Control, HIV Prevention Branch, Atlanta, United States, [2]US Centers for Disease Control and Prevention, Atlanta, United States, [3]Center for the AIDS Program of Research in South Africa, Durban, South Africa, [4]US Centers for Disease Control and Prevention, Durban, South Africa
Presenting author email: cot8@cdc.gov

Background: Randomized controlled trials and observational data have demonstrated that circumcision partially protects men from acquiring HIV and some sexually transmitted infections (STIs) through heterosexual sex. They also suggest that female partners receive some protection, possibly indirectly through lower infection prevalences among men. However, population-level data outside experimental settings is lacking. The HIV Incidence Provincial Surveillance System (HIPSS) is a longitudinal study in Vulindlela and Greater Edendale sub-districts, South Africa, which collected population-level baseline data in 2014 and 2015.
Methods: Female HIPPS participants were aged 15-49 years. Those with at least one past or current male sexual partner who were able to report his circumcision status were analyzed. Participants were assessed for HIV status via double 4th-generation ELISA testing with confirmatory Western Blot; N. gonorrhoeae, C. trachomatis, T vaginalis, and HPV infection with standard testing of self-collected vulvovaginal swabs; T. pallidum, HSV-2 and Hepatitis B with serology; and STI diagnosis history and current STI symptoms with self-report. They were grouped by circumcision status of their most recent partner, stratified into age below or at least equal to 25 years, and compared on presence of STI outcomes by chi-square testing, weighted for selection probability and nonresponse.
Results: 4766 women were included. Women with circumcised partners had similar numbers of lifetime partners (mean 2.45) to those with uncircumcised partners (mean 2.71). In the younger stratum, partner circumcision was negatively associated with HIV (24% vs. 35%, p<0.01) and HSV-2 (49% vs. 62%, p<0.01). In the older stratum, partner circumcision was negatively associated with syphilis (1.5% vs. 3.4%, p=0.04) and HSV-2 (83% vs. 86%, p=0.04), but was associated with ever having had an STI (11% vs. 7%, p<0.01).
Conclusions: Partner circumcision was associated with decreased prevalence of HSV-2 in all female HIPSS participants, decreased prevalence of HIV in younger women, and decreased prevalence of syphilis in older women. Its positive association with self-reported STI history in older participants may derive from differential ascertainment; circumcision typically involves STI screening in men, potentially leading to partner notification. Findings support community-level protection against HIV and some other STIs among women from male circumcision.

Effects of syringe distribution policy change at a syringe services program in Baltimore, MD: a forecast analysis

S. Allen[1], J. Park[2], B. Weir[1], D. Holtgrave[1], S. Sherman[1]
[1]Johns Hopkins University, Health, Behavior and Society, Baltimore, United States, [2]Johns Hopkins University, Epidemiology, Baltimore, United States
Presenting author email: sean.travis.allen@gmail.com

Background: Syringe services programs (SSPs) are associated with decreases in prevalence and incidence rates of blood-borne diseases (e.g., HIV and hepatitis C [HCV]), soft tissue infections, and other morbidities among people who inject drugs (PWID). The core goal of SSPs is to decrease the circulation time of contaminated syringes and to increase the volume of new syringes, effectively increasing the "coverage" of sterile needles and syringes for every injection. In 2014, the Baltimore City SSP shifted from a strict one-to-one syringe exchange policy to a needs-based distribution policy whereby PWID could receive as many syringes as they require. The purpose of this research is to examine the impact of this policy change on syringe distribution among PWID.
Methods: Syringe distribution data from April 2012 to November 2016 were abstracted from the Baltimore City SSP and divided into monthly observations. These data were used to build an ARIMA model that forecast the estimated number of syringes that would have been distributed had the syringe distribution policy not changed in the 26-month period following the policy change.
Results: There were significant (p< .05) differences in the mean number of syringes distributed per month in the pre- and post-policy change periods (44,410 and 96,187, respectively). During the post-policy change period, we forecast that 1,786,174 syringes would be distributed. In actuality, 2,500,857 syringes were distributed during this period. Changing to a needs-based syringe distribution policy resulted in the distribution of an additional 714,683 syringes.
Conclusions: Needs-based syringe distribution leads to greater circulation of sterile syringes and may prevent new HIV/HCV infections.

Presenting author email: jdamo@isciii.es

Background: To know if HIV acquisition among migrants living in Spain takes place before or after migration to the country.
Methods: Cross-sectional study in 18 centers/hospitals following patients with HIV. We selected patients diagnosed with HIV in the last 5 years, aged 18 and more, born outside Spain and able to complete the survey in one of the 15 available languages. Two questionnaires were used: one self-completed by participants in a computer/tablet and another about patients' clinical data. We collected epidemiological, socioeconomic, clinical, behavioral, migratory trajectory, previous HIV serology, CD4 determinations, viral load and viral subtype data. To estimate timing of HIV acquisition, Bayesian methods with longitudinal measurements of CD4 and viral load were used and estimates were made applying mixed linear models based on HIV natural history (data from the European collaboration of seroconverters CASCADE).
Results: 685 in 710 participants (97%) had data to estimate time of HIV acquisition (TA). Participants with information on TA had a median of 9 years [RI: 6-13] of residence in Spain, were mainly male (77%) and from Latin America and the Caribbean (LAC) (64%), Other European Countries (OEC) (17%) and Sub-Saharan Africa (SSA) (13%). Most common route of transmission was the relationship between men who have sex with men (MSM) (60%), followed by heterosexual transmission (34%); Injecting drug users (IDUs) were minority (3%) and in 3% were unknown. 76% of patients acquired HIV after migrating to Spain. HIV post-migration acquisition was higher among MSM (85%) than in heterosexuals (67%), and in people from LAC (77%) and OEC (75%) compared to those from SSA (62%). HIV was acquired after migrating in greater proportions among those aged more than 50 years (82%), with secondary or university studies (77%) and with legal residency status (79%).
Conclusions: A significant proportion of migrants living with HIV in Spain acquired HIV after migration. The proportion of post-migration HIV acquisition is higher among MSM and in people from LAC and OEC. These results show a failure in preventive interventions in specific migrants' groups and emphasize the need to design interventions taking into account migrants heterogeneity.

TUAC0502

Prevalence, trends and risk factors of transactional sex among men who have sex with men in metro Vancouver, Canada: a longitudinal event-level analysis

N.J. Lachowsky[1,2,3], L. Wang[1], J. Zhu[1], H. Armstrong[1,4], M. Taylor[5], G. Olarewaju[1], R. Hogg[1,6], E.A. Roth[7], D.M. Moore[1,4], Momentum Health Study
[1]British Columbia Centre for Excellence in HIV/AIDS, Division of Epidemiology & Population Health, Vancouver, Canada, [2]University of Victoria, School of Public Health and Social Policy, Victoria, Canada, [3]Centre for Addictions Research BC, Victoria, Canada, [4]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [5]Health Initiative for Men, Vancouver, Canada, [6]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [7]University of Victoria, Department of Anthropology, Victoria, Canada
Presenting author email: nlachowsky@cfenet.ubc.ca

Background: Debate continues with respect to whether transactional sex among men who have sex with men (MSM) constitutes increased risk of HIV transmission. We sought to identify factors associated with transactional sex using event-level data from a population-based longitudinal behavioural cohort of MSM in Metro Vancouver, Canada.
Methods: Sexually-active MSM aged ≥16 years were recruited using respondent-driven sampling (RDS), and from 02/2012-02/2016 participants completed study visits every six months, which included a computer-assisted self-interview. At each visit, participants provided event-level data by reporting on their last sexual encounter with their five most recent partners (e.g. participant and partner substance use, partner's relative age). We used a four-level mixed effects model (RDS recruitment chain; participant; visit; event) to evaluate temporal trends and factors associated with transactional sex. We built a multivariable model to compare events where money, drugs or goods were received for sex to events with no transaction reported using backward selection with minimization of QIC and type III p-values.
Results: Of 690 participants, 8990 sexual events were reported across 2792 study visits (median follow-up time of 3.62 years). Although 11.7% of participants reported any transactional sex, event-level reports were rare: 2.4% of events included receiving money/drugs/goods, 1.5% of events included providing money/drugs/goods, and 96.0% of events did not include transactional sex. Transactional sex decreased over time (3.8% to 1.0% from first to eighth visit: odds ratio [OR]=0.82, 95% confidence interval [CI]:0.73-0.92). After controlling for significant individual-level factors, the following event-level factors were associated with greater odds of transactional sex: having met online (adjusted OR [aOR]=3.32, 95%CI:1.32-8.37), having a shorter relationship (aOR=0.99 per month, 95%CI:0.99-1.00), having an older partner (aOR=2.42, 95%CI:1.02-5.75), and having a partner who used crystal methamphetamine (aOR=3.85, 95%CI:1.12-13.17) or used gamma-hydroxybutyrate (aOR=6.79, 95%CI:2.19-21.01). Across all events, sexual HIV risk was not associated with transactional versus non-transactional sex: 23% versus 24% reported condomless anal sex with a sero-concordant partner (p=0.212) and 17% versus 12% reported event-level condomless anal sex with a sero-discordant/unknown status partner (p=0.946).
Conclusions: Transactional sex events were rarely reported. Partner substance use was strongly associated with transactional sex, but we found no significant associations with HIV risk behaviour.

TUAC0503

Is on-demand HIV pre-exposure prophylaxis (PrEP) a suitable tool for men who have sex with men (MSM) who participate in chemsex? Results from a sub-study of the ANRS-IPERGAY trial

P. Roux[1], L. Fressard[1], M. Suzan-Monti[1], J. Chas[2], C. Capitant[3], L. Meyer[3], C. Tremblay[4], J.-M. Molina[5], G. Pialoux[2], B. Spire[1], ANRS IPERGAY Study Group
[1]INSERM, INSERM U912 - SESSTIM, Marseille, France, [2]Hôpital Tenon-APHP, Department of Infectious Diseases, Paris, France, [3]INSERM, Inserm SC10 US019, Villejuif, France, [4]Centre Hospitalier de l'Université de Montréal, Laboratoire de santé publique du Québec, Montréal, Canada, [5]University, Paris Diderot, Paris, France
Presenting author email: perrine.roux@inserm.fr

Background: Chemsex - the use of psychoactive substances during sexual encounters - is a growing concern among men who have sex with men (MSM). It includes the even riskier practice of "slamming", which consists in injecting a substance before having sex. On-demand HIV pre-exposure prophylaxis (PrEP) may be a suitable tool to prevent HIV transmission in "chemsexers" (i.e., those practicing chemsex). We used a sub-study of the ANRS-IPERGAY trial to describe chemsexers and their PrEP use.
Methods: Among the 361 MSM (3051 visits) enrolled in ANRS-IPERGAY's open-label extension study, we selected the 331 (1657 visits) who reported drug use during at least one sexual encounter. A two-monthly web questionnaire over 12 months collected socio-behavioral data including the use of PrEP and practicing chemsex. We compared sexual behaviors between visits where chemsex was reported and those where it was not. A GEE logistic regression was used to study whether practicing chemsex was associated with PrEP use.
Results: Among the 331 participants, during follow-up, 29% reported chemsex while 8% reported slamming at least once. Chemsex was reported in 16% of all visits (12 and 4%, respectively, with one and multiple partners) mainly involving the use of GHB/GBL (51%) and synthetic cathinones (46%). Chemsexers were not significantly different from non-chemsexers regarding sociodemographic characteristics, although they reported higher use of anxiolytics during the previous 12 months ($p< 10^{-2}$). When MSM reported chemsex during their most recent sexual encounter, it was associated with a greater likelihood of receptive anal sex ($p< 10^{-3}$), hardcore sexual practices ($p< 10^{-3}$), casual partner(s) ($p< 10^{-3}$), and a higher perception of risk ($p< 10^{-3}$). Those who reported chemsex at their most recent encounter were more likely to use PrEP than those who did not ($p< 10^{-3}$), and less likely to use condoms ($p< 10^{-3}$). After adjustment for other potential correlates, chemsex remained associated with PrEP use (OR[95%CI=2.18[1.04;4.59]).
Conclusions: Our findings show that chemsexers are more likely to report high-risk sexual practices but also have a higher perception of risk. Consequently, they are also more likely to use PrEP when practicing chemsex; PrEP may be a suitable tool to reduce HIV risk transmission among chemsexers.

TUAC0504

Assessing HIV prevalence and health outcomes of children of female sex workers in Port Elizabeth, South Africa to guide PMTCT programming for vulnerable populations

S. Schwartz[1], Z. Kose[2], M. Mcingana[3], A. Rao[1], A. Lambert[4], V. Srivatsan[1], N. Phaswana-Mafuya[2], H. Hausler[4], S. Baral[1]
[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Human Sciences Research Council, Port Elizabeth, South Africa, [3]TB/HIV Care Association, Port Elizabeth, South Africa, [4]TB/HIV Care Association, Cape Town, South Africa
Presenting author email: sschwartz@jhu.edu

Background: Female sex workers (FSW) are disproportionately affected by HIV. Although the majority of FSW are mothers, little is known about the health outcomes, including HIV prevalence and programmatic needs, among their children.
Methods: FSW in Port Elizabeth, South Africa were recruited at mobile clinics and within the community to bring their children ≤12 years to the study site. A cross-sectional interview with the mother, followed by health assessments for the mother and her children were completed. HIV testing was completed for mothers and children; children were tested using rapid antibody tests (≥18 months) or polymerase chain reaction (< 18 months). HIV outcomes and health status of mothers and children are characterized. Stunting and wasting were estimated using WHO 2006 Child Growth Standards.
Results: From July 2015-February 2016, 114 mothers and 200 children were enrolled. Overall, 77/114 (68%) mothers were living with HIV, of which 53% (41/77) were on antiretroviral therapy. On average, FSW continued sex work for a median of 5 months during their last pregnancy [IQR 4-7]. The median age of children attending was 6 years [IQR 3-9]. The majority (73%, n=145/200) of children were breastfed; the median and mean duration of breastfeeding were 6 (IQR 3-24) and 12 months (sd 12) respectively. Just over half (108/200) of children had ever been tested for HIV, including 95/133 (71%) of children with HIV-positive mothers. HIV prevalence among children was 3% (5% among those with HIV-positive mothers n=6/133). Seventy-three percent of children were reported as up-to-date on their vaccinations. Among the 79 children under 5, 29% were stunted according to height-for-age and 13% wasted per weight-for-age.
Conclusions: The majority of FSW mothers were HIV-positive and many were not on treatment. HIV prevalence among children was higher than the national average among children and nearly one-third of children with HIV-positive mothers had never received HIV testing. Aside from children's HIV risks, substantial chronic nutritional deficiencies were identified through height-for-age, alongside acute nutritional deficiencies (weight-for-age) and immunization gaps. Programs for FSW should address vertical transmission risks including treatment support during pregnancy and breastfeeding, and consider catch-up HIV testing and vaccination campaigns to promote children's health.

Presenting author email: khuepm@gmail.com

Background: In Vietnam, HIV control programs targeting persons who inject drugs (PWID), including harm reduction and scaled up ART have been implemented for about 10 years. Although HIV prevalence is declining in this group, the impact of this program on the rate of HIV new infections, but also on HCV transmission, remains unknown.
Methods: We carried out a community-based respondent driven sampling (RDS) survey among ‚active PWID' (i.e. with positive urine test for heroin and presence of injection marks) in Haiphong, with HIV and HCV testing. Then, HIV-negative participants and HCV-negative participants not on methadone maintenance therapy (MMT) were eligible for 1 year follow-up. HIV/HCV was tested at 6 months and 1 year along with routine harm reduction activities from community-based organizations (CBO) and support to access MMT. We estimated HIV and HCV incidence and risk factors associated with HCV seroconversion.
Results: Among 603 RDS participants, 90% were males, and their median age was 36.5 years. HIV prevalence was 25% (95%CI: 22-29) and HCV prevalence was 66% (95%CI: 63-70). 204 RDS participants were enrolled in the cohort, including 94 HIV-/HCV-, 5 HIV+/HCV-, 105 HIV-/HCV+. The cohort participants were mainly males (90%) with a median age of 37 years [IQR 30-44] and a median number of injections over the last month of 90 [IQR 60-90]. The retention rate at 63 weeks was 78%. No participant seroconverted for HIV during the 206.0 person-years of follow-up (HIV incidence unilateral CI: 0-1.8/100 persons-year). Eighteen participants seroconverted for HCV, mainly during the first six months (13/18), for a HCV incidence of 18.8/100 person-years [95%CI; 11.2-29.8]. In multivariable analyses, only injecting more than 75 times per month vs injecting less than 75 times per month (OR: 8.7 [95%CI; 2.1-41.4]) was associated with HCV seroconversion.
Conclusions: In Haiphong, harm reduction activities and high levels of antiretroviral treatment likely contributed to the reduction of HIV epidemic among PWID. However, HCV incidence is still unacceptably high. Current harm reduction activities cannot control the HCV epidemic, additional strategies such as universal ART and large-scale HCV treatment should be urgently evaluated to end the HIV epidemic and tackle HCV transmission among PWID in Vietnam.

TUAD01 Treat All: How to Make It Happen and Can We Afford It?

TUAD0101

Wide-ranging real-world impacts of a policy change on treatment eligibility on ART initiation and retention in care in Zambia

A. Mody[1], A. Zanolini[2], K. Sikombe[2], P. Somwe[2], I. Sikazwe[2], C. Bolton[2], C. Holmes[2,3], N. Padian[4], E. Geng[1]
[1]*University of California, San Francisco, Division of HIV, ID, and Global Medicine, San Francisco, United States,* [2]*Centre for Infectious Disease Research in Zambia, Lusaka, Zambia,* [3]*Johns Hopkins University, Division of Infectious Diseases, Baltimore, United States,* [4]*University of California, Berkeley, School of Public Health, Berkeley, United States*
Presenting author email: aaloke.mody@ucsf.edu

Background: Incomplete uptake as well as unforeseen consequences often accompany changes in public health guidance. In April 2014, Zambia increased the CD4 threshold for HIV treatment from 350 to 500 cells/μL. We evaluated the effect of this guideline change on ART uptake and retention in patients both targeted and not targeted by this change to evaluate for unintended consequences using a regression discontinuity design.
Methods: We analyzed non-pregnant ART-naïve patients in Zambia who newly enrolled within 6 months of the guideline change (September 1, 2013 to November 1, 2014), excluding patients enrolled within 30 days of the implementation date to account for imprecise rollout. We utilized a quasi-experimental regression discontinuity design with local linear regression to estimate the effects of this policy change on ART initiation within 3 months of enrollment and retention in care at 6 months (defined as clinic attendance between 3 and 9 months after enrollment) in all new enrollees, stratifying by enrollment treatment eligibility.
Results: 20,513 patients (53.1% female, median age 34 years [IQR 28 - 41]) were eligible for our analysis. Newly-eligible patients (CD4 350-500, 15.5% of patients) saw a significant increase in ART initiation within 3 months (risk difference [RD] +35.3%, 95% CI 28.1-42.4%, p< 0.001) and retention at 6 months (RD +7.4%, 95% CI 0.5-14.3%, p=0.034) with the policy change. Additionally, never-eligible patients (CD4>500, 17.0% of patients) also saw an increase in ART initiation with the guideline change (RD +16.3%, 95% CI 9.8-22.7%, p< 0.001), though retention was unaffected (p=0.203). Among always-eligible patients (CD4≤350 or WHO Stage≥3, 67.6% of patients), ART initiation at 3 months (p=0.955) and retention at 6 months (p=0.600) were unaffected.
Conclusions: Policy increasing CD4 threshold for treatment eligibility led to rapid changes in ART initiation practices as well as enhanced retention in the group targeted by the guidelines. ART initiation also improved amongst treatment-ineligible patients with the policy change, a positive spillover effect perhaps due to expansion of ART supply, while initiation and retention among those always-eligible was not compromised. Real-world implementation of evidence-based practice often has broader impacts than those directly targeted that should be routinely evaluated to guide policy interventions.

TUAD0102

Pre-ART peak and plateau: early lessons from Zimbabwe on operational impact of "pre-ART mop-up" on ART initiation rates under Treat All

K. Webb[1], V. Chitiyo[1], P. Nesara[1], S. Page-Mtongwiza[1], J. Murungu[2], T. Maphosa[1], P. Mbetu[1], B. Engelsmann[1]
[1]*Organisation for Public Health Interventions and Development, Harare, Zimbabwe,* [2]*Ministry of Health and Child Care, AIDS & TB, Harare, Zimbabwe*
Presenting author email: kwebb@ophid.co.zw

Background: WHO 2015 test and treat guidelines recommend ART initiation for all people living with HIV regardless of CD4 count or WHO clinical staging. Implementation of Treat All will require identification and return of pre-ART patients previously clinically ineligible for ART into care for timely initiation. Little is known about the feasibility and timelines required to conduct pre-ART mop-up in resource-limited settings. Our objective was to establish the proportion of clients initiated on ART from pre-ART mop-up following start of Treat All in 92 public health facilities in 7 districts of Zimbabwe.
Methods: We purposively selected 92 health facilities implementing Treat All learning phase. We analyzed routinely reported data from Apr-Dec-2016, comparing proportion of new ART initiations to patients newly diagnosed as HIV positive using Chi-square. A facility-based survey of pre-ART register data and health care worker (HCW) perceptions and experiences of pre-ART mop-up during initial stages of Treat All was conducted to identify key operational themes.
Results: Over the period of interest, 9,875 clients newly initiated on ART. The proportion of new ART initiations vs. newly-diagnosed peaked at 160% after start of Treat All, and plateaued back to below 100% of new diagnoses after 6 months, rates significantly higher than before Treat All (69.4% vs 91.9%, p< 0.0001).

[Proportion ART initiation from new HIV diagnosed]

Additional cell phones, air time and staff for identifying and contacting pre-ART patients were crucial for tracing large numbers of pre-ART clients at start of Treat All.
Conclusions: We demonstrate success of Treat All at returning previously ineligible HIV positive clients for ART initiation in a resource-limited, high-burden setting. Provision of additional resources to support pre-ART mop-up phase were required and recommended for replication as Treat All scales up. Following return to care of traceable pre-ART clients, ART initiations stabilise to rates above 90%, indicating the value of Treat All for progress towards the 2nd 90.

TUAD0103

Evaluating the feasibility of implementing UNAIDS' 90 90 90 strategy, achieving universal access to treatment and eliminating HIV in Malawi

S. Blower, L. Palk
UCLA Medical School, Semel Institute, Santa Monica, United States
Presenting author email: sblower@mednet.ucla.edu

Background: Malawi has a severe HIV epidemic: prevalence in the general population is ~11%. The majority of the population of ~16 million live in rural communities. We estimate the total number of HIV-infected individuals (both diagnosed and undiagnosed) in Malawi, and determine their geographic location. We use these results to evaluate the feasibility of implementing UNAIDS'90-90-90 strategy and of achieving universal access to treatment.
Methods: We constructed an epidemic surface prevalence (ESP) map using georeferenced HIV-testing data from ~14,000 individuals (15-49 years old) who participated in a nationally representative population-level survey: the 2010 Malawi Demographic and Health Survey. We constructed a density of infection (DoI) map by combining the ESP map with gridded demographic data from the WorldPop database and a census-based age-structure map. The DoI map shows the estimated number of HIV-infected individuals (15- 49 years old) in each square kilometer in Malawi, diagnosed and undiagnosed individuals. We calculated the total number of HIV-infected individuals by aggregating the mapped estimates.
Results: The ESP map shows prevalence (in 15-49 year olds) varies from ~1% to ~25%, there is a strong North-South trend in increasing prevalence, and a substantial urban-rural difference. Prevalence is highest in cities in the South (Blantyre and Zomba), Lilongwe in the Central region, Mzuzu in the North, and villages along Lake Malawi. The DoI map reveals the geographic dispersion pattern of all infected individuals. DoI ranges from one infected individual/ km^2 in rural areas to more than 1,000 infected individuals/km^2 in the four major urban centers. The map shows substantial regional differences in the DoI; our results show that these reflect differences in settlement patterns, population density, and prevalence. We estimate there were ~692,000 HIV-infected individuals (15-49 years old) in 2010 in Malawi, and only ~25% were living in urban areas.
Conclusions: Our results show the vast majority of HIV-infected individuals in Malawi live in rural areas in small communities where the DoI is low. This indicates that implementing the 90 90 90 strategy and achieving universal access to treatment may not be feasible. We recommend that HIV elimination strategies for resource-constrained countries are designed based on DoI, and not prevalence.

TUAD0104

Generic treatments for HIV, HBV, HCV, TB could be mass produced for <$90 per patient

A. Hill[1], M. Barber[2], D. Gotham[3], J. Fortunak[4], A. Pozniak[5]
[1]University of Liverpool, Liverpool, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Imperial College London, London, United Kingdom, [4]Howard University, Washington, United States, [5]Chelsea & Westminster Hospital, London, United Kingdom
Presenting author email: dzintarsgotham@googlemail.com

Background: High prices to treat HIV, viral hepatitis and TB can limit treatment access. This analysis aimed to determine prices currently feasible for HIV, HBV, HCV, and first-line (1L) DS-TB treatment, assuming competitive generic manufacture.
Methods: Data on API exported from India were collected from an online database (www.infodriveindia.com) for July 2014-July 2016. Linear regression was used to plot API cost/kg versus export date, weighted by export volumes: the generated model was used to calculate current average cost/kg of API. Target prices were calculated based on the per-pill cost of API, plus costs of manufacture ($0.01/pill), 10% profit margin, and assumed 27% tax on profit. Current lowest global prices are from public reports and the Global Drugs Fund (TB), US prices from the Centers for Medicare & Medicaid Services. Patent protection expiry dates are from FDA Orange Book and Medicines Patent Pool Patent Status Database.
Results: The Table shows current prices of antiretrovirals for HIV, entecavir (ETV) for HBV (per person-year), HCV treatments (per 12-week course) and 1L DS-TB treatment (RHZE, per 6-month course). API costs/kg were $1189 for ATV, $182 for TDF, $241 for 3TC, $109 for EFV, $380,965 for ETV, $1224 for SOF, $4448 for LDV and $852 for DCV. EFV, 3TC, ETV, and RHZE are already generic in USA. The US substance patents on atazanavir expire in 2017, TDF 2018, sofosbuvir 2030, daclatasvir 2031. Sofosbuvir+ledipasvir combination patents expire in 2032.

DRUG	USA	GLOBAL LOWEST	TARGET	PATENT EXPIRY
ATV	$16,093	$170	$151	2017
TDF/3TC/EFV	$23,965	$107	$83	2018
ETV	$5,915	$409	$82	GENERIC
SOF/LDV	$91,207	$408	$85	2032
SOF/DCV	$142,710	$66	$52	2031
TB: RHZE	$945	$27	$28	GENERIC
PRICES: HIV&HBV - PER YEAR, HCV - PER 12 WEEK COURSE, TB - PER STANDARD 6 MONTH FIRST-LINE REGIMEN. USD.				

[Prices and year of patent expiry]

Conclusions: Treatment of HIV, HBV, HCV, and TB could be achieved for < $90 per person globally, if robust generic competition is enabled. In most countries, generic TDF/3TC/EFV, TDF/3TC, ETV or 1L DS-TB treatment could be available for < $90 by early 2018, after patent expiry. Most HCV DAAs will remain on patent for ≥12 more years. Voluntary licensing or other mechanisms will be required to enable access to HCV DAAs at low prices.

TUAD0105

Comparative analysis of ARV costs before and after the Clinical Protocol and Therapeutic Guidelines for the management of adult HIV infection (PCDT) was adopted in 2013 in Brazil

M.C. Pimenta[1,2], L. Hasenclever[3,4], C.F. Rocha[3], G. Cunha[3], A. Ana Pati Pascom[5], M. Freitas[5], R. Girade Corrêa[5], G.F. Mendes Pereira[5], C.J. Braga Batista[6], J. Monteiro da Cruz[6]
[1]Ministry of Health of Brazil, STI/HIV/VH Department, Rio de Janeiro, Brazil, [2]Veiga de Almeida University, School of Nursing, Rio de Janeiro, Brazil, [3]Federal University of Rio de Janeiro, Institute of Economics, Rio de Janeiro, Brazil, [4]University Candido Mendes, Economics, Rio de Janeiro, Brazil, [5]Ministry of Health of Brazil, STI/HIV/VH Department, Brasilia, Brazil, [6]Ministry of Health, STI/HIV/VH Department, Brasilia, Brazil
Presenting author email: cpimenta48@gmail.com

Background: The PCDT of 2013 established standardization of treatment, practice of early treatment and treatment for all. These initiatives have diverse and opposing consequences on the costs of antiretrovirals (ARVs). Objectives were to know and ponder these consequences by comparing costs between the antiretroviral treatment structure used until 2013 and the PCDT changes applied since 2014. The problem evaluated was if the number of patients and the resulting increase in total costs would be counterbalanced by a significant reduction in average costs as consequence of recommendations for standardization and simplification of treatment, considering the 2020 timeline.
Methods: The study covered 2009-2013 and 2014-2015, scenarios before and after the adoption of the PCDT, in Brazil by the Institute of Economics of the Federal University of Rio de Janeiro with the Ministry of Health. The study design estimated the total and average costs for the total adult patients treated in December 2009 and 2015, comparing them to estimate the observed cost difference between the two strategies adopted; followed by a simulation of results for 2020. Scenarios of the evolution of costs of HAART took into account treatment targets of the analysed population and changes of schemes. The study population involves all adult patients under treatment 207.014 and 444.093 respectively. Data collection used Systems for Control of Laboratory Tests (CD4 and viral load), for ARV Dispensation, and price records of ARV.
Results: Findings indicate decrease in the average costs due to a higher concentration of patients in first-line regimens in 2015. The difference is even more important in the incoming population. The significance is that the total cost of patients in 2015, with an average cost of 41.46% lower, allowed savings of more than 250 million US$. With the average cost of 2009, the total annual cost of patients in 2015 would be 70.83% higher if the PCDT had not been adopted. This is enough to cover 675.000 new patients, and more than compensate for the adoption of treatment as prevention.
Conclusions: Results become even more relevant since cost savings were accompanied by a better clinical outcome of patients with simplification of treatments.

Association between user fees and dropout from methadone maintenance therapy: results of a cohort study in Vietnam

B. Johns[1], L.B. Chau[2], K.H. Hanh[3], N.D. Manh[4], H.M. Do[2], A.T. Duong[5], L.H. Nguyen[4]
[1]Abt, International Health, Bethesda, United States, [2]Hanoi School of Public Health, Hanoi, Vietnam, [3]Health Financing and Governance Project, Hanoi, Vietnam, [4]Vietnam Authority of HIV/AIDS Control, Hanoi, Vietnam, [5]Vietnam Authority of HIV/AIDS Control, Financing Department, Hanoi, Vietnam
Presenting author email: thuyanhvaac@gmail.com

Background: Starting in 2015 with the devolution of fiscal responsibility for methadone maintenance therapy (MMT) to provinces in Vietnam, some provinces started to collect user fees at MMT clinics to cover the costs of incidentals. A pilot study in Hai Phong province suggested that user fee collection is feasible and affordable to MMT clients. How user fees might affect clients' ability to maintain MMT attendance in other provinces has not been assessed. The primary objective of this study is to assess the association between user fees and client dropout from MMT exploiting the fact that some provinces had implemented user fees in 2015 while other had not. The secondary objective was to estimate the catastrophic payments associated with MMT.
Methods: An observational cohort study of 1,021 MMT clients in seven provinces from May/June 2015 to May/June 2016. Three provinces implemented user fees, while four provinces did not. Provinces and facilities were randomly selected, while all MMT clinics in the selected provinces were included. Box Cox proportional hazard models were used to assess the association between user fees and (i) dropout and (ii) being inactive.
Results: About 85% of the cohort was actively on MMT at the end of the observation period, including 10% of clients had transferred facilities and 1% of clients quit with facility staff permission. About 14% of the cohort had stopped MMT care, about 8% dropped out, 3.5% were incarcerated, 1.5% died, and 2% stopping for other reasons. The hazard ratio for paying user fees compared to not paying user fees ranged from 0.70 (unadjusted, p=0.26) to 0.29 (adjusted, p=0.33) for dropout and from 0.75 (unadjusted, p=0.24) to 0.50 (adjusted, p=0.48) for being inactive. However, 29% of clients at facilities paid more than 40% of non-subsistence expenditures for MMT associated user fees and transportation.
Conclusions: Over the course of one year, we do not find evidence that user fees increased dropout or reduced retention in MMT. Overall, dropout rates in Vietnam are very low compared to other countries. However, catastrophic payment rates remain a concern, and longer term follow-up is needed.

TUAD0202

A combination intervention strategy to enhance outcomes across the HIV care continuum and support epidemic control: data from a cluster-randomized trial in Mozambique

B. Elul[1,2], M. Lamb[1,2], L. Ahoua[3], F. Abacassamo[4], S. Kujawski[1], M. Lahuerta[1,2]
[1]Columbia University, Mailman School of Public Health, Department of Epidemiology, New York, United States, [2]ICAP at Columbia University, New York, United States, [3]ICAP at Columbia University, Maputo, Mozambique, [4]Center for Collaboration and Health, Maputo, Mozambique
Presenting author email: be2124@columbia.edu

Background: Identifying practical interventions that can be implemented at scale to enhance outcomes across the HIV care continuum is essential to maximizing individual and population benefits of ART.
Methods: Engage4Health, an implementation science study using a cluster-randomized design, was conducted at 10 health facilities in Mozambique and evaluated the effectiveness of a combination intervention strategy (CIS) vs the standard of care (SOC) on important HIV care continuum outcomes. CIS included: (1) point-of-care CD4+ count at HIV testing sites; (2) accelerated ART initiation for eligible patients; and (3) SMS appointment reminders. A subset of CIS participants additionally received non-cash financial incentives (CIS+FI). Adults ≥18 years newly diagnosed with HIV and willing to receive HIV care at the diagnosing health facility were enrolled from 4/13-6/15 and followed for 12 months. Clinic-based outcomes were assessed using electronic medical records, while death was determined by triangulating data from medical records, patient tracing, and mortality registries.
Results:
A total of 2004 participants (767 SOC, 744 CIS, 493 CIS+FI) were enrolled; the majority (64%) were female and the mean age was 34 years. In intent-to-treat analyses, participants at CIS vs SOC sites were more likely to link to care on the day they were diagnosed (89% vs 16%, RR=5.60, 95%CI 4.79-6.69); have their ART eligibility assessed (100% vs 77%, RR=1.30, 95%CI 1.25-1.35), be identified as ART eligible (75% vs. 60%, RR=1.24, 95% CI 1.15-1.33), initiate ART (65% vs. 54%, RR=1.20, 95% CI 1.10-1.30), and be retained at 12 months (58% vs 44%, RR=1.32, 95%CI 1.19-1.45). No additional benefits on these outcomes were observed when FI were added to the CIS. Neither CIS nor CIS+FI had a significant effect on mortality within 12 months of diagnosis or after ART initiation, but mortality prior to ART initiation was lower at CIS+FI vs SOC sites (1% vs. 4%, RR=0.27, 95% CI 0.10-0.69).
Conclusions: The CIS offers a promising, pragmatic approach for enhancing critical outcomes necessary for epidemic control. Further efforts are needed to identify interventions to reduce mortality, particularly among patients on ART.

Economic evaluation of non-financial incentives to increase couples HIV testing and counselling uptake in Zimbabwe

C. Mangenah[1], E. Sibanda[2], K. Hatzold[3], G. Maringwa[4], S. Gudukeya[5], N. Madidi[3], O. Mugurungi[6], F. Terris-Prestholt[7], F. Cowan[4], H. Thirumurthy[8]
[1]Centre for Sexual Health, HIV and AIDS Research (CeSHHAR), Health Economics, Harare, Zimbabwe, [2]Centre for Sexual Health, HIV and AIDS Research (CeSHHAR), Sexual and Reproductive Health Studies, Harare, Zimbabwe, [3]Population Services International, Zimbabwe, HIV Prevention, Harare, Zimbabwe, [4]Centre for Sexual Health, HIV and AIDS Research (CeSHHAR), Harare, Zimbabwe, [5]Population Services International, Zimbabwe, Harare, Zimbabwe, [6]Ministry of Health and Child Care (MOHCC), Harare, Zimbabwe, [7]London School of Hygiene and Tropical Medicine (LSHTM), London, United Kingdom, [8]University of North Carolina at Chapel Hill, Chapel Hill, Zimbabwe
Presenting author email: cmangenah1@gmail.com

Background: Uptake of couples HIV testing and counselling (CHTC) in southern Africa remains low despite multiple HIV prevention and health benefits. Small incentives can increase CHTC uptake by offsetting real and perceived costs to couples. We estimate cost-effectiveness of providing non-financial incentives for CHTC in a cluster randomized controlled trial (RCT).
Methods: 34 communities in rural Zimbabwe received standard community mobilization for HIV testing at mobile clinics while in 34 randomly selected communities individuals seeking CHTC were offered in-kind incentives (choice between a laundry bar, petroleum jelly, or cooking oil) worth $10,859.22. Costs for community mobilization, CHTC, and incentives were calculated from the program perspective (2015 US$). Incremental cost-effectiveness ratios (ICERs) were estimated for the number tested, number tested with a partner, and number of HIV-positive individuals tested.
Results: In control communities, 1,062/10,580 (10.0%) individuals tested as couples compared to 7,852/14,099 (55.7%) in intervention communities. 530 additional HIV-positive persons were identified in intervention communities. Total incremental intervention cost was $25,687.50, translating to an ICER of $7.98 per couple tested ($3.99 per individual client tested) and $48.47 per HIV positive diagnosis. Mean costs per person tested in control and intervention communities were $8.18 and $7.96 respectively, with costs per HIV-positive person identified $93.10 and $128.10, respectively.
Conclusions: This RCT provides evidence that in addition to increasing HTC access, policymakers, implementers, and external donors should consider providing in-kind incentives as they are cost-effective at increasing CHTC uptake and identifying HIV-positive persons.

Capital costs	Intervention Cost ($)	% contribution	Control Cost ($)	% contribution
Incentives	$10,859.22	10%	$0.00	0%
Human resources	$78,705.00	70%	$69,423.75	80%
Equipment	$1,154.95	1%	$1,154.95	1%
Medical supplies	$2,541.42	2%	$1,919.76	2%
HIV test kits	$2,266.16	2%	$1,537.96	2%
Stationary and other supplies	$16,753.95	15%	$12,556.78	15%
Total cost ($)	$112,280.70	100%	$86,593.20	100%
Mean cost/client	$7.96		$8.18	
Cost per HIV + client	$93.10		$128.10	

[Economic cost ($) calculation]

Intervention incremental cost (Incentive arm - standard mobilization arm)	$25,687.50
Intervention effect (incentive effects - non-incentive effects)	46%
Additional clients tested as a couple (14,099*46%)	6437
Additional clients tested individually	3519
Additional clients tested HIV positive	530
ICER per individual client tested HIV positive	$48.47
ICER per individual client tested ($25,687.50/6437)	$3.99
ICER per couple tested ($3.99x2)	$7.98

The effects of short-term cash and food incentives on food insecurity and labor force participation among HIV-infected adults initiating antiretroviral therapy in rural Tanzania

C. Fahey[1], P.F. Njau[2], N. Kapologwe[3], W.H. Dow[1], S.I. McCoy[1]
[1]University of California, Berkeley, United States, [2]Prevention of Mother-to-Child HIV Transmission Programme, Ministry of Health, Community Development, Gender, Elderly, and Children, Dar es Salaam, Tanzania, United Republic of, [3]President's Office - Regional Administration and Local Government Authorities (PO-RALG), Shinyanga, Tanzania, United Republic of
Presenting author email: cfahey@berkeley.edu

Background: We previously demonstrated that short-term cash and food incentives increased antiretroviral therapy (ART) possession and retention in HIV services in Tanzania. To elucidate potential pathways that led to these achievements, we examined whether these incentives also improved food security and labor force participation.
Methods: At three clinics, 805 food-insecure adults who recently initiated ART (≤90 days prior) were randomized to receive cash or food transfers (~$11/month for ≤6 months, conditional on visit attendance) or standard-of-care (SOC) ART. After 6 months, we re-assessed food security (Household Hunger Scale), body-mass index (BMI), employment, and functional limitation (illness prevented work or housework) among patients returning for ART. The incentives' effectiveness at increasing retention contributed to differential loss-to-followup (13% overall; 20% SOC; 8% cash; 15% food; p< 0.01), which we accounted for in the current analysis using inverse probability weighting.
Results: After 6 months, food security improved from 0% to 37% (p< 0.01) and did not differ comparing the SOC (33%) to cash (36%, p=0.64) or food (39%, p=0.37) groups. Mean BMI increased from 21.5 to 22.7 kg/m^2 (p< 0.01), with no differences comparing SOC (22.5 kg/m^2) to cash (22.6 kg/m^2, p=0.76) or food (22.9 kg/m^2, p=0.15). Employment rose from 58% to 76% (p< 0.01), with no differences between SOC (80%) and cash (75%, p=0.47) or food (75%, p=0.43). Functional limitation decreased from 55% in the year before enrollment to 12% in the following 6 months (p=0.02) and was significantly lower in the food group (9% vs. 18% SOC, adjusted OR=0.41, 95% CI: 0.18, 0.96, p=0.04); cash was non-significantly lower (13% vs. 18% SOC, adjusted OR=0.64, 95% CI: 0.27, 1.5, p=0.32).
Conclusions: Food security and employment substantially improved across all study groups after 6 months of ART. Short-term cash and food incentives did not augment these gains relative to standard-of-care ART, with the exception of significantly less functional limitation among the food group. This suggests that cash and

food transfers acted primarily via the price incentive (increasing ART adherence), rather than mitigating socioeconomic barriers through income effects. Future studies are needed to better understand the mechanisms through which incentives may increase and sustain retention in HIV services.

TUAD0205

Using conjoint analysis to model hospital directors' decision making in adoption of an evidence-based stigma-reduction intervention

C. Lin[1], L. Li[2], S.-J. Lee[2], Z. Wu[3]
[1]UCLA, NPI-Center for Community Health, Los Angeles, United States, [2]UCLA, Los Angeles, United States, [3]China CDC, Beijing, China
Presenting author email: chunqinglin@hotmail.com

Background: Behavioral interventions that have demonstrated efficacy in randomized trial conditions have been underutilized in healthcare delivery. This study used conjoint analysis, a marketing research technique, to quantify the impact of different aspects of intervention in hospital stakeholders' decision making in adoption of evidence-based interventions (EBI).
Methods: The used a real-life intervention with efficacious outcome to reduce HIV-related stigma in healthcare settings as a "product" to study adoption of EBI. Conjoint analysis was conducted among 60 hospital directors recruited from 30 hospitals of different levels and types in Fujian Province, China. The directors evaluated their willingness to adopt the evidence-based stigma reduction intervention in their hospitals by rating across eight hypothetical scenarios with preferred and non-preferred levels of seven attributes, including 1) administrative support, 2) cost, 3) personnel involvement, 4) format, 5) duration, 6) technical support, and 7) priority alignment with the hospital. A mixed effect model was fit to the likelihood of intervention adoption for the eight scenarios, and the seven attributes (categorized as preferred=1 or not preferred=0) served as independent variables in the model.
Results: Monetary cost of intervention implementation (impact score=24.8) had the greatest impact on the directors' willingness to adopt a certain EBI, followed by duration of the intervention (impact score=10.0), availability of technical support (impact score=7.5), and flexibility of format (impact score=4.6). The majority (88.3%) of the hospital directors perceived the conjoint administration process as clear and easy to understand. The data collection time was relatively short, which was approximately 30 minutes.
Conclusions: Conjoint analysis was proven to be feasible in modeling hospital directors' decision making in adoption of EBI. There were several issues that one should consider when operationalizing conjoint analysis in dissemination and implementation research, including selection of EBI example, assigning the component level of the attributes, generating scenarios, and interviewer training. The findings have implications for design and dissemination of existing EBI in healthcare settings to optimize the public health impact.

Combined IL-21 and IFNα treatment limits residual inflammation and delays viral rebound in SIV-infected macaques

L. Micci[1], J. Harper[1], S. Paganini[1], C. King[1], E. Ryan[1], F. Villinger[2], J. Lifson[3], M. Paiardini[4,5]

Background: Although antiretroviral therapy (ART) suppresses HIV replication, immune dysfunctions and chronic inflammation critically contribute to non-AIDS-related morbidity and mortality in infected subjects. Furthermore, inflammation facilitates HIV persistence during ART. We previously demonstrated that addition of Interleukin (IL)-21, an immunomodulatory cytokine, reduces chronic inflammation and HIV persistence in ART-treated, SIV-infected rhesus macaques (RMs). In this study, sought to combine the anti-inflammatory functions of IL-21 with the antiviral properties of IFNa to reinvigorate antiviral responses. We hypothesize an impact on viral rebound following ART treatment interruption (ATI).
Methods: 15 RMs were infected with SIV_{mac239} IV. RMs started a triple-formulation of TDF, FTC, and Dolutegravir (DTG) day 35 post-infection and continued for at least 12 months. Eight RMs received Macaquized (M)-IL-21-IgFc (100 mg/kg, SC, once weekly for four weeks) at initiation and mid-way thru ART. Additionally, this group received M-IFNa-IgFc (500,000 IU, SC, once weekly for five weeks) prior to ART-interruption. Upon ART-discontinuation, the eight IL-21-treated RMs received PEGylated-IFNa-2a (PEGASYS), 7 mg/kg, SC, once weekly for seven weeks; while the remaining seven RMs were ART-treated controls. Blood (PB), lymph nodes (LN), and colorectal (RB) biopsies were longitudinally collected to assess the effects of IL-21 and IFNa on inflammation, T cell subsets, and viral persistence.
Results: ART fully suppressed plasma viremia (pVL) (< 30 RNA copies/mL) in all RMs. During ART, IL-21 reduced levels of activated ($HLA\text{-}DR^+CD38^+$) and proliferating ($Ki\text{-}67^+$) T cells in PB, RB, and LN in comparison to ART-only controls ($P< 0.01$). Levels of inflammation remained significantly lower also during and after addition of IFNa ($P< 0.01$). Upon ART-interruption, IL-21/IFNa-treated RMs exhibited delayed viral rebound with a median of 21 days as compared to 9 days in the controls ($P=0.0009$). Moreover, IL-21/IFNa-treated RMs maintained reduced viremia in comparison to controls up to 45 days after ATI ($P=0.0004$).
Conclusions: These data support the safety of a combined IL-21 and IFNa treatment for HIV infection. While IL-21-treatment effectively reduces inflammation, addition of IFNa prior- and after- ART-discontinuation resulted in a prolonged and more effective control of viral rebound. The synergy of such therapeutics may promote reinvigoration of host responses toward reduction of latent HIV reservoirs.

Background: We have reported that IL-27 inhibits HIV replication in macrophages, T-cells and dendritic cells (DC), and proposed that IL-27 is a potent novel antiviral cytokine. We have also demonstrated that IL-27 induces HIV-resistance in macrophages via downregulating SPTBN1 (Spectrin-beta chain brain 1) expression, however, the mechanism whereby IL-27 induces HIV-resistance in T-cells or DC has not been described
Methods: T-cells and monocytes were isolated from healthy donor PBMCs. T-cells were stimulated with PHA. Monocytes were differentiated to DC in the presence of IL-4 and granulocyte macrophage colony-stimulating factor (GM-CSF) with or without IL-27. HIV replication was monitored using a commercial p24 ELISA kit. CD4 and chemokine receptor expression were analyzed by FACS. Post-translational modification (PTM) of proteins were analyzed using 2-Dimentional Difference in Gel analysis (2D-DIGE) and Western blotting. Genes of interest were knocked down using siRNA.
Results: IL-27-treated PHA-stimulated T cells (27-T) and IL-27-induced DC (27-DC) resisted HIV infection by 70% and > 90%, respectively, without significant change in the expression of CD4, CCR5 or CXCR4. To define the mechanism of these anti-HIV effects, microarray and western blotting were performed. In 27-T cells, 4 genes were up-regulated by >3-fold and no genes were significantly down-regulated by > 2-fold in microarray analysis of ~20,000 genes. 2D-DIGE revealed that the amounts of PTM Y box binding protein 1 (YB1: a Y-box transcription factor) was diminished in 27-T by 60%. Knockdown of YB-1 in control T-cells led to 70% resistance to HIV infection. In 27-DC, over 100 genes were upregulated or down-regulated by >2-fold. A series of qPCR and Western blot analyses confirmed that the expression of ANKRD22 (ankyrin repeat domain 22) was consistently induced in 27-DC. Knock down of ANKRD22 reversed resistance to HIV infection in 27-DC. These results indicated that IL-27 induced HIV resistance in T cells and DCs by a decrease in PTM-YB1 and an increase in ANKRD22, respectively.
Conclusions: PTM-YB-1 and ANKRD22 were identified as novel host dependency factors in T-cells and DC, respectively. Taken together with our previous report, these data demonstrate that IL-27 induces HIV resistance in macrophages, T-cells and DC in cell type dependent manners.

TUPDA0103

Increased effector cytotoxic lymphocytes in lymph nodes of hetIL-15 treated macaques suggest potential to disrupt SIV/HIV reservoirs

A. Valentin[1], E. Moysi[1], D.C. Watson[1], C. Petrovas[2], C. Bergamaschi[1], B.K. Felber[1], G.N. Pavlakis[1]

Background: Heterodimeric interleukin-15 (hetIL-15) activates and expands cytotoxic T and NK cells, which suggests that the cytokine could be useful for the treatment of malignancies and HIV infection. Based in these properties, hetIL-15 is currently evaluated in humans for the treatment of cancer. We also study the effects of hetIL-15 in infected macaques to evaluate its use in HIV infection.
Methods: Twelve rhesus macaques received six subcutaneous injections of hetIL-15 over 2 weeks using increasing doses of cytokine (step-dosing). At the end of the treatment, the animals were sacrificed and the hetIL-15 effects on different lymphocyte populations isolated from tissues collected at necropsy were monitored by multi-parametric flow cytometry and quantitative multiplexed confocal microscopy (Histo-cytometry).
Results: This protocol was safe in rhesus macaques and resulted in systemic expansion (Ki67+) of CD8+ T lymphocytes and NK cells with higher granzyme B content. These expanded cell populations were found in both effector sites, such as liver, vagina and rectum, and secondary lymphoid tissues. Among the gut-resident CD8+ T lymphocytes, we found a gradient, based on anatomical location, of the IL-15-induced T cell proliferation, which follows the proliferation pattern found in untreated animals. Importantly, a significant increase in cytotoxic effector memory CD8+ T cells was found in lymph nodes (LN) from all hetIL-15-treated macaques, and this increase was bigger than that in SIV-infected animals. CM9 tetramer staining demonstrated that the increase of CD8+ effector T cells in lymphoid organs included actively proliferating SIV-specific T cells with higher granzyme content. Imaging analysis by Histo-cytometry revealed that these effector CD8+ T cells infiltrated the B cell follicles where chronically infected follicular helper CD4+ T cells are located.
Conclusions: Step-dose administration of hetIL-15 is a well-tolerated regimen that results in systemic activation and expansion of cytotoxic leukocytes that infiltrate areas where chronic HIV-infected cells reside. These results suggest that hetIL-15 could be useful in disrupting or eliminating long-term viral reservoirs in HIV-1 infected individuals, thus contributing to a functional cure of the infection. Work assessing the long-term impact of hetIL-15 on the size of the viral reservoir is currently ongoing.

TUPDA0104

The human IL-15 superagonist ALT-803 activates NK and memory T cells, reactivates latent SIV and drives SIV-specific CD8+ T cells into B cell follicles

G. Webb[1], S. Li[2], J. Greene[3], J. Reed[1], J. Stanton[1], A. Legasse[1], B. Park[1], M. Axthelm[1], E. Jeng[4], H. Wong[4], J. Whitney[5], B. Jones[6], D. Nixon[6], P. Skinner[2], J. Sacha[1]

Presenting author email: sacha@ohsu.edu

Background: There is an urgent need to develop alternate approaches to activate and clear the latent HIV reservoir that do not negatively impact immune function and are independent of viral sequence. IL-15 is a key cytokine for homeostatic maintenance, proliferation, and expansion of memory CD4+ T cells, the primary HIV cellular reservoir. Here, we explored the human IL-15 superagonist, ALT-803, as an immunostimulatory molecule and potential latency reversing agent (LRA) in cART-suppressed SIV-infected macaques.
Methods: SIV-naïve and SIV-infected macaques were administered ALT-803 IV and subsequently monitored for NK and T cell proliferation. SIV-infected macaques treated with ALT-803 were assessed for intrafollicular migration via in situ staining of lymph nodes with MHC class I tetramers. ALT-803 was tested as an LRA in vitro with primary CD4+ T cells from cART-suppressed macaques, and in vivo in SIV-infected, cART-suppressed macaques.
Results: ALT-803 activated and induced robust proliferation in NK cells, and in both effector and central memory T cells. ALT-803 redirected activated cells to secondary lymphoid tissues, a known anatomical location of the viral reservoir, and in situ with MHC class I tetramer staining showed increased migration into B cell follicular sanctuaries. ALT-803 did not affect viral loads in macaques with uncontrolled SIV infection; instead, ALT-803 potentiated low-level viral replication in elite controllers. In experiments using CD4+ T cell from cART-suppressed macaques, ALT-803 induced robust viral replication in vitro. When administered to macaques with cART-suppression of plasma viremia, ALT-803 treatment resulted in plasma viral "blips" and unlike previous reports of other common g-chain cytokines like IL-7, ALT-803 did not cause an increase in the size of the latent viral reservoir.
Conclusions: ALT-803, an IL-15 superagonist, is well tolerated in SIV-infected, cART-suppressed macaques and induces virus reactivation both in vitro and in vivo. In addition to reactivating quiescent virus, ALT-803 potently activates NK and memory CD8+ T cells, which traffic to lymph nodes, specifically entering B cell follicles where latently-infected CD4+ T follicular helper cells reside. The ability of ALT-803 to potentially mediate both the "shock" and "kill" make it an appealing candidate for further studies aimed at durable cART-free HIV remission.

Background: Despite viral suppression with antiretroviral therapy, HIV-infected subjects face high risk of non-AIDS comorbidities, which is often associated with elevated immune activation and inflammation (IA/INFL) and hypercoagulability. Tissue factor (TF) may bridge IA/INFL and hypercoagulation via protease-activated receptor (PAR) signaling. We hypothesized that a TF pathway inhibitor can reduce the hypercoagulation and IA/INFL associated with HIV/SIV infection, and thus improve the disease outcome.
Methods: We compared the dynamics of TF expression on monocyte isolated from progressive (pigtail macaques, PTMs) vs. non-progressive (African green monkeys, AGMs) models of SIVsab infection to establish its role in SIV pathogenesis. We tested the specificity and potency of a new TF inhibitor, Ixolaris, ex vivo on nonhuman primate (NHP) plasma and monocytes stimulated with LPS. Ixolaris was administered to five SIVsab-infected PTMs, with three SIV-infected, untreated PTMs as controls. IA/INFL markers (CD38/HLA-DR and proinflammatory cytokines) and hypercoagulation markers (D-dimer) were monitored throughout Ixolaris administration in treated and control PTMs.
Results: Monocyte TF expression increased postinfection in PTMs while it remained at baseline levels in chronically infected AGMs, confirming the role of TF in exacerbating SIV pathogenesis. Ixolaris specifically inhibited the extrinsic coagulation pathway and strongly inhibited TF activity by monocytes stimulated with LPS. In vivo administration of Ixolaris resulted in significantly lower inflammation (IL-17) and immune activation ($HLA\text{-}DR^+$- and $CD38^+$-expressing $CD4^+$ and $CD8^+$ T cells) during early chronic infection in treated SIVsab-infected PTMs compared to controls. Ixolaris also reduced hypercoagulation levels (D-dimer) in acutely SIVsab-infected PTMs. While viral loads and CD4 counts were minimally impacted by treatment, Ixolaris improved PTM survival, with no PTMs developing disease during the first 100 days postinfection, which is rarely seen in untreated SIVsab-infected PTMs.
Conclusions: Our results support a role of TF pathway in promoting disease progression and cardiovascular comorbidities in SIV-infected NHPs. In vivo TF inhibition by Ixolaris resulted in reduced IA/INFL and hypercoagulation in SIVsab-infected PTMs independent of CD4 counts and plasma viremia, and improved the outcome of the SIVsab infection. Therefore, targeting TF pathway in HIV-infected subjects may represent an effective approach to prevent the deleterious consequences of HIV infection.

TUPDA0106

Engineering HIV immunity with a chimeric antigen receptor in the non-human primate model

A. Zhen[1], C. Peterson[2], M. Carrillo[1], V. Rezek[1], M. Kamata[1], J. Zack[1], H.-P. Kiem[2], S. Kitchen[1]
[1]David Geffen School of Medicine at UCLA, UCLA AIDS Institute, Los Angeles, United States, [2]Fred Hutchinson Cancer Research Center, Seattle, United States
Presenting author email: skitchen@ucla.edu

Background: HIV-1 specific cytotoxic T lymphocytes are crucial for the elimination of HIV infected cells. We have previously demonstrated using humanized mice that hematopoietic stem cells (HSCs) modified with a protective CD4 chimeric antigen receptor (CD4CAR) successfully differentiated into CD4CAR expressing T cells that significantly suppressed HIV replication. These results demonstrated the feasibility of engineering HIV-specific T cell immunity with a HSC based approach.
Methods: We tested the safety and feasibility of engineering T cell immunity via HSC in a non-human primate (NHP) model of SHIV infection. We utilized CD4CAR vectors that also carry an anti-HIV protective gene (C46) that would inhibit infection. 2 pigtailed macaques (Macaca nemestrina) were transplanted with C46CD4CAR modified autologous HSC and 2 were transplanted with HSC modified with control vector C46CD4CARdeltaZeta that lacks the signaling Zeta chain. After hematopoietic recovery, the animals were challenged with SHIV and went through combined anti-retroviral drug (cART) treatment and withdrawal. Animals were monitored for viral load, CAR cell detection, and immune function for over a year.
Results: We determined that engraftment of pigtailed macaques with C46CD4CAR-modified HSCs was safe and the animals had normal transplant recovery. We observed long-term engraftment and stable production of C46CD4CAR expressing cells without any significant toxicities and found that C46CD4CAR modified HSCs could differentiate into multiple hematopoietic lineages. Following challenge of the animals with SHIV, we observed significant expansion of C46CD4CAR expressing cells after infection and wide distribution of CAR expressing cells in multiple lymphoid tissues. Importantly, we found lower viral loads in lymphoid tissues in C46CD4CAR containing animals than in control animals, suggesting viral suppression by C46CD4CAR expressing cells.
Conclusions: This study in NHPs demonstrates the safety and feasibility of a HSC based therapy utilizing a HIV-specific chimeric antigen receptor for treating chronic HIV infection. These results set the stage for future investigational new drug (IND) development to eradicate viral infection and provide more effective immune surveillance of HIV.

TUPDB01 HIV Reservoirs: Ups and Downs

TUPDB0101

Dynamics of HIV-1 DNA in children over long-term sustained viral suppression: impact of the time of infection at viral control on reservoir size

M. Moragas[1], M. Distefano[1], D. Mecikovsky[2], S. Arazi Caillaud[2], R. Bologna[2], P. Aulicino[1], A. Mangano[1]
[1]Hospital de Pediatría "Prof. Dr. Juan P. Garrahan", Laboratorio de Biología Celular y Retrovirus-CONICET, Unidad de Virología y Epidemiología Molecular, Ciudad de Buenos Aires, Argentina, [2]Hospital de Pediatría "Prof. Dr. Juan P. Garrahan", Servicio de Epidemiología e Infectología, Ciudad de Buenos Aires, Argentina
Presenting author email: matias.moragas@gmail.com

Background: The dynamics of HIV-1 DNA reservoir in perinatally infected children throughout long-term sustained viral suppression (VS) -and how they are affected by the time of infection at VS- have not been defined. Improved understanding of HIV-1 dynamics is necessary for therapeutic interventions that aim to achieve sustained antiretroviral therapy-free HIV-1 remission.
Methods: This study included 37 perinatally HIV-1 infected children on suppressive antiretroviral therapy. Children were grouped according to the timing of antiretroviral therapy (ART) initiation (≤0.5 or >0.5 yrs) and the time to achieve VS (≤1.5, between >1.5 and 4, and >4 years). Decay of cell-associated HIV-1 DNA (CA-HIV-1 DNA) level -quantified by semi-nested real time PCR- and 2-long terminal repeats (2-LTR) circles frequency -detected by hemi-nested real time PCR- were analyzed over 4 years of viral suppression using piecewise linear mixed-effects model with two splines and logistic regression, respectively.
Results: CA-HIV-1 DNA in peripheral blood mononuclear cells (PBMC) had a high decay during the first two years of VS [-0.26 (95% CI: -0.43 to -0.09) log_{10} copies per one million (cpm) PBMC/year], followed by a slow decay and reaching a plateau between 2 and 4 years of VS [-0.06 (95% CI: -0.15 to 0.55) log_{10} cpm PBMC/year]. The level of CA-HIV-1 DNA in PBMCs highly correlated with those estimated in $CD4^+$ T cells (r=0.97, P< .0001) and whole blood (r=0.98, P< .0001). The initial decay according to time of infection at VS was -0.51 (95% CI: -0.94 to -0.07), -0.35 (95% CI: -0.83 to 0.14) and -0.21 (95% CI: -0.39 to -0.02) log_{10} cpm PBMC/year for children who achieved VS by 1.5, >1.5-4 and >4 years of infection, respectively. The frequency of 2-LTR circles decayed significantly, from 82.9% at pre-VS to 37.5% and 28.1% at 2 and 4 years of viral suppression, respectively (P=.0009).
Conclusions: A marked decay of HIV-1 DNA occurs during the first two years of viral suppression -where the earlier the time of infection at viral suppression, the higher the rate of decay- and seems to set HIV-1 reservoir size. After 2 years, HIV-1 DNA decreases slowly and independently of the time to achieve effective viral control.

Presenting author email: marta.massanella.luna@umontreal.ca

Background: Early antiretroviral therapy (ART) limits the size of the HIV reservoir and immune activation levels in adults; however pediatric data are limited. We evaluated the impact of immune parameters on the size of the HIV reservoir in early-treated vertically infected infants.
Methods: Virologically non-suppressed HIV-infected Thai infants (n=12, < 2 months old) and fully suppressed children (for >1 year) who started ART within the first 6 months of life (n=57, median 4 years old) were included. We quantified total HIV DNA in CD4 T-cells by RT-PCR. Immune activation and proliferation markers in CD4 and CD8 naïve, stem cell (SCM), central (CM), transitional (TM) and effector memory (EM) T cells as well as frequencies of effector (EMRA), recent thymic emigrants (RTE) and T-regulatory (Treg) cells were assessed by flow cytometry.
Results: High frequencies of naïve $CD4^+$ T-cells were observed in non-suppressed and ART-treated children (median 78 and 64, respectively). Interestingly, the frequency of RTE was significantly increased in ART-treated children despite their older age (median 81 vs 89, p=0.009), suggesting that HIV replication in non-suppressed infants may limit thymic production. Frequencies of T-cells undergoing proliferation ($Ki67^+$) were significantly lower in $CD4^+$ (median 4.8 vs 3.6, p=0.04) and $CD8^+$ (median 29 vs 4.6, p< 0.0001) T-cells from ART-treated children. Similarly, frequencies of activated $CD8^+$ T-cells ($HLA\text{-}DR^+CD38^+$) were significantly lower in ART-treated children (median 29 vs 4.6, p< 0.0001). High frequencies of Treg were observed in both groups (>5.1% of $CD4^+$ T cells) with no significant differences. In non-suppressed infants, the frequency of cells harboring HIV DNA was negatively correlated with the frequency of RTE (r=-0.9, p=0.01) and positively correlated with the frequency of memory Treg cells ($CD45RA^-CD27^-CD25^{bright}FOXP3^+$, r=0.7, p=0.04). Similarly, HIV DNA levels in ART-treated children negatively correlated with RTE (r=-0.3, p=0.02) and positively correlated with Treg (r=0.3, p=0.04).
Conclusions: The high frequencies of RTE resulting from enhanced thymic production in pediatric population may limit the establishment and persistence of the HIV reservoir. In contrast, the positive association between the frequency of HIV-infected cells and Treg, suggests that this subset may play a prominent role in the establishment of the HIV latent reservoir during infancy.

Presenting author email: timothy.henrich@ucsf.edu

Background: It is unknown if extremely early initiation of ART may be curative. We describe an individual who started ART an estimated 10 days after infection with plasma HIV RNA of 220 copies/ml. After extensive blood and tissue sampling, he underwent an analytical treatment interruption (ATI) following 34 months of ART.
Methods: Colorectal and lymph node tissues, bone marrow, cerebral spinal fluid (CSF), plasma and large numbers of PBMC obtained longitudinally were studied for HIV persistence in several laboratories using molecular and culture-based detection methods including a humanized mouse outgrowth assay.
Results: The individual initiated PrEP (TDF/FTC) during very early Fiebig stage I (HIV-1 RNA+ EIA-) followed by ART intensification (TDF/FTC/r/DRV/RAL) 8 days later. HIV RNA levels were 120 and < 40 copies/mL, 7 and 22 days after PrEP initiation, respectively, followed by no detectable level. Low-level cell-associated HIV RNA (3.2 copies/million CD4+ T cells) was detected 32 days after infection. Over the following 2 years, no further HIV could be detected, despite massive sampling from ileum, rectum, lymph nodes, bone marrow, CSF, CD4+ T cell subsets and plasma. 530 million CD4+ T cells were also assayed in a humanized mouse outgrowth assay. One mouse (53 million input cells) experienced very low level viremia (201 copies/mL) after 5.5 weeks, but sequence confirmation was unsuccessful. The participant stopped ART and remained aviremic for 7.4 months, rebounding with HIV RNA of 36 copies/mL that rose to 59,805 copies/mL 6 days later. ART was restarted promptly. Rebound plasma HIV sequences were identical to those obtained during acute infection by single-genome sequencing. Mathematical modeling predicted that the latent reservoir size was approximately 200 cells prior to ATI, and that only around 1% of individuals with a similar HIV burden may achieve lifelong ART-free remission.
Conclusions: We report HIV relapse despite initiation of ART at one of the earliest stages of acute HIV infection possible. Near complete or complete loss of detectable HIV in blood and tissues did not lead to indefinite ART-free HIV remission. However, the small numbers of latently infected cells in individuals treated during hyperacute infection may be associated with prolonged ART-free remission.

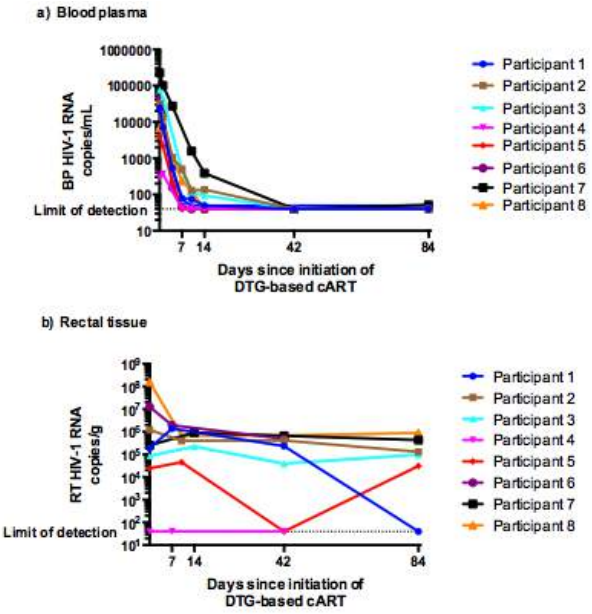
Background: Despite virologic suppression in blood plasma (BP) with combination antiretroviral therapy (cART), HIV eradication remains elusive, largely due to incomplete suppression in reservoir sites including gut-associated lymphoid tissue. We compared HIV RNA dynamics within BP and rectal tissue (RT) following initiation of cART with integrase strand transfer inhibitor dolutegravir (DTG).
Methods: Treatment naïve HIV+ volunteers began DTG-based (50 mg daily) cART and serial sampling of BP and RT through 84 days as per Figure 1. HIV RNA and DTG concentrations were quantified using Abbott Real-Time HIV-1 assays and tandem mass spectroscopy, respectively, in both compartments. Median DTG concentrations were compared between undetectable and detectable RT HIV RNA groups using Mann-Witney nonparametric tests.
Results: Eight participants were enrolled: 4 (50%) females, 6 (75%) black, median age 39.2 years (IQR 32.9-52.7). Median baseline CD4 and HIV RNA were 208 cells/mm^3 (IQR 104-320) and 24,847 copies/mL (IQR 6237-50,269), respectively. All participants (100%) had undetectable BP HIV RNA (< 40 cop/mL) by Day 42; only 3 achieved RT viral suppression at any time (Figure 1). DTG quantitation was performed on 22 paired BP and RT steady-state samples collected Days 7 through 84. The undetectable RT RNA group had higher median DTG RT concentrations than those with detectable RNA: 1340 ng/g (IQR 683-2100) vs 624 ng/g (IQR 377-939), p=0.03. There were no significant differences in BP DTG or RT:BP DTG ratios between undetectable and detectable groups: median 2810 ng/mL (IQR 1720-4140) vs 1400 ng/mL (IQR 687-3250) and median 0.45 (IQR 0.30-0.55) vs 0.40 (IQR 0.28-0.69), respectively.



[Figure 1. HIV RNA over time following initiation of DTG-based cART]

Conclusions: Despite rapid virologic suppression in BP, HIV RNA persisted in RT for the majority of participants. Along with larger studies examining DTG compartmental pharmacokinetic/pharmacodynamic relationships, assessment of the infective potential of HIV RNA recovered from RT are warranted, as this may have implications for ongoing rectal transmission notwithstanding plasma virologic suppression.

Presenting author email: jade.ghosn@aphp.fr

Background: Antiretroviral treatment interruption (ATI) leads to HIV replication rebound in both blood and semen, however dynamic of HIV-RNA rebound in semen is poorly known. We compared HIV-RNA timing of and level of rebound in blood and seminal plasmas (BP-SP) and characterized the HIV rebounding populations in both compartments after ATI in HIV-1 infected patients enrolled in the therapeutic vaccine trial VRI02/ANRS149-LIGHT.
Methods: Ten male from the VRI02/ANRS149-LIGHT trial with CD4 cells ≥600/mm^3 and HIV-RNA < 50cp/ml under treatment for at least 18 months were studied. ATI occurred from week (W)36 to W48. Paired blood and semen samples were collected at W32 (before ATI), W36, W38, W40, W42, W44 and W48 following ATI, for HIV-RNA and DNA quantification. Ultradeep sequencing (UDS, 454/Roche) of partial env (C2/V3) HIV-DNA and -RNA was performed in 5 out of 10 participants in PBMC before ATI and in plasma/semen during ATI. Sequenced reads were quality filtered and assembled using an in-house data processing pipeline.
Results: Patients had sustained suppressed blood viral load for a median of 44 months (range: 28-152) before ATI. HIV-RNA rebounded in blood and semen in all patients after ATI (median 5.12 $\log_{10}$ cp/ml (range: 4.61-6.35) and 4.26 $\log_{10}$ cp/ml (range: 3.20-4.67), respectively). BP HIV-RNA rebounded as soon as W38 in 8/10 patients, and SP HIV-RNA between W38 and W40 in 8/10 patients. HIV-DNA median level was 2.97 $\log_{10}$ cp/10^6 PBMC (range: 1.61-3.26) at W32 and 3.30 $\log_{10}$ cp/10^6 PBMC (range: 2.50-3.67) at W44. Non-sperm cells HIV-DNA was detected in at least one sample in 6/10 patients. Phylogenetic analysis of UDS revealed that 1) rebounding HIV-RNA population in BP and in SP originated from PBMC HIV-DNA at the time of ATI and 2) intermingled HIV-RNA populations in BP and in SP with no evidence of compartmentalization.
Conclusions: The rapid and intense HIV RNA rebound observed very early both in blood and semen after ATI emphasizes the need for targeted prevention strategies to reduce the risk of sexual transmission during ATI. PBMC HIV-DNA is the major contributor for HIV-RNA rebound in both compartments, even after several years of sustained suppressed viral replication.

Transgender women willingness to use PrEP in northeastern Brazil

F. Soares[1], I. Dourado[2], L. Magno[3], L.A. Vasconcelos da Silva[4], A. Nunn[5], PopTrans Study Group
[1]Federal University of Bahia, Institute of Collective Health, Salvador, Brazil, [2]Federal University of Bahia, Health Collective Institute, Salvador, Brazil, [3]State University of Bahia, Nursing, Salvador, Brazil, [4]Federal University of Bahia, Institute of Humanities, Arts and Sciences Professor Milton Santos, Salvador, Brazil, [5]Brown University, School of Public Health, Providence, United States
Presenting author email: ines.dourado@gmail.com

Background: PrEP can dramatically reduce HIV acquisition risks, particularly for transgender women and other sexual and gender minorities. However, access to PrEP in developing countries remains very limited. Brazil has one of the largest and oldest HIV treatment programs in the world and will soon integrate PrEP in the national public health system. We explored PrEP willingness among transgender women.

Methods: We recruited 127 transgender women using Respondent Driven Sampling (RDS) in Salvador, Brazil's third largest - and one of its lowest-income and highest afro-descendants- cities. Participants were interviewed about PrEP. Latent class analyses were used to identify those willing to take PrEP from the following list of variables: 1-disposition to use PrEP; 2 - willingness to use PrEP if available in the public health system; 3- willingness to use PrEP even if had to pay; 4- interest in using PrEP even if it is not 100% effective; 5-being less afraid of contracting HIV if using PrEP; 6- willingness to take one pill a day; 7- knowledge about PrEP. Entropy was 0.992 indicating good distinction of classes.
Results: Only 18.4% of women knew about PrEP. However, upon becoming aware, willingness to use PrEP was reassuring. Two latent classes were identified: Class 1-willingness to use PrEP (91.3%); Class 2- non willingness to use PrEP (8.6%). Most participants noted that PrEP was an important HIV prevention tool for transgender women. Correlates of Latent Class 2 were: Socio-behavioral factors including not being black, having a monthly income greater than R$900.00 and regular use of condoms in sexual intercourse. When asked about implementation strategies, participants suggested integrating conversations about PrEP into a suite of HIV prevention services, addressing health system services that address the broader social and structural factors influencing transgender health risks.
Conclusions: PrEP willingness was very high as 91% of transgender women wanted it in Northeast Brazil. While access to PrEP is still limited, uptake among transgender women will likely be high when Brazil releases PrEP. However, it is important to take into account socio-behavioral factors and combination prevention as those regular users of condom may not see and additional benefit of PrEP.

How are transwomen acquiring HIV? Insights from phylogenetic transmission clusters

H.-H.M. Truong[1], K. O'Keefe[2], S. Pipkin[2], T. Liegler[1], S. Scheer[2], W. Mc Farland[2]
[1]University of California, San Francisco, Department of Medicine, San Francisco, United States, [2]Department of Public Health, San Francisco, United States

Background: Worldwide, HIV prevalence among transwomen is 50 times higher than in the general adult population. In many surveillance systems and surveys, transwomen and their male sexual partners are classified as "men who have sex with men" (MSM), irrespective of gender identity and sexual orientation. Little is known about how transwomen acquire HIV, which may be due in part to this misclassification as "MSM". We sought insights on sexual and needle-sharing networks as potential sources of HIV among transwomen by examining phylogenetic transmission clusters. We also assessed a new transmission risk paradigm that re-classifies males closely linked to transwomen as non-MSM.
Methods: San Francisco residents diagnosed with HIV (2000-2015), in care at public facilities and with available viral pol sequences were included in the analysis. Transmission clusters with ≥2 cases were identified by bootstrap values ≥90% and mean pairwise genetic distances ≤0.025%.
Results: Transwomen were 275 of 5,200 cases with viral sequences; 86 transwomen were in 70 clusters; 44 (51%) had injection risk. Many clusters with transwomen contained MSM-persons who inject drugs (MSM-PWID) (47% of clusters) and non-MSM PWID (26%); whereas MSM were in 54% of clusters and heterosexual men in 1%. After re-classification, the profile of clusters shifted: 16% of clusters contained MSM-PWID, 57% had non-MSM PWID, 16% had MSM and 47% had heterosexual men. Similarly, among 130 clusters containing cis women, 27% had MSM-PWID, 41% had non-MSM PWID, 28% had MSM and 58% had heterosexual men.
Conclusions: Applying the new paradigm for classifying the transmission risk of transwomen and their partners suggests that transwomen may stand apart from the MSM epidemic. The risk profile of transwomen's transmission clusters is highly sensitive to whether or not male partners are classified as MSM. Under the new paradigm, transmission clusters containing transwomen closely resemble clusters containing cis women, with a strong presence of PWID and heterosexual men. There is increasing recognition that transwomen should be considered by their gender identity for health services and research. The same consideration perhaps should apply to male sexual partners of transwomen. Examining transmission clusters may bring new insights to the applicability of MSM-focused research to transwomen and their partners.

Presenting author email: reshmie@trcarc.org

Background: Transgender women (TG) are a high-burden population for HIV. Globally, their risk of HIV is 49 times higher compared to the general population, indicating that HIV-prevention and care services for TG are critical and urgent. To understand the facilitators and barriers for TG to access HIV-testing and antiretroviral therapy (ART) at community-based clinics, we studied socio-demographic characteristics, behavioral risk and knowledge and attitudes towards HIV and ART.
Methods: Thai TG aged ≥18 years were recruited from 6 community-based clinics in Thailand. Demographic characteristics, behavioral risk, HIV-knowledge and attitudes towards ART were assessed using questionnaires. Trained community health-workers provided same-day result HIV testing and sexually transmitted infection (STI) screening, as well as CD4 testing and linkage to care for HIV-infected participants.
Results: Of 734 TG participants enrolled, 56.1% were between 18 and 25 years old. Only 15.7% had a college degree or higher, and 36.8% earned less than 280 USD monthly. Prevalence of any STI was 32% (syphilis 3.5%, chlamydia 23.3%, gonorrhea 14.6%). Nobody (0.0%) reported a negative attitude towards people with HIV, 42.0% of participants knew that ART can reduce HIV transmission, and 65.4% thought all people with HIV should use ART. Almost 90% said they would start ART immediately if they were diagnosed with HIV. Multiple sexual partners in the last six months was reported by 53.5%. While 77.4% of TG reported unprotected sex in the last 6 months and 91.1% identified proper condom use as a manner of decreasing HIV-risk, only 17% perceived their HIV-risk as high. Almost half (45.0%) had never tested for HIV. HIV prevalence was 9.0%, and among 66 HIV-infected participants, median (IQR) CD4 count was 406 (306-562), 84% initiated ART within 2 weeks of diagnosis.
Conclusions: Among these young Thai TG presenting for HIV-testing at community-based clinics, the prevalence of HIV and STIs was high. Attitudes towards HIV and ART were positive, and ART uptake was high. However, there was a remarkable discrepancy between risky sexual behavior and perceived HIV risk. Our findings are crucial to informing HIV education and prevention programs targeting TG in Thailand.

Engaging transgender women of color in HIV prevention: findings from mixed methods community-based research

T. Poteat[1], M. Malik[1], A. Wirtz[1], E. Cooney[2]
[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States
Presenting author email: tpoteat123@gmail.com

Background: Transgender women (TW) across the globe are highly vulnerable to HIV. TW of color (TWOC) in the US are particularly burdened, with an estimated HIV prevalence over 50% in some studies. Effective HIV interventions are needed to prevent HIV acquisition and onward transmission, and to improve health outcomes. We used mixed-methods approaches to understand how to develop and implement accessible, acceptable, and effective HIV interventions for TWOC.
Methods: Qualitative, in-depth key informant (KI) interviews (n=20) were conducted with TW and health and social service providers. Interviewer-administered surveys and rapid HIV tests were implemented among TWOC (n=46) in Baltimore, USA.
Results: Among TWOC, HIV prevalence was 48%, with 18% unaware of their HIV status and 33% who had not been tested for HIV in the last 12 months. History of sex work (78%) and condomless anal intercourse (47%) were high. Most participants had heard of PrEP (89%); of those, 78% knew where to get it and 23% had ever taken it. Of those who had ever taken PrEP (n=9), 67% had done so in the prior 12 months.

Despite low uptake, 81% of HIV-negative TWOC stated they would take PrEP if it was made available to them. Interviews elicited diverse reflections on how to better engage TWOC in HIV programs. KIs emphasized the importance of embedding HIV services within social service programs that are responsive to community needs (e.g., job readiness, mental health support, housing), to improve access and acceptability of HIV programs for TWOC. KIs also recommended regular staff training in transgender competent care (e.g., using correct gender pronouns), recognizing that experiencing discrimination in health venues deters TWOC from future care seeking. Other suggestions included: offering services where TWOC regularly visit, hiring TWOC to lead programs, and doing tailored outreach and advertising.
Conclusions: Acceptable high-impact HIV prevention and care interventions for TWOC are urgently needed as evidenced by an elevated HIV prevalence and low PrEP uptake. Noting the disconnect between willingness and uptake of PrEP among TWOC, HIV prevention programs could better bridge this gap by incorporating strategies voiced by TW and responding to identified access barriers.

TUPDC0105

Factors associated with HIV infection among transgender women in Cambodia: results from a national integrated biological and behavioral survey

S. Yi[1,2], S. Chhim[3], P. Chhoun[1], S. Tuot[1], P. Mun[4], K. Pal[1], C. Ngin[1]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]Touro University California, Center for Global Health Research, Vallejo, United States, [3]FHI 360 Cambodia, Phnom Penh, Cambodia, [4]National center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia
Presenting author email: siyan@doctor.com

Background: Transgender women are at high risk for HIV infection, and little is known about the burden of HIV infection and its related factors in this population worldwide. This study was conducted to examine factors associated with HIV infection among transgender women in Cambodia.
Methods: This cross-sectional study was conducted between December 2015 and February 2016 in the capital city of Phnom Penh and 12 HIV high-burden provinces. Respondent driven sampling was used to recruit sexually active transgender women aged 18 and over. A structured questionnaire was used for a behavioral survey, and rapid finger-prick HIV testing was performed using Determine™ antibody test. Multivariate logistic regression analysis was conducted to identify factors associated with HIV infection using STATA.
Results: A total of 1,375 transgender women participated in the study with a mean age of 25.9 years (SD= 7.1). The overall HIV prevalence among this population was 5.9%. In multivariate logistic regression, participants living in urban areas were twice as likely to be HIV infected as those living in rural areas. Participants with primary education were 1.7 times as likely to be infected compared to those with high school education. HIV infection increased with age; compared to those aged 18-24, the odds of being HIV infected were twice among transgender women aged 25-34 and 2.8 times higher among those aged ≥35. Self-injection of gender affirming hormones was associated with a fourfold increase in the odds of HIV infection. A history of genital sores over the previous 12 months increased the odds of HIV infection by threefold. Transgender women with stronger feminine identity dressing up as a woman all the time were twice as likely to be HIV infected compared to those who did not dress up as a woman all the time. Having never used online services developed for transgender women was also associated with higher odds of being HIV infected.
Conclusions: Transgender women in Cambodia are at high risk of HIV. To achieve the goal of eliminating HIV in the country, effective combination prevention strategies focusing on the above risk factors among transgender women are urgently needed.

TUPDC0106

Prevalence and correlates of police harassment among transgender women in Jamaica: implications for HIV prevention and care

C.H. Logie[1], A. Lacombe-Duncan[1], K. Levermore[2], N. Jones[2], A. Neil[2], T. Ellis[2], Y. Wang[1], P.A. Newman[1]
[1]University of Toronto, Toronto, Canada, [2]Jamaica AIDS Support for Life, Kingston, Jamaica
Presenting author email: carmen.logie@utoronto.ca

Background: Criminalization of homosexuality limits access to HIV prevention and care. Little is known about police harassment targeting transgender women in contexts where homosexuality is criminalized, such as Jamaica. We examined prevalence of police harassment and its association with HIV infection and risk factors among transgender women in Jamaica.
Methods: We implemented a cross-sectional survey with transgender women in Kingston, Ocho Rios, and surrounding areas in Jamaica using chain referral sampling. Unadjusted and adjusted logistic regression analyses were conducted to identify health (e.g., HIV status), intrapersonal (e.g., sex work), interpersonal (e.g., social support), and structural (e.g., transphobic violence) factors associated with ever experiencing police harassment perceived to be due to transgender identity.
Results: Participant (n=137) mean age was 24.0 years (SD: 4.5; range 18-44); two-thirds (n=92; 67.2%) lived in Kingston, and half (n=71; 51.8%) reported sex work involvement. Three-quarters (n=103; 75.7%) had received an HIV test; of these, one-quarter (n=26; 25.2%) were HIV-positive. Almost half (43.8%; n=60) reported experiencing police harassment due to their transgender identity. Of participants with complete data (n=127), 16.5% (n=21) reported a history of incarceration due to transgender identity. Of those, 71.4% (n=15) reported being incarcerated 1 to 3 times and 28.6% (n=6) were incarcerated 4 to 6 times. In unadjusted analyses, police harassment was associated with: sociodemographic (< high school education vs. ≥ high school [OR: 3.04, 95% CI: 1.1-8.4]), health (HIV positive serostatus [OR: 2.44, 95% CI: 1.01-5.86], depression [OR: 1.23, 95% CI: 1.01- 1.50]), intrapersonal (sex work [OR: 2.61, 95% CI: 1.30-5.25]), interpersonal (higher need for social support [OR: 1.09, 95% CI: 1.03-1.15]) and structural (transphobic physical violence [OR: 6.97, 95% CI: 3.14-15.51]). In adjusted multivariable analyses, HIV positive serostatus (AOR: 2.96, 95% CI: 1.04, 8.43) and transphobic physical violence (OR: 6.06, 95% CI: 2.53, 14.55) maintained strong associations with experiences of police harassment.
Conclusions: Nearly half of transgender women in this Jamaican study reported police harassment, and this was associated with HIV positive serostatus and physical violence. Criminalization and violence are structural drivers of HIV, constraining access to the HIV care continuum. Human rights for transgender women are central to HIV prevention and care in Jamaica.

Poor retention and care-related sex disparities among youth living with HIV in rural Mozambique

A. Ahonkhai[1,2], M. Aliyu[1,3], C. Audet[1,3], M. Simmons[1], G. Claquin[4], S. Vermund[1,2,5], W. Wester[1,2]
[1]Vanderbilt University Medical Center, Vanderbilt Institute for Global Health, Nashville, United States, [2]Vanderbilt University Medical Center, Division of Infectious Disease, Nashville, United States, [3]Vanderbilt University School of Medicine, Department of Health Policy, Nashville, United States, [4]Friends in Global Health, Maputo and Quelimane, Mozambique, [5]Vanderbilt University Medical Center, Division of Pediatrics, Nashville, United States
Presenting author email: gael.claquin@fgh.org.mz

Background: Despite a 30% decline in HIV-related deaths over the past decade, HIV remains still the leading cause of death among African adolescents. Our objective was to summarize performance along the continuum of HIV care, and identify predictors of loss to follow-up (LTFU) among youth enrolled in HIV care in rural Mozambique.
Methods: We analyzed a retrospective cohort of youth (15-24 years) accessing care at one of 89 PEPFAR-supported clinics in Mozambique between 2012-2015. We determined the proportion of patients pre-antiretroviral therapy (ART) LTFU at 6 months, cumulative incidence of post-ART LTFU and mortality 1 year post-initiation. We defined LTFU as being > 60 days late for the last scheduled visit (pre-ART), or ART pick-up (post-ART). We used logistic and multivariable Cox regression models to identify predictors of pre- and post-ART LTFU, respectively, in the year after enrollment.
Results: Of 23,322 patients in the cohort, 19,287 (83%) were female. Primary referral source was prevention of mother-to-child transmission clinics for females (49%, n=8,639), and voluntary counseling and testing sites for males (65%, n=2,314). Females enrolled in care at earlier HIV disease stage (median CD4 469 vs. 363 cells/mm^3, p< 0.001) and initiated ART more expeditiously than males (median 6 [IQR 0-129] vs. 35 [IQR 2-180] days, p<0.001). Pre-ART LTFU at 1 year was 36% overall, and lower for females vs. males (33% vs. 56%, OR=0.28; 95%CI:0.24-0.33). The cumulative incidence of post-ART LTFU was 36% overall (95%CI:35-36%), with small differences by sex (F:M 35% vs. 37%, aHR 0.66 95%CI:0.58-0.75). Adjusted one-year mortality rate for ART patients retained in care was 12.6% (95%CI:6-22%).
Conclusions: In the cohort of youth enrolled in care four-fifths were female. Females were enrolled in care earlier in their disease course, initiated on ART more quickly, and less likely to experience pre-ART LTFU than young males. After ART initiation, 1/3rd of all patients were LTFU, and mortality rates were high. While outcomes were poor overall in this setting, young women may require enhanced prevention efforts, while young men need targeted testing and treatment interventions.

Gender age considerations and likelihood of viral load suppression at sub-national level in five counties, Kenya

S. Muga[1], J. Onyalo[1], M. Obuya[1], P. Njoka[1], R. Kithuka[1], C. Komen[1], L. Muyumbu[1], G. Obanyi[1], E. Ashiono[1], C. Muturi[1], R. Odhiambo[1], P. Mwarogo[2]
[1]FHI360, USAID-APHIAPlus Nuru ya Bonde, Nakuru, Kenya, [2]FHI360, Country Office, Nairobi, Kenya
Presenting author email: smuga@fhi360.org

Background: Sub-Saharan Africa accounts for 66% of new HIV infections globally. Program responses need to focus on sub-national contexts if epidemic control is to be achieved. The objective of this paper is to describe the likelihood of viral suppression at sub-national level, considering age and gender in five counties in Kenya.
Methods: This retrospective correlational survey reviewed the significance of age and gender on the likelihood of viral load suppression among clients on antiretroviral therapy (ART) who had accessed at least one viral load test in the period October 2015 to September 2016. ART was initiated as per the national guidelines in Kenya. Raw viral load data was assessed from the national viral load database for 139 facilities in five counties (Baringo, Kajiado, Laikipia, Nakuru and Narok) and 38,113 records were analyzed. The survey used logistic regression to assess relationships between gender, age and viral load suppression (< 1000 copies ml), with P <0.05.
Results: Overall, females were 16% more like to be virally suppressed compared to males. Females aged 1-9 years,10-14 years, 20-24 years were (62%, p=0.00), (26%, p=0.024), (79%, p=0.001) respectively more likely to be virally suppressed than males. There was no significant difference in the likelihood of viral suppression between females and males for clients under one-year-old, (p=0.230), 15-19 years (p=0.254), and in 25 years or older (p=0.079).
In Laikipia, males aged 10-14 years were 25% less likely to be virally suppressed. In Nakuru and Narok, males aged between 1-9 years were 53% less likely to be virally suppressed. Further, in Nakuru those aged 20-24 years were 48% less likely to virally suppressed compared to female counterparts.
In Kajiado, Baringo and Laikipia counties, the likelihood of clients being virally suppressed increased with age. While in Narok and Nakuru counties, it was not dependent on increase in age.
Conclusions: The likelihood of achieving viral suppression seemed to agree with literature that female clients are likely to be suppressed. However, there are sub-national differences in the suppression rates. There are also differences in suppression rates through age groups in the counties. This information can be used for further research and effective programming.

[1]Management Sciences for Health, Mbabane, Swaziland, [2]Mniistry of Health, Strategic Information Department, Mbabane, Swaziland, [3]University of Swaziland, Faculty of Health Sciences, Mbabane, Swaziland, [4]Harvard Medical School, Harvard Pilgrim Healthcare Institute, Boston, United States, [5]Management Sciences for Health, Arlington, United States

Background: It has been observed over the past five years that there is limited use of data stored in electronic data systems for making targeted programmatic decisions and conducting operational research. To demonstrate how routine data stored in these electronic systems can be used to inform HIV programming, SIAPS worked with the Ministry of Health (MoH) to conduct a study to determine the survival period to switching for adult patients (15+ years) on antiretroviral therapy (ART).
Methods: This was a retrospective cohort design study. The study population consisted of 117,586 adult (≥15 years) ART patient records identified as active between years 2010 to 2015 in the national ART database. The survival rates from time of ART initiation to time of regimen switch were evaluated according to gender and age using Kaplan-Meier models i.e. outcome variable was switching (binary event) and explanatory variables were: WHO staging I; II; III; IV, Age categories: 15-24; 25-34; 35-44; and 45 years and above, and Sex: Male; Female.
Results: 3.6% (n = 4266) of the studied ART patients were found to have switched at some point during the course of treatment. Median survival time for all ART patients switching from first to second line regimen was found to be 607 days (95%CI: 601 - 613) days or 19 months. Patients aged 45 years and older at ART initiation remained on the first line regimen for longer periods than other age groups at 93.5%. Survival times for males were less than those of females. Only 83% of patients initiated at WHO stage IV remained on first line regimen by end of a 5 year follow up period.
Conclusions: There were significant differences in survival periods with men exhibiting a poorer survival period. Also, for the 18-25-year age group, we found that women actively switch regimen more often than men. Further studies would be required to understand the factors contributing to these findings. This can inform policies in HIV programming that target the unique needs of males and female clients.

TUPDD0104

Tanzanian men more successful than women in referring sexual partners to HIV testing via partner notification

K. Curran[1], M. Plotkin[2], C. Kahabuka[3], A. Christensen[3], R. Kisendi[4], W. Maokola[4], M. Betron[5], K. Grabbe[5], M. Drake[3], E. Mlanga[6], V. Wong[7]
[1]Jhpiego, HIV and Infectious Diseases, Washington, United States, [2]Jhpiego, Chapel Hill, United States, [3]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [4]National AIDS Control Programme, Ministry of Health, Dar es Salaam, Tanzania, United Republic of, [5]Jhpiego, Washington, United States, [6]USAID, Dar es Salaam, Tanzania, United Republic of, [7]USAID, Washington, United States
Presenting author email: kelly.curran@jhpiego.org

Background: Partner notification (PN) is effective at increasing uptake of HIV testing services (HTS) and identifying previously undiagnosed individuals. 2016 Guidance from WHO recommends inclusion of PN into HTS programs. PN and referral to HTS can be conducted by the index client (passive notification) or with provider-assisted strategies. Passive PN involves HIV status disclosure and is impacted by socio-cultural dynamics surrounding sex and gender. This abstract describes the success of male vs. female index clients in listing and referring sexual partners for testing in Tanzania.
Methods: A cross-sectional observational study was conducted in three hospitals in Njombe region, Tanzania, from June - September 2015. Individuals newly diagnosed with HIV in VCT or PITC were offered their choice of passive or provider-assisted referral for partner HIV testing. Odds ratios were calculated for likelihood of male and female index clients to successfully refer partner(s) to HTS or list multiple partners, and in-depth interviews were conducted with 40 index clients and partners.
Results: Almost all (91.6%) of the 390 (183 males and 207 females) index clients chose passive rather than provider-assisted referral. Of the 439 listed partners, 249 (56.7%) were successfully referred to HTS (63.4% of female partners; 49.8% of male partners). Male index clients were 2.2 (1.4 - 3.5) (p<0.001) times more likely than female index clients to successfully refer at least one partner, and 6.2 (2.7 - 14.1) (p<0.001) times more likely to list more than one partner. In qualitative analysis, both gender-specific (feeling undervalued if the relationship had not produced children; lacking contact info for commercial sex partners) and non-gender specific (difficulty communicating with past partners) challenges were described.
Conclusions: PN has been shown to be effective and is being scaled up in multiple African countries, but little discussion has addressed gender and PN. In this study, men were more likely to list multiple partners and to successfully refer at least one partner to HTS. This strength could be built upon in programmatic approaches which target men for PNS. Women's more limited ability to successfully refer their partner(s) could signal a need for different approaches to support women in the PN process.

Male engagement strategies effective in improving Option B+ retention in rural Mozambique

C. Audet[1], E. Graves[2], M. Bravo[3], M.F.S. Alvim[3], A. Green[2], Y.M. Chire[4]
[1]Vanderbilt University, Health Policy, Nashville, United States, [2]Vanderbilt University Medical Center, Nashville, United States, [3]Friends in Global Health, Maputo, Mozambique, [4]Friends in Global Health, Quelimane, Mozambique
Presenting author email: carolyn.m.audet@vanderbilt.edu

Background: Retention in antiretroviral therapy services initiated during antenatal care (ANC) in Mozambique is less than 30% at one year. To nurture supportive prevention of mother-to-child transmission (PMTCT) services we introduced a Male Engagement Strategy (MES) that involved partnering with Traditional Birth Attendants and training a new cadre of male-to-male community health agents, "Male Champions." Together they counseled expectant couples to change community norms around male engagement in spousal/partner pregnancies and uptake of HIV services.
Methods: We conducted a retrospective analysis of women (>15 years) enrolled in HIV care and treatment through PMTCT services at 112 sites in rural Zambézia province, Mozambique. We compared clinical retention rates among sites receiving MES vs. those receiving standard of care (SOC) using chi-squared tests, Wilcoxon rank sum tests, and Cox regression models. In addition, we assessed the effect of MES on retention by implementation time using a Cox regression model.

Results: Six thousand five hundred women were enrolled in PMTCT care at MoH-run clinics receiving Friends in Global Health technical support from January 2015 - November 2016. Median age was 24 years (IQR: 20-29), 84% were married or living with a partner, median CD4 cell count was 463 cells/mm^3, and 51% were enrolled in sites supported by MES. Cumulative incidence of ART loss to follow-up (LTFU) at six months was 38.1% (36.4%, 39.8%) among those enrolled at MES sites vs. 43.3% among those who received SOC (p=0.001). Controlling for clinical (e.g. CD4 cell count) and social (e.g. education, marital status) characteristics, those who attended MES clinics had a 33% lower risk of being LTFU at 6 months vs. those receiving SOC (p <0.001). Longer duration of MES exposure at a clinic was associated with increased retention: covariate-adjusted hazard ratios for late ART pick-up decreased from 0.75 (0.65, 0.86) at 12 months to 0.47 (0.38, 0.58) at 36 months.
Conclusions: Programs designed to encourage PMTCT services should include community and clinic-based interventions targeting male involvement in ANC and HIV services to improve maternal retention. Successful programs should see continuous improvement in clinical outcomes as activities become more socially acceptable and better integrated into clinical services.

TUPDD0106

Using traditional techniques to increase uptake of male circumcision and HIV testing and counselling services of males ages 15-29 through Lihawu Male Mentoring Camp

R. Britch, T. Churchyard, M. Sibanda
Kwakha Indvodza, Mbabane, Swaziland
Presenting author email: britch.ryan@gmail.com

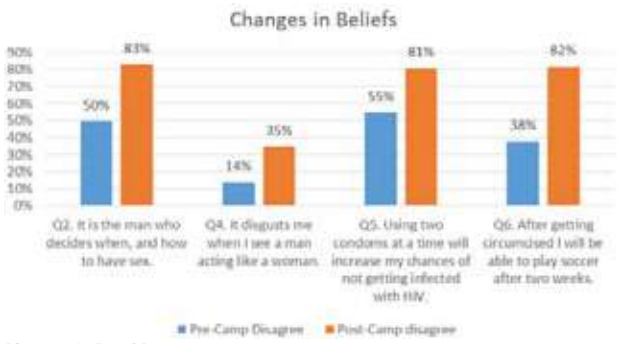
Background: Swaziland's HIV prevalence remains the world's highest at 26%. However, Swazi men often report fear and suspicion towards VMMC, mostly caused by solely biomedical approaches. In response, KI's innovative project, Lihawu Male Mentoring Camp (LMMC), offers 15-29 year old men a comprehensive package of adolescent male mentoring and health services, sensitization and interventions, with the following objectives:

- To increase number of circumcisions in the pivot age.
- To create a conducive space for VMMC clients to engage with mentors and peers in a fun way, clarifying myths and misconceptions about male health issues, masculinity and MC.
- To increase adherence to post-operative MC complementary care, conduct and lifestyle choices.

Methods: LMMC is a three-day residential camp of activities aimed at age pivot adolescents, combining behaviour change tenants of traditional Bantu initiation rites of passage with clinical best practice in VMMC.
Activities include challenges, games and cultural observances as well as sensitization on masculinity and gender awareness, goal setting, HIV and male health issues and services.
At the end of the camp, participants are offered a comprehensive package of male health services including HTC and VMMC.
Results: Increased VMMC (86%) and HTC (87%) uptake amongst pivot-age clients (national av. 19%) exposing them to a package of interventions and life skills marking a transition from childhood to adulthood. Pre and post camp surveys show a dramatic increase in gender equitable beliefs and acceptance of gender deviance, as well as increases in post-circumcision care and conduct, and in condom usage and efficacy knowledge.

Health service	HIV status knowledge on entry	HIV status knowledge on exit
HTC	93/352 (26%)	307/352 (87%)
	# of clinically eligible clients	# of Circumcisions performed
VMMC	318/352	275/318 (86%)

[Increases of VMMC and HTC]



[Changes In Beliefs]

Conclusions: Contrary to common beliefs, traditional approaches may be utilized as effective methods to sensitize men on positive masculinity, SRH issues, and the benefits of VMMC, as well as dramatically increase uptake in prevention services.

Presenting author email: shankarem@cutn.ac.in

Background: Invariant natural killer T (iNKT) cells are unique subset of T-lymphocytes that expresses a highly restricted T cell receptor (TCR) to recognize glycolipid and phospholipid antigens presented in context to CD1d molecules. iNKT cell involvement is implicated in human chronic viral infections. However, the determinants of cellular dysfunction across the iNKT cell subsets are seldom defined during HIV infection. Herein, we explore the contribution of negative check point regulatory molecule 2B4 on iNKT cells phenotype and function, and their relevance to clinical parameters associated with HIV disease progression.
Methods: We analyzed peripheral blood mononuclear cells (PBMCs) obtained from antiretroviral therapy (ART) naïve (n=23), ART-treated (n=19), elite controllers (ECs, n=6) and healthy controls (n=15). We employed flow cytometry to asses the phenotypic and functional alterations in iNKT cells. Briefly, PBMC were labeled with PBS-57 loaded/ CD1d tetramer along with panel of antibodies. For IFN-γ detection, intracellular staining was performed on α-galactosylceramide (aGalCer) stimulated cells.
Results: We report an exaggerate 2B4 expression on peripheral blood iNKT cells in naïve subjects compared to healthy controls. Further, there was a severe $CD4^+$iNKT cell subset depletion in naïve subjects. In sharp contrast to $CD4^-$iNKT cells, 2B4 was predominantly expressed by $CD4^+$iNKT cell subset in naïve subjects. Given the suppressive role of 2B4 in HIV-specific $CD8^+$ T cells, we examined the levels of 2B4 expression on T-cell subsets. There was a marked increased on bulk of $CD3^+$ T cells. In contrast to $CD4^+$ T cells, $CD8^+$ T cells displayed significantly higher levels of 2B4 in naïve individuals. Notably, the increased level of 2B4 on iNKT cells strongly correlated with parameters of HIV disease progression. Functionally, iNKT cells from naïve individuals were defective in IFN-γ production and HIV disease severity.
Conclusions: Our results suggest that the levels of 2B4 expression and the downstream co-inhibitory signaling events potentially contribute to impaired iNKT cell responses. Hence, the 2B4 pathway could be a key target for prospective immunotherapeutic interventions against HIV infection.

NK cell subset frequency and developmental markers are altered in HIV-1^+ pregnancies

A. Cocker[1], N. Shah[1], S. Dermont[2], W. Khan[2], N. Imami[1], M. Johnson[1]
[1]*Imperial College London, London, United Kingdom,* [2]*Chelsea and Westminster Hospital, London, United Kingdom*
Presenting author email: a.cocker15@imperial.ac.uk

Background: HIV-1^+ pregnancies are associated with increased incidence of preterm labour, thought to be due to the disruption of normal alterations of the immune cell function and phenotype induced by pregnancy. An association has been seen between preterm HIV-1^+ women and increased $CD56^+$ cell count, implying natural killer (NK) cells may be involved in this disorder. This study aims to investigate NK cell phenotype in HIV-1^+ pregnant women.
Methods: HIV-1^- pregnant women (n = 11) and HIV-1^+ pregnant women on antiretroviral therapy (ART) (n = 12) were recruited, their peripheral blood mononuclear cells isolated, and flow cytometric analysis of NK cells performed to determine the expression of differentiation and activation markers on NK cells. Statistical analysis was carried out using Prism version 7.0. Intergroup variation was assessed by Mann-Whitney tests and statistical significance defined as $p \leq 0.05$.
Results: There was no difference seen in total NK ($CD56^{bright}$, cytolytic and anergic) frequency between groups, though total HIV-1^+ NK cells with phenotype $CD11b^+CD27^-$ were significantly decreased ($p = 0.0036$), and $NKG2D^+$ cells had higher median fluorescence intensity (MFI) of NKG2D marker ($p = 0.0052$). $CD56^{bright}$ NK ($CD56^+CD16^-$) frequencies did not differ, however HIV-1^+ women had decreased cytolytic NK ($CD56^+CD16^+$) and increased anergic NK ($CD56^-CD16^+$) frequencies ($p = 0.0053$ and $p = 0.0164$ respectively). HIV-1^+ $CD56^{bright}$ NK populations demonstrated a lower frequency of $CD11b^+CD27^+$ cells ($p = 0.0317$), whereas cytolytic NK populations showed decreased $CD11b^+CD27^-$ profile and higher $NKG2D^+$ marker MFI ($p = 0.0086$, $p = 0.0283$). Anergic NK cells exhibited decreased $CD11b^+CD27^-$ profile, $NKG2A^+$, $NKp30^+$, and $NKp46^+$ cells, and higher $NKG2D^+$ marker MFI ($p = 0.0036$, $p = 0.0473$, $p = 0.0036$, $p = 0.0037$, and $p = 0.0230$).
Conclusions: Despite ART NK cell subsets in HIV-1^+ pregnant women demonstrate both disrupted frequency and altered phenotype from HIV-1^- pregnant women. Differences in CD11b and CD27 expression indicate potential dysregulation of NK cell maturation, and altered expression of inhibition and activation markers in both cytolytic and anergic cell subsets supports this. These findings contribute to understanding the modifications of NK cell function by pregnancy and HIV-1 infection.

Differential distribution of M1 and M2 macrophages in the decidua and chorionic villi of placentas from HIV-1-infected mothers on combination antiretroviral therapy

M.Z. Zulu[1], L. Fick[1], N. Chanzu[1], N. Bangani[1], A. Perez[2], T. Malaba[2], H. Madlala[2], L. Myer[2], G. Cianci[3], T. Tilburgs[4], M.-L. Newell[5], C.M. Gray[1,6]
[1]*University of Cape Town, Department of Pathology, Cape Town, South Africa,* [2]*University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa,* [3]*Northwestern University, Department of Cell and Molecular Biology, Chicago, United States,* [4]*Harvard University, Department of Stem Cell and Regenerative Biology, Boston, United States,* [5]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom,* [6]*National Health Laboratory Services/ Groote Schuur Hospital, Cape Town, South Africa*
Presenting author email: zulumic@gmail.com

Background: A balance of M1 and M2macrophages plays a critical role in regulating maternal tolerance to a developing fetus. ART provision to HIV-infected pregnant women is known to reduce mother-to-child HIV transmission, but also results in poor birth outcomes, such as premature and small-for-gestational age infants. We hypothesize that prolonged exposure to ART in utero results in disruption of the balance between M1 and M2 macrophages at the feto-maternal interface.
Methods: Using immunohistochemistry, we enumerated the density of $CD68^+$ (M1), $CD163^+$ (M2) and $CD206^+$ (M2) macrophages within tissue sections of decidua parietalis (DP), decidua basalis (DB) and chorionic villus tissue (CVT) taken from placentas at delivery from HIV-1-infected mothers. Placentas were collected from women who were stable on ART (commenced ART before pregnancy) (n=9) and women initiating ART at ±20 weeks gestation (n=11). DAB-stained cells were enumerated using an automated software from 5 separate random images after sections were counterstained with Mayer's hematoxylin. Cell density was expressed as a ratio of DAB stain (numerator) by nuclei stain (denominator).
Results: The duration of ART exposure had no effect on the distribution of $CD68^+$, $CD163^+$ and $CD206^+$ cells within DP and DB membranes of placentas from mothers who were either stable or initiating ART. However, there was a higher density of CD163/nuclei (median of 2.47) in the decidua parietalis (DP) of mothers initiating ($p=0.0037$) or on stable ART ($p=0.0085$) compared to CVT (median of 0.45). $CD206^+$/nuclei in the DP was significantly higher when compared to the DB (median of 1542.9 to 1.57; $p=0.0005$) and CVT (median of 1542.9 to 1.60; $p=0.0021$) from mothers initiating or on stable ART. There was no difference in the CD68/nuclei ratio in any of the placental tissue compartments for mothers in either of the ART groups.
Conclusions: Overall, the duration of ART exposure appeared to have no effect on the distribution of M1 (CD68) and M2 (CD163/CD206) macrophages in the decidua. The higher density of M2 macrophages within the maternal decidua compared to the chorionic villi, suggests that ART exposure may not disrupt these regulatory macrophages at the feto-maternal interface.

TUPEA0098

Influence of the genetic LILRA3-deletion on HIV and Hepatitis C

G. Ahrenstorf, H.Z. Low, K. Katja, F. Ahmad, D. Ordonez, M. Stoll, R.E. Schmidt, T. Witte
Hannover Medical University, Hannover, Germany
Presenting author email: ahrenstorf.gerrit@mh-hannover.de

Background: Members of the the leukocyte immunoglobulin-like receptor family (LILRs) exert various immunmodulatory functions. A naturally occuring 6.7 kbp deletion in the gene locus of LILRA3 results in a null allele and an absence of the

protein. The genetic LILRA3 deletion has been associated with autoimmune and malignant disorders. The influence of LILRA3 and of the genetic LILRA3 deletion on the transmission and the clinical course of HIV and Hepatitis C was assessed in this study.
Methods: LILRA3 genotypes of patients and controls were determined by polymerase chain reaction. Studies of LILRA3 gene regulation and protein concentrations were performed using real-time PCR, intracellular flow cytometry and ELISA. An infectivity assay was performed for HCV after addition of recombinant LILRA3 protein.
Results: The prevalence of homozygous LILRA3 deletion was significantly higher in HIV positive individuals (n= 439) than in controls (n= 651) (p= 0.02). In contrast, in the hepatitis C positive population (n=314) the prevalence of the homozygous LILRA3 deletion was reduced compared to controls (p<0.02).
The disease progression of HIV was faster in patients with homozygous LILRA3 deletion with a higher proportion of short-term progressors among homozygously deleted patients than in heterozygous
(p= 0.03) and in homozygously positive (p=0.002) individuals. Functional analysis revealed an upregulation of the LILRA3 gene in real-time PCR in treated HIV patients when compared to untreated patients (p= 0.007) and controls (p= 0.02) resulting in a higher LILRA3 expression in $CD4^+$ (p= 0.008) and $CD14^+$ (p= 0.02) cells of untreated patients than in controls in intracellular flow cytometry. No up-regulation could be found in the Hepatitis C infected individuals.
LILRA 3 concentrations in the sera were similar between the groups, in untreated HIV patients a correlation between viral load and LILRA3 concentration was found. An infectivity assay showed a reduced infectivity of HCV when recombinant LILRA3 protein was added.
Conclusions: The homozygous LILRA3 deletion is associated with a higher susceptibility for HIV infection and with a faster disease progression.
In Hepatitis C the LILRA3 leads to a reduced infecivity of HCV, thus the deletion is risk factor for the transmission of Hepatitis C.

TUPEA0099

Sensing of HIV-1 entry triggers a type I interferon response in human primary macrophages

Presenting author email: vteixeir@curie.fr

Background: Along with CD4+ T lymphocytes, macrophages are a major cellular source of HIV-1 replication, and a potential viral reservoir. Following entry and reverse transcription in macrophages, cloaking of the viral cDNA by the HIV-1 capsid limits its cytosolic detection, enabling efficient replication. However, whether incoming HIV-1 particles are sensed by macrophages, prior to replication, remains unclear.
Methods: Macrophages were diferentiated from monocytes of healthy human blood donors. Viruses and viral-like particles were produced by transfection of the corresponding pro-viral DNA in HEK 293 T cells.
Results: Here, we show that HIV-1 triggers a broad expression of interferon-stimulated genes (ISG) in monocyte-derived macrophages within a few hours after infection. This response does not require viral reverse transcription or the presence of HIV-1 RNA within particles, but viral fusion is essential. This response is elicited by viruses carrying different envelope proteins and thus different receptors to proceed for viral entry. Expression of ISG in response to viral entry requires TBK1 activity and type I IFNs signaling. Remarkably, the ISG response is transient but impacts on subsequent viral spread.
Conclusions: Together, our results shed light on an early step of HIV-1 sensing by macrophages at the level of entry, which confers an early protection through type I IFN signaling and has potential implications in controlling the infection.

Presenting author email: lamine.alaoui@cea.fr

Background: Dendritic cells (cDC) play a major role in the early immune responses that tip the balance toward viral control or persistence. Previous in vitro studies suggest that HIV increases the binding capacity of LILRB2 inhibitory receptor for MHC class I leading to cDC dysregulations and thus inefficient immune responses. However the dynamic of LILRB2 during the course of HIV infection in vivo and its relationship with cDC dysregulations is still unknown.
Methods: Here we use a cynomolgus macaque model of infection by SIV to monitor LILRB2 expression on cDC throughout time.
Results: Our data show that LILRB2 expression is enhanced on cDC from blood and lymph nodes in the early phase of infection and reach a peak 10 days after infection. Moreover, up-regulation of MHC class I, the ligand of LILRB2, is also induced in the early phase of SIV infection. By contrast, infection of cynomolgus macaque by chikungunya virus, that elicit efficient anti-viral immune responses, revealed a decrease of LILRB2 on cDC during acute phase of infection despite similar plasmatic cytokine profiles in both models. Ex-vivo analysis of cDC in blood from early HIV infected patients confirmed that LILRB2 expression is up-regulated during acute phase of infection. Moreover, ex vivo infection of human DC by HIV enhances the expression of LILRB2 in productively infected cells.
Conclusions: Altogether our data reveal a specific up-regulation of LILRB2 and MHC class I in the early phase of SIV / HIV infection that may account for the dysregulations of cDC at a critical stage of the anti-viral immune response.

TUPEA0101

Allogeneic NK-CD4 co-cultures reveal potential protective KIR/HLA mechanisms against HIV

J. Hens, W. Jennes, O. Goovaerts, A. Ceulemans, L. Kestens
Institute of Tropical Medicine, Antwerp, Belgium
Presenting author email: jhens@itg.be

Background: KIR/HLA incompatibility between HIV-exposed seronegatives (ESN) and their partners has been identified as a potential HIV-protective mechanism, whereas HIV-transmission was linked to the presence of an allogeneic KIR/HLA match. This protective effect has been ascribed to the missing-self mechanism, where activated NK cells eliminate the influx of allogeneic HIV-infected cells. We aim to provide evidence for the existence of these alloreactive Natural killer (NK) cell responses against HIV patient derived CD4 T cells.
Methods: NK cells were isolated from 62 healthy individuals and co-cultured with CD4 T cells derived from 62 HIV patients. After 4 hours, co-cultures were analyzed for 7-AAD, CD107a and inhibitory KIR (iKIR) expression using an 8-color flow cytometer. KIR and HLA genes were genotyped using PCR KIR/KIR-ligand kits.
Results: We observed higher percentages of CD4 T cell death in co-cultures with a KIR/HLA mismatch between NK cells and CD4 T cells, compared to KIR/HLA matched co-cultures (p>0.0001). NK cell degranulation by single iKIR expressing NK cells was also increased in the presence of their respective KIR/HLA mismatch as compared to KIR/HLA matches (KIR3DL1:p=0.0005; KIR2DL1:p≤0.0001 and KIR2DL2/3:p≤0.0369). Extrapolation of these results to the total NK cell population showed a strong relation between the total degranulating NK cell population induced by a KIR/HLA mismatch and CD4 T cell death (p>0.0001; R=0.8109), while no clear relation was found in context of a KIR/HLA match (p=0.0008; R=0.3498). Independent of KIR/HLA mismatches, CD4 T cell killing and NK cell degranulation were elevated in the presence of a telomeric activating KIR profile (p=0.0203, p=0.0115 respectively) compared to donors with a telomeric inhibiting KIR profile.
Conclusions: Our results suggest that the presence of a KIR/HLA mismatch is the driving force behind the killing of allogeneic CD4 T cells. Additionally, the presence of activating KIRs increases the cytotoxic capacity of NK cells. These results illustrate a potential contribution of alloreactive NK cells to HIV restrictive mechanisms in ESN.

TUPEA0102

HIV-1 Vif adaptation to host immune pressure impact of cytidine deaminases and host HLA

N. Reddy[1], K. Reddy[1], T. Ndung'u[2]
[1]Africa Health Research Institute, Durban, South Africa, [2]KwaZulu Natal Research Institute for Tuberculosis and HIV, Durban, South Africa
Presenting author email: nicolereddy1502@gmail.com

Background: Members of the APOBEC3 cellular cytidine deaminase family inhibit HIV-1 replication in the absence of the HIV-1 Vif protein. However, HIV-1 Vif is able to counteract the inhibitory action of all key APOBEC3 proteins by targeting them for premature proteasomal degradation. The ability of transmitted/founder virus Vif to adapt to immune pressure mediated by diverse cytidine deaminases and other host proteins such as human leukocyte antigen (HLA), and the subsequent impact on disease pathogenesis has not been fully characterized. We hypothesized that the transmitted/founder virus Vif adapts in vivo to specific APOBEC protein mediating most immune pressure as well as to host HLA class I mediated host immune pressure.
Methods: 17 HIV-1 acutely infected individuals from Durban, South Africa were studied. HIV-1 vif was amplified and cloned into the pCRV1 expression vector. For each patient sample, 2-4 clones were generated at both 1-month post-infection and 1-year post-infection. Putative sequence changes mediated by APOBEC or HLA-I immune pressure were analysed.
Results: In total, 64 clonal sequences were generated. All HIV-1 vif clones were subtype C. Sequence analysis showed that most APOBEC-3G, -3F and -3H binding sites in HIV-1 vif were conserved. However, at Vif amino acid position 17, located within the APOBEC3F binding site ^{14}DRMK^{17}, 64% of 1-month post infection (transmitted/founder) viruses had a non-consensus subtype C Arginine (R) which increased to 71% at 1-year post-infection.
Although there was sequence variability at APOBEC3G binding domains between individuals, there were no predictable changes noted over the course of infection. Analysis of Vif HLA epitopes within transmitter/founder viruses showed that 43% had cytotoxic T cell mutations associated with the host HLA, whereas 26% possessed known CTL escape mutations not associated with the infected person's HLA genotype.
Conclusions: This data suggests a high rate of transmission of Vif HLA-associated immune escape variants and adaptation to pressure exerted by the host HLA over 1 year. There was also evidence of Vif adaptation to APOBEC3F but not to the other APOBEC proteins. The impact on Vif adaptation to host pressure on its ability to bind and counteract APOBEC proteins requires further investigation.

TUPEA0103

Blood precursor DCs are the most efficient transmitters of HIV-1 to T cells

N. Ruffin[1], E. Gea-Mallorquí[1], M. San Roman[1], F. Brouiller[1], C.-A. Dutertre[2,3], P. See[3], K. Duan[3], M. Poidinger[3], F. Ginhoux[3], P. Benaroch[1]
[1]Institut Curie, PSL Research University, INSERM U 932, Paris, France, [2]Duke-NUS Graduate Medical School, Program in Emerging Infectious Disease, Singapore, Singapore, [3]Singapore Immunology Network (SIgN), A*STAR, Singapore, Singapore*
Presenting author email: nicolas.ruffin@curie.fr

Background: Blood dendritic cell precursors (preDCs) can give rise to conventional cDC1 and cDC2. As DCs represent critical targets for the establishment of HIV-1 infection and for efficient anti-viral immunity, the present study aims to evaluate the impact of HIV-1 exposure on preDCs as compared to other blood DC subsets.
Methods: DC populations (plasmacytoid pDC, conventional cDC1 and cDC2, and preDC) were sorted from PBMCs of healthy donors. Cells were then infected using HIV-$1_{NL4.3}$ or HIV-1_{AD8} virus expressing GFP in the presence or not of Vpx for 48h. For transmission experiments, 24h p.i. DCs were co-cultured with activated CD4$^+$ T cells and cells were harvested 48h later. Transcription profile of HIV-1 infected preDCs were analysed using the Human Gene 2.1 ST array.
Results: We found that among the DC subsets freshly purified from seronegative blood donors, preDCs are slightly more susceptible to HIV-1 infection than cDC2; 4.3±2.5% vs 3.2±2.6% infected cells at 48h, while cDC1 and pDCs were hardly infected (0.2±0.4% and 0.6±0.5%, respectively). However, when SAMHD1 restriction was counteracted by the addition of Vpx, preDCs became much more susceptible to HIV-1 than any other DC subset including cDC2 (48.0±8.4% for preDCs vs 6.2±4.0% for cDC2). In contrast to terminally differentiated DC populations, preDCs were susceptible to both CXCR4 and CCR5-tropic HIV-1.
Moreover, HIV-1-infected preDCs efficiently transmitted the infection to activated primary CD4$^+$ T lymphocytes. HIV-1 infection of preDCs induced an up-regulation of genes involved in T cell activation as seen by transcriptomic analyses. Investigations are underway to assess the impact of preDC exposure to HIV-1 on their capacity to activate T lymphocytes and on their differentiation into conventional cDC1 and cDC2.
Conclusions: We showed that preDCs, a novel blood DC population preferentially transmits HIV-1 infection to T cells as compared to known DC subsets, owing to its higher infectability. Thus, in addition to their role in the ontogeny of DCs, preDCs appear as a subset endowed with specific properties and functions that HIV-1 may exploit. Unravelling the impact of HIV-1 infection on preDC biology should provide insights in key steps of viral spreading and open new venues on therapeutic strategies.

TUPEA0104

SUMOylation influences the sensitivity of SAMHD1 to Vpx-mediated degradation

C. Martinat[1], N. Palmic[2], F. Margottin-Goguet[3], A. Saïb[2], A. Zamborlini[2,4]
[1]INSERM U 944-CNRS/P7 7212, Batiment Jean Bernard, Paris, France, [2]INSERM U 944-CNRS/P7 7212, Paris, France, [3]INSERM U 1016 - CNRS/P5 UMR8104, Paris, France, [4]Conservatoire national des arts et metiers (Cnam), Paris, France
Presenting author email: charlotte.martinat@gmail.com

Background: SAMHD1 inhibits the HIV-1 replication in non-cycling myeloid cells and resting T cells. Some related viruses of the HIV-2/SIVs lineage counteract this restriction by expressing Vpx, an accessory protein which promotes the proteasomal degradation of SAMHD1. Numerous lines of evidence indicate that SAMHD1-mediated restriction relies on its ability to degrade dNTPs, keeping their concertation below a threshold required for reverse transcription of the viral genome. Phosphorylation of T592 is proposed to inactivate SAMHD1 antiviral activity in cycling cells. Consistently, SAMHD1 harboring T592D mutation to mimic phosphorylation does not restrict HIV-1. However, reports that this mutation does not affect dNTPs hydrolysis question whether SAMHD1-mediated restriction relies exclusively on its dNTPase activity or might require additional post-translational modifications or cell-type specific cofactors.
Methods: Cells expressing HA-SAMHD1 and His-SUMO proteins were lysed in denaturing conditions and SUMOylated SAMHD1 was enriched on Ni-NTA beads and analyzed by Western blotting. SUMOylation sites were confirmed by site-directed mutagenesis. The localization of endogenous SUMOylated SAMHD1 was studied by Proximity Ligation Assay and fluorescence microscopy. The antiviral activity of SUMOylation-deficient SAMHD1 variants was tested in differentiated U937 cells. After challenge with VSVg-pseudotyped HIV-1 or HIV-2 harboring a GFP reporter gene, infected cells were quantified by flow cytometry. To assess the sensitivity SUMOylation-deficient SAMHD1 mutants to Vpx-dependent degradation, U937 cell lines were incubated with Virus-like particles carrying or not Vpx.
Results: .We found that SAMHD1 is modified by SUMO proteinsand that endogenous SUMOylated SAMHD1 accumulates in the nucleus. Residues K469 and K622 are major SUMO-conjugation sites. SAMHD1 variants where these sites are mutated restrict the infection of Vpx-deficient viruses. Strikingly, infection of Vpx-positive viruses is also inhibited, likely because SUMOylation-deficient SAMHD1 mutants are resistant degradation by Vpx.
Conclusions: Our results suggest that SUMOylation is required for Vpx-mediated degradation of SAMHD1 and, as a consequence, influences its antiviral activity.

Interplay between infection and innate sensing mechanisms of the HIV vaccine vector MVA in human dendritic cells

M. Döring, T. Satoh, M. Gentili, X. Lahaye, N. Manel
Institut Curie, Cancer and Immunity, Paris, France
Presenting author email: marius.doring@curie.fr

Background: Modified vaccinia virus Ankara (MVA) a promising candidate live attenuated vaccine vector for HIV, induces antigen-specific T cell responses. MVA replicates in human cells but does not produce viral progeny. Multiple innate sensors including TLRs, cytosolic DNA and RNA sensors as well as the inflammasome have been implicated in MVA sensing by myeloid cells. Among myeloid cells, dendritic cells (DCs) are critical for the induction of protective immune responses. In DCs, MVA infection leads to vaccine antigen expression, but paradoxically also to cell death. How DCs sense and respond to MVA infection remains incompletely understood. We have studied the immune response of human monocyte-derived DCs (MDDCs) to MVA and compared it to HIV-1 with Vpx a well-establish model of cGAS-dependent sensing in MDDCs.
Methods: Monocyte-derived DCs (MDDCs) were generated from healthy donors. We overexpressed a dominant-negative IRF3 (IRF3DN) and silenced cGAS using shRNA containing lentivectors. MDDCs were infected with MVAGFP or HIVGFP. CD86, Siglec-1, GFP and cytokine expression were analyzed by FACS.
Results: We found that CD86 was induced on uninfected bystander DCs, while it was downregulated on MVA-infected DCs. IRF3DN inhibited DC activation by MVA and HIV. In contrast, cGAS depletion only modestly decreased DC re-

sponse to MVA, while it abrogated the DC response to HIV. Cross-talk between MVA-infected and bystander DCs was mediated by soluble factors. Using blocking antibody cocktails, we showed that transactivation partially required type I IFN, and also additional JAK/STAT pathways. Unexpectedly, we found that MVA did not replicate in DCs, while it did in control HeLa cells. We identified a restriction factor responsible for blocking MVA replication in DCs. Alleviating this restriction increased MVA antigen expression in DCs.
Conclusions: Our results highlight the interplay between infected and bystander human DCs in response to MVA. Interestingly, our results show that MVA antigen production in DCs is largely compromised by the activity of a restriction factor. Altogether, these insights may help to improve MVA as a HIV vaccine vector.

TUPEA0106

Plasmacytoid dendritic cells (pDC) produce Interferon-λ intrinsically, whereas BDCA3⁺ DC rely on cellular cross-talk, in response to HIV-1 and HIV-2

S. Isnard, M. Iannetta, J.-B. Guillerme, B.C. Ramirez, R. Cheynier, A. Hosmalin
Institut Cochin, Infection, Immunity and Inflammation, Paris, France
Presenting author email: stephane.isnard@inserm.fr

Background: Interferons (IFN)-lambda1, 2 and 3, also called IL-28A, IL-28B, and IL-29, constitute the Type III IFN family. They display antiviral properties similar to those of type I IFN, but use a different receptor. Polymorphisms in the IFN-λ2 gene were correlated with responsiveness to HCV infection treatment and with spontaneous clearance and IFN-λ was tested for HCV therapy. Despite this important role in a major chronic viral infection, IFN-λ responses to HIV have not been studied. We studied these responses to HIV-1, which induces AIDS in most infected patients in the absence of antiretroviral treatment, and to HIV-2, which is less pathogenic because of a different host-virus interaction which needs better understanding.
Methods: We isolated PBMC from cytapheresis residues obtained from healthy donors by the Etablissement Français du Sang. We sorted them by flow cytometry into pDC, BDCA1⁺ DC and BDCA3⁺ DC. We stimulated them, either unseparated or as sorted populations, for 18 h with replicative HIV-1 (NL4.3) or HIV-2 (GLAN), compared to a RNA-virus, Influenza-A/PR8, a DNA-virus, HSV-1, both well-known to induce IFN-α and -λ, or to Toll-like receptor (TLR)-3 (polyI:C) or -7/8 (R848) ligands. We assessed IFN mRNA transcription by RT-qPCR, measured IFN secretion by ELISA, and intracellular production using flow cytometry.
Results: After stimulation of PBMC with HIV-1 or HIV-2, we detected IFN-α and to a lesser extent IFN-λ in the supernatants. Large amounts of IFN-α and -λ were detected after polyI:C, influenza or HSV stimulation, and weak amounts after R848 stimulation. Flow cytometric analysis demonstrated that among PBMC, HIV1 and HIV2 induced the production of IFN-λ by pDC and BDCA3⁺ DC. However, when using sorted cells, HIV-1 and -2 induced the production of IFN-λ only by pDC. Despite some variability, transcription of IFN-α, -λ1 or -λ2/3 mRNA followed similar patterns as protein production.
Conclusions: This is the first study evidencing IFN-λ production by human pDC and BDCA3⁺ DC after in vitro stimulation by HIV. HIV-1 and HIV-2 induced IFN-λ expression and secretion in PBMC. The ability to produce IFN-λ in response to HIV-1 or -2 is cell-intrinsic for pDC but relies on cellular cross-talk for BDCA3⁺ DC.

Comparison of genital tract immune mediators between HIV-infected and HIV-uninfected Malawian women randomized to the depot medroxyprogesterone acetate injectable or levonorgestrel implant

J. Tang[1,2], N. Davis[3], A. Kourtis[3], L. Chinula[1,2], A. Msika[1], G. Tegha[1], S. Hurst[3], M. Hosseinipour[1,2], J. Nelson[2], K. De Paris[2]
[1]UNC Project-Malawi, Lilongwe, Malawi, [2]University of North Carolina at Chapel Hill, Chapel Hill, United States, [3]U.S. Centers for Disease Control and Prevention, Atlanta, United States
Presenting author email: jennifer_tang@med.unc.edu

Background: Studies suggest that the depot medroxyprogesterone acetate (DMPA) injectable, but not other progestin-only contraceptives, may increase the risk of HIV acquisition and transmission. The biological mechanisms may include local immune alterations in the genital tract. We therefore compared changes in soluble immune mediators between HIV-infected and HIV-uninfected Malawian women randomized to DMPA or the levonorgestrel (LNG) implant.
Methods: Between May 2014-April 2015, we randomized 97 women (73 HIV-infected, 24 HIV-uninfected) to DMPA or LNG implant. We obtained samples at 6 time points: 2 prior (follicular/luteal phase) and 4 after contraceptive initiation (day 3; months 1, 3, 6). ELISA and Luminex were performed on cervicovaginal lavage (CVL) samples to measure 19 immune mediators. Baseline values were calculated as the mean of the follicular and luteal phase samples. The following comparisons were performed using the nonparametric Wilcoxon-Mann Whitney test:
1) Baseline levels between HIV-infected and HIV-uninfected women,
2) Immune marker levels at day 3 and 6 months after contraceptive initiation between HIV-infected and HIV-uninfected women, and;
3) Differences at each time point from baseline between DMPA and LNG implant users.
Results: At baseline, HIV-infected had higher CVL levels of CXCL-10 (p=0.036), BD-3 (p=0.002), and IL-1a (p=0.009) when compared with HIV-uninfected women. LNG implant initiation did not result in significant differences in any mediators between HIV-infected and HIV-uninfected women at day 3 or month 6. However, DMPA initiation led to reduced CVL levels of CXCL-10 (p=0.043), IL-6 (p=0.024), TNF-a (0.002), and GM-CSF (p=0.029) in HIV-infected women at day 3 (but not month 6), which was not seen among HIV-uninfected women. Among HIV-infected women (but not HIV-uninfected women), DMPA compared with LNG implant was associated with a decrease in 8 different immune mediators after contraceptive initiation. None of the comparisons remained significant after Bonferroni correction (p>0.0006).
Conclusions: Among HIV-infected women, changes in some CVL immune mediators were observed after contraceptive initiation in the DMPA, but not the LNG implant arm. The decreases were mostly of inflammatory cytokines. While our sample size is small, these results are generally reassuring regarding the genital effects of DMPA over 6 months of use, particularly among HIV-uninfected women.

Seminal plasma exposures strengthen vaccine responses in the female reproductive tract mucosae

R. Marlin[1,2,3], M.-T. Nugeyre[1,2,3], N. Tchitcheck[1], M. Parenti[1], N. Dereuddre-Bosquet[1], H. Hocini[3], F. Barré-Sinoussi[3,4], G. Scarlatti[3,5], R. Le Grand[1,3], E. Menu[1,2,3]
[1]CEA, U 1184 ImVA-IDMIT, Fontenay aux Roses, France, [2]Institut Pasteur, MISTIC Group - Virology, Paris, France, [3]Vaccine Research Institute, Créteil, France, [4]Institut Pasteur, International Division, Paris, France, [5]San Raffaele Scientific Institute, Viral Evolution and Transmission Unit, Milan, Italy
Presenting author email: romain.marlin@cea.fr

Background: HIV-1 sexual transmission occurs mainly via semen exposures. Seminal plasma (SP) induces physiological modifications, including inflammation, in the female reproductive tract (FRT) mucosae. An effective HIV vaccine should elicit mucosal immunity. However, modifications of vaccine responses by local environment remain to be characterized. The aim of this study was to determine whether HIV-1⁺ SP has an impact on the local immune responses in a vaccination context.
Methods: Twelve female cynomolgus macaques were vaccinated by two subcutaneous inoculations of the ANRS-MVA-HIV B, used as a vaccine model. Two weeks after the second vaccine inoculation, animals received four intravaginal inoculations of PBS (n=6) or SP pool from HIV-1⁺ individuals (n=6). Immune composition and vaccine responses were analysed in the blood, lymph nodes and FRT compartments, by flow cytometry, ELISA and transcriptomic analyses.
Results: Tissue characterisation by cytometry and transcriptomic approaches highlighted the compartmentalisation of the immune cell distribution in the FRT. Specific anti-MVA CD8⁺ T cells were characterized in all the FRT compartments. Anti-MVA IgG/IgA were detected in vaginal fluids after the second vaccine inoculation.
Multiple HIV-1⁺ SP exposure did not impact the anti-MVA antibody responses. Interestingly, SP exposures induced local cell recruitment of antigen presenting cell (APC), especially CD11c⁺ cells; and CD8⁺ T cells recruitment in the FRT draining lymph nodes. Analyses of differentially expressed genes confirmed the impact of SP exposures on cell recruitment in the cervix and the draining lymph nodes. The frequency of specific anti-MVA CD8⁺ T cells increased, especially in the cervix. Furthermore, anti-MVA response quality enhanced in the FRT exposed to SP since percentage of polyfunctional CD8⁺ T cells (IFNγ, MIP1β, TNFα and IL-2 production) increased. Interestingly, SP exposures revealed an anti-MVA response mediated by CD4+ T cells, which was not observed in the control group.
Conclusions: Our results clearly show a local recruitment of APCs and an increase of the frequency and quality of the specific immune responses within the FRT after HIV-1⁺ SP exposures. These data highlight the fact that physiological conditions, such as SP exposures, should be taken into consideration to test and to improve vaccine efficacy against HIV-1 and other sexually transmitted infections.

Mucosal neutrophil activation is associated with gastrointestinal and systemic T-cell activation

T. Hensley-McBain[1,2], J. Manuzak[1,2], C. Miller[1,2], A. Zevin[1,2], A. Burgener[3,4,5], P. Hunt[6], M. Somsouk[6], T. Hope[7], N. Klatt[1,2]
[1]University of Washington, Department of Pharmaceutics, Seattle, United States, [2]Washington National Primate Research Center, Seattle, United States, [3]National HIV and Retrovirology Labs, Public Health Agency of Canada, Winnipeg, Canada, [4]University of Manitoba, Department of Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [5]Karolisnka Institutet, Solna, Sweden, [6]University of California, Department of Medicine, San Francisco, United States, [7]Northwestern University, Department of Cell and Molecular Biology, Chicago, United States
Presenting author email: thmcbain@uw.edu

Background: HIV disease progression, comorbidities, and mortality are associated with mucosal dysfunction and systemic inflammation. However, the mechanisms underlying these dysfunctions are not resolved. Neutrophils infiltrate the gastrointestinal (GI) tract during HIV infection, yet their contribution to inflammation is unknown. In inflammatory bowel disease, activated neutrophils contribute to tissue damage and disease pathogenesis. In HIV, blood neutrophils expressing high levels of PD-L1 suppress T-cell function and correlate with T-cell exhaustion. However, neutrophil phenotypes in the GI have yet to be examined during HIV . Our study assessed neutrophil activation and whether suppressive neutrophils are present in the GI in HIV infection. Additionally, we determined how these neutrophil states associate with markers of GI and systemic T-cell dysfunction known to contribute to HIV disease progression.
Methods: Isolated leukocytes from colon biopsies taken from treated, HIV-infected (n=14) and uninfected (n=11) individuals were phenotyped by flow cytometry to examine the expression of CD11b (activation) and PD-L1 (suppression) on neutrophils, and CD38 (activation) and PD-1 (exhaustion) on colon and blood T-cells.
Results: We found increased CD11b expression on GI neutrophils from HIV-infected indviduals compared to uninfected controls (p=0.0128). Importantly, GI neutrophil activation levels positively correlated with the percentage of CD8 and CD4 T-cells expressing CD38 in both the GI and blood (p< 0.01). Furthermore, we found a decrease in suppressive (PD-L1+) neutrophils in the GI tract (p= 0.0457), which may contribute to aberrant T-cell activation during HIV infection, as these myeloid-derived suppressor cells (MDSC) are known to regulate T-cell activation.
Conclusions: Overall, these are the first quantitative data demonstrating neutrophil infiltration in the GI tract of HIV-infected individuals, and that GI neutrophil activation may play an important role in contributing to GI tissue damage and T-cell activation in HIV infection. These data also increase our understanding of the relationship between neutrophils in the blood and GI mucosa and importantly, how neutrophils in these compartments differ in their phenotypes and their likely functional interactions with the immune system. It will be important to better understand whether these neutrophils contribute to local tissue damage and systemic biomarkers of disease progression, and studies are currently underway to assess this.

TUPEA0110

T cell immune exhaustion in gut-associated lymphoid tissue during treated primary HIV infection: implications for HIV persistence

J.P. Thornhill[1], G.E. Martin[2], C. Herrera[1], J. Hoare[1], S. Peake[1], S. Fidler[1], J. Frater[2], & the CHERUB collaborators
[1]Imperial College London, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom
Presenting author email: thornhillj@gmail.com

Background: Early ART in primary HIV infection (PHI) limits both HIV reservoir size and immune dysfunction in blood. Gut-associated lymphoid tissue (GALT) harbours the largest anatomical HIV-1 reservoir and supports viral persistence. Exhausted CD4+T-cells are enriched for HIV-1 DNA in peripheral blood. Furthermore, CD4+ and CD8+ T-cell exhaustion predict disease progression and viral rebound on treatment cessation. The significance of exhausted T-cells in tissue is less clear.
This study investigates the expression of immune exhaustion markers in GALT and the relationship with their expression in peripheral blood (PBMC).
Methods: Gut biopsy samples from terminal ileum (TI) and rectum were collected from HIV+ virally suppressed individuals enrolled in HEATHER, an observational study of treated PHI. Biopsy tissue was processed by collagenase digestion. Lineage (CD3, CD4, CD8) and exhaustion (PD-1, Tim-3, TIGIT) marker expression were assessed on mucosal mononuclear cells and PBMCs by flow cytometry. Comparisons were made with healthy control GALT.
Results: 26 individuals were included in this analysis; 13 HIV+ individuals and 13 controls. Significantly lower CD4/CD8 ratio was noted in HIV+ TI GALT compared to controls (p=0.03), but not in rectal GALT.
Overall, exhaustion marker expression (PD-1, TIGIT & Tim-3 on CD4+T-cells and Tim-3 & PD-1 on CD8+T-cells) was significantly higher in GALT compared to PBMC (all p<0.01) HIV+ GALT had significantly higher CD4+PD-1+ (p=0.02) and CD4+TIGIT+ (p<0.01) expression compared to controls. Among HIV+ individuals CD4+PD-1+ (p=0.01), CD4+TIGIT+ (p=0.03) and CD4+Tim-3+ (p=0.02) was significantly higher in rectum compared to TI.
CD8+TIGIT+ was higher in HIV+ GALT than HIV- GALT (p=0.01), with this difference most marked in the TI (p=0.04).
Expression of exhaustion markers PD-1, TIGIT and Tim-3 on CD4+ and CD8+ T-cells in rectal GALT correlated with TI GALT, but no significant correlation was observed between markers of exhaustion measured in either GALT site compared to PBMC.
Conclusions: Differential expression of T-cell exhaustion markers by anatomical compartment may reflect and support varying levels of HIV persistence in GALT despite early ART initiation in PHI. Measurement of immune exhaustion markers in blood does not reflect expression in GALT and highlights the importance of tissue sampling in HIV cure studies.

Impaired genital wound-healing pathways in women experiencing chronic sexual abuse: implications for HIV acquisition

M. Ghosh[1], J. Daniels[1], M. Pyra[2], M. Juzumaite[1], M. Jais[1], K. Murphy[3], T. Taylor[4], S. Kassaye[5], L. Benning[6], M. Cohen[7], K. Weber[7]
[1]George Washington University, Epidemiology and Biostatistics, Washington, United States, [2]University of Washington, Department of Epidemiology, Seattle, United States, [3]Albert Einstein College of Medicine, Montefiore Health System, Bronx, United States, [4]SUNY Downstate Medical Center, New York, United States, [5]Georgetown University Medical Center, Washington, United States, [6]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [7]Cook County Health & Hospital System, Chicago, United States
Presenting author email: mghosh@gwu.edu

Background: Sexual violence is associated with increased risk for HIV acquisition/transmission in women. Chronic exposure to sexual abuse can result in genital tract trauma and psychosocial stress subsequently affecting immune functions. Specifically, HIV susceptibility can be enhanced if genital epithelium is wounded as a consequence of sexual assault and wound-healing pathways are impaired. We hypothesized that levels of specific immune mediators that play a role in wound healing will be dysregulated in women experiencing chronic sexual abuse.
Methods: Using the Women's Interagency HIV Study (WIHS) repository, we identified 4 groups of HIV+ and HIV- women (8-10/group) representing chronic sexual abuse exposure and depression (CES-D score > 16): 1) no history of sexual abuse at baseline or depression (Control); 2) no history of sexual abuse at baseline but current depression (Depression); 3) chronic sexual abuse but no depression (Abuse); 4) chronic sexual abuse with current depression (Abuse+Depression). Endogenous growth factors (PDGF, VEGF, EGF, FGF, IGF) and cytokines (TGF-beta, Gro-alpha) that are critical for wound healing functions, were analyzed in cervical-vaginal lavage (CVL) by ELISA assay. Linear regression was used to model levels of biomarkers with both depression and abuse as predictors. Models were run separately for HIV+ and HIV- women, with CD4 counts and viral load as covariates for HIV+ group.
Results: In HIV- women reporting chronic sexual abuse and depression, we found significantly lower levels of platelet-derived growth factor (PDGF) (p< 0.01) and transforming growth factor beta (TGF-beta) (p< 0.01), compared to Control. The associations were maintained after adjusting for total protein content of CVL. There were no significant changes in these growth factors and cytokines within the HIV+ groups. However, Control HIV+ women had significantly lower levels of PDGF compared to Control HIV- women indicating an effect of HIV status.
Conclusions: PDGF and TGF-beta are critical initiators of wound healing response and exogenous PDGF is FDA approved to treat non-healing ulcerative wounds. Our data indicate genital wound healing might be impaired in women who experience chronic sexual abuse. As wounds in genital epithelium can allow easier access to HIV and other pathogens, specific interventions might be explored in these women to promote healing.

TUPEA0112

Distribution and phenotype characterization of HIV-specific CD8 T cells *in situ* in the rectal mucosa of HIV+ elite controllers

S. Li[1], K. Kovacs[1], B. Kiniry[2], R. Wagstaff[1], A. Ferre[2], P. Hunt[3], M. Somsouk[3], B. Shacklett[2], P. Skinner[1]
[1]University of Minnesota, Department of Veterinary and Biomedical Sciences, Minneapolis, United States, [2]University of California, Department of Medical Microbiology and Immunology, Davis, United States, [3]San Francisco General Hospital, San Francisco, United States
Presenting author email: lixx3054@umn.edu

Background: Mucosal tissues including the gastrointestinal tract are important reservoirs for HIV replication. HIV-specific CD8 T cells are essential in controlling HIV infection. Elite controllers (EC) can suppress the viral replication without treatment and represent less than 1 % of the HIV-infected population. In order to gain insights into HIV-specific CD8 T cells in EC, we characterized this important cell population in rectal mucosa of HIV+ EC.
Methods: Rectal biopsies from EC were collected and stained using in situ tetramer staining combined with immunohistochemistry. Distribution and phenotypes of tetramer+ HIV-specific CD8 T cells were characterized by confocal microscopy and quantitative analysis.
Results: Results showed that tetramer+ HIV-specific CD8 T cells distributed unevenly throughout the rectal mucosa including within lymphoid aggregates. Frequencies of tetramer+ HIV-specific CD8 T cells ranged from 2 to 25 cells/mm^2. A mean of 45% tetramer+ HIV-specific CD8 T cells did not express the effector protein perforin. Of the 55 % tetramer+ HIV-specific CD8 T cells were positive for perforin, the majority expressed low to medium levels of perforin and relatively few expressed high levels.
In addition, we also observed a subset of perforin+ HIV-specific CD8 T cells in which perforin was located exclusively within the cell membrane, possibly representing a novel subset of armed resident or effector memory cells. Almost all tetramer+ HIV-specific CD8 T cells in the rectal mucosa were negative for Ki67, a marker for activation and proliferation (mean of 96%); a mean of 59% of tetramer+ HIV specific CD8 T cells in rectal mucosa were PD-1+, a marker for recent T cell stimulation or exhaustion (mean of 59%), and some expressed CD103, a marker for a subset of resident memory T cells (mean of 6%).
Conclusions: Taken together, these findings suggest that EC maintain diverse populations of memory HIV-specific CD8 T cells distributed throughout the rectal mucosa including within lymphoid aggregates and suggests that these cells are likely continually being exposed to antigen, but not dividing.

Sexually transmitted infections (STIs) increase levels of cytokine and cellular biomarkers of HIV risk

S. Mhlungu[1], N. Yende-Zuma[1], S. Ngcapu[1,2], L. Mansoor[1], S. Abdool Karim[1,3], Q. Abdool Karim[1,3], J. Passmore[1,4], L. Liebenberg[1,2]
[1]Centre for The AIDS Programme of Research in South Africa, University of KwaZulu-Natal, Durban, South Africa, [2]College of Health Science, University of KwaZulu-Natal, Department of Microbiology, Durban, South Africa, [3]Mailman School of Public Health, Columbia University, Department of Microbiology, New York, United States, [4]Institute of Infectious Diseases and Molecular Medicine, Division of Medical Virology, University of Cape Town, Cape Town, South Africa
Presenting author email: sn.mhlungu@gmail.com

Background: Recent studies of women at high risk of HIV infection have demonstrated that increased concentrations of inflammatory cytokines in the female reproductive tract can increase the risk of HIV acquisition. Here, we investigated an association between STI and genital inflammation; and whether genital inflammation is characterised by high levels of HIV target cell recruitment and immune cell activation.
Methods: The concentrations of 48 cytokines were measured by multiplex ELISA in cervicovaginal lavage samples (CVLs) collected from 166 high risk HIV-uninfected women participating in the CAPRISA 008 trial. In addition, genital T cell immune activation status [CD38+/HLA-DR+] and HIV target cell frequency (CD4+CCR5+) were investigated in cervical cytobrushes by flow cytometry. Genital swabs were screened for Neisseria gonorrhoeae, Chlamydia trachomatis, Trichomonas vaginalis and Mycoplasma genitalium by PCR.
Results: No correlations were observed between immune cell activation and either individual cytokines or genital inflammation in the 166 participants. However, women with high levels of immune activation had elevated frequencies of CD4+CCR5+ T cells compared to women with low levels of immune activation (p< 0.0001). Women infected with C. trachomatis had significantly higher frequencies of CD4+CCR5+ cells compared to women without any STIs (p=0.0040). Higher prevalence of C. trachomatis (p=0.0034) or T. vaginalis (p=0.0024) was observed in women with genital inflammation compared to those without inflammation.
Conclusions: Our findings suggest that STIs play a crucial role in cellular recruitment of target cells and are potential drivers of inflammation and immune activation in the genital tract and may foster an environment conductive to HIV acquisition.

TUPEA0114

Potential immune mechanism for the relationship between HIV risk and multiple concurrent HPV infections

J. Jewanraj[1,2], A. Rositch[3], S. Mhlungu[1], A. Mtshali[1], K. Leask[1], L. Mansoor[1], S. Abdool Karim[1,4], Q. Abdool Karim[1,4], J.-A. Passmore[1,5,6], L. Liebenberg[1,2]

Presenting author email: janine.jewanraj@gmail.com

Background: In Sub-Saharan Africa women are disproportionately affected by both human papillomavirus (HPV) and HIV. Concurrent infection with multiple HPV strains has commonly been implicated as a risk factor for HIV acquisition, but the biological mechanism for this remains unclear. Here we investigated whether pro-inflammatory immune responses associated with multiple HPV infections contribute to a genital immune environment conducive to an increased risk of HIV infection.
Methods: This study included a baseline assessment of 133 women of the CAPRISA 008 trial, aged between 18-40 years, and all without PCR evidence of common STI (Trichomonas vaginalis, Chlamydia trachomatis, Neisseria gonorrhoeae, and Mycoplasma genitalium). The Roche Linear Array was used to detect the presence of HPV genotypes. The frequency of highly activated (CD38+ and/or HLA-DR+) T cells were assessed on cervical cytobrush-derived specimens by multiparametric flow cytometry. Multiplex ELISA was conducted at baseline to detect the concentrations of 48 different cytokines in the CVL supernatant.
Results: The prevalence of HPV in the population was 50.9% (95% CI 43.2-58.5), with 44% of women presenting with multiple HPV strains at the genital tract. HPV infected women had a greater frequency of lymphocytes compared to uninfected women, even after adjustment for multiple comparisons (p=0.0132). Infection with multiple HPV types predicted significant increases in lymphocyte (β=3.3%; p=0.021) and HLA-DR+ CD3+ T cell frequencies (β=3.0%; p=0.04). In addition, infection with multiple HPV types was associated with increased concentrations of the chemokine RANTES (β=14.1pg/ml; p=0.041).
Conclusions: Concurrent infection with multiple HPV strains is associated with increased frequencies of activated immune cells, and with increased concentrations of the chemokine responsible for HIV target cell recruitment. These data suggest a potential biological mechanism for the relationship between HIV risk and infection with multiple HPV types.

Degranulating immune cells are associated with higher viral load at cervico-vaginal surface of HIV-infected women in India

V. Saxena[1], S. Bichare[1], I. Khan[1], R. Majumdar[1], M. Ghate[2], M. Thakar[1]
[1]National AIDS Research Institute, Department of Immunology & Serology, Pune, India, [2]National AIDS Research Institute, Department of Clinical Sciences, Pune, India
Presenting author email: vsaxena@nariindia.org

Background: Heterosexual contact is the most predominant mode of HIV transmission in women, accounting a global annual estimate of 30-40%. It is important to understand the local factor(s) contributing towards HIV immunopathogenesis at female genital mucosa. Hence we characterized the cellular immune components at the cervicovaginal mucosa and determined their association with cervical viral load (VL) and CD4 count.
Methods: HIV seropositive women (n=37) including 29 progressors & 8 LTNPs, and seronegative women (n=24) in their premenopausal phase were enrolled. Cervico-vaginal lavage (CVL) and cytobrush samples were collected. CVL from HIV infected women was used to determine the viral load. From the cytobrush, mucosal mononuclear cells were separated and stained for various markers to identify the effector cells (natural killer [NK], DCs, CD4+ and CD8+T cells) and their degranulation using flowcytometry. Samples were acquired on FACSAria and analyzed. Their association with cervical VL and CD4 count was determined using Spearman-Correlation test.
Results: Higher frequencies of CD8+T cells and lower frequencies of CD4+T cells were found in HIV-infected women than HIV-ve women (p<0.05), while the frequencies of DCs, mDCs and pDCs remain unchanged at the cervicovaginal mucosa. Among NK cell subsets, frequency of only defective NK cells (NK_{def}) was

higher in both progressors and LTNPs than HIV-ve women. Though total NK, cytotoxic NK (NK_{cyt}) and regulatory NK (NK_{reg}) cell frequencies were similar in all study groups, the expression of CD107a on all NK subsets was higher in HIV-infected progressors than both LTNPs and HIV-ve women (p<0.05).
Further the frequency of CD107a expressing CD4+T cells was higher in HIV-infected progressors than the HIV-ve women. CD107a expressing CD4 and NK_{def} cells were inversely associated with CD4 count (r=-0.46; p<0.02 & r=-0.55; p<0.004 respectively). CD107a expressing T cells were significantly associated with cervical VL (r=0.62; p<0.003 & r=-0.59; p<0.005 respectively), while CD107a expressing NK_{reg} and NK_{cyt} were found to be associated with cervical VL close to significance level (r=0.43; p<0.057 & r=-0.43; p<0.056 respectively).
Conclusions: Degranulating NK and T cells at the mucosal surface of female genital mucosa are associated with higher cervical viral load and lower CD4 count and may contribute towards increased HIV transmission.

TUPEA0116

Early antiretroviral therapy (ART) initiation improves gut mucosal immunity in SIV-infected Chinese rhesus macaques

O. Farnos[1], G. Andreani[2,3], F. Moukambi[2,3], H. Rabezanahary[2,3], G. Racine[2,3], J. Estaquier[2,3], M.-A. Jenabian[1]
[1]Université du Québec à Montréal (UQAM), Department of Biological Sciences and BioMed Research Centre, Montreal, Canada, [2]Research Center of CHU de Québec, Québec, Canada, [3]Université Laval, Faculty of Medecine, Québec, Canada
Presenting author email: jenabian.mohammad-ali@uqam.ca

Background: Both HIV and SIV infections result in higher immunosuppressive regulatory T-cells (Tregs) frequency, rapid CD4 T-cells depletion and increased immune activation in gut mucosal tissues, beginning in early infection. Here, we assessed the dynamic of gut mucosal CD4 T-cells following early ART initiation in SIV-infected monkeys.
Methods: Nine outbred, Chinese-origin, female rhesus macaques were infected with SIVmac251 virus (20 AID_{50}) intravenously. The ART cocktail contained reverse transcriptase inhibitors Tenofovir (20 mg/kg) and Emtricitabine (20 mg/kg), protease inhibitors Indinavir (2 mg/kg) and Ritonavir (20 mg/kg), and integrase inhibitor Raltegravir (20 mg/kg). ART was initiated at day 3 post-infection and administered once daily via the subcutaneous route. Four ART-treated monkeys were sacrificed at days 11, 14, 27 and 35 post-infection. In three monkeys, ART was interrupted after 53 days of treatment and animals were sacrificed at days 10, 15 and 18 post ART-interruption. Two monkeys remained untreated and were sacrificed at days 33 and 60 post-infection. Mucosal cells were freshly isolated via mechanical purification from ileum, jejunum, colon as well as mesenteric lymph nodes. Mucosal CD4 T-cells were characterized by multi-parameter flow cytometry in comparison with matched peripheral blood samples.
Results: As expected, CD4 depletion was observed in untreated animals. Early ART initiation resulted in a decreased frequency of total Tregs (FoxP3+) and Tregs expressing immunosuppressive ectonucleotidase CD39 - also known as a marker of immune activation - compared to untreated animals in both blood and gut mucosal tissues. Early ART also reduced the frequency of CCR6+ memory CD4 T-cells, suggesting a lower CD4 recruitment in gut mucosal tissue. Furthermore, early ART diminished CD8+CD39+ T-cells as a cellular marker of immune activation linked to the local viremia within the gut. ART-interruption resulted in an increase in frequencies of total and CD39+ Tregs, CCR6+ memory CD4 T-cells and CD8+CD39+ cells in gut mucosal tissues.
Conclusions: Initiation of ART within the first few days of SIV-infection of Chinese rhesus macaques improved gut mucosal immunity by decreasing immunosuppressive Tregs, immune activation and CD4 T-cells recruitment, which in turn could reduce the fuel of local viral reservoirs.

TUPEA0117

PD-1, KLRG1, and Eomesodermin^{High} as potential markers of CD8$^+$ T-cell exhaustion in rectal mucosa during chronic HIV infection

B. Kiniry[1], A. Ganesh[1], P. Hunt[2], M. Somsouk[2], S. Deeks[2], B. Shacklett[1]
[1]University of California, Davis, United States, [2]San Francisco General Hospital, San Francisco, United States
Presenting author email: blshacklett@ucdavis.edu

Background: T-cell exhaustion (T_{EXH}) is a hallmark of chronic HIV-1 infection. As the rectal mucosa is an important site of HIV pathogenesis and rectal CD8$^+$ T-cells differ functionally and phenotypically from blood, understanding T_{EXH} in this compartment may inform the development of therapeutics aimed at blocking exhaustion pathways to boost the immune response. Co-expression of PD-1 and Eomesodermin (Eomes^{High}) has been associated with terminally exhausted T-cells that retain some cytotoxic potential. We previously observed increased Eomes expression in rectal CD8$^+$ T-cells from HIV$^+$ individuals not on antiretroviral therapy (ART) compared to those on ART (Kiniry et al., 2016), and hypothesized this might indicate greater T-cell exhaustion.
Methods: To elucidate the co-expression of Eomes with inhibitory receptors on mucosal Gag-specific CD8$^+$ T-cells, flow cytometry was used to assess KLRG1, PD-1, Tim-3, and 2B4, along with transcription factors T-bet and Eomes on rectal CD8$^+$ T-cells from HIV+ and HIV- adults. Functionality was assessed in a 6h ex vivo assay, stimulating with DMSO, HIV Gag peptides, or Staphylococcal Enterotoxin B, and staining for CD107a, IFNγ, TNFα, perforin and Granzyme B.
Results: Expression of PD-1 and KLRG1, but not Tim-3 or 2B4, was significantly greater in HIV$^+$ Non-Controllers and Controllers compared to ART-treated and HIV- adults. Furthermore, HIV$^+$ Controllers undergoing ART had reduced expression of exhaustion markers compared to Controllers not on treatment. KLRG1 and PD-1 expression were positively correlated with an Eomes^{High} phenotype and CD8$^+$ T-cells co-expressing these molecules were elevated in Non-Controllers and Controllers compared to all other groups. Expression of Perforin and GrzB, although significantly lower in gut compared to blood, were positively correlated with PD-1 expression, and Gag-specific degranulating CD8$^+$ T-cells tended to be Eomes^{High}PD-1$^+$.
Conclusions: Through co-expression of PD-1, KLRG1, and Eomes^{High}, Gag-specific rectal CD8 T-cells displayed an ‚exhausted' phenotype. Nevertheless, they appeared to retain some functionality, suggesting a spectrum of T-cell activation and dysfunction that remains to be fully elucidated. As the mucosa houses a large fraction of tissue-resident CD8$^+$ T-cells with characteristically low KLRG1 expression, KLRG1 may be an especially valuable marker of mucosal T-cell dysfunction. Further exploration of factors that differentiate T-cell dysfunction from activation is warranted.

TUPEA0118

Enhancement of HIV-1 spreading and persistence by MIF/CD74 interaction in primary monocyte-derived macrophages (MDM) and CD4$^+$ T-lymphocytes (CD4TL) in vitro

C. Trifone[1], J. Salido[1], M.J. Ruiz[1], L. Leng[2], R. Bucala[2], H. Salomon[3], F. Quiroga[1], Y. Ghiglione[1], G. Turk[1]
[1]Uni, Microbiology Department, Buenos Aires, Argentina, [2]Yale University School of Medicine, Department of Medicine, New Haven, United States, [3]Institut of Biomedical Research in Retrovirus and AIDS, University of Buenos Aires, Microbiology Department, Buenos Aires, Argentina
Presenting author email: hsalomon@fmed.uba.ar

Background: Understanding the mechanisms involved in HIV-1 infection would facilitate the identification of new therapeutic targets to control the infection in the face of HAART limitations. CD74 membrane expression is up-regulated in infected cells during HIV-1 infection and correlates with immune hyperactivation in HIV-infected individuals. Additionally, plasma level of CD74 activating ligand MIF (Macrophage Migration Inhibitory Factor) is increased in infected subjects. However, the role played by MIF/CD74 interaction in HIV pathogenesis remains unexplored.
Aim: to study the effect of MIF/CD74 interaction in primary HIV-infected monocyte-derived macrophages (MDMs) and CD4$^+$ T-lymphocytes (CD4TLs).
Methods: CD4TL and MDMs were obtained from healthy donors. MDMs were infected, with a R5-tropic HIV-1 virus, and stimulated with MIF concentrations ranging from 1 to 200 ng/ml. Cytokine production and Toll-like receptor 4 (TLR4) expression were measured. Resting CD4TLs were treated with MDM supernatants or exogenous cytokines to evaluate stimulation of permissiveness to X4-tropic HIV-1 infection by p24 quantitation. Cell death was measured by flow cytometry in infected and MIF-treated CD4TLs. Data analysis was performed by parametric methods.
Results: Treatment of infected MDMs with MIF resulted in a dose-dependent increase in IL-6, IL-8, TNFα, sCD23 and sICAM production (p=0.006; p=0.013, p=0.0003, p<0.0001, p=0.022, respectively) compared to untreated cells. Similarly, there was a MIF-driven 2-fold increase in TLR4 expression. By using an anti-CD74 antibody, MIF/CD74 interaction was blocked and these effects were reverted. Treatment of quiescent CD4TL with MIF-treated MDM-derived culture supernatants led to an enhanced permissiveness to HIV-1 infection manifested as 2-fold increase in viral production. MIF itself induced enhanced permissiveness to HIV infection in a dose-dependent manner. This effect was recapitulated by exogenous addition of IL-6, IL-8, or IL1β. Moreover, MIF stimulation reduced the percentage of necrotic cells within the HIV$^+$ population by 50% compared to unstimulated infected cells (p=0.0006).
Conclusions: These findings indicate that MIF/CD74 interaction in infected MDMs contributes to the generation of an inflammatory microenvironment. This effect enhances resting CD4TL permissiveness to HIV infection, viral replication and spreading. Moreover, MIF also increases HIV-infected CD4TL survival, contributing to viral persistence. Overall, these results support a novel role for the MIF/CD74 axis in HIV pathogenesis.

TUPEA0119

Expression and role of chemokine fractalkine in HIV neuro-pathogenesis: a new approach to understand and treat HAND

V. Sénécal, C. Barat, M. J Tremblay
Centre de Recherche du CHU de Québec, Centre de Recherche en Infectiologie, Québec, Canada
Presenting author email: vincent.senecal2@crchudequebec.ulaval.ca

Background: HIV infection of microglia and astrocytes causes release of neurotoxic viral proteins with a neuro-inflammatory environment. Clinically, this results in HIV-associated neurocognitive disorders (HAND) with an uncontrolled prevalence in treated individuals. The objective is to shed light on HAND pathogenesis by studying the interactions of HIV with neuroprotective factors. We focus on fractalkine, an anti-inflammatory chemokine highly produced by neurons that controls microglia neurophysiologic functions and reduces neuronal apoptosis. We hypothesize a potential modulation by HIV affecting HAND severity.
Methods: Human astrocytes were infected and/or stimulated with pro-inflammatory cytokines (IL-1β, IL-6, TNF, IL-8) and fractalkine measured by qPCR (RNA), bioluminescence (transfecting a luciferase-conjugated fractalkine promoter), ELISA (soluble form) and flow cytometry (membrane-anchored form). The enzymatic activity of ADAM-10, the metalloprotease responsible for fractalkine shedding, was evaluated with a fluorimetric assay. Infected macrophages were co-cultured with astrocytes to analyse fractalkine secretion upon cell contact. Microglia were infected and evaluated for fractalkine receptor expression and their responses to fractalkine (MAPK phosphorylation by Western blot and production of neurotoxic products by ELISA).
Results: First, we did not see any differences in terms of fractalkine expression/secretion upon infection. Nonetheless, we saw a concentration dependant increase in TNF or IL-1β treated astrocytes. Surprisingly, we obtained a potent impact of HIV on TNF and IL-1β stimulating potential; a decrease in fractalkine secretion and an increase in the membrane-anchored form in infected and stimulated cells (compared to non-infected and stimulated cells).
We used ADAM-10 inhibitor GI-254023X to demonstrate the role of this enzyme in fractalkine shedding in astrocytes, and observed a reduced ADAM-10 activity in infected astrocytes. MTS assays confirmed cell viability. Establishment of infected macrophages/astrocytes co-cultures enhanced fractalkine secretion by astrocytes, possibly by cell contact. At last, HIV reduced fractalkine receptor expression in microglia/macrophages.
Conclusions: In conclusion, our results indicate a new and clear impact of HIV on fractalkine secretion in astrocytes (by ADAM-10) and receptor expression in microglia. Considering anti-inflammatory functions of fractalkine, reducing its shedding and functional responses in microglia could have important outcomes/implications in chronic inflammation and immune activation for HAND. Overall, intervention with fractalkine-based treatment could offer neuroprotection and reduce HAND severity.

Presenting author email: nicholas.funderburg@osumc.edu

Background: HIV infection and ART alter lipid profiles. Among HIV-infected (HIV+) populations the concentrations of various lipid classes (i.e. ceramides, lysophosphatidylcholine, LPC) and their saturated (SaFA), monounsaturated (MUFA), and polyunsaturated fatty acid (PUFA) composition are related to inflammation and cardiovascular disease risk. Associations among changes in the lipidome and immune activation in persons initiating ART have not been described.
Methods: Plasma concentrations (μM) of lipid species (N=1,300) and FA composition (mol%) were measured by differential mobility spectroscopy (TrueMass Complex Lipid Panel, Metabolon), and markers of inflammation were measured by ELISA in plasma samples from HIV+ participants initiating raltegravir (RAL) based ART (N=35, baseline and week 48), and from HIV-individuals (N=13) of similar demographics. All analyses (paired t-tests, 2-sample t-tests, and Pearson correlations) were exploratory.
Results: Compared to levels in HIV- donors, the plasma concentrations of multiple lipid species are altered in HIV+ persons pre-ART (32.2% increased, 4.9% decreased, p<0.05) and at 48 weeks of ART (29.6% increased, 2.2% decreased, p<0.05). Levels of PUFAs (including 18:3, 20:4, and 20:5) are enriched in HIV- donors compared to HIV+ donors pre-ART (p<0.01); levels of these PUFA species increased by 48 weeks of ART. Levels of SaFAs (including 16:0 and 18:0) tend to be enriched in HIV+ participants (pre-and post-ART). Levels of palmitic acid (16:0) were positively correlated with levels of IL-6, sCD14, and TNFR1 at baseline and week 48 (p<0.02 for all). LPC levels are increased in HIV+ participants, both pre- and post-ART vs HIV- participants (204 μM, 216 μM, and 184 μM, p=0.003, p<0.001), and the composition of LPC is enriched for SaFAs (16:0 and 18:0) among HIV+ individuals. Also at baseline and week 48, several LPC molecules containing SaFAs were positively correlated with sCD14, D-dimer, and TNFR1 (p<0.01, for all) and levels of PUFA containing LPC (18:3, 20:5, 22:5, 22:6) were positively correlated with CD4 counts and inversely correlated with sCD14 and IL-6 (all p<0.01).
Conclusions: The composition of the lipidome is altered in HIV-infection and changes with ART. Alterations in SaFAs were generally associated with inflammatory markers and may contribute to immune activation and comorbid disease pathogenesis.

TUPEA0121

IP-10 and IL-18 are good markers of persistent inflammation in HIV-1 elite controllers

H.H.S. de Paula[1], D. Gama Caetano[1], G. Bello[1], B. Hoagland[2], B. Grinsztejn[2], V.G. Veloso[2], M.L. Guimarães[1], M.G. Morgado[1], F.H. Côrtes[1]
[1]Instituto Oswaldo Cruz/FIOCRUZ, Rio de Janeiro, Brazil, [2]Instituto Nacional de Infectologia Evandro Chagas/FIOCRUZ, Rio de Janeiro, Brazil
Presenting author email: diogogc@globo.com

Background: Elite controllers are rare individuals able to natural control of HIV replication below the detection limit of commercial assays. Some studies have pointed a higher immune activation and/or inflammation in elite controllers when compared to HIV negative individuals, whereas others have found no significant differences between both groups. Answer this question is essential to help in the decision to start or not cART or other non-specific HIV therapy in elite controllers.
Methods: We used ELISA assays to evaluate the plasmatic levels of IP-10, IL-18, sCD163, sCD14, CRP and IL-6. The frequency of CD8+CD38+HLA-DR+ T cells was evaluated by flow cytometry. The analyses were performed in 16 elite controllers (eight with persistent undetectable viremia [EC] and eight with occasional viral blips [EEC]), 12 viremic controllers (VC - plasma viral load between 80-2000 RNA copies/ml), 15 cART-treated patients (cART- with >5 years of viral load suppression) and 15 HIV-negative individuals (HIVneg) from Rio de Janeiro/Brazil. All EC, EEC and VC have at least four years of follow-up. The Mann-Whitney test and Spearman correlation were used for statistical analyses.
Results: Among the plasmatic markers evaluated, the levels of IP-10 and IL-18 in VC and EEC were higher than in HIVneg (P <0.005) and in EC (P <0.005), but not significantly different between EC and HIVneg. The cART group showed higher IP-10 and sCD163 levels than HIVneg and EC (P < 0.05). We found a positive correlation between CD8+ T cell activation and the IP-10 (P = 0.0009; R = 0.4252) and IL-18 (P = 0.0019; R = 0.3987) levels. The sCD14, CRP and IL-6 levels were similar among all groups.
Conclusions: Our results showed that IP-10, IL-18 and sCD163 are important markers for evaluating persistent inflammation in the setting of undetectable viremia in both HIV controllers and cART-treated patients. The high IP-10 levels observed in cART-treated individuals indicate that therapies, other than cART, should be considered to reduce chronic inflammation in elite controllers.

TUPEA0122

Combination antiretroviral therapy has minimal effect on the HIV-associated expansion of adaptive, memory-like NK cells and NK cell activation

A. Hearps[1,2], P. Agius[3], J. Zhou[1], S. Brunt[4], M. Chachage[1], T. Angelovich[1], M. Giles[2,5], P. Price[6], J. Elliott[2,5], A. Jaworowski[1,2]
[1]Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, [2]Monash University, Department of Infectious Diseases, Melbourne, Australia, [3]Burnet Institute, Centre for Population Health, Melbourne, Australia, [4]University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, [5]Alfred Hospital, Infectious Diseases Unit, Melbourne, Australia, [6]Curtin University, School of Biomedical Science, Perth, Australia

Background: Innate immune dysfunction persists in HIV+ individuals despite effective combination antiretroviral therapy (cART) and is thought to contribute to the increased risk of chronic non-AIDS disease. We recently demonstrated that an

adaptive CD56dim NK cell population lacking the signal transducing protein FcRγ is expanded in HIV+ individuals. Here we used a longitudinal study to investigate the effect of suppressive cART on adaptive NK cells and on HIV-related NK and T cell activation.
Methods: We analyzed a cohort of HIV+ men who have sex with men (MSM, n=20) at baseline and following 6, 12 and 24 months of cART, and compared them with uninfected MSM (n=15) to investigate the impact of cART on NK cell dysfunction using immunophenotyping and mixed effects modelling.
Results: Proportions of HLA-DR+/CD38+ and CD69+ activated NK cells were elevated in cART-naïve HIV+ MSM (p=0.015 and 0.004, respectively), as were adaptive FcRγ- NK cells (p=0.003). Using latent growth curve modelling, we show that cART did not reduce levels of adaptive FcRγ- NK cells (p=0.115) or activated HLA-DR+/CD38+ NK cells (p=0.129) but did reduce T cell and monocyte activation (p< 0.001 for all). Proportions of adaptive FcRγ- NK cells were not associated with NK cell, T cell or monocyte activation, suggesting different factors drive adaptive NK cell expansion and immune activation in HIV+ individuals.
Whilst proportions of activated CD69+ NK cells declined significantly on cART (p=0.003), the rate of decline was significantly slower than that of T cell and monocyte activation, with 12 months of suppressive cART reducing 40% and 70% of CD4+ and CD8+ T cell activation respectively, but only 20% of CD69+ NK cell activation.
Conclusions: Levels of activated NK cells and adaptive, memory-like FcRγ- NK cells remain elevated in virologically suppressed HIV+ individuals for a minimum of 24 months after cART initiation with no evidence of decay over time. The persistence of NK cell activation and adaptive NK cell expansion after normalisation of other immune parameters indicates a reduced potency of cART against NK cell activation, and may have implications for the development of malignancies and chronic inflammatory disease in cART-treated HIV+ individuals.

TUPEA0123

Platelets of HIV-infected patients release a large amount of Growth-regulated Oncogence Alpha (GRO-a): a chemokine stimulating HIV replication

A. Gagneux-Brunon[1], F. Lucht[1], T. Bourlet[1], C.-A. Arthaud[2], F. Cognasse[2], H. Hamzeh-Cognasse[2]
[1]University Hospital of Saint-Etienne, Saint-Etienne, France, [2]Université de Saint-Etienne, Groupe Immunité des Muqueuses et Agents Pathogènes, Saint-Etienne, France
Presenting author email: thomas.bourlet@chu-st-etienne.fr

Background: Platelets are not only cells involved in hemostasis, they are able to produce pro and anti-inflammatory cytokines, and may contribute to immune activation in HIV-infected patients. Our aim was to assess whether the ability of platelets to produce inflammatory cytokines was altered in HIV-infected patients compared to healthy blood donors.
Methods: We enrolled 94 HIV-infected patients, and 108 healthy blood donors. Plasma was collected and platelet-rich plasma samples were prepared by centrifugating peripheral blood at 150 × g for 10 min. Platelets were stimulated, or not, with thrombin receptor-activating peptide (TRAP-6, 50 µg/ml for 30 min). Soluble (s) CD40L, GRO-α, RANTES, and sCD62P were quantitated in platelet supernatants by Luminex® technology and concentrations of factors released by platelets were normalized for 3×10^8 platelets to enable comparisons. For each individual, the reactivity of platelets to thrombin stimulation was evaluated by calculating the ratio of cytokine concentration released after stimulation to the respective concentration observed without stimulation.
Results: Mean age was comparable between blood donors (49±12.7 years old) and HIV-infected patients (48.2 ±11 years old, p=0.599). Seventy-four patients (85.1%) were receiving antiretrovirals, 69 of them had an HIV-viral load under 40 copies/mL. No difference was observed for plasma concentrations of sCD62P, sCD40, GRO-a, and RANTES between HIV-infected patients and blood donors. In the same way, we did not evidence any statistical difference between platelets from HIV-infected patients compared to blood donors with regard to their ability to release sCD62P or sCD40L upon stimulation. However, TRAP-6 stimulation of platelets from HIV infected patients induced a 28.5-fold (±107) increase of GRO-a while only a modest 5.6-fold increase in blood donors (p=0.028). In addition, we also observed a higher, although not significant, increase of released RANTES level after platelet stimulation in HIV-infected patients compared to healthy blood donors, 407-fold (±1037) vs 185.5 fold (± 668) increase, respectively (p=0.068).
Conclusions: Platelets of HIV-infected patients display an increased ability to release inflammatory cytokines, particularly GRO-a, which may support residual viral replication in cells, and contribute to the maintenance of immune activation and systemic inflammation.

TUPEA0124

Altered macrophage phenotype in HIV-infection may contribute to vascular inflammation

E.R. Bowman[1], M. Kulkarni[1], B. Snyder[1], J. Gabriel[1], P. Yan[2], R. Bundschuh[2], M. Broe[2], L. Walker[2], S. Koletar[3], L. Schlesinger[4], N.T. Funderburg[1]

Presenting author email: emily.bowman@osumc.edu

Background: HIV-infected individuals are at increased risk of vascular thrombosis, likely driven by interactions between activated leukocytes and the endothelium. Proportions of inflammatory (CD14+CD16+) and patrolling ($CD14^{Dim}CD16+$) monocytes are expanded in HIV-infection, and these cells express altered levels of vascular homing molecules. Monocytes differentiate into macrophages in the vessel wall and produce factors that contribute to subendothelial inflammation and atherosclerotic plaque formation. The mechanisms by which macrophages contribute to increased cardiovascular disease (CVD) risk in ART-treated HIV+ individuals are incompletely understood.
Methods: PBMCs were isolated from HIV- (n=16) and ART-treated HIV+ participants (n=22) and cultured in Teflon wells for 5 days in medium containing 20% autologous serum to generate monocyte derived macrophages (MDMs). Immune activation was assessed by flow cytometry and by ELISA. MDM transcriptomes were analyzed using ribo-depleted RNA-Seq. Reactive oxygen species (ROS) production was assessed by flow cytometry following CellRox Deep Red incubation. MMP activity was evaluated using AnaSpec matrix metalloproteinase (MMP) assay kits. Mean values were compared by parametric t test.
Results: Mean age of study participants was 33 years for HIV- (88% male) and 48 years for HIV+ subjects (90% male). All HIV+ participants had suppressed viremia (< 40 copies/mL), and a mean CD4+ T cell count of 573 cells/mL. Serum levels of myeloid and endothelial cell activation (sCD14, sCD163, ICAM-1, VCAM-1, TNFR-I/II, IL-6, and Lp-PLA2) were increased in samples from HIV+ participants (p<0.05). We identified 54 differentially expressed genes in MDMs from HIV+ subjects (p<0.05), including MMP-14 and CD300E, which are related to plaque instability and innate immune activation. Surface protein expression of CD300E was also increased, and the costimulatory molecules CD80 and CD40, and the scavenger receptor SR-A, were decreased on MDMs from HIV+ donors (all p<0.005). Increased MMP activity was detected in supernatants collected from HIV+ MDMs, and these cells produced more TNFα, IL-6, and ROS spontaneously (p=0.01), and in response to LPS (p=0.007), compared to cells from HIV- donors.
Conclusions: MDMs obtained from ART-treated HIV+ participants produce increased levels of several mediators that contribute to vascular inflammation, including MMPs and ROS, potentially leading to increased CVD risk.

TUPEA0125

High cannabis levels associated with decreased T cell activation in HIV-infected individuals

J.A. Manuzak[1,2], T.M. Gott[1,2], J.S. Kirkwood[1], E. Coronado[1,2], T. Hensley-McBain[1,2], C. Miller[1,2], A.C. Collier[3], M.C. Wu[4], J.N. Martin[5], N. Isoherranen[1], P.W. Hunt[5], N.R. Klatt[1,2]

Presenting author email: manuzakj@uw.edu

Background: Despite advancement of antiretroviral therapies (ART) that provide stable and sustained viral suppression, ART-treated HIV-infected individuals have elevated risk of morbidities and mortality compared to uninfected individuals. Even with long-term consistent ART, HIV-infected individuals experience more inflammation, T-cell activation, and altered CD4+ T-cell frequencies. Cannabis is a widely used drug in the United States. However, how cannabis may affect HIV pathogenesis is unknown.
Methods: Plasma and PBMCs from 185 HIV-1-infected, ART-suppressed individuals recruited through the SCOPE cohort (San Francisco, CA) who self-reported either no or daily cannabis, and all reported no use of other drugs of abuse, were sampled. Positive cannabis levels were confirmed in plasma by mass spectrometry. The interquartile range of the cannabis metabolite, 11-nor-carboxy-THC, was used to stratify the cannabis-using group into low (below 38.5nM), medium (38.55-251.8nM) and high (above 251.8nM) cannabis levels. Inflammatory biomarkers were quantified in plasma by Luminex. Flow cytometry was used to determine

expression of PD-1 (exhaustion) and HLA-DR+CD38+ (activation) on CD4+ and CD8+ T-cells. Differences between groups were assessed using a Mann-Whitney test.
Results: No differences in clinical characteristics (Table1) or inflammatory biomarkers were found between the non-cannabis users and any cannabis-using groups. Significantly lower frequencies of PD-1 and HLA-DR+CD38+ expressing CD4+ (p=0.01; p=0.03) and CD8+ (p=0.03; 0.045) T-cells were detected in the high cannabis level group compared to non-cannabis users (Table1). Differences remained significant after adjusting for age, gender, CD4 count, tobacco and alcohol use (p<0.05 for all).
Conclusions: High-level cannabis use is associated with lower levels of T-cell activation and exhaustion in ART-suppressed HIV-infected individuals, highlighting a potential immunologic benefit of cannabinoids that could be assessed in future studies. Further research is also underway to determine the mechanisms of this reduced activation, impact on reservoir, and whether non-psychoactive cannabinoids may exert similar effects.

Presenting author email: shalena@sun.ac.za

Background: There is limited knowledge of the immunological mechanisms contributing to HIV subtype C persistence in infected children. Observations in adult cohorts have implicated proinflammatory cytokines in viral reservoir establishment and long-term persistence through low-level viral replication despite long-term therapy. This study therefore aimed to longitudinally compare inflammatory cytokine levels in virologically suppressed children soon after therapy initiation and at 7-8 years.
Methods: Baseline (within 6 months of age) and follow-up (7-8 years) plasma samples originating from the Children with HIV Early Antiretroviral Therapy (CHER) trial were evaluated. The trial included three study arms (Arm 1: delayed therapy; Arms 2 and 3: early therapy until interruption at 40 and 96 weeks). Children evaluated began ART at < 1 year of age and sustained viral suppression at follow-up. Twenty-six cytokines were measured using validated Luminex® Multiplex assays. Statistical analysis employed a Wilcoxon matched paired test for nonparametric data. A subset of participants was also tested for total HIV-1 DNA using qPCR targeting a conserved region in HIV integrase.
Results: Thirty-eight samples were evaluated. The median baseline viral load at ART initiation was 738,500.5 copies/ml (range: 399-750001 copies/ml). Six participants had detectable viral loads from <40 to 19,549 copies/ml at follow-up. The median CD4 counts at baseline and follow-up were 1,853.5 (range: 823-3450) and 933.5 (range: 20-2063) respectively.
In Arm 1, significantly higher levels of INF-γ (P = 0.0117), IL-17A, TNF-α, RANTES (all P = 0.0039) and G-CSF (P = 0.0078) were observed at baseline. A significant increase in cytokine expression was observed for IL-13, IL-4 (P = 0.0156), VEGF, MCP-1, and PDGF-BB (all P = 0.0039) at follow-up. Cytokine expression in Arm 2 showed highly significant elevations at follow-up for IL-13 (P = 0.0005), VEGF (P<0.0001), FGF-basic (P<0.0001), MCP-1 (P<0.001), and PDGF-BB (P<0.0001). Similar trends of significant markers were noted for Arm 3.
In 23 children assessed for HIV-1 DNA at follow-up, a median of 32.5 copies/million cells (range: 0-247.6) was observed.
Conclusions: Children initiated on ART early showed an increase in chronic inflammatory disease-cytokine expression following 7-8 years on suppressive therapy. Despite the low level of cell-associated DNA detected, the persistence of HIV appears associated with upregulation of chronic inflammatory cytokines.

TUPEA0127

CD49d expression in T-lymphocytes subsets and cardiovascular risk in HIV-positive subjects

M.A. Zingaropoli[1], M. Iannetta[1,2], A. D'Abramo[1], O. Alessandra[1], S. Savinelli[1], M. Lichtner[1], G. d'Ettorre[1], C.M. Mastroianni[1], M.R. Ciardi[1], V. Vullo[1]

Presenting author email: m.antonellazingaropoli@gmail.com

Background: The integrin-α4 (CD49d) is a transmembrane co-stimulatory molecule, involved in lymphocyte homing from peripheral blood to the gut (α4β7) and to the central nervous system (α4β1). In this study CD49d expression on T-lymphocyte subsets and its relationship with cardiovascular damage was evaluated in the context of HIV infection.
Methods: Thirty HIV+ subjects (6 females/24 males) with a mean age ± standard deviation (SD) of 52±10.1 years, on effective antiretroviral treatment (ART) and 15 age- and sex-matched healthy donors (HD), were enrolled. T-lymphocyte immunophenotype and CD49d median fluorescence intensity (MFI), were detected by flow cytometry. Carotid-Intima Media Thickness (c-IMT) was assessed by ultrasound. Pathological c-IMT was defined as a measured value greater than 0.9 mm.
Results: HIV+ subjects showed lower CD4+ T-lymphocyte absolute counts (p=0.04) and increased levels of CD4 and CD8 immune activation (p<0.001 and p<0.001, respectively) and immune senescence (p=0.02 and p<0.001, respectively) compared to HD. CD4 and CD8 naïve [N] cells were decreased (p=0.02 and p=0.01) while CD8 effector memory [EM] cells were increased (p=0.007) in HIV+ subjects compared to HD. CD49d expression was increased on CD4 (N: p=0.01, central memory [CM]: p<0.001, EM: p<0.001, effector [E]: p=0.05) and CD8 (N: p=0.0006, CM: p<0.001, EM: p<0.001, E: p=0.003 and intermediate [I]: p<0.001) of HIV+ subjects compared to HD. In HIV+ subjects, a positive correlation between CD49d MFI on CD4 and CD4 immune activation was found (p=0.0012). c-IMT values were increased in the HIV+ group than in HD (mean±SD: 0.85±0.17 vs 0.28±0.24 mm, p<0.001). Among HIV-infected patients, 15 (50%) had a normal c-IMT and 15 (50%) a pathological c-IMT. c-IMT was positively correlated with CD49d MFI on CD4 and CD4 immune activation (p=0.04, p=0.085, respectively). Moreover, HIV+ subjects with pathological c-IMT showed higher levels of CD49d MFI in the CD4 CM subset than HIV+ subjects with normal c-IMT (p=0.02).
Conclusions: During chronic HIV infection, CD49d increased expression on T-lymphocytes could be considered an alternative marker of immune activation related to cardiovascular comorbidities. The integrin-α4 could represent a therapeutic target to reduce cardiovascular comorbidities in chronic HIV patients.

Host determinants associated to immunological non-response in patients on cART

M. García[1,2], L.M. Medrano[3], C. Restrepo[1,2], J. Blanco[4], Y.M. Pacheco[5], M. Górgolas[6], A. Cabello[6], M. Gutiérrez-Rivas[3], S. Resino[3], J.M. Benito[1,2], N. Rallón[1,2]
[1]Instituto de Investigación Sanitaria-FJD, UAM, Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [3]Instituto de Salud Carlos III, Madrid, Spain, [4]AIDS Research Institute IrsiCaixa, Badalona, Spain, [5]Instituto de Biomedicina de Sevilla (IBiS), Sevilla, Spain, [6]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain
Presenting author email: normaibon@yahoo.com

Background: Host determinants of CD4 T-cell restoration in HIV patients with cART and suppression of viral replication are not well understood. A subset of HIV patients, termed immunological nonresponders (INR), achieve only modest increases of CD4 counts that is more frequent in patients starting cART with low CD4 counts. Herein, we have analyzed the association of several host genetic variants with the phenomenon of immunological discordance.
Methods: A case-control study was conducted in 412 HIV infected patients on cART. Inclusion criteria were: naïve patients starting cART with CD4 counts< 200 cels/μL and maintaining complete viral suppression for two years. INR patients (cases) were defined as those patients with CD4 counts ≤250 cells/μL after two years on cART, and immunological responder patients (controls) as those with CD4 counts >250 cells/ μL. An array of 51 single nucleotide polymorphisms (SNPs) previously involved in HIV pathogenesis were selected and genotyped using Sequenom's MassARRAY platform. Association studies were performed using SNPStats software.

Results: Ninety-three patients were classified as cases and 319 as controls. CD4 counts at two years after cART were (median[IQR]) 180 [132-210] and 422[337-554] cels/μL in cases and controls respectively (p<0.0001). After adjusting by gender, age, years of infection from diagnosis, baseline CD4 counts and cART regimen (PI-containing vs. NNRTI-containing), three SNPs were significantly associated with INR: rs1493013 in IL15 gene (p=0.021), rs1799864 in CCR2 gene (p=0.042) and rs2280789 in CCL5 gene (p=0.028). Mechanisms underlying this association could include: modulation of IL15 production, a cytokine with a pivotal role in T-cell proliferation and survival; variation of the CCR2 transmembrane region, an alternative HIV coreceptor; and CCL5 downregulation, a chemokine that blocks HIV infection. Otherwise, 2 SNPs were significantly associated to IR: rs2430561 in IFNg gene (p=0.016), and rs724710 in BIM gene (p=0.012). Variation in rs2430561 has been shown to increase IFNg production, a cytokine with a pivotal role in cell-mediated antiviral immunity; and variation at rs724710 diminish BIM-mediated signaling of the intrinsic apoptosis pathway.
Conclusions: Our results suggest that mechanisms underlying the phenomenon of immunological discordance are multifactorial, and involve disturbance of T cell homeostasis and of host viral defense.

TUPEA0129

Chronic immune activation as a cause of poor T-helper cell migration in successfully ART-treated HIV-1-infected individuals

Presenting author email: valentina.cecchinato@irb.usi.ch

Background: CD4+ T-cell depletion, and in particular Th17 cell loss in the mucosal compartment, is a hallmark of HIV-1 infection in humans. Alterations in the integrity of the mucosal barrier have been indicated as cause for chronic immune activation and disease progression, which occur despite successful anti-retroviral therapy (ART). In this study we have investigated the effect of chronic immune activation, or selective Toll-like receptors (TLRs) triggering on the homing capacity of lymphocytes, with the aim of understanding the mechanisms at the basis of a poor repopulation of T-helper cells in the gut during successful treatment with ART.
Methods: Blood samples were collected from a total of 58 HIV-1-infected individuals, either ART-naïve (n=15) or on long-term ART (n=43), and from healthy donors (HD). T-helper cell dynamics, their migration capacity, and levels of soluble CD14 (sCD14) were assessed. A mouse model, mimicking the alterations observed in HIV-1 infection was also used to assess the impact of chronic immune activation on T-helper cell migration. In vitro triggering of selective TLRs, was performed on HD samples to dissect the involvement of the different TLRs in modulating cell migration capacity.
Results: CCR6+ and CXCR3+ T-helper cells accumulate in the blood of ART-treated HIV-1-infected individuals, and their frequency positively correlates with the levels of sCD14. In HIV-1-infected individuals, migration of T-helper cells in response to chemotactic stimuli is impaired, regardless therapy. Chronic immune activation induced by TLR signaling is sufficient to dampen T-helper cell migration, which can be restored by pharmacological modulation of cytoskeleton activity.
Conclusions: In patients under long-term ART, chronic immune activation contributes, by altering T-helper cell migration, to the poor gut repopulation observed. This study calls for novel pharmacological approaches targeting the cytoskeleton machinery to achieve a better reconstitution of the mucosal compartments.

TUPEA0130

Reduced naïve CD8+ T-cell priming efficacy in HIV-infected patients

L. Papagno[1], F. Nicoli[1], O. Briceno[1], A. Lissina[1], E. Gostick[2], O. Lambotte[3], C. Katlama[4], D.A. Price[2], R. Mallone[5], U. Karrer[6], D. Sauce[1], V. Appay[1,7]

Presenting author email: laura.papagno@upmc.fr

Background: Priming of de novo immune responses from the naïve CD8+ T-cell repertoire in order to recruit cells with new antigenic specificities or to replenish waning lymphocyte populations is a prerequisite for the long-term control of persistent viruses, and responsiveness to vaccination. However, our knowledge of individual capacity to prime new T-cell responses is limited, in particular due to the lack of practical approaches to examine such capacity in humans. In this study we set out to examine the potential of HIV-infected patients to mount de novo antigen specific CD8+ T-cell responses. In addition, as HIV-positive individuals experience premature immunosenescence, their priming capacity was compared to that of elderly subjects.
Methods: To this end, we have developed and used a simple and original in vitro assay to assess CD8+ T-cell priming efficacy from antigen specific precursors. This approach is based on the in vitro stimulation of naïve CD8+ T-cells that are specific for a model antigen, chosen for the high frequency of specific precursors in individuals.
Results: Using this approach, we found that HIV-infected patients consistently mounted quantitatively and qualitatively impaired de novo CD8+ T-cell responses. Interestingly, priming capacity of HIV-positive subjects was comparable to that of elderly individuals. This immune deficit was directly associated with the number of antigen-specific precursors and the size of the naïve CD8+ T-cell pool. Based on our recent finding that the combination of TLR8 ligand with FLT3 ligand improves effector capacity of in vitro primed naïve T cells, we tested whether this combination of adjuvants could restore priming capacity in HIV-infected patients. However, the addition of TLR8L/FLT3L did not improve, either quantitatively or qualitatively, de novo CD8+ T-cell responses in HIV-positive individuals.
Conclusions: These findings provide experimental evidence of reduced capacity to mount de novo CD8+ T-cell responses in HIV infected patients, and further expose the functional insufficiencies that accompany HIV disease progression and immune aging.

TUPEA0131

Pre-senescent state of hematopoietic progenitors from HIV-1-infected treated patients with immunological failure

T. Fali[1], L. Papagno[1], C. Bayard[1], S. Fastenackels[1], J. Boddaret[2], C. Katlama[3], V. Appay[1,4], D. Sauce[1], Laboratory of Pathogenesis of Viral Infections and Immune Aging

Presenting author email: laura.papagno@upmc.fr

Background: Chronic immune activation (IA) is predictive of disease progression in HIV-1 infection. However, the consequences of IA and its links to the failure to reconstitute and maintain the CD4+ T cell pool with antiretroviral therapy (ART) in HIV-1 infection remain a matter of debate. The capacity to regenerate the immune system, including CD4+ T cells, depends on the ability of CD34+ hematopoietic progenitor cells (HPCs) to initiate adequate lymphopoiesis. We hypothesized that high systemic IA and recurrent inflammation drive an exhaustion of the primary immune resources, which is an important determinant of immunological failure with ART. The objective of the study is therefore to characterize further the HPC compartment resources in HIV-1 infected patients.
Methods: We studied circulating HPCs from HIV-1 infected patients (aged 25-55 years) with successful immune reconstitution or not under ART, compared to healthy adults stratified by age (18-95 years). We performed ex vivo phenotypic analyses as well as telomere length and telomerase activity measurements by q-PCR on circulating CD34+ cells, in vitro T-lymphocyte differentiation assays using OP9hDL1 culture system line, and measured plasmatic inflammation markers.
Results: HIV-1 infected patients exhibited quantitatively and qualitatively altered lymphopoietic capacity. Our in vitro approach revealed biases in the capacity of

HPCs from HIV-1 infected patients to produce and differentiate into lymphocytes, compared to HPCs from aged matched healthy individuals. The presence of proinflammatory factors like IL-6, IP-10 or LPS in the culture of control HPCs, restricted the differentiation pattern towards T lymphocytes in a similar way. Interestingly, HPCs from patients failing to reconstitute their CD4+ T cell pool under ART presented an obvious loss of common lymphoid progenitors, together with marked telomere attrition and lack of telomerase activity, reminiscent of HPCs uninfected elderly people.
Conclusions: Our study provides direct evidence for the defective capacity of CD34+ HPCs from HIV-1 infected patients to differentiate along the T lineage due to intrinsic (senescence) and extrinsic (inflammation) factors. This work brings new lights into the potential cause of immune failure with ART, due to exhausted lymphopoiesis with HIV infection.

TUPEA0132

Microbial dysbiosis does not alter immune activation or disease progression in SIV-infected Asian macaques

A. Ortiz, S. DiNapoli, J. Flynn, M. Long, S. Lai, O. Sortino, M. Quinones, J. Estes, J. Brenchley
NIH, Bethesda, United States
Presenting author email: alexandra.ortiz@nih.gov

Background: Progressive HIV infection is associated with systemic immune activation that is not fully ameliorated with effective antiretroviral therapy. Measures of immune activation - including elevated concentrations of circulating pro-inflammatory cytokines, low frequencies of intestinal T_H17 cells, and exacerbated T-cell activation - have been shown to correlate with the enrichment of disease-associated intestinal microflora, namely an expansion of bacteria within the phylum Proteobacteria at the expense of the Firmicutes and Bacteroidetes. Although several studies have indicated that the therapeutic administration of probiotic, or commensal species may significantly improve disease progression in non-human primate models of HIV infection, an empirical assessment of the contribution of microbial dysbiosis to disease progression has not yet been executed.
Methods: To assess the contribution of microbial dysbiosis to untreated lentiviral disease progression, we administered vancomycin (10 mg/kg p.o.; 5 doses/month) to 7 rhesus macaques prior to and throughout SIV infection. Prior to infection, vancomycin treatment resulted in a significant increase in the frequency of fecal Proteobacteria and Fusobacteria and a concordant decrease in Bacteroidetes and Firmicutes, as compared to 6 control animals. We infected all animals with SIVmac239 and routinely measured lymphocyte frequency and function by polychromatic flow cytometry, viral loads by SIV-Gag qRT-PCR, and fecal microbial frequencies by 16S sequencing by Illumina.
Results: Fecal microbial instability was evident throughout SIV infection, with increased frequencies of Deltaproteobacteria and Gammaproteobacteria, and decreased frequencies of Bacteroidales and Clostridia. Surprisingly, despite evidence for progressive and high levels of dysbiosis, no significant differences in viremia, immune activation, or systemic microbial translocation were noted between the experimental groups throughout SIV infection. Furthermore, clinical indices of disease progression including survival curves did not reveal any evidence for enhanced disease progression in the dysbiotic animals.
Conclusions: Our results demonstrate that microbial dysbiosis does not significantly influence host/viral dynamics during untreated SIV infection and may suggest that observed dysbioses in untreated HIV infection may be ancillary to disease progression.

TUPEA0133

Nadir CD4+ T-cell count strongly predicts gut disbyosis in HIV infection

Y. Guillén[1], M. Noguera-Julian[1], J. Rivera[2], M. Casadellà[1], M. Rocafort[1], M. Parera[1], C. Rodríguez[1], J. Carrillo[1], B. Mothe[1], J. Coll[3], J. Navarro[4], M. Crespo[4], C. Brander[1], E. Negredo[3], J. Blanco[1], M.L. Calle[2], B. Clotet[1], R. Paredes[1], The Meta-HIV Study Group
[1]Irsicaixa, Badalona, Spain, [2]Universitat de Vic, Vic, Spain, [3]HIV Unit & Lluita Contra la SIDA Foundation, Badalona, Spain, [4]Hospital Universitari Vall d'Hebrón, Infectious Diseases Unit, Barcelona, Spain
Presenting author email: yguillen@irsicaixa.es

Background: HIV-1 infection exerts rapid, severe and continuous damage to the intestinal lining and gut-associated lymphoid tissues, followed by chronic inflammation and severe immune deregulation, which are only partially restored with antiretroviral treatment. However, the nature, extent, constrains and mechanisms by which HIV infection may alter the composition and function of the gut microbiome remain controversial. Whole metagenome shotgun sequencing (WMGS) analyses could advance our understanding on HIV disbyosis by providing higher taxonomic and functional resolution over 16S rDNA sequencing.
Methods: Fecal WMGS (Illumina HiSeq, 10 million sequences/sample) was used to characterize the taxonomic (Metaphlan.v2), genetic (Integrated Gene Catalogue) and functional (KEGG) composition of the intestinal microbiome of HIV-1-negative (N=27) and HIV-1-infected (N=129) individuals with different immune profiles. The relative abundance of microbial species and functions were correlated with gene richness, soluble inflammation and bacterial translocation markers and CD4+ counts, using Wilcoxon and Kruskal-Wallis tests with Benjamini-Hochberg correction and Spearman rank tests, as needed. Multivariate linear regression was used to identify independent predictors of low microbial gene richness.
Results: Microbial gene richness showed a bimodal distribution, enabling the classification of subjects into Low (LGC) and High Gene Count (HGC) categories. Most (89.3%) HIV-1-infected subjects but only 40.7% HIV-negatives clustered in the LGC group ($p<0.001$). Lower nadir CD4+ count was a strong independent predictor of LGCs [OR for <100 c/mm3 vs HIV negative: 14.0 (95%CI: 2.0, 288.7), $p=0.023$]. HGCs were significantly enriched in Reactive Oxygen Species (ROS)-sensitive methanogenic archaea and butyrate-producing and cellulose-consuming bacteria, and showed increased methane and butanoate metabolism, as well as pathways linked to DNA replication. Conversely, subjects in the LGC group were enriched in gram-negative ROS-resistant bacteria, including Proteobacteria, and had increased LPS biosynthesis, complex carbohydrate metabolism and microbial antioxidant enzymes able to counterbalance ROS accumulation. Microbial species associated with higher gene richness were negatively correlated with soluble markers of systemic inflammation and bacterial translocation.
Conclusions: HIV-induced immune deficiency is linked to significant shifts in the composition and function of the gut microbiome, which suggest adaptation to oxidative stress. Loss of methane and butyrate-producing anti-inflammatory microbes and increase in LPS biosynthesis and Proteobacteria might contribute to self-perpetuate HIV disbyosis.

TUPEA0134

Gut dysbiosis during acute HIV infection

B. Liao[1,2], J.V. Garcia[1], A. Wahl[1]
[1]University of North Carolina at Chapel Hill, Infectious Diseases, Chapel Hill, United States, [2]Guangzhou No. 8 People's Hospital, Guangzhou Medical University, Guangzhou, China
Presenting author email: awahl@med.unc.edu

Background: Gut dysbiosis contributes to HIV disease progression. However, little is known about the critical changes that occur to the gut microbiome during the course of HIV infection and how they may affect the establishment and maintenance of the HIV reservoir. A clear understanding of how the gut microbiome is altered during the course of acute HIV infection and its role in disease is essential to inform the development of novel interventions that could interfere with the establishment of the HIV reservoir and curtail disease progression. Direct experimentation in humans to establish gut microbiota's role in HIV disease and persistence is not possible. Therefore, we used a new in vivo model consisting of bone marrow/liver/thymus (BLT) humanized mice that have been colonized with human gut microbiota (HuM-BLT mice).
