Methods: HuM-BLT mice were generated from germ-free NOD/SCID/IL2Rγc-/- (NSG) mice maintained in germ-free isolators. Germ-free NSG mice were colonized with human gut microbiota by oral fecal transplantation of a well-characterized human fecal sample. HuM-BLT mice were exposed vaginally to HIV. Fecal pellets collected longitudinally from HuM-BLT mice before and after HIV exposure (6 weeks) were analyzed with 16S amplicon sequencing. Infection was monitored longitudinally by measuring peripheral blood levels of HIV-RNA, CD4+ T cells, and CD8+ T cell activation.
Results: Consistent with HIV infection in humans, we observed significantly decreased CD4+ T cell levels ($p=0.0101$) and increased CD8+ T cell activation ($p=0.0241$) in the peripheral blood of HIV-infected HuM-BLT mice. Consistent with the composition of the human inoculum, the gut microbiome of HuM-BLT mice was dominated by Bacteroidetes, Firmicutes, and Verrucomicrobia. Our analysis demonstrated significant alterations in the frequency of genera Coprococcus and Dorea ($p=0.0163$ and $p=0.0167$ respectively) in the gut microbiome of HuM-BLT mice during acute HIV infection.
Conclusions: Our results show that alterations in gut microbiome composition begin during acute HIV-infection and suggest that gut dysbiosis likely develops overtime. This is in agreement with data collected from a limited number of recently infected patients. Administration of novel interventions that promote maintenance of healthy gut microbiota during acute HIV infection are needed to inhibit the development of gut dysbiosis during chronic infection and disease progression.

TUPEA0135

High levels of polymicrobial vaginal communities and genital inflammation in HIV-infected women

S. Pinto-Cardoso[1], M. Chavéz[1], M. Gómez[1], O. Briceño[1], D. Garrido-Rodriguez[1], K. Romero[1], N. Klatt[2], G. Reyes-Terán[1]
[1]National Institute of Respiratory Diseases, Centre for Research in Infectious Diseases (CIENI), Mexico, Mexico, [2]University of Washington, Department of Pharmaceutics, Seattle, United States
Presenting author email: sandra.pinto@cieni.org.mx

Background: Studies on the vaginal microbiome (VM) in HIV infection have been primarily focused on HIV transmission and acquisition. Data on the VM after HIV infection is limited. Understanding how HIV infection and antiretroviral therapy (ART) shapes the VM and the local host inflammation may inform on women's reproductive health and contribute towards developing therapies aimed at manipulating the VM of HIV-infected women.
Methods: We conducted a cross-sectional study by enrolling HIV+ (n=28) and HIV- (n=26) women. Metagenomic shotgun sequencing was performed on total DNA extracted from vaginal swabs and analysed using MetaPhlAn2 package. Bacterial communities were clustered into Lactobacillus- and polymicrobial-dominant VM. Microbial diversity was calculated by computing the Shannon index. Principal coordinate analysis (PCoA) was performed based on UNIFRAC distances using QIIME. Cytokines were measured in supernatants obtained from the cervical cytobrushes using a 30-plex Luminex assay. Comparisons between groups were performed using non-parametric Mann-Whitney test. Correlations were performed using Spearman rank correlation coefficient.
Results: Demographic and clinical characteristics are presented in Table 1.

	HIV-	HIV+	p
N	26	28	
Age	40 [25.50-44.50]	41 [34.50-49]	0.1764
Vaginal pH	5.5 [5-6.0]	5.5 [5-6.5]	0.8109
CD4 T cell count (cells/mm3)	NA	491 [329-728]	
Plasma Viral Load (HIV-1 copies/mL)			
Undetectable (n=23)	NA	<40	
Detectable (n=5)	NA	82 [52-8324]	
N ART-Naïve; N on ART	NA	5/28; 23/28	
Values are given as median and 25%-75% percentiles. NA: not applicable			

[Table 1]

We found a trend for a higher percentage of Lactobacillus-dominant VM in HIV- compared to HIV+ women (61.8% versus 39.2%; p=0.17). Mucosal microbial diversity (Shannon index) was similar between HIV- and HIV+ women (p=0.61). PCoA analysis revealed no clustering of bacterial communities according to HIV status (PERMANOVA p=0.56). Overall, low abundance of Lactobacillus spp. inversely correlated with higher pH (r=-0.3148, p=0.021). Several cytokines including IL-1β, TNF-α, IL-17 and IL-10 were significantly increased in women with polymicrobial VM compared with Lactobacillus-dominant VM (p= 0.043, p=0.0138, p=0.0368 and p=0.0308 respectively).
Conclusions: Profiling of the VM revealed that the majority of HIV+ women had polymicrobial VM and high levels of pro-inflammatory cytokines indicative of local host inflammation. Our work suggests that intervention studies targeting the VM would benefit women´s reproductive health in addition to ART.

TUPEA0136

High abundance of *Prevotella* in gut microbiota of perinatally HIV-infected children despite suppressive antiretroviral therapy is indirectly associated with CD4 T cells

U. Kaur[1], N. Rajnala[2], B. Parachalil Gopalan[2], R. D'souza[2], A. Shet[2], R. Tandon[1]
[1]Jawaharlal Nehru University (JNU), School of Biotechnology, Delhi, India, [2]St. John's Research Institute, Bengaluru, India
Presenting author email: s.urvinder@gmail.com

Background: Perinatal HIV infection is characterized by rapid HIV disease progression with high initial HIV replication rate compared to adults. Although antiretroviral therapy (ART) has greatly reduced HIV replication to undetectable levels, there is persistent HIV-associated inflammation. While gut microbiota changes have correlated with increased levels of inflammation in HIV-infected adults, little is known about microbiota composition and inflammation in perinatally HIV-infected children.
We hypothesized that compared to uninfected children, perinatally HIV-infected children will have distinct microbiota composition, that will be associated with persistent inflammation and disease progression despite ART.
Methods: We performed bacterial 16s ribosomal DNA sequencing on fecal samples collected from 26 HIV-infected children; treatment-naïve (n=14), ART-experienced, virologically suppressed (n=12); and age-matched HIV-negative controls (n=6) as described in Table 1. Multi-analyte bead-based assays were used to analyze soluble cytokines, TNF-α and IP-10.

Parameters	Treatment-naive	ART-experienced	HIV negative controls
Number of subjects	14	12	6
Age (years)	10 (8-12)	11 (7-12)	9 (7-15)
Male/Female ratio	11/3	8/4	3/3
CD4 count (cells per µl)	644 (330-1334)	1141.5 (523-2406)	1343 (863-1884)
Plasma viral load (HIV RNA copies per ml)	33,779 (1,461-4,31,237)	Not detectable	Not applicable

[Table 1: Subject characteristics]

Results: HIV-infected children had, compared to HIV negative controls, significantly higher levels of Prevotella (median 70.8% vs 7.33%; p=0.02), and decreased Bacteroides (median 0.27% vs 15.25%; p=0.01). The ART therapy had no effect on the relative abundance of Prevotella between treatment-naïve and ART-experienced HIV-infected children. Compared to controls, Prevotella levels remain elevated in HIV-infected children despite ART therapy (p=0.03, median 77.9% vs 7.33%). Prevotella levels negatively correlated with the absolute CD4 counts in treatment-naïve (p=0.03, r=-0.69) or ART-experienced HIV-infected children (p=0.03, r= -0.75). Untreated HIV-infected children had higher levels of soluble TNF-α (median 5.91 vs 0; p=0.0001) and IP-10 (median 1692 vs 394; p=0.001) compared to controls. The levels of soluble IP-10 and TNF-α decreased during ART-therapy (p<0.05). However, IP-10 remains elevated in ART-experienced group compared to controls (median 523 vs 394; p=0.03). The levels of IP-10 positively correlated with Prevotella in treatment-naïve HIV-infected children (p=0.03, r=0.66), however this correlation was lost during ART therapy.
Conclusions: Compared to controls, HIV-infected children present unique gut-microbiota with higher abundance of Prevotella and decreased Bacteroides, and elevated levels of IP-10 that persists despite ART.

TUPEA0137

The study of gorilla enteric virome dynamics: association with SIV infection

M. D'arc[1], C. Furtado[2], J.D. Siqueira[2], A. Ayouba[3], M. Peeters[3], M.A. Soares[1]
[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Instituto Nacional de Câncer, Rio de Janeiro, Brazil, [3]Institut de Recherche pour le Développement, Montpellier, France
Presenting author email: mireladarc@gmail.com

Background: The pathogenicity of Simian Immunodeficiency Virus (SIV) in great apes is unclear, but infection in chimpanzees has already been associated with progression to an AIDS-like disease. The expansion of the enteric virome associated with disease progression in an AIDS-like context has also been described in the rhesus macaques model. The aim of this study was to identify and compare enteric viromes of SIV-infected and uninfected gorillas, and to assess their relationship with SIVgor pathogenesis in their natural host.
Methods: We have used Next-Generation Sequencing (NGS) to analyze non-invasive samples (faeces) of 22 wild gorillas from Cameroon, 11 SIV-infected and 11 uninfected individuals. NGS was carried out in a HiSeq 2500 Illumina platform and analyses were conducted with an in-house pipeline using the programs FastQC, Sickle-Master, BlastX - Viral Database from GenBank/NCBI, MEGAN5 and RStudio.
Results: The viral families Bromoviridae, Myoviridae, Podoviridae, Rhabdoviridae and Tymoviridae were statistically (p< 0.01) more abundant in the uninfected group, whereas Alloherpesviridae, Herpesviridae, Reoviridae and Siphoviridae families were more abundant (p< 0.01) in the SIV-infected group. Also, two distinct clusters were recognizable when a 1,000 cp/mL cutoff of SIVgor viral load in faeces (ranged in 655 to 31,497 cp/mL) was used to assess within-group diversity. Finally, we are able to detect adenovirus-assigned reads (virus associated with intestinal disease in rhesus monkeys with advanced AIDS) only in the SIV-infected samples that belong to the smaller viral load group with known infection status for at least 3 years. In general, we clearly notice that few families can serve as proxies for SIV infection, such as Reoviridae and Alloherpesviridae associated with SIV-infected samples.
Conclusions: This is the first evidence for the association of some mammalian viral families (like Adenoviridae, Herpesviridae and Reoviridae) with the presence of the SIVgor in a putative dysbiosis context, linking this phenomenon to disease progression. Virome stability studies clearly provide better markers of pathogenic infection progression than bacteriomes. However, further studies are still needed to better understand the influence of SIV pathogenesis on infected gorilla populations in the wild, and to associate deeper taxa (virus genera and species) to SIV status in these animals.

TUPEA0138

Changes in the gut and blood microbiome after starting antiretroviral therapy in HIV-1-infected patients

K. Vigil[1], N. Ajami[2], D. Lewis[1], J. Couturier[1], J. Adachi[1,2,3], J. Petrosino[2]
[1]*The University of Texas - Houston- Mc Govern Medical School, Houston, United States,* [2]*Baylor College of Medicine, Houston, United States,* [3]*MD Anderson Cancer Center, Houston, United States*
Presenting author email: karen.j.vigil@uth.tmc.edu

Background: HIV infection is characterized by intestinal damage, gut microbiome dysbiosis, immune activation and systemic inflammation.
We aim to examine whether starting ART altered the GI and serum bacterial microbiota of HIV-1-infected-subjects and whether immune activation markers correlated with microbiome changes
Methods: 23 HIV-1 infected subjects were enrolled. Six patients were elite controllers (EC) or viremic controllers (VC) who did not receive ART. Blood and stool samples were collected at baseline and 4 weeks after starting ART. Microbiota-community composition was profiled by 16S-rRNA sequencing in stool and serum. sCD14 was measured by EIA
Results: There was no significant difference in the GI-microbiome alpha-diversity between HIV-infected and historical non-infected subjects.
The main dominant phyla in HIV-infected patients based on relative abundance were Firmicutes and Bacteroidetes, followed by Proteobacteria and Actinobacteria. At the genus level, demonstrated that the most abundance taxa were Faecolobacterium, followed by Prevotella, Lachnospiraceae, Blautia and Bacteroides.
At week 4, median HIV RNA was 41copies/mL. ART did not significant increase alpha-diversity in the GI-microbiome. There was decrease of Bacteroidetes and increase of Firmicutes. At the genus level, there was an increase in the abundance of Prevotella, Lachnospiraceae, Blautia and decrease of Bacteroides. Median sCD14 level was 2500 +/-926 ug/mL pre-ART and 2175 +/-803 ug/mL post-ART (p=0.6)
EC and VC patients have reduced alpha diversity of the GI microbiome compared to HIV non-controllers. Moreover, they have different microbiota composition at the genus level. EC patients have more Bacteroides and less Prevotella compared to the other groups. Both EC and VC cases have more Clostridiales and Pseudobutyrivibrio compared to the HIV non-controllers. EC and VC had higher sCD14 compared to HIV-naïve-subjects (2812+/-1206 ug/mL vs 2500+/-926 ug/mL p=0.07) and treated subjects (2812+/-1206 ug/mL vs 2175+/-803ug/ml, p=0.07).
Bacterial microbiome was not identified in serum samples of any of the patients.
Conclusions: HIV-1-infected-patients microbiome has increased abundance of pathobionts such as Prevotella. There was a trend of ART to improve markers of immune-activation and alter the microbial communities. HIV-controlers have a more favorable GI-microbiome. Further HIV studies are needed to better understand the GI-microbiome in this population.

Presenting author email: brettwilliams0@gmail.com

Background: Individuals with HIV have increased gut microbial translocation and distinct gut microbiota compared to uninfected controls. Prior studies were small and included few women or matched controls, it remains unclear whether this difference is caused by behavior in men who have sex with men (MSM) or HIV. To determine if differences in gut microbiota are due to HIV versus behavioral factors, we evaluated rectal swab derived microbiota of HIV-infected and well-matched uninfected women from similar neighborhoods in the Chicago cohort of the Women's Interagency HIV Study (WIHS).
Methods: Rectal swabs were collected with a Dacron swab at two time points one year apart. Samples were snap frozen in liquid nitrogen. DNA was extracted using PowerSoil® DNA Isolation Kit (MO BIO Laboratories, Carlsbad, CA) and amplified for sequencing of fragments of bacterial small subunit (SSU or 16S) ribosomal RNA (rRNA) genes. Sequence data were processed using a QIIME pipeline. Shannon and Bray-Curtis indices were calculated with default parameters in R using the vegan library. The rarefied genera data, taxonomic level 6, were used to calculate both indices. For Bray-Curtis indices, the rarefied data were filtered to remove any taxon with an abundance of less than 1% of the total abundance in the dataset.
Results: Rectal microbiota of HIV infected (n=136) and uninfected women (n=55) did not differ by Shannon diversity index (p=0.14), Bray-Curtis dissimilarity indices (ANOSIM, R=0.0027, p=0.488) or copy number of individual taxa. Bray-Curtis analysis of samples from the same individuals collected one year apart demonstrated similar rectal microbiome stability over time in both HIV infected and HIV uninfected women (p=0.889).
Conclusions: This large study of rectal microbiota in WIHS women suggests that HIV infection alone does not alter the diversity, composition or stability of the rectal microbiome. Differences in prior serostatus findings may be driven by sex/gender differences in sexual practices rather than HIV specifically. Additionally rectal swab samples were highly acceptable, feasible, and efficient to collect. The microbiome was relatively stable over time suggesting that this method of microbiome investigation does not suffer disproportionately from artifact. Further studies should assess whether differences exist in the microbiome of the proximal bowel.

TUPEA0140

Alterations in dendritic cells status and B cell subsets in HIV-1-infected children at different stages of disease

H. Aggarwal[1], O. Chaudhary[1], M.A. Makhdoomi[1], R. Singh[2], K. Sharma[3], R. Lodha[2], M. Srinivas[3], S.K. Kabra[2], R.M. Pandey[4], B.K. Das[5], K. Luthra[1], HIV-1 infected children
[1]*All India Institute of Medical Sciences, Biochemistry, New Delhi, India,* [2]*All India Institute of Medical Sciences, Pediatrics, New Delhi, India,* [3]*All India Institute of Medical Sciences, Pediatrics Surgery, New Delhi, India,* [4]*All India Institute of Medical Sciences, Biostatistics, New Delhi, India,* [5]*All India Institute of Medical Sciences, Microbiology, New Delhi, India*
Presenting author email: hinaaggarwal@outlook.com

Background: Multiple B cell defects have been reported in HIV-1 infected individuals including alterations in distribution of B cell subsets and excessive B cell activation. Dendritic cells (DCs) regulate B-cell activation through B lymphocyte stimulator (BLyS). Disease progression is faster in children than adults. Less than 5% children maintain stable CD4 counts beyond 7 years of infection without ART and are termed as Long Term Non Progressors (LTNPs). Hence understanding the effect of HIV-1 on DC mediated B cells dysfunction in HIV-1 infected children at different stages of the disease is important to develop strategies for intervention and restoration of B cell function.
Methods: A total of 19 asymptomatic, perinatally HIV-1 infected, ART naïve children, and 14 seronegative children (controls) were recruited. Based on the CD4 counts and years post infection, they were categorized as LTNPs (n=11), and progressors (n=8). Median Fluorescent Intensity (MFI) of BLyS on dendritic cells surface, percentages of myeloid dendritic cells (mDCs), plasmacytoid dendritic cells (pDCs), naïve B cells, mature activated B cells and memory B cells were determined by flow cytometry.
Results: Progressors demonstrated significantly lower CD4 counts and higher viral load as compared to LTNPs ($p < 0.05$). Lower percentages of mDCs and pDCs were observed in progressors vs. LTNPs and controls. The expression of BLyS on mDCs and pDCs was significantly higher in progressors vs. controls ($p<0.05$), whereas in LTNPs it comparable to that in the controls ($p>0.05$). We observed higher percentages of mature activated B cells and significantly lower percentages of memory B cells in Progressors compared to LTNPs ($p<0.05$).
Conclusions: Our study suggests that lower percentages of DCs subsets is associated with faster disease progression in HIV-1 infected children. Higher expression of BLyS on the surface of DCs is associated with lower percentages of memory B cells and higher percentages of mature activated B cells in progressors vs. LTNPs, thereby promoting disease progression

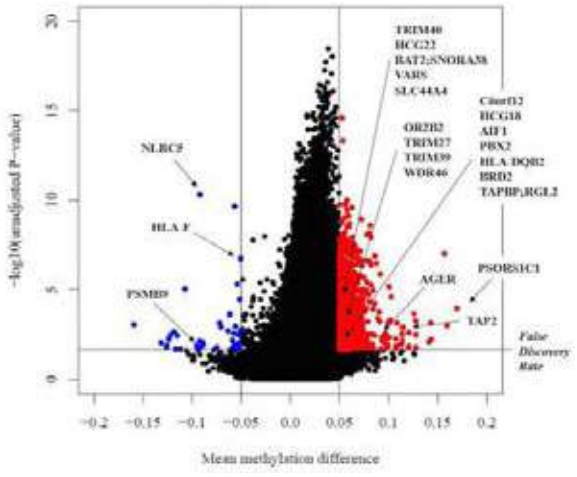
TUPEA0141

Epigenetic dysregulation of the major histocompatibility complex region in HIV-infected children on antiretroviral therapy

S. Shiau[1,2,3], R. Strehlau[3], S. Wang[4], A. Violari[5], M.B. Terry[2], F. Patel[3], E.J. Abrams[2,3,6], A. Liberty[5], S.M. Arpadi[1,2,6], A. Coovadia[3], L. Kuhn[1,2,3]

Sergievsky Center, New York, United States,* [2]*Columbia University, Mailman School of Public Health, Department of Epidemiology, New York, United States,* [3]*University of the Witwatersrand, Rahima Moosa Mother and Child Hospital, Empilweni Services and Research Unit, Johannesburg, South Africa,* [4]*Columbia University, Mailman School of Public Health, Department of Biostatistics, New York, United States,* [5]*University of the Witwatersrand, Chris Hani Baragwanath Hospital, Perinatal HIV Research Unit, Johannesburg, South Africa,* [6]*ICAP at Columbia University, New York, United States*
Presenting author email: ss2568@columbia.edu

Background: Recent data in adults suggest HIV infection and antiretroviral therapy (ART) affect the host epigenome. However, epigenetic dysregulation in children with HIV has not been reported. We performed an epigenome-wide association study (EWAS) to identify differential DNA methylation patterns between treated HIV-infected and HIV-uninfected South African children.
Methods: Genome-wide DNA methylation was profiled using the Illumina Infinium HumanMethylation450 BeadChip array in whole blood from 120 HIV-infected children (46% male) and 60 age-matched HIV-uninfected children (50% male) aged 4-9 years (mean 6.4 years) in Johannesburg, South Africa. HIV-infected children were initiated on ART <2 years of age and were all suppressed <400 copies/mL on a lopinavir/ritonavir-based regimen when methylation was assessed. Pre-processing was performed with the R/Bioconductor RnBeads package. Differentially methylated CpG sites (DMCs) were selected (limma) if they had a False Discovery Rate q-value <0.05 and $|\Delta\beta|>0.05$, where $\Delta\beta$ is the mean methylation difference between groups. Differentially methylated regions (DMRs) were selected (DMRcate) if they had a Stouffer p-value <0.05, maximum $|\Delta\beta|>0.05$, and contained ≥2 CpG sites. Analyses were adjusted for age, sex, and estimated cell type proportions (minfi).
Results: 370,683 CpG sites and 179 samples were suitable for analysis after pre-processing. 1,309 DMCs were selected (Figure 1), including 1,271 hyper-methylated and 38 hypo-methylated in HIV-infected children. The top hypo-methylated DMC was located in the promoter region of the NLRC5 gene on chromosome 16 which regulates major histocompatibility complex (MHC) class I molecule expression. Many additional sites were associated with genes on the extended MHC region on chromosome 6. The selection of 315 DMRs also identified 23 genes located in this region.
Conclusions: We found extensive DNA methylation dysregulation in treated HIV-infected children compared to age-matched uninfected children. Many of these methylation changes were on genes involved in adaptive immunity. These results provide novel insights into immunology pathways affected by HIV.



[Figure 1. Volcano plot displays mean DNA methylation difference between HIV-infected and HIV-uninfected children at genome-wide CpG sites vs. -$\log_{10}$ (unadjusted P-value), after adjustment for age, sex, and cell type proportion; selected sites on genes related to major histocompatibility complex region are labeled]

Biomarkers of progression after HIV acute/early infection: nothing compares to CD4⁺ T-cell count?

G. Turk[1], Y. Ghiglione[1], M. Hormanstorfer[2], N. Laufer[1,3], R. Coloccini[1], J. Salido[1], C. Trifone[1], M.J. Ruiz[1], J. Falivene[1], M.P. Holgado[1], M.P. Caruso[1], M.I. Figueroa[2,3], H. Salomón[1], L.D. Giavedoni[4], M.A. Pando[1], M.M. Gherardi[1], D. Rabinovich[1], P.A. Pury[5], O. Sued[2]

Fernández, Unidad Enfermedades Infecciosas, Buenos Aires, Argentina,* [4]*Southwest National Primate Research Center, Texas Biomedical Research Institute, San Antonio, United States,* [5]*FaMAF, Universidad Nacional de Córdoba, Córdoba, Argentina*
Presenting author email: omar.sued@huesped.org.ar

Background: Progression of HIV infection is variable among individuals. Despite implementation of effective ART, definition of disease progression biomarkers is still fundamental. Apart from CD4⁺ T-cell count (CD4TC) and viral load (VL), several parameters have been individually proposed as biomarkers by our group and others. Here, we aimed to categorize their predictive potential using decision trees and analyze their possible implementation in the clinical setting.
Methods: A total of seventy-five subjects were enrolled during acute/early HIV infection (< 6 months postinfection). CD4TC and VL determinations were performed at enrollment (baseline sample) and during 1 year. This study only included samples and data from subjects while off-treatment. Immune activation (HLA-DR and CD38 expression), HIV-specific immune response (ELISPOT) and HLA haplotype were determined in a subset of 41 individuals at baseline sample. Within this group, plasma levels of 39 cytokines were determined by Luminex in 27 individuals. Progression was defined as CD4TC decreasing below 350 cells/µl or experiencing AIDS-related B/C events within 12 months post-infection. Data was analyzed by machine learning and non-parametric methods and adjusted for multiple comparisons. Variable hierarchization was performed by Weka correlation based feature selection and J48 decision tree
Results: Plasma IL-10, IP-10, sIL-2Rα and TNF-α directly correlated with baseline VL while IL-2, TNF-α, FGF-2 and Mip-1β inversely correlated with CD4+ T-cell activation ($p<0.05$). However, none of these cytokines had good predictive value to distinguish progressors from non-progressors. Similarly, immune activation, HIV-specific immune responses and HLA haplotypes had lower discrimination power when compared to clinical parameters (CD4TC and VL). Baseline CD4TC was the most potent variable to distinguish progressors from non-progressors with a cut-off of 436 cells/µl (accuracy=0.93, k-Cohen=0.85)
Conclusions: In our cohort, baseline CD4TC was the strongest predictor of disease progression early after infection. Limited discerning power of the other factors might be related to frequency, variability and/or sampling time. Surprisingly, high baseline CD4TCs were observed even in subjects that progressed rapidly, reinforcing the importance of early ART initiation. Also, efforts should be made to develop and make available CD4TC determination techniques to all possible settings. Future studies based on decision trees to identify biomarkers of posttreatment control are warrantied.

TUPEA0143

Illicit drug use alters the composition and HIV inhibitory function of semen exosomes

J. Welch[1], C. Okeoma[1,2]
[1]*University of Iowa, Microbiology, Iowa City, United States,* [2]*University of Iowa, Molecular and Cellular Biology, Iowa City, United States*
Presenting author email: jennifer-welch@uiowa.edu

Background: Sexual contact is one of the most common modes of HIV transmission. Although semen is the primary vector, the likelihood of transmission per act of heterosexual coitus with an infected individual is less than 1%. These facts suggest that in addition to the protection provided by the mucosa, semen contains factors that may render HIV non-infectious. Previously, we showed that the nanovesicles called exosomes that were isolated from semen of HIV-uninfected men who do not use illicit drugs robustly inhibit infectivity of HIV-1. Exosomes have emerged as efficient vesicles of intercellular communication, whose composition and function depends on their originating cell. Because the cellular response to HIV infection is impaired by illicit drug use and has been associated with worsening disease progression, it is critical to evaluate the effect of illicit drug use on the characteristics of semen exosomes and their protective property against HIV infection.
Methods: Exosomes were isolated from semen of illicit drug users (n=3) and non-users (n=4). Transmission electron microscopy, NanoSight NTA, and dynamic light scattering were used to examine the physical properties of exosomes. SDS-PAGE gel silver staining, acetylcholine esterase assay, flow cytometry, and qRT-PCR were used to evaluate exosomal composition. TZM-bl HIV-1 infectivity reporter assay was used to assess exosomal function.

Results: Illicit drug use does not alter the physical properties or overall protein footprint of semen exosomes. However, assessment of exosome-specific markers revealed reduced proteinaceous and RNA content from donors that used illicit drugs. Functionally, semen exosomes from donors that used illicit drugs did not inhibit HIV infection, while exosomes from non-users potently inhibit HIV infection. Correlative comparisons suggest that reduced expression of the exosome markers CD63 and CD9 may be linked to the diminished HIV-inhibitory phenotype of semen exosomes from illicit drug users.
Conclusions: These findings suggest that illicit drugs may alter the composition and function of semen exosomes during biogenesis. Further comprehensive analyses are required to identify the mechanistic action of illicit drugs on semen exosome cargo composition and function. These studies will provide the knowledge necessary to disentangle the complex nature of illicit drugs and increased susceptibility to HIV infection from a biological perspective.

TUPEA0144

Multiple effects of nef on host by-stander cells: from cholesterol metabolism to epigenetic changes

M. Bukrinsky[1], L. Dubrovsky[1], D. Sviridov[2]
[1]George Washington University School of Medicine and Health Sciences, Microbiology, Immunology, and Tropical Medicine, Washington, United States, [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia

Background: The Nef protein of HIV-1 is the main factor of viral pathogenesis. The mechanisms of Nef-mediated impairment of cholesterol metabolism in HIV-infected cells involve downregulation and inactivation of the main cellular cholesterol transporter, ABCA1, via Nef binding to ER chaperone calnexin and disrupting the interaction between calnexin and ABCA1. Recent studies demonstrated that Nef is included into exosomes produced by HIV-infected cells, and exosomal Nef has pathogenic activity against by-stander cells. However, mechanisms of this activity remain unknown.
Here, we present analysis of the effects of exogenously added Nef on cholesterol metabolism and inflammatory responses of uninfected monocyte-derived macrophages.
Methods: For cholesterol metabolism studies, MDM were incubated overnight with recombinant myristoylated Nef (100 ng/ml) or exosomes harvested from supernatant of Nef-transfected HEK293T cells (1 ng/ml of Nef measured by ELISA). ABCA1 was measured by Western blot and ABCA1-calnexin interaction - by co-immunoprecipitation. For innate memory analysis, undifferentiated monocytes were incubated with rNef during the first 24 h of differentiation, Nef was removed, and cells were allowed to differentiate for additional 6 days. MDM were stimulated with 25 ng/ml LPS (TLR4 ligand), 25 ng/ml PAM (TLR 2/3 ligand), or 500 ng/ml R848 (TLR 7 ligand), and IL-6 and TNFα release was measured by ELISA. Inflammatory gene expression was analyzed by QIASeq RNA panel.
Results: Nef-treated cells expressed reduced levels of ABCA1 and cholesterol efflux. Nef also disrupted interaction between ABCA1 and ER chaperone calnexin. Similar levels of inhibition were observed with recombinant and exosomal Nef, despite the fact that exosomes contained 100-fold less Nef. Stimulation of Nef-exposed macrophages with TLR7 ligand resulted in a significant (3 fold) increase in IL-6 and TNFα release. The increase after TLR4 stimulation was smaller (about 50%), but significant, whereas no increase was observed after TLR2/3 stimulation. Expression analysis revealed overexpression of a number of genes, including IL6, IFITM1, MIF, IFI27.
Conclusions: This study reveals a potent effect of exosomal Nef on cholesterol metabolism of MDM. It also shows that Nef induces pro-inflammatory memory in MDM. Given that Nef is produced in ART-treated subjects, these results may explain sustained inflammation and metabolic co-morbidities in this population.

Comorbidities in people living with HIV (PLWHIV) compared to general population: an epidemiological analysis using a claims database in France

V. Pourcher[1], S. Bouee[2], J. Gourmelin[3]
[1]Hôpital Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Pierre et Marie Curie University, Infectious and Tropical Diseases Department, Paris, France, [2]Cemka, Bourg en Reine, France, [3]INSERM, Villejuif, France
Presenting author email: valerie.martinez@aphp.fr

Background: Improvements in diagnosis and care, including the development of antiretroviral therapies (ART), has increased the life expectancy of PLWHIV. Several studies have assessed the epidemiology of comorbidities in HIV patients; however a gap remains to see the prevalence of these comorbidities when compared to a control group (non-HIV infected). Despite the treatment improvements, comorbidities continue to complicate patient outcomes. We aimed to assess the current prevalence of comorbidities of the HIV infected population and compare to a matched control group from the general population in France.
Methods: This study is a retrospective health insurance claims database analysis using Echantillon Généraliste de Bénéficiaires (EGB), comprising of 1% representative sample of subjects covered by the general health insurance scheme. A cohort of patients diagnosed with HIV in 2011 was extracted from the database and followed to 2014. Comorbidity prevalence, assessed using ICD-10 codes, were estimated and compared with a non HIV infected control group (1 HIV infected to 2 controls) matched based on an age, gender, area of residence and socioeconomic status.
Results: 1,092 subjects were HIV infected and 2,183 were identified in the control group: in both populations 68.9% were male, mean age was 46.6 years. Results for comorbidities are shown in Table 1. More prevalent in the HIV than the control group were hypertension (27.8% versus 23.6% (p=0.003), (21.9% versus 14.7% (p< 0.0001)) and chronic renal disease (1.0% versus 0.1% p = 0.0007). Prevalence of diabetes and bone fractures were similar between the two groups.
Conclusions: In this HIV population with a mean age approaching 50, the prevalence of important non-AIDS-related comorbidities is higher that matched HIV negative controls. In this analysis, cardiovascular diseases and risk factors are more frequent in HIV patients, highlighting the need for changes in HIV management including regular monitoring and specific therapy to reduce long term risk.

	HIV infected (%)	General Population (%)	p Value
Cardiovascular diseases*	7.5	4.1	<0.0001
Hepatitis B or C Coinfection	15.0	0.4	<0.0001
Chronic Renal Disease	1.0	0.1	0.0007

*Cardiovascular diseases include any of the five comorbidities: Chronic Ischaemic heart disease; Cardiac failure; Chronic Rheumatic Heart disease; Stroke or TIA or Peripheral artery disease.

[Table 1: Prevalence of comorbidities amongst HIV + and control group]

Class-modeling analysis reveals T-cell homeostasis disturbances involved in loss of immune control in elite controller patients

J.M. Benito[1,2], A. León[3], N. Rodríguez[1,2], C. Restrepo[1,2], L.A. Sarabia[4], R. Placios[5], M. García[1,2], A. Cabello[6], M. Górgolas[6], M. Leal[7], J. Ligos[8], N. Rallón[1,2]
[1]Instituto de Investigación Sanitaria-FJD, UAM, Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [3]Hospital Clinic of Barcelona, IDIBAPS, Barcelona, Spain, [4]Universidad de Burgos, Burgos, Spain, [5]Hospital Virgen de la Victoria, Málaga, Spain, [6]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [7]Hospital Virgen del Rocío, Sevilla, Spain, [8]Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain
Presenting author email: jbenito1@hotmail.com

Background: Although elite controller (EC) patients are able to maintain undetectable HIV-viral load, not all of them achieve immunological control (stable CD4 T-cell counts), which can lead them to relevant clinical implications. Therefore, it is important to elucidate mechanisms involved in the CD4 T-cells loss in these subjects. In this study, a deep approach of the immunological factors related to the CD4 T-cells loss was explored.
Methods: A total of 36 EC patients, 22 with stable CD4 counts („control group") and 14 with CD4 decline („case group") were included, plus 20 healthy controls (HC). Different aspects of HIV immunopathogenesis (activation, maturation, exhaustion, thymic production, senescence, Treg-cells) were evaluated using a comprehensive flow cytometry analysis. Statistical analysis was approached by means of Partial Least Squares (PLS)-class modeling methodology in order to detect subtle differences associated with loss of immunological control.
Results: Both groups of patients were comparable in terms of age, sex or CD4 counts at the moment of the analysis. Two PLS models were developed: one to discriminate between EC patients and HC (PLS1), and another to discriminate between case and control groups of patients (PLS2). Both PLS models showed very high levels of sensitivity (98% and 97% for PLS1 and PLS2 respectively) and specificity (98% and 97% respectively). Thus, PLS-class modeling enabled us to decide whether a sample belonged to one of the three categories: control group, case group, or HC. Using this approach we were able to detect subtle, but determinant, alterations in T-cell homeostasis parameters associated to loss of immunological control in EC. Among them, high-levels of exhaustion of CD4 (p=0,01) and CD8 (p=0,04) T-cells, high levels of effector CD8 T-cells (p=0,008), high levels of senescence of CD8 T-cells (p=0,02), and low levels of naïve CD8 T-cells (p=0,02).
Conclusions: Our results demonstrate the existence of a state of T-cell homeostasis disturbance associated to immunological progression in EC patients, suggesting the existence of active pathogenic mechanisms operating even in the face of undetectable viral replication. Knowledge of mechanisms underlying T-cell homeostasis disturbance will be of pivotal.

TUPEA0147

Older age at infection is associated with long-term non-progression in women infected with non-subtype B HIV-1

V. Mochache[1], B. Richardson[2], L. Masese[3], K. Mandaliya[4], J. Shafi[3], J. Kinuthia[5], W. Jaoko[6], J. Overbaugh[7], S. McClelland[8]
[1]National AIDS Control Council, Policy, Monitoring and Research, Nairobi, Kenya, [2]University of Washington, Biostatistics, Seattle, United States, [3]Women's Health Project, Mombasa, Kenya, [4]Coast Provincial General Hospital, Mombasa, Kenya, [5]Kenyatta National Hospital, Research, Nairobi, Kenya, [6]University of Nairobi, Medical Microbiology, Nairobi, Kenya, [7]Fred Hutchinson Cancer Research Center, Seattle, United States, [8]University of Washington, Epidemiology, Seattle, United States
Presenting author email: vmochache@yahoo.com

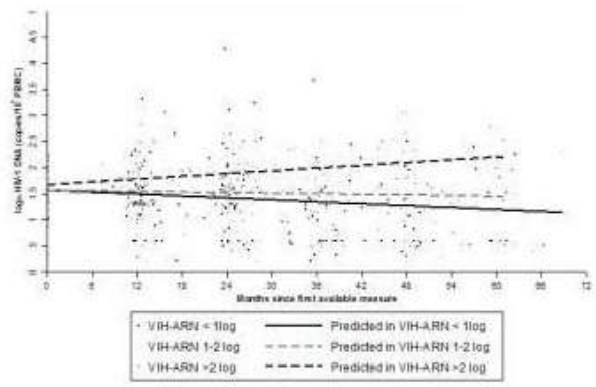
Background: A number of studies of people infected with HIV-1 have reported on antiretroviral (ART)-naïve individuals who show little disease progression despite prolonged infection (long-term non-progressors [LTNPs]). Few have assessed the prevalence and correlates of LTNPs in populations predominantly infected with non-subtype-B HIV-1.
Methods: We analyzed data from the Mombasa Cohort, a prospective study of female HIV-1 seroconverters in Kenya with estimated dates of infection. We defined two LTNP groups: LTNP-7 had ART-naïve duration of infection ≥7 years with the majority of CD4+ counts ≥600 cells/mL; LTNP-10 had a duration ≥10 years with the majority of CD4+ counts ≥500 cells/mL. We conducted a nested case-control study comparing correlates among LTNPs (7 and/or 10) versus non-LTNPs who accrued similar, ART-naïve follow-up using logistic regression.
Results: Between February 1993 and March 2014, there were 332 HIV-1 seroconverters with estimated dates of infection. Of 77 women with sufficient follow-up to be evaluated for LTNP status, 13 (16.9%) were categorized as LTNPs based on one or both definitions (8 LTNP-7 and 2 LTNP-10 and 3 both). The predominant infecting HIV-1 subtype was A (75.0%). Significant correlates of LTNP status in multivariable analyses included age >30 years versus ≤30 years at infection (adjusted odds ratio [aOR]=29.02, 95% confidence interval [CI]: 2.72-309.83, P=0.005) and history of prior pregnancy at enrollment compared to nulliparity (aOR=0.02, 95% CI: 0.00-0.47, P=0.02). Each log10 increase in plasma viral load set point was associated with a significantly lower likelihood of LTNP status (aOR=0.23, 95% CI: 0.08-0.68, P=0.008).
Conclusions: Long-term non-progression was strongly associated with older age at time of infection and parity. The association between older age and LTNP status was not attenuated by adjustment for viral set point, suggesting an alternative mechanism for long-term non-progression.

TUPEA0148

Decrease of blood HIV reservoirs over years in HIV-controllers

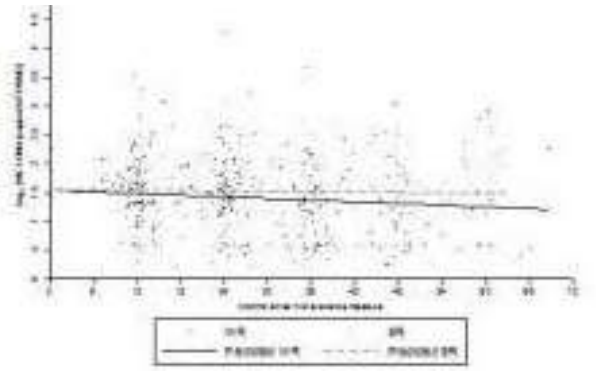
V. Avettand-Fenoel[1,2], F. Boufassa[3], E. Gardiennet[4], P. Lopez[4], C. Lecuroux[3,5], A. Saez-Cirion[6], O. Lambotte[3,7,8], C. Rouzioux[1,2], CODEX ANRS Cohort Study Group
[1]Université Paris Descartes EA 7327, Paris, France, [2]AP-HP, Laboratoire de Virologie, CHU Necker-Enfants Malades, Paris, France, [3]INS, Kremlin Bicêtre, France, [4]Université Paris Descartes, Paris, France, [5]CEA, DSV/iMETI, Division of Immuno-Virology, IDMIT, Fontenay, France, [6]INS, Paris, France, [7]CEA, DSV/iMETI, Division of Immuno-Virology, IDMIT, Fontenay aux Roses, France, [8]APHP Hôpital Bicêtre, Le Kremlin Bicêtre, France
Presenting author email: veronique.avettand@aphp.fr

Background: Total HIV-DNA is a convenient marker to monitor the reservoir size in HIV-infected patients. This study aimed to describe the HIV-DNA dynamics in blood of HIV-1 infected individuals showing natural long-term virological and/or immunological control (ANRS CODEX cohort).
Methods: HIV-DNA was quantified prospectively by ultrasensitive real-time PCR in frozen PBMC during follow-up of 36.4 months [24.2-48.2]. 192 subjects (95 men) with at least two measurements (median 3 measurements, [2-7]) were analyzed. Marker dynamics were modeled by mixed-effect linear models.
Results: At the time of the first HIV-DNA quantification in the cohort, CD4 count was 760 (196-2063) cells/mm3 (median (range)), HIV-RNA load was 0.71 (0.01-2.87) log cp/mL andHIV-DNA was 1.45 (0.00-3.36) log cp/Million PBMC. Individuals with HIV-RNA>2log at inclusion in the cohort (n=9) increased their total HIV-DNA over time (slope: +0.108 log/year, p=0.02), whereas HIV-DNA decreased in HIV controllers with 1 log< HIV-RNA< 2log (slope: -0.024log/year, p=0.38)(n=31) or HIV-RNA< 1log (slope: -0.072log/year, p< 0.001)(n=54).



[Fig 1. HIV-DNA kinetics according to HIV-RNA levels]

HIV-DNA decreased overtime in subjects with weak anti-HIV CD8 T cell responses (slope: -0.060log/year)(n=130) whereas the slope was not significantly different from 0 in individuals with strong anti-HIV CD8 T cell responses (n=62).



[Fig 2. HIV-DNA kinetics according to weak responder or strong responder status]

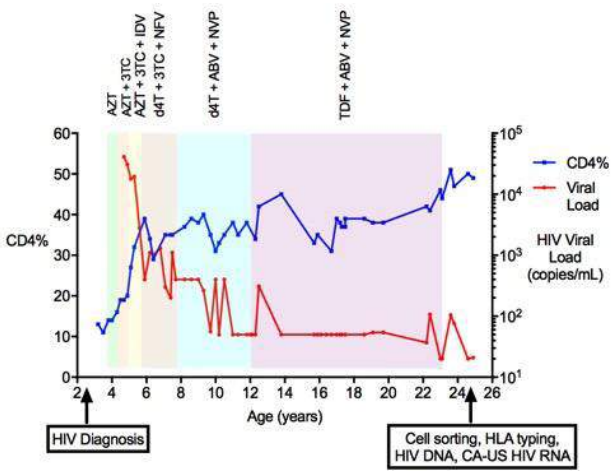
Conclusions: In this large long-term study, we report that HIV blood reservoirs significantly decrease over years in some HIV controllers, similarly to post-treatment controllers. We hypothesize that this decrease contribute to the maintenance of high control. This is in contrast with the HIV-DNA increase observed in HIV-infected progressors. Weak CD8 T cell responses among controllers might be the result of a tighter control of infection.

TUPEA0149

Post treatment control in an adult with perinatally acquired HIV following cessation of antiretroviral therapy

J. McMahon[1,2,3], J. Chang[4], S. Tennakoon[4], A. Dantanarayana[4], C. Cherry[1,2,3], R. Doherty[5,6], P. Cameron[1,4], S. Lewin[1,4]
[1]Alfred Hospital, Infectious Diseases, Melbourne, Australia, [2]Monash University, Infectious Diseases, Melbourne, Australia, [3]Burnet Institute, Melbourne, Australia, [4]Peter Doherty Institute for Infection and Immunity, The University of Melbourne and Royal Melbourne Hospital, Melbourne, Australia, [5]Monash University, Department of Paediatrics, Melbourne, Australia, [6]Monash Children's Hospital, Department of Infectious Diseases, Melbourne, Australia
Presenting author email: james.mcmahon@monash.edu

Background: Virological remission is reported after antiretroviral therapy (ART) cessation in adults and one infant treated very early after infection. However post-treatment control [PTC] has never been described in chronic infection after perinatal acquisition and rarely in adults.
Methods: Clinical review and laboratory analysis of a perinatally HIV infected adult with PTC. We quantified HIV persistence by PCR including HIV DNA and cell-associated unspliced (CA-US) HIV RNA in total and sorted CD4+ T-cell subpopulations (naïve, central, transitional, effector memory and terminally differentiated, [N/CM/TM/EM/TD]). Four-digit HLA typing was performed.
Results: A 25-year-old woman diagnosed at age 2.2 years and no prior opportunistic infection, commenced ART at 3.5 years with one and then two antivirals. She achieved virological suppression after combination ART from age 7.5-23 years with 26/33 plasma HIV RNA measurements below limit of detection. When detected, HIV RNA ranged 37-309 copies/mL. At age 25, two years before enrolment, ART was ceased, HIV RNA ranged from < 20-104 copies/ml off ART, with stable CD4+ T-cell counts (704-869 cells/μL) and percentage (47-51%).



[ART history HIV viral load and CD4%]

The participant had subtype B virus, was homozygous for wild-type CCR5 and demonstrated one HLA-allele associated with viral control (B14:02/C08:02) and two alleles seen in the previously reported perinatally infected PTC (A23:01, C08:02). CA-US HIV RNA was 2.4 log_{10}copies/million copies. 18S and HIV DNA was 0.9 log_{10}/million cell equivalents. Flow cytometry sorting of naive (0.8%), central (0.6%), transitional (23.1%), effector memory (0.7%) and terminally differentiated (71.9%) CD4+ subpopulations revealed all cells were infected with highest to lowest levels of CA-US HIV RNA in CM>EM>N>TM>TD and HIV DNA was CM>N>TM>EM>TD.
Conclusions: We describe PTC in an adult with perinatally acquired HIV and prolonged viremia before ART. Virus was enriched in long lived T-cell subsets and one protective HLA allele was detected. Understanding PTC in different clinical settings may identify new strategies to achieve HIV remission.

Presenting author email: mathieu.claireaux@pasteur.fr

Background: Follicular helper T cells (Tfh) play an essential role in the maturation of the antibody response by providing help to B cells. To determine whether this CD4+ T cell subset may contribute to the spontaneous control of HIV replication, we analyzed the phenotype and function of circulating Tfh (cTfh) in HIV Controllers from the ANRS CO21 CODEX cohort.
Methods: HIV Controllers (HIC, n=13) with a viral load < 50 copies/mL were compared to treated patients with a similarly low viral load (HAART, n=16). HIV-specific cTfh were detected ex vivo by MHC-II tetramer labelling of CD4+CD45RA-CXCR5+ T-cells. The transcriptional profile of tetramer-positive cells was determined by single-cell multiplexed qPCR analysis (Biomark). To evaluate cTfh function, cocultures of cTfh with autologous CD20+ CD27+ memory B lymphocytes (BL) were tested for plasmablast differentiation (CD38hi BL) and total or gp140-specific IgG secretion.
Results: The total cTfh population was predominantly central memory (CCR7+) and showed comparable PD-1 expression levels in both groups (medians: HIC: 29%; HAART: 26%). The study of HIV-specific CD4+ T cells revealed a marked increase in PD-1 expression (medians: HIC: 76%; HAART: 77%) in the cTfh compartment of both groups, suggesting that specific cTfh received chronic antigenic stimulation in spite of low viremia. At the transcriptional level, HIV-specific cTfh expressed low Blimp-1 levels, as expected, but did not upregulate Bcl-6. While cTfh from healthy donors proved highly functional, cTfh from both the HIC and the HAART groups showed a degree of dysfunction as measured by the number of plasmablasts and by total IgG secretion. This defect appeared reversible, as it was abrogated by the addition of IL-6 in the cTfh/BL cocultures. Of note, the HIV-specific memory B cell response differed in the HIC and HAART groups, with higher Env-specific IgG production in cTfh/BL cocultures from Controllers (P=0.02). Supplementation with IL-6 increased the difference, resulting in 60x higher Env-specific IgG concentrations in cocultures from the HIC group (P=0.004).
Conclusions: These findings suggest that key Tfh/BL interactions are preserved in naturally controlled HIV infection, resulting in potent memory B cell responses that may play an underappreciated role in HIV control.

Presenting author email: fdiezf@isciii.es

Background: Long-term non-progressors (LTNP) are a heterogeneous group of HIV-1 infected individuals characterized by their ability to maintain high $CD4^+$ T cell counts and control viral replication for years in the absence of antiretroviral therapy. Nevertheless, LTNP phenotype is far to be fully understood. The present study aims to identify host functional determinants of non-progression in a Spanish cohort of LTNPs.
Methods: An exome genotyping microarray interrogated 247,722 single nucleotide polymorphisms (SNPs) of 85 LTNP. The allelic frequencies of this group were compared with a healthy population of 267 individuals through Fisher´s test. Different populations were used to confirm an aberrant frequency of rs1127888 in LTNP, including a group of HIV-1 infected individuals with a typical pattern of disease progression (TP; n=58) and two reference populations, 1000 Genomes Project (EUR; n=503) and Exome Sequencing Project (EA; n=4300). UBXN6-knockdown mediated by siRNAs were conducted to assay the role of this gene in HeLa and mature dendritic cells (MDC) infected with different HIV-1 luciferase-expressing recombinant viruses, including NL4.3-Luc (CXCR4-tropic), JR-Ren (CCR5-tropic) and VSV-NL4.3Luc-R−E− (CD4/coreceptor-independent entry). Cell infection was assessed through measurement of Relative Luciferase Units (RLU). The expression of UBXN6 and UBXN6-interacting protein CAV1 was measured by Western-blot and immunofluorescence assays.
Results: The SNP rs1127888 located in 19p13.3 and associated with UBXN6 reached genome-wide significance ($p=7.34x10^{-11}$; $q=2.11 \times 10^{-6}$, after Bonferroni correction) in the LTNP/control association study. The anomalous allelic and genotypic frequencies of rs1127888 observed in LTNP were confirmed with reference populations (EUR and EA) and by sequencing in TP population. The predicted effect of rs1127888 causes A31T missense variant in UBXN6 protein. UBXN6-knockdown in HeLa cells increases CAV1 expression by 33% and its accumulation in the plasma membrane. UBXN6-knockdown increased infection with VSV-NL4.3Luc-R−E− by 29.5% compared with controls whereas no differences were found after the infection with NL4.3-Luc. Preliminary results in MDC showed an increase in RLU by more than 3 times after the infection with JR-Ren in cells where UBXN6 were silenced.
Conclusions: The SNP rs1127888 causing A31T variant of UBXN6 was associated with LTNP phenotype. UBXN6-silencing resulted in altered CAV1 availability and increased HIV-1 infection through enhancement of CD4/coreceptor-independent endocytosis.

TUPEA0152

Compromised macrophage-mediated HIV *trans* infection of CD4 T cells is linked to lipid raft dissociation

D. Campbell DeLucia, G. Rappocciolo, J. Martinson, C. Rinaldo
University of Pittsburgh, Pittsburgh, United States
Presenting author email: dmc111@pitt.edu

Background: A small percent of persons control HIV infection without antiretroviral therapy. We previously showed that this non-progressor (NP) phenotype is linked to dysfunctional cholesterol-dependent trans infection of HIV from profes-

sional antigen-presenting cells (APC; dendritic cells [DC] and B cells) to CD4 T cells. Macrophages (MΦ) have enhanced cholesterol sensing abilities and are involved in HIV dissemination. We sought to determine if MΦ cholesterol is altered in NP, and what effects cholesterol content and distribution have on trans infection and surface protein expression.
Methods: MΦ were generated in vitro from monocytes. Trans infections were performed by co-culture of R5 HIV Bal-exposed APC with autologous CD4 T cells followed by p24 ELISA. Total cell cholesterol was measured with the Amplex Red assay. Cell membrane cholesterol was visualized by flow cytometry.
Results: MΦ trans infection was undetectable in NP compared to progressors (PR). NP MΦ displayed less total cholesterol, but similar cell membrane cholesterol concentrations compared to PR. DC-SIGN expression on MΦ was significantly lower in NP, suggesting NP and PR may have differential plasma membrane lipid rafting that is required for functional surface expression of DC-SIGN. Within seronegatives (SN), MΦ trans infection efficiency positively correlated with the percentage of DC-SIGN$^+$ MΦ. Deficient trans infection in SN was associated with dissociated lipid rafting in APC. Interestingly, lowering cholesterol synthesis in SN MΦ decreased trans infection efficiency and cis infection, as well as lipid rafting.
Conclusions: We linked MΦ-mediated trans infection with HIV progression. Differential MΦ cholesterol concentrations and DC-SIGN expression in NP and PR, and the ability of statins to impede lipid rafting and decrease trans infection, suggest that a cholesterol-associated, virus-cell interaction is paramount for HIV trans infection and disease progression. We are currently comparing NP and PR by RNA Seq to elucidate mechanistic components of cholesterol mediated trans infection. Based on APC-T cell proximity and interactions in lymphoid organs, our data support APC-mediated trans infection as an important mechanism of virus dissemination and reservoir maintenance.

TUPEA0153

Functional characterization of a public TCR clonotype identified against the HIV-1 Gag A2-FK10 epitope

G. Anmole[1], S. Jin[1], X.T. Kuang[1], J. Wang[1], S. Mujib[2], M.A. Ostrowski[2], M.A. Brockman[1,3,4]
[1]Simon Fraser University, Molecular Biology and Biochemistry, Burnaby, Canada, [2]University of Toronto, Immunology, Toronto, Canada, [3]Simon Fraser University, Health Sciences, Burnaby, Canada, [4]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada
Presenting author email: gsa26@sfu.ca

Background: T cell receptor (TCR) repertoire diversity determines the breadth and specificity of an individual's cytotoxic T lymphocyte response against HIV infection. A better understanding of features associated with highly active antiviral TCR may inform strategies to reduce or eliminate latent HIV-1 infection, particularly in the context of diverse or "escaped" epitopes.
Methods: Tetramer+ CD8 T cells against Gag FS8 (FLGKIWPS) were isolated by FACS from HLA-A*02+ HIV non-progressors. Paired TCR alpha and beta CDR3 sequences were determined using single-cell RT-PCR. Full-length TCR genes were reconstructed and transfected into Jurkat cells along with CD8 alpha and NFAT-driven luciferase reporter. TCR+ Jurkat "effector" cells were co-cultured with A*02+ "target" cells pulsed with FK10 peptide or variants and TCR-mediated signaling was quantified by luminescence.
Results: A dominant TCR clonotype reactive against A2-FK10 was observed in two unrelated individuals. In one case, clone 1A9 was observed at ~60% frequency in tetramer-sorted cells. In the second case, clone 4A4 was observed at 100% frequency. 1A9 and 4A4 encoded identical alpha and beta Variable genes (TRAV12-1, TRBV7-2). Furthermore, their alpha CDR3 sequences differed by 1 amino acid, and their beta CDR3 sequence differed by 4 amino acids. 1A9 and 4A4 showed similar antigen sensitivity to FS8 (EC50: 0.29 ng/μL and 0.23 ng/μL, respectively) and FK10 (EC50: 2.1 ng/μL and 0.97 ng/μL) in a TCR signaling assay. Analysis of FS8 variants indicated that positions 4, 6 and 7 were critical for signaling by both TCR, and a natural polymorphism at peptide position 4 (Gag K436R) similarly abrogated their activity.
Conclusions: We have identified a novel "type 2" public TCR clonotype against A2-FK10 with nearly identical sequences, signaling capacities and peptide cross-reactivity profiles. Our results indicate that the T cell response elicited towards this HIV epitope may be highly restricted, but nevertheless effective once generated.

TUPEA0154

Evaluation of combined protective effect of five variant genotypes on susceptibility to HIV infection in discordant couples

N. Lebedeva[1], I. Efremov[2], R. Turakulov[3], A. Pronin[4]
[1]GUZ of Moscow Region, Moscow Regional Center of AIDS and Infectious Diseases Prevention and Treatment, Diagnostics, Moscow, Russian Federation, [2]Emanuel Institute of Biochemical Physics of Russian Academy of Sciences, Moscow, Russian Federation, [3]Australian Genome Research Facility, Melbourne, Australia, [4]Moscow Region AIDS Center, Moscow, Russian Federation
Presenting author email: lebedevanatalya@rocketmail.com

Background: HIV-negative partners in discordant couples provide a fair opportunity to study highly exposed seronegative individuals (HESN). Having analyzed epidemiological information about 500 HESN from discordant couples, we selected a subgroup to analyze a number of allele variants contributing to HIV resistance.
Methods: The study was performed in 2016 and included HESN from heterosexual discordant couples with history of sexual relationship ranging 1 to 12 years. These couples are being followed-up in Moscow Regional AIDS Center. DNA was extracted from venous blood. Allelic variants were determined by PCR/RFLP in five polymorphic loci related to HIV susceptibility (CCR5-Δ32, CCR5-T303A, CCR2-V64I, DC-SIGN-VNTR, and SDF-1 3'A). Combined contribution of the genotypes to presumable protective effect was evaluated using the total genotype score (TGS) approach. In statistical comparisons, exact Fisher test was used.
Results: For genotype analysis, we selected HESN who
(i) had lived together for 6-12 years,
(ii) had partners with confirmed viral load,
(iii) self-reported regular unprotected sexual contacts, and
(iv) had been passing regular medical examination in the AIDS Center.
This HESN subgroup consisted of 9 men and 25 women, though in the total HESN sample the proportions of men and women were almost equal (247 and 253). Having stratified our HESN sample by years of sexual relationship, we found that proportion of women increased with time: from 43.5% after 1-5 years to 69.1% after 6-12 years ($p<0.001$). A control group (matched by age and gender) was composed of 34 HIV patients who had been infected through heterosexual contacts. Genotypes in the selected loci were determined in both groups. Allele and genotype frequencies evaluated separately for each locus did not show significant difference between the groups. To analyze a possible combined effect, TGS values were ascribed to each individual, based on published data. TGS distributions in the HESN and control groups were significantly different ($p=0.030$).
Conclusions: Our results, indicating protective role of the combined variation in five genes affecting HIV entrance into cells, contribute to understanding the genetic background of HIV susceptibility. The TGS method proved to be a useful tool for evaluation of genotype interplay in samples of limited size.

Background: Interleukin-21 (IL-21) controls HIV-1 infection through the elicitation of different antiviral mechanisms, including Th17 lineage commitment and the induction of microRNA(miR)29, a miRNA endowed with anti-HIV activity whose expression is significantly increased in HIV-exposed seronegative individuals (HESN). We investigated possible interactions between IL-21 and the overall immunological outcome responsible for natural control of HIV-1 infection.
Methods: CD4+ T lymphocytes isolated from 15 Italian HESN exposed to HIV through unprotected sexual intercourses and from 15 HIV-unexposed healthy controls (HC) were in vitro infected with an R5 tropic HIV-1_{Ba-L} strain .
Seven days post infection we evaluated:
1) p24 production (ELISA);
2) CD4+/IL21+ and CD4+/IL17+ T lymphocytes (FACS);
3) IL-21 and IL-17 concentration in supernatants (ELISA); and
4) IL-21, IL-17 as well as mir29a, b, c expression by CD4+ T lymphocytes (qPCR).
The same analyses were performed at baseline on 15 HIV+ partners.
Results: At baseline, IL-6 and IL-21 expression was significantly higher in HESN and HIV+ patients compared to HC. Seven days after in vitro HIV-1 infection, CD4+/IL21+ and CD4+/IL17+ T lymphocytes, as well as IL-6, IL-17 and IL-21 expression and

production were significantly augmented in HESN compared to HC. Interestingly, IL-21 upregulation correlated with a significantly increased expression of miR29a, b, c and reduced susceptibility to in vitro HIV-1 infection in HESN alone.
Conclusions: The IL-21-miR-29 axis is upregulated by HIV infection in HESN; this axis could play an important role in the natural resistance to HIV-infection seen in HESN. Approaches that exogenously increase IL-21 production or prompt pre-existing cellular IL-21 reservoir could confine the magnitude of the early HIV-1 infection.

Immune signatures linked with HIV-1 neutralization breadth

C. Kadelka[1,2], T. Liechti[1], H. Ebner[1], P. Rusert[1], R. Kouyos[1,2], H. Günthard[1,2], A. Trkola[1], The Swiss HIV Cohort Study
[1]University of Zurich, Institute of Medical Virology, Zurich, Switzerland, [2]University Hospital Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland
Presenting author email: kadelka.claus@virology.uzh.ch

Background: The factors that drive broadly neutralizing antibodies (bnAbs) development in natural infection are still poorly understood. In the Swiss 4.5K Screen, a systematic survey of bnAb activity in 4,484 HIV-1 infected individuals (Rusert, Kouyos Nat Med 2016), we identified 239 bnAb inducers, and showed that viral load, infection length, viral diversity, and black ethnicity were positively and independently associated with bnAb development. We recently found several HIV-1 antibody binding profiles predictive of neutralization breadth (Kadelka CROI 2017). Here, we compare the parameters associated with binding activity with those associated with bnAb activity, and report on improved predictors of neutralization breadth.
Methods: Using an in-house established Luminex bead assay, we probed 4,283 plasma samples included in the Swiss 4.5K Screen for binding antibodies of IgG subclasses 1, 2 and 3 against 13 HIV-1 proteins and peptides encompassing Gag (p17, p24) and Env. Multivariable regression models were used to detect associations. Predictive power was measured using the area under the ROC-curve (AUC).
Results: Viral load differentially steered responses to HIV-1 antigens affecting both the magnitude of the response and the IgG subclass diversification; high viral load was linked with low binding titers of IgG1 p17&p24, and IgG3 gp41 (each $p< 10^{-9}$), but also with high binding titers of IgG1 gp41 ($p< 10^{-7}$) and IgG2 gp120 ($p=0.01$-10^{-10}). Viral diversity was positively associated with gp120 responses, particularly strongly with IgG1 BG505 trimer ($p< 10^{-9}$). Interestingly, diversity had no influence on Gag and gp41, both of which have lower genetic variability than gp120. Infection length was in contrast linked with high IgG1 binding titers across diverse antigens highlighting that breadth development requires time. Independent from viral subtype, black ethnicity was associated with high IgG1 BG505 trimer responses ($p<10^{-24}$) and IgG1 BG505 trimer responses were most predictive of neutralization breadth (AUC=0.85). Advanced prediction models based on multiple binding responses and patient characteristics provided even better bnAb prediction.
Conclusions: Previously identified independent drivers of bnAb activity proved to be associated with distinctive HIV-1 binding antibody immune signatures. Importantly, binding antibody responses to the BG505 trimer reliably predict neutralization breadth, providing a valuable assessment tool of forthcoming vaccine efficacy trials.

Presenting author email: mangin@pasteur.fr

Background: Compared with HIV-1, HIV-2 infection is characterized by a larger proportion of slow or non-progressors. A better understanding of HIV-2 pathogenesis should open new therapeutic avenues to establish control of HIV-1 replication in infected patients.
Methods: In this study, we performed a fine characterization of HIV-2-specific CD8+ T cells in HIV-2 infected controllers from the French ANRS CO5 HIV-2 cohort, taking in consideration CD8+ T-cell production capacity, the phenotype of HIV-2 tetramer positive cells and HIV-2 suppressive capacity.
Results: HIV-2 controllers display a robust capacity to support long-term renewal of the CD8+ T-cell compartment by preserving immune resources, including hematopoietic progenitors and thymic activity, which could contribute to the long-term maintenance of the CD8+ T cell response and the avoidance of premature immune aging. Our data support the presence of HIV-2 Gag-specific CD8+ T cells that display an early memory differentiation phenotype and robust effector potential in HIV-2 controllers. We show for the first time to our knowledge that HIV-2 controllers possess also CD8+ T cells that show an unusually strong capacity to suppress HIV-2 infection in autologous CD4+ T cells ex vivo. The HIV-2 suppressive capacity of CD8+ T cells correlated with patient CD4+ T cell counts, supporting a role of these cells to limit disease progression.
Conclusions: Our data suggest that the effective and durable control in HIV-2-infected individuals probably participates in a virtuous circle, during which controlled viral replication permits the preservation of immune functions, including potent HIV-2-specific CD8+ T cells, thus preventing HIV-2 disease progression.

HLA-C expression levels and binding stability to β_2m modulate HIV-1 infectivity

F. Parolini[1], P. Biswas[2], M. Serena[3], F. Sironi[2], S. Mutascio[1], V. Muraro[4], E. Guizzardi[4], M. Malnati[2], A. Beretta[2], M.G. Romanelli[1], D. Zipeto[1]
[1]Università degli Studi di Verona, Neurosciences, Biomedicine and Movement Sciences, Verona, Italy, [2]IRCCS Ospedale San Raffaele, Milan, Italy, [3]University of Oxford, Oxford, United Kingdom, [4]Service of Transfusion Medicine, AOUI Verona, Verona, Italy
Presenting author email: francesca.parolini@univr.it

Background: HLA-C expression levels lead to different HIV-1 infection outcomes. A higher expression is associated with a better activation of cytotoxic T lymphocytes (CTLs) and thus a better HIV-1 infection control. Vice versa, a lower HLA-C expression leads to a rapid progression toward AIDS. Thus, HLA-C highly and lowly expressed alleles are defined as protective and non-protective, respectively. Furthermore, different HLA-C alleles have different binding stabilities to $\beta_2$microglobulin (β_2m). Interestingly, HLA-C protective alleles are also those that bind β_2m more efficiently, while the non-protective variants present more free chains (not bound to β_2m) on the cell surface. It is also known that virions lacking HLA-C have reduced infectivity and increased susceptibility to neutralizing antibodies.
Methods: The A3.01 cell line and its HIV-1-infected counterpart ACH-2 were used as an in vitro infection model. 293T β_2m negative cells, generated using CRISPR/Cas9 system, were utilized to produce HIV-1 pseudoviruses. PBMC from healthy blood donors, harboring both protective or non-protective alleles, were exploited to

characterize the proportion between HLA-C associated to β_2m and HLA-C presents as free chains on the cell surface. In addition, PBMC from the same donors were tested for their ability to support HIV-1 infection in vitro.
Results: HLA-C free chains, specifically more represented on the surface of infected cells, are responsible for the increase of virions' infectivity. We observed that HIV-1 Env-pseudotyped viruses produced in β_2m negative cells, thus lacking HLA-C on their envelope, are less infectious than those produced in the presence of β_2m.
In PBMC we found that protective HLA-C variants are more stably bound to β_2m than non-protective ones and that HIV-1, in vitro, infects more efficiently PBMC harboring non-protective, weakly bound to β_2m, HLA-C alleles.
Conclusions: We propose that the outcome of HIV-1 infection might be driven both by the HLA-C surface expression levels and by the HLA-C/β_2m binding stability. According to this model, the expression of non-protective HLA-C alleles, which bind weakly β_2m, leads to a reduction of immunocompetent complexes expressed on the cell surface and to an increase of HLA-C free chains that raises viral infectivity, both leading to a rapid progression toward AIDS.

HIV-specific CD8+ T cells from natural HIV-1 controllers have a distinct signature associated with enhanced metabolic plasticity and antiviral function. ANRS CO21 CODEX

M. Angin[1], S. Volant[2], C. Lecuroux[3], M.-A. Dillies[2], F. Boufassa[4], M. Muller-Trutwin[1], O. Lambotte[5], A. Sáez-Cirión[1], ANRS CO21 CODEX Study Group

Presenting author email: mathieu.angin@pasteur.fr

Background: HIV-controllers (HIC) are a rare group of infected patients who can control the virus below the limit of detection without antiretroviral therapy. This control is usually associated with a strong capacity of HIV-specific CD8 T cells to eliminate infected autologous CD4 T cells ex vivo. This capacity seems to be related to inherent characteristics of CD8 T cells but the mechanisms are still not well understood. We made the hypothesis that such enhanced antiviral capacity could be engraved in the transcription profile of HIV-specific memory CD8 T cells from controllers.
Methods: To define a transcriptional signature associated with control of infection, and take into account cellular heterogeneity, single HIV-specific central memory CD8 T cells from HIC and antiretroviral treated individuals were flow-sorted. Single cell gene expression was then measured by real time PCR. Statistical analyses were performed to identify markers that are differentially expressed between the two groups and to identify clusters of cells sharing common characteristics. Intracellular cytokine staining was used to assess HIV-specific CD8 T cells responses under metabolic stress conditions.
Results: Single cell profiling showed that HIV-specific memory CD8 T cells from HIC and non-controllers have distinct transcriptional signatures. When compared with non-controllers, HIC upregulated genes linked to effector function and survival. In contrast non-controllers upregulated genes associated with proliferation and exhaustion. These profiles were associated with higher expression of genes promoting glycolysis in non-controllers and a different balance of the mTORC1/mTORC2 pathways in HIC and non-controllers. Functional analyses showed that HIV-specific CD8 T cells from HIC were partially dependent on glucose and mitochondrial activity, while cells from non-controllers were exclusively dependent on glucose.
Conclusions: Overall our results suggest that poor functionality of HIV-specific CD8 T cells from non-controllers could be related to their dependence on glycolysis as primary energy source. In contrast cells from HIC appear to diversify their metabolic resources. Our data highlight the inherent singularity of HIV-specific CD8 T cells from HIC and hint to a metabolic profile compatible with better cell survival and potential to develop anti-HIV effector function under metabolic stress conditions. HIV-specific CD8 T cells metabolism appears to be paramount for control of infection.

Functionality of tissue-resident SIV-specific CD8+ T cells

C.E.C. Starke, J.M. Brenchley
National Institutes of Health, NIAID, Bethesda, United States
Presenting author email: carlyelizabeth.starke@nih.gov

Background: Simian immunodeficiency virus (SIV)-specific CD8+ T lymphocytes can reduce SIV replication, slowing disease progression. However, SIV-specific CD8+ T cells are incapable of reducing viral replication to low levels for the lifespan of most SIV-infected rhesus macaques (RM) and the majority of animals progress to simian AIDS. Recent studies demonstrated that SIV persists in lymphoid follicles. In a small group of elite controller Asian macaques, SIV replication is spontaneously controlled.
This phenomenon is suggested to be attributed to the unique ability of some CD8+ T cells to penetrate into lymphoid follicles and reduce SIV infection of CD4+ follicular helper T (T_{FH}) cells.
Methods: To determine whether there are signatures of tissue-resident SIV-specific CD8+ T cells associated with increased virologic control, we analyzed molecular and immunological characteristics of SIV-epitope specific CD8+ T cells in lymphoid and gastrointestinal tract tissues of 12 SIVmac239, SIVsmE543, or SIVsmE660 infected RM. Seven macaques with viral load less than 10,000 copies/mL were considered to be controllers while the remaining 5 were noncontrollers. MHC-I tetramers loaded with SIV epitopes were used to identify SIV-specific CD8+ T cells and flow cytometric and gene chip analyses were used to unravel phenotypic and functional qualities.
Results: While we found no differences in the magnitude of SIV-specific T cell responses based upon their ability to control viral replication, RM who controlled viral replication to low levels exhibited increased CXCR5 expression in lymphoid tissues compared to RM with higher viral loads and frequencies of CXCR5+ SIV-specific CD8+ T cells negatively correlated with plasma RNA viral load and viral DNA within T_{FH} cells. Additionally, frequencies and phenotypes of SIV-specific CD8+ T cells were closely associated with those found in the gastrointestinal tract.
Conclusions: Our data suggest that inherent functionality and particular trafficking of SIV-specific CD8+ T cells are important for virologic control. Additionally, these results demonstrate that analysis of lymphoid tissues may be reflective of T cell responses within the gastrointestinal tract. These results will help to better understand the mechanisms that underlie SIV disease progression and the role of SIV-specific CD8+ T cells in SIV pathogenesis, which may lead to rational vaccine development.

NK cell capacity to accumulate in lymph node follicles is associated with SIV control

N. Huot[1,2], P. Rascle[1,2], B. Jacquelin[1], T. Garcia[1], M. Ploquin[1], R.K. Reeves[3], N. Derreudre-Bosquet[4], M. Müller-Trutwin[1,2]
[1]Institut Pasteur, HIPER, Paris, France, [2]Vaccine Research Institute, Creteil, France, [3]Center for Virology and Vaccine Research, BIDMC, Boston, United States, [4]CEA, IDMIT, Fontenay aux Roses, France
Presenting author email: nicolas.huot@pasteur.fr

Background: During cART, HIV persists in lymph nodes (LN), in particular in B-cell follicles. LN follicles also represent a niche for HIV to hide from most CD8+ T cells in HIV/SIV controllers. In this study, we explored mechanisms that allow control of viral replication within follicles using a natural host of SIV model, the African Green monkey (AGM), which has an uncommon capacity to efficiently control SIV replication in LN.
Methods: Six AGM and six cynomolgus macaques were infected respectively with SIVagm.sab$_{92018}$ and SIVmac$_{251}$ and followed for 6 months. Blood, peripheral LN and rectal biopsies were collected at regular intervals before, during acute and during chronic infection. Viremia as well as cell-associated viral RNA and DNA were quantified. Confocal microscopy was used to determine viral RNA distribution, changes in NK cell localization and cytokine expression. NK cell phenotypes and IL-15+cells were analysed by flow cytometry. Functional assays for evaluating NK cell suppressive activity were performed.
Results: We confirmed that AGM show a strong control of viral replication in LNs, in particular in follicles. Surprisingly, SIVagm infection induced the accumulation of high numbers of NK cells within follicles, associated with a high frequency (25%) of CXCR5+ NK cells in secondary lymphoid organs not observed in gut. Follicles during SIVagm infection were a large source of IL-15 suggesting a contribution in NK cell survival and/or differentiation. We observed an increase of differentiated NK cells in AGM LNs at the end of the acute phase when the virus starts to be controlled. CXCR5+NK cells from LN displayed a cytotoxic phenotype. We also observed a strong capacity of LN AGM NK cells to degranulate. In contrast, intestinal NK cells were rare in AGM in contrast to MAC and did not show an increased degranulation during infection.

Conclusions: We present the first evidence for a distinct anatomical location of NK cells between pathogenic and nonpathogenic SIV infection. The discovery of NK cell accumulation in follicles reveals a new feature of NK cells in primates. Their cytotoxic phenotype brings us to consider NK cells as one possible player in the control of HIV/SIV infections in LN.

TUPEA0162

Dolutegravir-based simplification of antiretroviral therapy (mono- and dual therapy) in humanized mice with chronic HIV infection

A. Heredia[1], S. Hassounah[2], S. Medina-Moreno[1], N.M. Le[1], J.C. Zapata[1], Y. Han[2], T. Mesplede[3], R.R. Redfield[1], M.A. Wainberg[2]
[1]Institute of Human Virology, University of Maryland School of Medicine, Medicine, Baltimore, United States, [2]McGill AIDS Centre, Lady Davis Institute, Montréal, Canada, [3]McGill University AIDS Centre, Lady Davis Institute for Medical Research, Jewish General Hospital, Montréal, Québec, Canada., Montréal, Québec, Canada

Background: The integrase inhibitor Dolutegravir (DTG) has a high genetic barrier to drug resistance. To date, clinical resistance to DTG has not been reported in first-line therapy of ART-naïve patients. Proof-of-concept studies suggest that DTG might simplify current ART regimens from 3 to 2, or even to 1, drug. Yet, it is unclear whether DTG-based mono- or dual-drug therapy will durably sustain HIV suppression, without the emergence of resistance.
Methods: In a first study, we evaluated the efficacy of 20-week monotherapy with DTG or raltegravir (RAL) in humanized mice (HSC-NSG) infected with HIV_{BaL}. In a second study, using the same animal model, we evaluated dual therapy with DTG plus lamivudine (3TC). Plasma HIV RNA was measured by qRT-PCR every 2-3 weeks, lymphocyte subsets by flow cytometry, and drug levels by LC/MS/MS. Escape viruses were genotyped and analyzed for replication capacity and drug susceptibility in tissue culture.
Results: In the monotherapy study (DTG vs RAL), mice in the RAL group had decreases in HIV viremia, which became undetectable in 3/4 mice within 6 weeks of treatment. However, such suppression by RAL lasted for 2-3 weeks only, rebounding in all animals afterwards. In contrast, DTG suppressed viremia to undetectable levels in 5/5 mice within 6 weeks, and suppression was durable in all but one mouse that rebounded. Levels of RAL and DTG in plasma were within ranges in humans. Viruses from mice failing RAL monotherapy had developed mutations G140S and Q148H/K in IN, and were resistant to both RAL (EC_{50} values of > 100 nM) and DTG (EC_{50} values ranging 8.8-13.3 nM). The only mouse with viremia during DTG monotherapy had mutations E138K, G140S, Q148H, N155H and S230R. The virus from this mouse was highly resistant to both RAL (EC_{50} > 1000 nM) and DTG (EC_{50} of 550 nM), and replicated to high levels in primary PBMCs. In contrast, viruses from untreated mice were sensitive to RAL (EC_{50} < 8 nM) and DTG (EC_{50} < 1 nM). In a follow-up, ongoing study, mice treated with dual therapy (DTG+3TC) maintain durable suppression.
Conclusions: DTG monotherapy does not maintain HIV suppression, suggesting therapy simplification may require dual therapy.

Modeling viral kinetics predicts a rapid establishment of the cytotoxic immune response targeting distinct infected cell compartments in SIV controller macaques (ANRS SIC study)

V. Madelain[1], C. Passaes[2], A. Millet[3], V. Avettand-Fenoel[3], C. Rouzioux[3], N. Dereuddre-Bosquet[4,5], R. Legrand[4,5], B. Vaslin[4,5], A. Saez-Cirion[2], J. Guedj[1]
[1]IAME, UMR 1137, INSERM, Univ Paris Diderot, Sorbonne Paris Cité, Paris, France, [2]Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France, [3]Université Paris Descartes EA7327, AP-HP, Hôpital Necker, Paris, France, [4]CEA, DRF/iMETI, Fontenay aux Roses, France, [5]Center for Immunology of Viral Infections and Autoimmune Diseases-Inserm U1184 (Joint Research unit CEA-Université Paris Sud-INSERM) and IDMIT, Fontenay aux Roses, France
Presenting author email: vincent.madelain@inserm.fr

Background: Our group recently demonstrated that long term control of SIV can be obtained in cynomolgus macaques presenting a H6 MHC allele or in non-H6 animals infected with a low dose inoculum of SIVmac251 by mucosal route (see abstract by Passaes et al.).
Methods: Here we applied mathematical modeling to viral kinetics in this model to help unraveling the determinants of viral control. The kinetics of SIV-RNA and SIV-DNA was obtained for 18 months in 16 macaques in 3 groups:
i) H6 macaques infected with 50 AID50 (n=6) ;
ii) non-H6 macaques infected with 5 AID50 (n=4) ;
iii) non-H6 macaques infected with 50 AID50 (n=6, controls).
SIV-RNA and SIV-DNA data were jointly fitted with a mechanistic model of viral infection, using population approach (Monolix software).
Results: The rapid viral decline after the peak in controllers could be best reproduced assuming a cytotoxic immune response with a saturable infected cells-dependent growth rate. Interestingly in our model viral control did not correlate with the strength of the immune response per se, but rather with an early effective response after peak viremia, as corroborated independently by longitudinal ex-vivo assessment of CD8 T cells cytotoxic activity (Passaes et al.). Further, SIV-DNA after the peak declined slowly in a biphasic manner, suggesting that SIV-DNA after the peak largely originates from not or low actively productive cells. In fact, best fit to SIV-RNA and SIV-DNA kinetics was obtained assuming 3 compartments of infected cells: highly productive cells with a short half-life decreasing from 5.5 days (early infection) to 0.3 days after peak viremia, and two populations of weakly or nonproductive cells, with half-life of 5.1 and 118 days. Thus one predicts that these compartments respectively account for about 1, 5 and 96% of circulating infected cells, respectively, in typical controllers at the setpoint viremia.
Conclusions: In conclusion modeling predicts that an early establishment of an effective CD8 response is key to achieve viral control. Discrepancy between SIV-RNA and SIV-DNA kinetics reveals that more than 90% of SIV-DNA containing cells are not highly producing and not highly targeted by the immune response in these controllers.

TUPEA0164

RNA-Seq reveals lymph node resident pDCs as the primary cellular producer of type I IFN in SIV infection

R. Dawoud[1], C. Grech[1], N. Patel[2], G. Tharp[2], S. Bosinger[3]
[1]Emory University & Yerkes National Primate Research Ctr, Div. of Microbiology & Immunology, Atlanta, United States, [2]Emory University & Yerkes National Primate Research Ctr, Yerkes Genomics Core Laboratory, Atlanta, United States, [3]Emory University, Pathology & Laboratory Medicine, Atlanta, United States
Presenting author email: steven.bosinger@emory.edu

Background: Type I IFN has been long implicated as driver of pathogenesis in untreated HIV infection, and recently has been demonstrated to be a barrier to eradicating latent virus. Despite its importance, and although elevated expression of Interferon Stimulated Genes has long been reported in pathogenic HIV and SIV infection, the source of Type I IFN (IFNA and IFNB) has remained elusive.The goal of this study was to investigate the transcriptional profiles of pDCs in the blood and tissue of pathogenic and non-pathogenic NHPs and test if tissue resident pDCs produce Type I IFN in pathogenic SIV infection (Rhesus macaques) and in NHP species that do not develop AIDS (Sooty mangabeys).
Methods: Approximately 5,000 pDCs from blood were harvested from 4 SIV- Rhesus macaques, and 8 SIV+ Rhesus, 4 SIV+ Sooty mangabeys, and 4 SIV- Sooty mangabeys. We also tested pDCs from 10 SIV+ RMs from lymph node, blood and gut at necropsy. We profiled gene expression in each subset using Illumina RNA-Seq. Samples were sequenced to depths of 15 M reads in 100-base single read reactions. The reads were aligned to the Macaca mulatta reference genome MacaM 7.0 using the STAR algorithm, and gene expression assessed using DESeq2 software.
Results: Strikingly, we found that although IFN-A and IFN-B transcripts were absent from pDCs isolated from blood and mucosa, but high levels of transcripts were detectable in in pDCs isolated from LNs of SIV-infected rhesus macaques. IFNA transcripts were not detectable CD4 T cells from either LN or blood. A contrast of transcriptional signatures in pDCs between rhesus (AIDS susceptible) and sooty mangabeys (AIDS resistant) demonstrated that pDCs in rhesus had significant upregulation of Interferon Stimulated Genes in SIV-infected RM, but not in SMs. Expression of lentiviral restriction factors and inhibitory genes was consistent across species and infection status of pDCs from the blood.
Conclusions: In this study, we demonstrate that Type I IFN is robustly detectable in pDCs isolated from LN, but not blood or gut in SIV-infected rhesus macaques. The identification of LN pDCs as the main source IFNA production provides a cellular target for depletion-based therapies.

JC virus progressive multifocal leucoencephalopathy clinical presentation and prognosis in HIV and non-HIV patients: a case series

M. Drapeau[1,2], S. Grandjean Lapierre[2,3], F. Coutlée[2,3], V. Lavergne[4], C. Fortin[2,3], S. Barkati[2], C. Renaud[5], L.-P. Haraoui[6,7], L. Leblanc[4], N. Khairallah[8], V. Martel-Laferrière[2,3], D. Rouleau[2,3]
[1]Université de Montréal, Montreal, Canada, [2]Centre Hospitalier de l'Université de Montréal, Montreal, Canada, [3]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montreal, Canada, [4]Hôpital du Sacré Coeur de Montréal, Montreal, Canada, [5]Centre Hospitalier Universitaire Ste-Justine, Montreal, Canada, [6]Centre Universitaire de Santé McGill, Montreal, Canada, [7]Hôpital Charles Lemoyne, Montreal, Canada, [8]Hôpital Maisonneuve Rosemont, Montreal, Canada

Background: Human polyomavirus JC (JCV) is responsible for progressive multifocal leucoencephalopathy (PML). Introduction of combined antiretroviral therapy (cART) and increased use of immunosuppressive and oncologic therapies have modified the epidemiology and prognosis of PML. This study objective was to evaluate and compare the prognosis, diagnostic delays and clinical and radiological presentation of PML in HIV and non-HIV patients.
Methods: This retrospective observational multicentre study was performed in 4 university-affiliated hospitals of Montreal (Quebec). Patients were recruited through laboratory information systems and clinical archives interrogation. Patients with positive JCV polymerase chain reaction on cerebrospinal fluid and/or with a clinical diagnosis of PML during a hospitalization episode between January 2009 and December 2016 were included. Clinical data were collected through medical chart review following institutional review board approval. Fisher´s exact test and Mann-Whitney tests were used for comparative analysis of categorical and continuous variables.
Results: The study includes 13 HIV-infected-patients and 8 non HIV-infected-patients. One-year survival and time to diagnosis delay data were respectively available for 13 and 10 patients in the HIV positive group and for 6 and 8 patients in the HIV negative group. One-year survival was 91.7 and 16.7 percent in the HIV positive and negative groups respectively (p=0.0039). Median time between initial symptoms and PML diagnostic was 70.5 (IQR: 32-147) and 31.5 (IQR 20-133.5) days in the HIV positive and negative groups respectively (p=0.45). No differences between groups were noted in clinical and radiological presentations.
Conclusions: Preliminary data suggest that PML prognosis is significantly better among HIV positive patients. Modern cART and immune status restoration could explain this finding. Whether PML or the underlying neoplastic or immunosuppressive condition is responsible for high mortality rates in the non-HIV population needs further exploring. Diagnostic delays, clinical and radiological presentations between HIV positive and negative patients showed no significant differences.

No effect of adjunctive corticosteroids on CD4 cell count recovery in HIV patients with *Pneumocystis jirovecii* pneumonia

T.I. de Vries, B.J. van Welzen, J.E. Arends, T. Mudrikova
UMC Utrecht, Department of Internal Medicine and Infectious Diseases, Utrecht, Netherlands
Presenting author email: tamarirene.devries@gmail.com

Background: Pneumocystis jirovecii pneumonia (PJP) remains an important cause of morbidity and mortality in HIV-infected patients. In case of severe hypoxemia, corticosteroids are added to the antibiotic therapy. As corticosteroids are known to cause lymphocytopenia, there are concerns that corticosteroid use will cause slower CD4 cell count increase after commencement of combined antiretroviral therapy (cART). The aim of this study was to evaluate CD4 cell count recovery after adjunctive corticosteroid treatment in ART-naïve HIV-infected patients with PJP starting cART.
Methods: HIV-infected patients who presented with PJP in the University Medical Center Utrecht (Utrecht, The Netherlands) between 1996 and 2015 were included in this retrospective study. Demographic and laboratory data, details on ART and corticosteroid treatment were retrieved from the hospital charts. The primary outcome was the difference in mean CD4 count increase between the corticosteroid-treated (CS) group and the non-corticosteroid (non-CS) group after 1-year follow-up. The association between corticosteroids and CD4 cell count increase was evaluated with linear mixed model adjusted for baseline CD4 counts, age and gender. Secondary outcomes were the time needed to achieve plasma HIV-RNA <400 copies/mL, and 1-year mortality and recurrence of or new opportunistic infections (OIs).
Results: Sixty-two patients (n=36 in the CS- and n=26 in the non-CS group) were included. The groups were matched at baseline except the more profound hypoxemia in the CS-group. There was no significant difference in the mean increase of CD4 cell counts at 1-year follow-up between the CS and non-CS group (243 versus 222; p=0.60). There was no significant association between the corticosteroid use and the increase in the CD4 count (p=0.41). Furthermore, there was no significant difference in the time to achieve HIV RNA < 400 copies/mL and occurrence of OIs between both groups in the first year after PJP diagnosis. All patients were alive at the end of follow-up.
Conclusions: No deleterious effect of adjunctive corticosteroids on CD4-cell count was seen in our cohort of HIV patients with PJP. It is reassuring for the treating physicians to know that this short course of corticosteroid therapy does not put these vulnerable patients at risk for future OIs.

TUPEB0367

Prevalence and determinants of rifampicin resistance among patients screened for tuberculosis by gene xpert assay in a military hospital, Lagos State, Nigeria January to June, 2016

O.B. Odegbemi[1,2,3], A. Abiodun[3], M.S. Balogun[1], L. Okeke[1]
[1]Nigeria Field Epidemiology and Laboratory Training Program, Laboratory Epidemiology, Abuja, Nigeria, [2]University of Ibadan, Epidemiology and Medical Statistics, Ibadan, Nigeria, [3]Nigerian Navy Reference Hospital, Medical Laboratory, Lagos, Nigeria
Presenting author email: kbprudence2000@yahoo.com

Background: Tuberculosis (TB) is an infectious disease which develops under conditions of deficient immunologic response. Antibiotic resistance is a growing problem with increasing rate of multi-drug resistant tuberculosis (MDR-TB). MDR-TB is a serious public health issue in many developing countries in that its treatment is longer and requires more expensive drugs. GeneXpert assay is a molecular technique that simultaneously detects Mycobacterium tuberculosis (MTB) and Rifampicin resistance (RR) in approximately 2 hours. This study was done to determine the prevalence of RR among MTB patients and associated risk factors.
Methods: A retrospective cross sectional review of patients screened for TB with GeneXpert assay at Nigerian Navy Reference Hospital, Ojo, Lagos State, Nigeria from January to June, 2016 was performed (n=257). Data analysis was done using Epi-Info Software, version 7.2 and Microsoft Office Excel 2007.
Results: Mean age of subjects was 35.1 ± 17.2 years and 132(51.4%) were females. 51(19.8%) were confirmed TB positive and age group 20-29 years were mostly affected 15(29.4%). Majority of the cases were students, 14(27.5%) and predominantly males 31(60.8%). Six (11.8%) of the MTB positive subjects were HIV positive and the prevalence of RR-TB was 11.8%. Age, (OR=0.3; CI=0.10-0.92), HIV status, (OR=0.3; CI=0.11-0.67) and Tribe, (OR=3.46; CI=1.75-6.81) were all significantly associated with TB while occupation, marital status and gender were not statistically significant. Of all tribes in the data, even though there were more Igbo/Urhobos, Yoruba accounts for the most affected ethnic category, accounting for 29(56.9%) TB confirmed cases as well as having 5(83.3%) out of the RR-TB cases (OR=10.1; CI 1.16-88.0). Other factors such as age, gender and HIV status were not significantly associated with the development of RR-TB.
Conclusions: There was high prevalence of Rifampicin resistant tuberculosis among the population studied and HIV/TB co-infection was present. Tribe was a determinant of RR-TB. We recommend that active surveillance should be intensified for early detection of cases and embarking on all-year mass public health sensitizations targeted at students and young adults on the knowledge and prevention of tuberculosis.

TUPEB0368

Increasing TB case detection through the active case findings (ACF) in selected slums project in Ajeromi local government area of Lagos state

E.I. Enwefah[1], Z. Williams[2], D. Owoyomi[3], B. Joseph[4]
[1]Rhoda Haven Network for Women Living with HIV and AIDS, Programme, Lagos, Nigeria, [2]Rhoda Haven Network For Women Living With HIV and AIDS, Monitoring and Evaluation, Lagos, Nigeria, [3]Health Alive Foundation, Program, Ilorin, Nigeria, [4]Health Alive Foundation, M&E, Ilorin, Nigeria
Presenting author email: evans_enwefah@yahoo.com

Background: Issues: Nigeria TB burden higher than previously estimated by WHO as revealed by the national TB Prevalence survey - 610,688 TB cases estimated out of which only 91,354 cases were notified (NTBLCP, 2014) Case detection for all forms now 17%-lowest in the world. Where resources is dwindling specific community targeted intervention must be carried out in TB prone slums using the vi-

sion 90;90;90 model. The Global Fund supported new funding model Active case findings (ACF) is designed to reach every household within a specific slum through door to door case search, while slum cost effective Advocacy Communication Social Mobilization (ACSM) interventions must be adopted to provide seamless support and referral linkages.
Methods: Appropriate Advocacy visit to key stakeholders facilitated the selection of 10 community TB workers (CTWs) 2 per slums to carry out daily door to door active search within specific slum. Community level mobilization, sensitization and demand creation for TB/HIV services through Behaviour Change Communication strategies were conducted in each slums. Quarterly stakeholders launch meeting was held in each of the 5 slums to provide feedback mechanism to address community related issues and provide action points. The trained CTWs carried out daily door to door search within the slums for presumptive TB clients while the program team fast track sputum collection and transport to Laboratory for diagnosis and referrals to DOTs for enrollment and treatment A total of 7,660 households were reached, 598 presumptive TB Clients were identified made up of Male,345 Female 253 and refer for AFB diagnosis. HIV Testing services (HTS) were routinely provided for all PTB clients.
Results: The ACF project in selected slums in Ajeromi Local Government Area in Lagos recorded huge increase in numbers of cases detected within the first eight months (March - December 2016). A total of 90 Active positive Cases referred by CTWs were diagnosed and place on treatment out of which 4 were co-infected (Male 60 Female 30) The quarterly stakeholder meeting provided feedback mechanism and needed impetus for community ownership
Conclusions: The active TB case finding in selected slums is yielding the expected result and can be scaled-up and replicated.

TUPEB0369

Performance of the interferon gamma release assay Quantiferon® TB gold in-tube for the diagnostic of tuberculosis in HIV-infected children

A. Vasiliu[1], P. Pean[2], M. Inghammar[1,3], N.L. Nguyen[4], A. Kabore[5], S.I. Eyangoh[6], O. Marcy[1,7], G. Carcelain[8], L. Borand[1], ANRS 12229 PAANTHER 01 Study Group
[1]Institut Pasteur du Cambodge, Epidemiology and Public Health Unit, Phnom Penh, Cambodia, [2]Institut Pasteur du Cambodge, Immunology Platform, Phnom Penh, Cambodia, [3]Lund University, Department of Clinical Sciences, Section for Infection Medicine, Lund, Sweden, [4]Pham Ngoc Thach Hospital, Biochemistry Laboratory, Ho Chi Minh City, Vietnam, [5]Centre Muraz, Departement des Sciences Biomédicales, Bobo-Dioulasso, Burkina Faso, [6]Centre Pasteur du Cameroun, Mycobacteriology, Yaounde, Cameroon, [7]Université de Bordeaux, Bordeaux Population Health - Centre INSERM U1219, Bordeaux, France, [8]Robert-Debré Hospital, APHP, Immunology Laboratory, Paris, France
Presenting author email: ancavasiliuro@yahoo.com

Background: Diagnosing tuberculosis is challenging in children, especially in those HIV-infected. There is a need for additional diagnostic tools. We assessed the performance of the Interferon Gamma Release Assay QuantiFERON Gold In-Tube (QFT) for tuberculosis diagnosis in HIV-infected children.
Methods: From April 2010 to May 2014, HIV-infected children ≤13 years with a suspicion of tuberculosis were included in the ANRS 12229 PAANTHER 01 study in Burkina Faso, Cambodia, Cameroon, and Vietnam after parental consent. In addition to clinical and microbiological assessment, QFT assays were performed. We evaluated sensitivity, specificity, positive and negative predictive (PPV, NPV) value of the QFT both in intention-to-diagnose (ITD) and per protocol approaches, using tuberculosis microbiologically-confirmed by culture or Xpert MTB/RIF as reference standard. We assessed the area under the-receiver operating characteristic curve (AUROC) for quantitative results of QFT. We identified factors associated with indeterminate QFT as compared with interpretable results using logistic regression models.
Results: Of 438 children enrolled in the study, 420 had QFT performed and were included in this evaluation. Their median age was 7.3 (IQR: 3.4-9.7) years and CD4 14% (IQR 3.2-24). 172 (39.5%) children were on ART. 54 (12.9%) children had microbiologically-confirmed tuberculosis. Overall, QFT was positive in 52 (12.4%) children, negative in 270 (64.3%), and indeterminate in 98 (23.3%). In those with microbiologically-confirmed tuberculosis, it was positive in 27 (50%), negative in 13 (24%), and indeterminate in 14 (26%). In intention-to-diagnose, QFT sensitivity was 50% (95%CI 45.2-54.8), specificity was 70% (95%CI 65.8-74.6), NPV was 90.5% (95%CI 87.7-93.3), and PPV 19.9% (95%CI 16.0-23.7). Per protocol, QFT sensitivity was 66.5% (95%CI 62.4-72.6) and specificity was 91% (95%CI 62.4-72.6). NPV and PPV were 95% (95%CI 92.8-97.5) and 52% (46.5-57.4), respectively. AUROC of QFT quantitative results for tuberculosis diagnosis was of 0.76. Factors independently associated with indeterminate QTF were: age <4yo (OR 2.6; IC95% 1.5-4.5), moderate and severe anemia [(OR 2.4; IC95% 1.3-4.7) and (OR 6.7 IC95% 3-14.9)], and CD4%< 10% (OR 2.4; IC95% 1.5-4.1).
Conclusions: QFT performed poorly due to a high proportion of indeterminate tests and sub-optimal sensitivity in microbiologically-confirmed tuberculosis, as reported previously.

TUPEB0370

TB diagnosis in HIV+ patients in Mozambique. A field study of combined point-of-care evaluation with GeneXpert, LAM and symptom screening

F. Ciccacci[1], M. Giuliano[2], M. Andreotti[2], M. Floridia[2], A. Hassane[3], Z.J. Sidumo[4], S. Orlando[5], E. Abramo[5], S. Mancinelli[5], F. Riccardi[5], L. Palombi[5], M.C. Marazzi[6]
[1]DREAM Program, Rome, Italy, [2]Istituto Superiore di Sanità, National Center for Global Health, Rome, Italy, [3]DREAM Program, TB Department, Maputo, Mozambique, [4]DREAM Program, Molecular Biology Laboratory, Maputo, Mozambique, [5]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [6]LUMSA University of Rome, Rome, Italy
Presenting author email: fausto.ciccacci@gmail.com

Background: Tuberculosis (TB) is a major public health concern in many African countries, especially in HIV+ patients, with important economic impact. Systematic screening and early diagnosis are keystones of the WHO End-TB strategy, and effective diagnostic algorithms and prevalence data are urgently needed.
Methods: All HIV+ patients >15 years eligible for antiretroviral therapy (ART) in the NGO DREAM health centres of Maputo, Machava and Beira (Mozambique) between September 2014 and October 2016 were screened for TB before starting ART, with a combined approach: the WHO 4-symptom screening (fever, cough, night sweats, weight loss) (4SS), a rapid test for detection of mycobacterial lipoarabinomannan in urine (LAM), and a molecular TB assay on sputum (GeneXpert, repeated if first result was negative). Patients positive to either GeneXpert or LAM were considered TB-infected, with TB treatment prescribed. All patients were prescribed ART.
Results: At closure of enrolment, 1004 patients (58.2% women) had WHO symptom screening, together with GeneXpert (n:999), LAM (n:1003), or both (n:998). Population characteristics at entry were the following (interquartile ranges): age 30-43; body mass index 19.4-25.4kg/m^2; CD4 count 142-396 cells/mm^3 (< 50/mm^3: 9.4%), plasma HIV-RNA 3.2-5.1 $\log_{10}$copies/ml, haemoglobin 10.3-13.1 g/dl. Most of the patients (66.2%) were clinically asymptomatic (HIV-WHO stage I). Rates of positivity were: 35.0% (352/1004) for 4SS (at least one symptom) and 10.2% (102/1004) for either GeneXpert or LAM, with significant territorial differences. Among 90 GeneXpert-positive patients, 16 had a first negative GeneXpert result. Among 38 LAM-positive patients, 26 were GeneXpert-positive, 10 GeneXpert-negative and 2 had no GeneXpert done. Among patients positive for either GeneXpert or LAM, 22 (21.6%) had negative WHO 4SS, corresponding to a prevalence in symptom-negative patients of 3.4%. Among GeneXpert-positive patients, LAM-positive patients had significantly lower median CD4 counts than LAM-negative patients (78 vs. 149/mm^3, p=0.005). Three of the GeneXpert-positive cases had rifampicin resistance (3.3%).
Conclusions: Based on point-of-care diagnostic tests, we found a 10.2% TB prevalence among HIV-positive patients eligible for ART in Mozambique, with limited occurrence of rifampicin resistance. Data underline the need of combined diagnostic approaches, possibly based on test repetition, in order to reduce the late-stage disease prevalence and its economic effects.

TUPEB0371

Isoniazid preventive therapy uptake and completion in the era of differentiated HIV care

K.H. Tram[1], F. Mwangwa[2], M. Atukunda[2], A. Owaraganise[2], J. Ayieko[3], A. Plenty[4], D. Kwariisima[2], T.D. Clark[5], M.L. Petersen[6], E.D. Charlebois[4], M.R. Kamya[7], G. Chamie[4], D.V. Havlir[4], C. Marquez[4]
[1]Stanford University School of Medicine, Stanford, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]University of California, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [5]University of Californi, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [6]University of California, Berkeley School of Public Health, Berkeley, United States, [7]Makerere University College of Health Sciences, School of Medicine, Kampala, Uganda
Presenting author email: ktram@stanford.edu

Background: HIV care is moving towards a differentiated care delivery model with less frequent ART visits. We measured the success of isoniazid preventive therapy (IPT) delivery, requiring 6 monthly visits for completion, when initiated in the context of a streamlined HIV care model with 3-month visits.
Methods: We screened a convenience sample of 137 HIV-infected adults receiving universal ART with streamlined HIV care for IPT eligibility at five government-sponsored clinics in rural Uganda as part of the SEARCH test and treat trial (NCT01864603). Streamlined care included patient-centered care with annual viral load measurements and clinic visits every 3 months for stable patients. During IPT, visit frequency was increased to monthly, per country guidelines. We measured: (1) IPT uptake: proportion who initiated IPT; (2) IPT completion: proportion

who picked up 6 refills of isoniazid; and (3) IPT/ART success: proportion achieving IPT completion and HIV viral load <500 copies/ml. We used multivariable logistic regression to examine factors associated with IPT completion.
Results: Of the 137 HIV-infected adults screened for IPT, 134 (98%) were eligible for IPT, 133 (97%) started IPT, and 97 (71%) completed IPT. Viral suppression was 93%, and 68% achieved both viral suppression and IPT completion. Mean age was 41.6. 75% were female. Median CD4 count was 513 (IQR:395-665). Median time since ART initiation was 2.3 years. 15% of patients reported a side effect within 2 weeks from IPT, with dizziness reported most frequently (10%). IPT completion was associated with age tertile (>45 years: aOR 5.8, 95%CI: 1.1-31.3, ref <36 years), wealth tertile (highest: aOR 3.9, 95%CI: 1.3-12.0, ref lowest), any education (aOR 2.8, 95%CI: 1.1-7.0), and experiencing a side effect in the first two weeks of treatment (aOR: 0.20, 95%CI: 0.11-0.39). Gender, marital status, and CD4 count were not associated with IPT completion.
Conclusions: Over 90% of screened patients receiving streamlined HIV care achieved viral suppression, but despite high IPT uptake, only 68% achieved both IPT completion and viral suppression. Harmonizing visit frequency for IPT and ART delivery while preserving safety in an era of differentiated HIV care may be necessary to achieve higher IPT completion rates.

TUPEB0372

Prevalence of darunavir resistance in the United States (2010-2015)

K. Brown[1], L. Stewart[1], J. Whitcomb[2], D. Yang[2], R. Nettles[1], E. Lathouwers[3]
[1]Janssen Scientific Affairs, LLC, Titusville, United States, [2]Monogram Biosciences, LabCorp, South San Francisco, United States, [3]Janssen Infectious Diseases BVBA, Beerse, Belgium
Presenting author email: elathouw@its.jnj.com

Background: Emergence and transmission of antiretroviral drug resistance is a concern among HIV-1-infected patients. Darunavir (DRV), approved for once-daily dosing in the US in 2010, has shown a high genetic barrier to resistance and its use in protease inhibitor (PI)-containing regimens has increased.
Methods: DRV and primary PI resistance were assessed in US clinical samples submitted to Monogram Biosciences for PhenoSenseGT® testing from January 2010-December 2015. 11 DRV and 23 primary PI resistance-associated mutations (RAMs) were evaluated. Annual frequency of individual RAMs and DRV RAMs were assessed among all samples and a subset with phenotypic resistance to ≥1 PI (fold-change >2x lower clinical/biological cut-off). Phenotypic resistance to DRV, atazanavir (ATV), and lopinavir (LPV) was evaluated.
Results: Among all samples (n=48,786), the proportion with 0 DRV RAMs was 92% in 2010 and 95% in 2015 (Table). During this period, the median number of DRV and primary PI RAMs was 0. The proportions of samples with phenotypic resistance to DRV, ATV, and LPV were respectively 3%, 6%, and 5% in 2010, and 2%, 4%, and 3% in 2015. Among the subset with phenotypic resistance to ≥1 PI (n=4,259; 9% of samples), the proportion with 0 DRV RAMs was 36% in 2010 and 2015. The median number of DRV RAMs was 1 in 2010 and 2015; correspondingly, the median numbers of primary PI RAMs were 3 and 2. The proportions with phenotypic resistance to DRV, ATV, and LPV were respectively 26%, 59%, and 54% in 2010, and 29%, 57%, and 48% in 2015.
Conclusions: The prevalence of DRV RAMs among commercially-tested isolates remained low and generally stable from 2010-2015. In 2015, 98% of samples demonstrated phenotypic sensitivity to DRV. Among the subset with phenotypic PI resistance, DRV sensitivity was maintained in 71% of samples, which was numerically greater than ATV (43%) and LPV (52%) in 2015.

	All samples (N=48,786)		Samples with phenotypic PI resistance (n=4,259)	
	2010	2015	2010	2015
Proportion of samples with 0 DRV RAMs[a]	92%	95%	36%	36%
Proportion of samples with ≥3 DRV RAMs[a]	3%	2%	28%	30%
Median number of DRV RAMs[a]	0	0	1	1
Median number of primary PI RAMs[b]	0	0	3	2
Frequency of individual DRV RAMs[a]	<1-4%[c]	<1-3%[c]	4-38%[c]	2-44%[c]
Frequency of individual primary PI RAMs[b]	<1-7%[d]	<1-5%[d]	1-50%[d]	<1-45%[d]
Proportion of samples with phenotypic resistance to DRV	3%	2%	26%	29%
Proportion of samples with phenotypic resistance to ATV	6%	4%	59%	57%
Proportion of samples with phenotypic resistance to LPV	5%	3%	54%	48%

PI, protease inhibitor; DRV, darunavir; RAM, resistance-associated mutation; ATV, atazanavir; LPV, lopinavir.

Feasibility of TB screening of unselected HIV-positive hospital admissions in sub-Saharan Africa: the STAMP trial

A. Gupta-Wright[1,2], E. Corbett[1,2], J.J. van Oosterhout[3], D. Wilson[4], M. Alufandika-Moyo[3], J. Peters[1], L. Chiume[2], S.D. Lawn[1], K. Fielding[1]
[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Dignitas International, Zomba, Malawi, [4]Edendale Hospital, Pietermaritzburg, South Africa
Presenting author email: ankurgw@outlook.com

Background: HIV-associated tuberculosis (TB) remains a significant cause of mortality in patients admitted to hospital in sub-Saharan Africa, much of which is left undiagnosed. The rapid urine-based Screening for TB to reduce AIDS-related Mortality in hospitalised Patients in Africa (STAMP) trial aims to determine the impact of a sensitive TB screening strategy on mortality, measured at 2-months, in Malawi and South Africa.
Methods: The study recruited unselected HIV-positive adult admissions to medical wards, irrespective of presenting complaint or presence of TB symptoms. 50mls of urine and a single sputum sample were requested at enrolment for TB screening. We report early enrolment data from the STAMP trial describing the feasibility and acceptability of this TB screening approach.
Results: 1,875 eligible patients were screened to date, with only 25 (1.3%) citing additional samples for TB screening as the reason for non-participation. Of the 1,629 patients enrolled across both sites, 56.1% were female. TB symptoms were common; current cough was reported by 52.7%, fever 62.2%, weight loss 70.2% and night sweats 42.2%. Overall, 91.5% were positive using the WHO four-symptom TB screen. In contrast, only 39.2% were suspected of having TB by the admitting clinical team. 248 (15.3%) of participants were newly diagnosed with HIV. Of those with an existing HIV diagnosis, 83.3% were currently taking antiretroviral therapy (ART). The median CD4 cell count was 212 cells/mm^3 (interquartile range 69-421). 99.1% of participants were able to produce a urine sample for TB screening but only 54.8% produced a sputum sample. 97.6% of sputum samples and 98.8% of urine samples tested with Xpert MTB/RIF produced valid results. 47.4% of participants had a chest x-ray done during their admission.
Conclusions: TB screening of unselected HIV-positive hospital admissions in sub-Saharan Africa is both feasible and acceptable to patients. Twice as many patients reported TB symptoms compared to those suspected of having TB by their clinicians, although both were common despite high ART coverage and median CD4 cell count >200cells/mm^3. Urine specimens could be produced by almost all patients, in contrast to sputum, and were tested using Xpert MTB/RIF with a very low error rate.

Distinct patterns of clinical characteristics in adult tuberculosis patients from urban compared to rural settings in Tanzania

G. Sikalengo[1,2], J. Hella[1,3,4], F. Mhimbira[1,3,4], L. Rutaihwa[1,3,4], K. Said[1,3,4], F. Bani[1,2], R. Ndege[1,2], E. Letang[1,3,4], M. Weisser[1,3,4], L. Fenner[1,3,4]
[1]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [2]St Francis Referral Hospital, Morogoro, Tanzania, United Republic of, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]University of Basel, Basel, Switzerland
Presenting author email: gsikalengo@ihi.or.tz

Background: Rural-urban settings could account for some of the differences in the epidemiology of tuberculosis (TB) in Tanzania. We aimed to study the epidemiology of TB and co-infections in adult patients from two distinct settings in Tanzania.
Methods: We included adult patients (>18 years) with smear-positive pulmonary TB consecutively enrolled in two ongoing cohort studies in the largest city of Tanzania, Dar es Salaam with ~4.3 million inhabitants (urban), and Ifakara in the sparsely populated Kilombero district with ~400,000 inhabitants (rural). Clinical and laboratory data were collected electronically from all participants at recruitment. Stool and urine were examined for intestinal helminths using Kato-Katz, Baermann, urine filtration and Circulating Cathodic Antigen tests. Differences between groups were assessed by Chi-square or Wilcoxon rank sum test as appropriate.
Results: We analyzed 602 participants enrolled between August/2015 and November/2016, 412 (68.4%) at the urban and 190 (31.6%) at the rural site. The median age was 34 (interquartile range [IQR] 27-41), 408 (67.8%) were men, and 152 (25.3%) were HIV-positive with a median CD4 cell count of 161 (IQR 117-295 cells/μL). Patients from the rural site were significantly older (median age 38 vs. 33 years, p=0.001), had a lower median body mass index (17.5 vs. 18.5 kg/m2, p=0.001), a lower median hemoglobin concentration (10.6 vs. 11.3, p=0.001), borderline lower median CD4 count (147 vs. 220, p=0.06) and a higher proportion of relapse cases (9.5% vs 1.2%, p< 0.001) compared to those from urban. There was no significant difference in the prevalence of HIV (23.5% vs. 29%, p=0.16) and diabetes mellitus (7.1% vs. 2.8%, p=0.07) between urban and rural settings. The overall prevalence of intestinal helminth co-infection was 22.1% (n=133) with no significant

difference across sites, with a higher prevalence of Schistosoma mansoni (15.9% vs. 3.5%, p< 0.001) at the rural site and lower prevalence of Strongyloides stercoralis at the urban site (5.5% vs. 15.9%, p=0.001).
Conclusions: Clinical and sociodemographic characteristics differ in TB patients from urban and rural Tanzania. The observed differences underline the need for public health interventions tailored to urban as well as rural settings to improve clinical outcomes of TB and co-infections.

Mycobacterium tuberculosis lateral flow urine lipoarabinomannan assay (TB-LAM) and cryptococcal antigen lateral flow assay (CRAG LFA) as screening among patients with advanced HIV-disease in Conakry, Guinea

L. Ndayisenga[1], J.D. Yuma[1], S. Boutouaba[1], A. Diallo[1], I. Adjaho[1], F. Kabongo[1], O. Tiemtoré[1], T. Ellman[2], P. Isaakidis[2], MSF B Guinea Study Group
[1]MSF Belgique, Santé, Brussels, Belgium, [2]MSF Belgium, SAMU HIV/TB Advisors, Johannesburg, South Africa
Presenting author email: msfocb-conakry-sida-coach@brussels.msf.org

Background: Guinea is a low HIV prevalence country (1.7%) with a high number of documented AIDS-related deaths in 2015[4600 (3700 - 5600), http://aidsinfo.unaids.org/] . Routine hospital morbidity and mortality data from tertiary hospitals consistently highlight tuberculosis and cryptococcal meningitis to be commonly leading causes of mortality and frequently diagnosed among advanced HIV-infected patients. Médecins sans Frontières (MSF) started systematically screening for tuberculosis and cryptococcus infection advanced HIV- infected patients using point-of-care technologies to foster early detection and treatment. The aim of this study was to document this screening strategy at an MSF HIV-clinic in Conakry, Guinea.
Methods: Retrospective analysis of routine data collected in laboratory registers. TB-LAM tests and CrAg LFA were used to screen HIV-infected patients >15 years presented to care with CD4 count <100 cells/ul, irrespective of antiretroviral treatment (ART) status, between 1st January 2015 to 30th June 2016. We estimated screening up-take and the yield of TB and cryptococcal antigenemia among patients screened.
Results: Among 616 HIV- infected patients with CD4 count < 100 cells/ml, mean age was 37 years [Inter Quartile Range (IQR): 15-86], median CD4-count was 28 cells/ml (IQR: 1-100), female were 66%, and 15 (2%), 47(7%), 388 (62%), 74 (12%) were on stage I, II, III & IV respectively. Up-take of screening was: 174/616 (28 %) for TB-LAM. and 366/616 (59%) for CRAG test. Respectively, 32 % of patients were TB-LAM Positive and 4% of patients screened using lateral flow assay for CrAg were positive. According to the ART status, the prevalence of TB-LAM positive tests was 37% in post ART, 26% in pre-ART patients and 4% , the same in pre ART and post ART patients, for CRAG test.
Conclusions: Up-take of a screening strategy using point-of-care tests for TB and cryptococcal infection among patients with advanced HIV disease in Guinea was low, especially for TB. The yield was high for TB and relatively low for cryptococcal disease. The implementation of a systematic screening strategy in settings with high advanced HIV disease burden is challenging but remains essential.

TUPEB0376

Use and effects of pediatric isoniazid preventative therapy (IPT) in HIV-positive patients at the Baylor Clinical Center of Excellence (COE) in Mbabane, Swaziland

A.L. Rosen-Gooding[1], A.W. Kay[1], N. Mthethwa[2], S. Dlamini[2], K. Ngo[1], A. Mandalakas[1]
[1]Baylor College of Medicine, Department of Pediatrics, Global Tuberculosis Program, Houston, United States, [2]Baylor College of Medicine - Bristol Meyers Squibb Children's Center of Excellence, Mbabane, Swaziland
Presenting author email: anyalynn.rg@gmail.com

Background: People living with HIV (PLHIV) are especially susceptible to tuberculosis (TB), with >70% of TB cases in Swaziland occurring in PLHIV. Isoniazid preventative therapy (IPT) has been recommended for PLHIV ≥1 year of age regardless of TB exposure since 2009 and all PLHIV including infants <1 year of age following close exposure to infectious TB. To enhance IPT program strategies, we assessed IPT prescribing practice and effectiveness in pediatric HIV patients (ages 1-17 years) at the Swaziland-Baylor Children's Foundation Center of Excellence (COE).
Methods: Retrospective analysis was conducted using patient data from the COE electronic medical records (EMR), from February 2006 through November 2016, focusing on which patients were prescribed IPT, effect of IPT on antiretroviral therapy (ART) adherence, and risk factors for developing TB after IPT. Crude odds ratios were obtained and adjusted odds ratios calculated using logistic regression. A paired t-test was used to evaluate ART adherence before and after IPT.
Results: Of 1664 eligible pediatric patients identified with over 10 visits to the COE and at least one visit after 2009, 922 (55.4%) have been prescribed IPT. Of 305 patients who initiated IPT over four years ago, 64 (20.1%) later developed TB. Past TB, age >14 years, <40 clinic visits, and ART adherence <95% were negatively associated with being prescribed IPT, while CD4 < 500 and age <5 years were positively associated with IPT prescription. Children with CD4 counts <500 and ART naïveté at IPT initiation were more likely to develop TB following IPT. Average ART adherence (measured via pill count) decreased by 0.5% (p=0.001) during IPT as compared to the preceding year in the cohort as a whole; however, those with <95% ART adherence before IPT initiation (n=23) increased ART adherence by 4.4% (p<0.001) during IPT.
Conclusions: We have identified patients at increased risk for IPT failure and missed opportunities for IPT prescription. Although clinicians were wary of prescribing IPT to children with low ART adherence, this population experienced an increase in ART adherence during IPT. Children at higher risk of developing TB after IPT may benefit from additional courses of IPT.

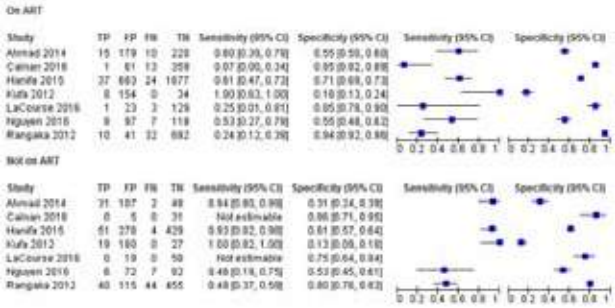
WHO four-symptom screening for tuberculosis in people living with HIV receiving antiretroviral therapy: a systematic review

Y. Hamada[1], J. Lujan[1], N. Ford[2], H. Getahun[1]
[1]World Health Organization, Global TB Programme, Geneva, Switzerland, [2]World Health Organization, Department of HIV/AIDS, Geneva, Switzerland
Presenting author email: yohei.hamada0@gmail.com

Background: WHO currently recommends the use of four-symptom screening (defined as positive by the presence of any one of cough of any duration, loss of weight, night sweats and fever) to exclude active tuberculosis (TB) prior to initiation of TB preventive treatment in people living with HIV (PLHIV). We systematically reviewed the published evidence supporting the diagnostic accuracy of WHO symptom screening.
Methods: We searched studies published between 2011 and 2016 using Pubmed and Embase as well as abstracts from TB and HIV international conferences. We included primary studies reporting data on the four-symptom screening in PLHIV. The gold standard of the diagnosis of active TB was at least one positive culture or Xpert MTB/RIF. Randomized trials, cross-sectional studies, and cohort studies were included. We assessed the potential influence of ART status and pregnancy in subgroup analysis. We also assessed the additive effect of chest x-ray.
Results: From an initial screen of 3683 records we included 17 studies; additionally 3 conference abstracts were included from 16 countries. Of these 20 studies, data disaggregated by HIV status were available from 7 studies (Figure). The pooled sensitivity and specificity of the four-symptom screening for PLHIV on ART was 51.0% (95% confidence interval [CI] 28.4%-73.2%) and 70.7% (47.7%-86.4%), respectively compared to 88.5% (55.0%-98.0%) and 46.5% (24.5%-70.0%) for those not receiving ART. For studies that also included chest x-ray pooled sensitivity was higher (77.8%, 63.4%-87.6%) but specificity was lower (30.3%, 27.0%-33.8%).
Conclusions: The available data suggest the four-symptom screening can still be used for excluding active TB before preventive treatment. Consideration should be given to adding chest x-ray to the four-symptom screening in PLHIV on ART to improve sensitivity for detecting and ruling out active TB prior to initiation of TB preventive treatment.



[Forest plot of the sensitivity and specificity]

Could GeneXpert MTB/RIF be useful in detecting NTM infections in HIV patients?

C.R. Swathirajan[1], R. Vignesh[1,2], S.S. Solomon[1,3], S. Saravanan[1], P. Balakrishnan[1]
[1]YRG Centre for AIDS Research and Education, Chennai, India, [2]UniKL-Royal College of Medicine Perak, Laboratory-Based Department, Ipoh, Malaysia, [3]Johns Hopkins School of Medicine, Baltimore, United States
Presenting author email: swathi@yrgcare.org

Background: Tuberculosis (TB) continues to be a leading cause of morbidity and mortality in developing countries. Rapid diagnosis is essential for controlling and preventing spread of TB infection. The Real-Time PCR based GeneXpert MTB/RIF assay is a promising diagnostic tool, owing to its rapid and accurate results in detecting Mycobacterium tuberculosis (MTB) and rifampicin (RIF) resistance.
We propose an additional utility of GeneXpert MTB/RIF to detect non-tuberculous mycobacteria (NTM) among cases tested negative for MTB, following an algorithm.
Methods: The performance characteristics of GeneXpert MTB/RIF assay was evaluated with stored sputum specimens and EQAS strains (n=140) with known AFB culture results based on BACTEC-MGIT. Seventy two of them were negative for MTB and NTM, 39 were MTB positive and 29 were culture positive for NTMs. The detailed results of GeneXpert MTB/RIF assay were investigated for the presence of any significant markers to detect NTM positivity.
Results: It was observed that in 13 of the 29 NTM specimens tested, the molecular beacons (either probe A or probe C) were amplified and all these cases were smear positive as well. Thus, when evaluated based on the C_t values of the molecular beacons, the sensitivity and specificity of GeneXpert MTB/RIF assay in detection of NTMs were found to be 44.8% and 100%, respectively.
Conclusions: The results show potential utility for detection of NTMs using GeneXpert MTB/RIF assay. The lower sensitivity observed for detection of NTMs could possibly be related to the mycobacterial species tested. Therefore, GeneXpert negative sputum specimens, but smear positive and positive Ct values in probe A or C should be suspected for possible presence of NTMs and these specimens should be subjected to either culture or other available assays for the detection of NTM infection. This algorithm could be particularly more useful in HIV care settings, where the NTMs are common.

TUPEB0379

High mortality among HIV-positive patients with MDR-TB and second-line drug resistance reflects the urgent need for new drug regimens

E. Mohr[1], J. Hughes[1], L. Trivino Duran[1], J. Daniels[1], B. Chabalala[1], S.J. Steele[2], G. Ferlazzo[3], A. Shroufi[2], E. Goemaere[3], V. De Azevedo[4], T. Ellman[5], A. Moore[1], H. Cox[6]
[1]Medecins Sans Frontieres, Khayelitsha, South Africa, [2]Medecins Sans Frontieres, Cape Town, South Africa, [3]Medecins Sans Frontieres, South African Medical Unit, Cape Town, South Africa, [4]City Health Department, Cape Town, South Africa, [5]Medecins Sans Frontieres South African Medical Unit, Cape town, South Africa, [6]University of Cape Town, Cape Town, South Africa
Presenting author email: msfocb-khayelitsha-doc2@brussels.msf.org

Background: Treatment success rates for MDR-TB patients with resistance to second-line (SL) injectable agents and/or fluoroquinolones are approximately 15-40%, with high rates of mortality.
Methods: Mortality and patient outcomes from a treatment programme in Khayelitsha, South Africa were assessed 24-months after MDR-TB diagnosis, among patients with SL-resistance detected at diagnosis or during SL-treatment.
Results: From 2008-2013, 167 patients, 71% HIV-positive, were diagnosed with MDR-TB with resistance to either ofloxacin (n=52,31%) or amikacin (n=59,35%) or both (XDR-TB, n=56,34%). Fifteen percent (25/167) of patients never started treatment; 88% were HIV-positive. Another 39 (n=28, 72% HIV-positive) MDR-TB patients, had SL-resistance detected during treatment.
Overall, 24-month mortality was 47% (97/206); 54%(79/146) among HIV-positive and 30%(18/60) among HIV-negative patients(p<0.01). Of those that died, 22%(21/97) died before treatment initiation within a median of 21-days (IQR 13-35); 84%(21/25) that never started treatment died. Mortality was 37% compared to 46% for MDR-TB with ofloxacin resistance only or amikacin resistance only at diagnosis, respectively (p=0.32).
Patients diagnosed with XDR-TB had high mortality at 64% (36/53) (p<0.01 compared to resistance to only one SL-drug). Mortality among MDR-TB patients with SL- resistance detected during SL-treatment was 39% (15/39). Mortality was 70% (30/43) among HIV-positive patients with XDR-TB. Overall, 12% (25/206) were successfully treated.
Conclusions: Mortality was extremely high 24-months following diagnosis of MDR-TB with SL-resistance detected at diagnosis or during treatment. The presence of resistance to ofloxacin or amikacin had similar impacts on mortality. HIV-infection contributed substantially to mortality, but mortality remains high among HIV-negative patients, particularly those with XDR-TB. There is a pressing need for urgent treatment initiation and more effective regimens at initial diagnosis of SL-resistance.

TUPEB0380

Usefulness of screening latent tuberculosis infection (LTBI) using interferon-gamma releasing assay and treating LTBI to prevent developing active tuberculosis in Korean HIV-infected patients

S. Lee, J.H. Mok, J.E. Lee, J.S. Kang, K.-H. Kim, S.G. Lee, S.H. Lee
Pusan National University Hospital, Busan, Republic of Korea
Presenting author email: ebenezere.lee@gmail.com

Background: HIV-infected patients are high risk group of developing active tuberculosis. Howere, there is few study concerning usefulness of interferon-gamma releasing assay (IGRA) for developing active tuberculosis among HIV infected patients in country with intermediate tuberculosis burden.
Methods: To identify the usefulness of IGRA test to diagnose latent tuberculosis and predict active tuberculosis, retrospective cohort study was conducted at a large tertiary care hospital in Korea. HIV-infected patients who had ≥ 1 IGRA test results from Jan 2006 to Dec 2015 were enrolled excluding patients with active tuberculosis or previous tuberculosis history. We evaluated the effectiveness of isoniazid prophylaxis to prevent developing active tuberculosis.
Results: Among 603 HIV-infected patients with IGRA tests, 35 active tuberculosis patients and 94 patients with previous tuberculosis history were excluded. Sixty four patients (13.5%) were positive for IGRA test, 400 (84.4%) negative and 10 (2.1%) equivocal.
Sixty three IGRA positive patients and 345 IGRA negative patients were retained in care for more than 1 year. Incidence rate of active tuberculosis of IGRA positive versus negative patients were 12.05 (95% CI 3.06-32.79)/1000 person-years versus 0.72 (95%CI 0.03-3.55)/1000 person-years (p=0.001). Sensitivity, specificity, positive predicative value and negative predictive value of IGRA test was 75% (19.4-99.4%), 85.2% (81.3-88.5%), 4.8% (1.0-13.3%), and 99.7% (98.4%-99.9%), respectively. Among 63 patients with positive IGRA test, 26 were treated for latent tuberculosis infection (LTBI) and 37 were not. There was no active tuberculosis development among patient with LTBI treatment while 3 active tuberculosis developed among patients without LTBI treatment.
Among 345 patients with negative IGRA test, 264 patients received follow-up IGRA test and 34 (12.9%) patients converted to positive. There was a tendency to conversion of IGRA test in patients with low initial CD4 + T cell counts although there was no statistical significance (CD4 ≤100, 19.6% vs. > 100, 11.5%, p = 0.136). No active tuberculosis developed in patients with IGRA conversion.
Conclusions: Screening of LTBI using IGRA test and treatment of LTBI can be useful to protect developing active tuberculosis in intermediate tuberculosis burden country such as Korea. Clinical significance of conversion of IGRA test is not clear and further study is warranted.

Gemycircularviruses in HIV-positive patients, France

P. Biagini[1], C. Tamalet[2], P. Colson[2]
[1]EFS Alpes-Méditerranée, UMR 7268 ADES, Aix Marseille Université, CNRS, EFS; IHU Méditerranée Infection, Marseille, France, [2]IHU Méditerranée Infection, Assistance Publique-Hôpitaux de Marseille, Centre Hospitalo-Universitaire Timone, Pôle des Maladies Infectieuses et Tropicales Clinique et Biologique, Fédération de Bactériologie-Hygiène-Virologie, Aix-Marseille University, URMITE UM 63 CNRS 7278 IRD 198 INSERM U1095, Marseille, France
Presenting author email: philippe.colson@univ-amu.fr

Background: Gemycircularviruses (family Genomoviridae) are a group of highly diverse single-stranded DNA viruses (genome length ~2,100 nt), initially found in fungi and plants. Their identification in animal and human biologic samples, including blood, was described recently, as exemplified by our characterization of a full-length viral genome from a HIV-positive plasma sample (Uch et al, Emerg Infect Dis 2015).
In order to add clue to potential co-infections occurring in HIV-infected persons, we tentatively investigated both distribution and diversity of gemycircularviruses DNA in a French cohort of patients.
Methods: Five hundred HIV-positive patients entered the study; initial investigation focused on the PCR screening of 10 plasma pools (10 microliters of 50 plasma samples). In a way to optimise the detection of viral DNA, pools were pre-treated by nucleases, followed by particle-protected nucleic acids extraction (NucliSENS easyMag, bioMérieux) and 2-hour Phi-29 DNA polymerase treatment.

Gemycircularviruses DNA was investigated using in-house PCR systems based on updated data (Krupovic et al., Arch Virol 2016): 6 hemi-nested amplifications systems were designed (<200 bp), following alignment of Rep gene sequences and subsequent selection of clusters harbouring at least one gemycircularvirus sequence identified in humans. Resulting amplification products were cloned, sequenced, and analysed phylogenetically.
Results: Of the 10 plasma pools tested, 3 exhibited positive signals for 1 PCR system; sequence analysis confirmed the gemycircularvirus origin of corresponding amplification products. Nucleotide divergence in the range 1-9% (140 nt tested) were identified with the closest genomic sequences characterized previously in human blood or pericardial fluid. Observed genetic diversity between amplified sequences reached 8%.
Conclusions: These first data confirm the presence of gemycircularviruses in circulating blood of HIV-infected patients. They also suggest significant genetic diversity with gemycircularvirus sequences previously detected in humans based on short sequences analysed.

TUPEB0382

CMV disease and CMV specific IFN-gamma/IL-2 response impairment despite CD4+ lymphocyte recovery

T. Katsivas[1], C. Chan[2], N. Weidner[3], W. Freeman[2], R. Schrier[3]
[1]Univeristy of California, Medicine, San Diego, United States, [2]Univeristy of California, Ophthalmology, San Diego, United States, [3]Univeristy of California, Pathology, San Diego, United States
Presenting author email: tkatsivas@ucsd.edu

Background: CMV end organ disease in HIV after CD4+ recovery is poorly understood. In a case of active de novo CMV retinitis (CMV-R) in a patient with CD4+ count of 405 with prior history of CMV proctocolitis, we investigated the immunologic responses to CMV at 8, 44 and 80 wks after presentation, induction and ongoing suppression of CMV-R.
Methods: PBMCs from JM and HIV+/CMV+ asymptomatic controls and CSF from JM were assayed at each time point. Immune function assays following 24 hrs or 6 days of culture with CMV and HIV antigens, intracellular cytokine expression and T-cell proliferation at 6 days, intracellular staining for CD4+ and CD8+ cell populations and flow cytometry were performed.
Results: At 8 wks, JM exhibited high levels of TNFa by PBMCs and CSF, with no PBMC TNFa responses to CMV at 24 hrs, but detectable TNFa responses to CMV by both CD4+ and CD8+ in CSF; there were no IFNg and IL-2 responses to CMV at 24 hrs and 6 days, compared to control. JM displayed strong CD4+ and CD8+ CMV proliferative responses at 6 days by PBMC and CSF cells. At 44 wks, there was borderline IFNg and IL-2 response by CD8+ to CMV in CSF and PBMCs. At 80 wks, there was detectable low IFNg response by CD4+ and CD8+ to CMV in PBMCs and CSF.
Conclusions: CMV-R can occur in failure of CMV proliferation responses reconstitution; but high IFNg, IL-2 and TNFa cytokine expression are maintained. JM's robust proliferative response suggests recovery of CMV central memory CD4+ and CD8+ responses both locally (in CSF) and in blood, but there were no IFNg and IL-2 responses at 24 hours and 6 days. The high lymphocyte count in CSF, strong CMV proliferative response, elevated proliferation at 6 days and TNFa at 24 hours, indicate continued activation and inflammation in CSF. Absence of IFNg and IL-2 responses partially restored at 80 weeks. Predominant proliferating cells in response to CMV at 8 weeks were CD4+CD8+ and at 80 weeks CD3-CD4-CD8-CD56+ NK-like cells. The impairment in IFNg and IL-2 responses and immune signaling might explain CMV-R in this subset of patients.

TUPEB0383

Effect of sex and hepatitis C co-infection on HIV treatment and mortality: a 15-year follow-up

T.J. O'Neill[1,2], J. Raboud[3,4], C. Cooper[5], M. Loutfy[6,7], M.B. Klein[8], R.H.H. Thein[1], A.N. Burchell[1,9,10], Canadian Observational Cohort Collaboration
[1]Dalla Lana School of Public Health, University of Toronto, Division of Epidemiology, Toronto, Canada, [2]Ontario HIV Treatment Network, Toronto, Canada, [3]Toronto General Research Institute, Toronto General Hospital, University Health Network, University of Toronto, Toronto, Canada, [4]Dalla Lana School of Public Health, University of Toronto, Division of Biostatistics, Toronto, Canada, [5]Ottawa General Research Institute, The Ottawa General Hospital, Ottawa, Canada, [6]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [7]Maple Leaf Medical Clinic, Toronto, Canada, [8]McGill University Health Centre, McGill University, Montreal, Canada, [9]Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada, [10]University of Toronto, Department of Family and Community Medicine, Toronto, Canada
Presenting author email: t.oneill@mail.utoronto.ca

Background: We aimed to investigate if hepatitis C (HCV) co-infection is modified by biologic sex on time to virologic suppression (VS)(two consecutive viral loads < 50 copies ≥3 months apart), rebound (VR)(two consecutive viral loads ≥50 copies/mL ≥3 months apart), and all-cause mortality in HIV disease.
Methods: Using data from the Canadian Observational Cohort Collaboration, a multi-site cohort of HIV+ adults (≥18 years) initiating antiretroviral therapy (ART) 2000-14, Fine and Gray models adjusted for competing risk of death estimated the hazard ratio (HR) and 95% confidence intervals (CI) of sex and HCV on time to VS following ART initiation and to VR following VS. A Cox proportional hazard model estimated time to death following ART initiation. Multiple imputation methods estimated missing HCV status (5% missing), race (37%), IDU (13%), and MSM (20%).
Results: Of 10,400 participants (median follow-up 5.0 years), 1865 were women (38% HIV-HCV) and 3583 men (21% HIV-HCV). Cumulative incidence differed significantly ($p < 0.001$) for
(i) VS at 48 weeks between men (HIV: 88.8%; HIV-HCV: 85.8%) and women (HIV: 93.5%; HIV-HCV: 80.0%)
(ii) VR (1134 events) 12 weeks following VS for men (HIV: 4.8%; HIV-HCV: 13.5 %) and women (HIV: 11.8%; HIV-HCV: 21.1%) and
(iii) for all-cause mortality at one year between men (HIV: 2.2%; HIV-HCV: 6.5%) and women (HIV: 0.1%; HIV-HCV: 7.0%).
Compared to HIV+ men, co-infected participants were less likely to achieve VS and at higher risk for mortality. Risk of VR was higher for HIV+ women and co-infected participants relative to HIV+ men. We failed to detect significant interaction effects.

		HIV	HIV-HCV	HCV within sex	p value
Outcomes	**Sex**	**aHR* (95% CI)**	**aHR* (95% CI)**	**aHR* (95% CI)**	**(HCV*sex)**
(i) Virologic Suppression	**Male**	1.00	0.86 (0.79, 0.93)	0.86 (0.79, 0.93)	0.48
	Female	1.04 (0.90, 1.13)	0.82 (0.79, 0.98)	0.96 (0.86, 1.07)	
(ii) Virologic Rebound	**Male**	1.00	1.57 (1.32, 1.89)	1.57 (1.32, 1.89)	0.42
	Female	1.35 (1.07, 1.73)	1.96 (1.54, 2.49)	1.44 (1.08, 1.94)	
(iii) All-Cause Mortality	**Male**	1.00	1.83 (1.44, 2.33)	1.83 (1.44, 2.33)	0.59
	Female	0.79 (0.52, 1.20)	1.81 (1.33, 2.47)	2.30 (1.46, 3.64)	
*Adjusted for variables shown plus age, race, injection drug use, men having sex with men status, province, baseline viral load, CD4 cell count, AIDS defining illness, ART class, and year of ART initiation.					

[Adjusted models with marginal effect of infection]*

Conclusions: HIV-HCV co-infected have poorer responses to ART with greater risk of mortality. Although women were more likely to rebound, sex did not moderate outcomes. Further work is necessary in other observational settings and in response to modern HCV therapies.

TUPEB0384

Glecaprevir/pibrentasvir fixed dose combination for 8 or 12 weeks in patients co-infected with HCV and HIV-1: a sub-analysis of the phase 3 ENDURANCE-1 study

M. Puoti[1], J.J. Feld[2], S. Wang[3], R. Bruck[4], C. Moreno[5], J.-F. Dufour[6], G. Sepulveda-Arzola[7], H. Laferl[8], F. Nevens[9], R. Soto-Malave[10], F. Felizarta[11], B. Müllhaupt[12], S.C. Gordon[13], C.-W. Lin[14], T.I. Ng[15], B. Fu[15], F. Mensa[15]
[1]AO Ospedale Niguarda Ca Granda, Milan, Italy, [2]Toronto Centre for Liver Disease, Toronto, Canada, [3]AbbVie, Redwood City, United States, [4]Tel Aviv Medical Center, Tel Aviv, Israel, [5]CUB Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium, [6]Bern University Hospital, Hepatology, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland, [7]Instituto de Investigación Científica del Sur, Ponce, Puerto Rico, [8]Kaiser Franz Josef Hospital, 4th Medical Department with Infectious Diseases and Tropical Medicine, Vienna, Austria, [9]University Hospitals KU, Leuven, Belgium, [10]University of Puerto Rico, San Juan, Puerto Rico, [11]Private Practice, Bakersfield, United States, [12]University Hospital, Zurich, Switzerland, [13]Henry Ford Health System, Detroit, United States, [14]Abb, North Chicago, United States, [15]AbbVie, North Chicago, United States
Presenting author email: stanley.wang@abbvie.com

Background: The once-daily direct-acting antivirals (DAAs) glecaprevir (identified by AbbVie and Enanta)/pibrentasvir (G/P) have demonstrated high efficacy in patients with hepatitis C virus (HCV) infection. The Phase 3 ENDURANCE-1 study evaluated G/P (300 mg/120 mg) for 8 versus 12 weeks in HCV genotype (GT) 1-infected, non-cirrhotic patients with or without HIV-1 co-infection. Rates of sustained virologic response 12 weeks post-treatment (SVR12) were >99% in mono-infected, DAA-naïve patients, demonstrating non-inferiority of 8-week to 12-week treatment. Herein we report the efficacy and safety of G/P in HCV/HIV-1 co-infected patients.
Methods: ENDURANCE-1 was an open label, randomized study evaluating 8- versus 12-week G/P in treatment-naïve and -experienced HCV GT1-infected non-cirrhotic patients. HIV-1 co-infected patients with suppressed HIV RNA on stable antiretroviral regimens including the backbone agents of emtricitabine/tenofovir disoproxil fumarate or abacavir/lamivudine with an anchor agent of raltegravir, dolutegravir or rilpivirine, or antiretroviral-naïve patients with stable CD4 counts (≥500 cells/mm^3) were allowed. Safety, CD4 count and HIV-1 RNA levels were monitored. The primary endpoint was SVR12 (HCV RNA < 15 IU/mL).
Results: In total, 33 HCV/HIV co-infected patients were enrolled. Demographics and safety are shown in Tables 1 and 2, respectively.

Characteristic	8-Week G/P	12-Week G/P
Male, n/N (%)	14/15 (93)	15/18 (83)
Age, median (range) years	47 (31-69)	47 (26-60)
HCV treatment-experienced	5/15 (33)	6/18 (33)
HCV RNA, median (range), log10 IU/milliliter	6.26 (5.27-7.14)	6.30 (5.36-6.90)
Raltegravir-containing ART, n/N (%)	7/15 (47)	3/18 (17)
Dolutegravir-containing ART, n/N (%)	5/15 (33)	12/18 (67)
Rilpivirine-containing ART, n/N (%)	3/15 (20)	3/18 (17)
CD4+ cell count, median (range), cells/mm3	644 (211-1098)	801 (362-1208)

[Table 1. Baseline Demographics and Disease Charact]

SVR12 rates were 100% in both 8- and 12-week arms. No adverse events (AEs) occurred in more than 10% of overall patients; no patient experienced confirmed HIV virologic failure (HIV RNA ≥200 copies/mL). Prevalence of baseline polymorphisms in NS3 and NS5A will be presented.

Event, n/N (%)	8-Week G/P	12-Week G/P
Any AE	6/15 (40)	11/18 (61)
AEs leading to study drug discontinuation	0	0
Serious AEs	0	1/18 (6)
ALT Grade ≥2 (>5 × ULN), post nadir	0	0
AST Grade ≥2 (>5 × ULN)	0	0
Total Bilirubin Grade 3 (>3-10 × ULN)	1/15 (7)	0

[Table 2. Safety and Laboratory Abnormalities]

Conclusions: The once-daily, interferon- and ribavirin- free regimen of G/P administered for 8 or 12 weeks in HCV GT1/HIV-1 co-infected patients without cirrhosis was well-tolerated and achieved a 100% SVR12 rate, suggesting that co-infection with HIV has no impact on the efficacy of G/P.

TUPEB0385

Association of uncontrolled HIV-RNA with failure to direct acting antiviral (DAA) combinations in HIV/HCV co-infected patients on antiretroviral therapy (ART): ANRS CO13 HEPAVIH cohort

Background: In HIV/HCV co-infection, DAA treatment regimens achieve virological cure in ≥90%. Factors associated with failure and frequency of resistance-associated substitutions (RASs) are not well documented.
Methods: This sub-study, performed in the French ANRS CO13 HEPAVIH cohort, included HIV/HCV co-infected patients starting a first all-oral DAA regimen before January 2016 (3 months treatment) or October 2015 (6 months treatment). Failure was defined as:
i) a non-response if HCV-RNA remained detectable at any time during treatment, at end of treatment (EOT) or still detectable after EOT,
ii) a breakthrough if HCV-RNA became undetectable at least once during treatment and was again detectable at EOT and thereafter,
iii) a relapse in case of a detectable HCV-RNA after EOT after suppression at EOT,
iv) a death during treatment with last HCV-RNA positive.
Exact logistic regression was used to identify factors associated with failure.
Results: Of 516 patients fulfilling inclusion criteria, 33 patients (6.4% [95%CI: 4.4-8.9]) failed DAA therapy with 24 relapses, 4 non-responses, 1 breakthrough, 1 death under treatment and 3 non evaluable failures (viral load at EOT not known) on the following regimen: sofosbuvir (SOF) + daclatasvir (DCV) ± ribavirin (RBV) in 11 patients (33%), SOF + RBV in 11 (33%), SOF/ledipasvir ± RBV in 8 (25%) and SOF + simeprevir in 3 (9%). Mean treatment duration was 16 weeks [1-50]; 70% were HCV treatment-experienced; HCV genotype was 1/3/4 in 45%/15%/27%, respectively. All failing patients were on ART with suppressed HIV-RNA (< 50 copies/mL at DAA treatment initiation in 72%); 48% were cirrhotic. Post-treatment NS3 or NS5A RAVs were detected in 8/14 (57%) of patients with samples available for sequencing analysis. In patients receiving at least 2 DAA +/-RBV, after adjustment for age, sex, ribavirin use, cirrhosis stage and treatment duration, a detectable HIV-RNA was the only factor associated with a higher risk of failure (OR: 2.8; 95%CI: 1.02-7.6).
Conclusions: In this prospective real-life cohort, failure to all-oral DAA regimens occurred in 6.4% of the patients. The low rate of HIV control despite ART in patients failing HCV treatment might indicate poor adherence to both ART and anti-HCV treatment.

TUPEB0386

HBV co-infection is associated with high one-year mortality in HIV-infected Tanzanians on ART

B. Christian[1], E. Fabian[1], L.R. Ammerman[2], I. Macha[1], C. Gawile[1], S. Mpangala[1], N. Ulenga[1], C. Thio[3], R. Murphy[2], C. Hawkins[2]
[1]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [2]Northwestern University Feinberg School of Medicine, Chicago, United States, [3]Johns Hopkins University, Baltimore, United States
Presenting author email: c-hawkins@md.northwestern.edu

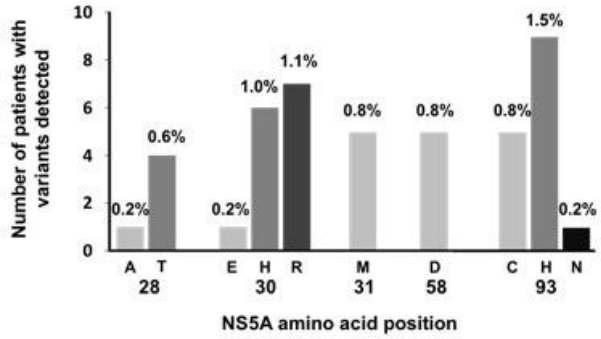
Background: There is limited data on the effect of HBV-active antiviral therapies on liver fibrosis progression and other clinical outcomes in HIV- and HBV-infected individuals in sub-Saharan Africa.
Methods: We conducted a prospective analysis of 267 HIV-monoinfected, 165 HBV-monoinfected and 63 HIV/HBV-coinfected adults (≥18), enrolled between April 2014- Dec 2015 and followed for 12 +/- 2 months on HBV-active therapy, at Management and Development for Health (MDH) supported HIV Care and Treatment clinics in Dar es Salaam, Tanzania. All HIV-monoinfected and HIV/HBV-coinfected patients received tenofovir, lamivudine plus efavirenz; all HBV-monoinfected patients received lamivudine. Multivariate (MV) regression models were constructed to identify factors associated with mortality in HIV- and HIV/HBV-coinfected patients.
Results: At baseline, HBV-monoinfected patients were younger and had higher BMI´s than HIV-monoinfected and HIV/HBV-coinfected patients. Median APRI was higher in HIV/HBV-coinfected compared to HIV- and HBV-monoinfected patients [0.36 (IQR 0.40) vs. 0.23 (0.17) vs. 0.29 (0.16); p<0.01]. HIV RNA levels were higher in HIV-monoinfected compared to HIV/HBV-coinfected patients, whereas CD4+ T cell counts were similar. After a median of 370 (IQR 57) days on HBV-active therapy, 61% HIV-infected vs. 74% HIV/HBV-coinfected patients achieved HIV RNA <20 copies/mL (p=0.09). Similar rates of HBV virologic suppression (<20 IU/mL) were observed in HBV-monoinfected and HIV/HBV-coinfected patients (80% vs. 79%; p=0.6). A greater decline in APRI was observed in HIV/HBV-coinfected patients. Mortality at 1 year was higher among HIV/HBV-coinfected patients compared to HIV and HBV-monoinfected patients [10/63 (16%) vs. 26/267 (10%) vs. 2/165 (1%); p<0.01]. In univariate analyses of all HIV-infected patients, HIV/HBV co-infection, lower CD4+ T cell counts, higher HIV RNA levels and APRI at baseline were all significantly associated with higher mortality (p's <0.01), however, only CD4+ T cell counts [OR 0.99, (95%CI 0.98, 0.99); p=0.01] and HIV RNA [OR 3.53, (1.66, 7.51); p<0.01] predicted mortality in adjusted MV models.
Conclusions: Mortality at one year was high among HIV/HBV-coinfected individuals compared to patients with HIV or HBV alone, despite similar rates of virologic suppression and greater APRI declines on HBV active ART. HIV-related factors rather than liver disease severity may explain the excess risk of mortality in HIV/HBV-coinfected individuals.

TUPEB0387

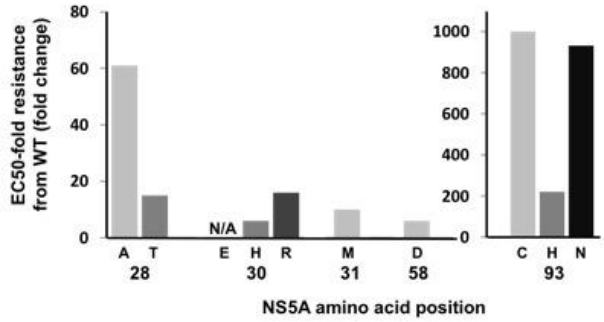
Low frequency of NS5A relevant resistance-associated substitutions to Elbasvir among hepatitis C virus genotype 1a in Spain: a cross-sectional study

C. Palladino[1], M. Sánchez-Carrillo[2], I. Mate-Cano[2], S. Vázquez-Morón[2], M.Á. Jimenez-Sousa[2], M. Gutiérrez-Rivas[2], S. Resino[2], V. Briz[2]
[1]University of Lisbon, Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Lisboa, Portugal, [2]Institute of Health Carlos III, Laboratory of Viral Hepatitis, National Center for Microbiology, Majadahonda, Spain
Presenting author email: veronica.briz@isciii.es

Background: Naturally resistance associated variants (RAVs) to the new HCV NS5A inhibitor elbasvir (EBR) may limit its efficacy and lead to no cure in HCV-GT1a-infected. To assess the prevalence and impact of clinically relevant natural NS5A RAVs to EBR in HCV-GT1a infected patients from Spain and predict the proportion of patients who could benefit from treatment with zepatier®.
Methods: A multicenter cross-sectional study of 617 treatment-naïve HCV-G1a-infected individuals attended in 84 Spanish hospitals. The samples were collected between 2014-2015. Sanger sequencing (HCV population sequencing) was used to identify natural NS5A RAVs. NS5A mutational pattern and drug sensitivity were confirmed by geno2pheno[HCV].
Results: Viruses bearing natural NS5A RAVs to EBR were present in 38 samples (6.2%) of HCV-G1a infected patients, six of those having viruses with double RAVs. The most common natural RAVs were the Y93C/H/N (2.4%; n=15) and Q30E/H/R (2.3%; n=14), while M28A/T, L31M and H58D being less represented (0.8%, n=5, each). The double mutations Q30H+Y93H and Q30R+Y93H had a low frequency (0.6%, n=4, and 0.3%, n=2). Only 3.4% (n=21) of the identified RAVs to EBR conferred reduced susceptibility to EBR by geno2pheno[HCV]. This algorithm identified exclusively the positions Q30H/R (n=7) and Y93C/H/N (n=8) as single mutations and Q30H+Y93H (n=4) and Q30R+Y93H (n=2) as double mutations considered as major NS5A RAVs to EBR.



[Fig1A. Types and prevalence of NS5A variants]



[Fig1B. Fold change of NS5A variants]

Conclusions: Naïve HCV-G1a-infected patients had a low prevalence of NS5A RAVs to EBR in Spain. This information may be essential to guide the implementation of zepatier® in Spain and the management of G1a-infected patients.

Chronic hepatitis C in human immunodeficiency virus infected patients: real-life treatment with new generation direct-acting antivirals in a Portuguese centre

A. Silva-Pinto, R. Ruas, I. Abreu, F. Ceia, A.C. Carvalho, N. Neves, A.S. Santos, J. Soares, C. Piñeiro, R. Serrão, A. Sarmento
Centro Hospitalar São João, Infectious Diseases, Porto, Portugal
Presenting author email: carmela_pinheiro@hotmail.com

Background: The Direct-Acting Antivirals (DAA) revolutionized the Hepatitis C virus (HCV) infection treatment. Since 2015, DAA became available in Portugal due to a universal access policy. Its use in Human Immunodeficiency Virus (HIV) infected patients has some peculiarities, specially due to drug interactions. Our aim is to assess the DAA efficacy in real life and to monitor fibrosis and alpha-fetoprotein (AFP) changes with treatment.
Methods: We performed a retrospective study of HCV-HIV patients treated with DAA between 02/2015 and 12/2016. The primary outcome was "sustained virologic response" (SVR) at week 12 after treatment and the secondary outcomes were changes in fibrosis, transaminases and AFP. We used the most appropriate measures of central tendency/distribution and statistical test.
Results: We included 291 patients that completed 12 weeks after treatment evaluation (from 402 patients with chronic HCV-HIV). Eighty-night percent (n=260) were men and the mean age was 47,96 (SD 9). The majority acquired the infection through drug abuse (90%) and 64% were HCV treatment naïve.
The most frequent HCV genotype was 1 (74,3%), followed by 3 (13,4%). The cirrhotic rate was 30%.
Concerning the HIV treatment, 99% of patients were on treatment. In 68 patients (23,4%) the HIV treatment had to be changed due to drug interactions: efavirenz (38,3%), boosted atazanavir (27,9%), boosted lopinavir (23,5%), nevirapine (8,8%) and boosted elvitegravir (1,5%). The patients changed the HIV treatment to raltegravir, rilpivirine, boosted darunavir or dolutegravir.
Regarding HCV treatment, the majority did sofosbuvir/ledipasvir (81,8%), followed by sofosbuvir/ribavirin (11,3%), sofosbuvir/ledipasvir/ribavirin (5,5%) and sofosbuvir/daclatasvir/ribavirin (1,4%). The duration of treatment was 12 weeks in 49,8% and 24 weeks in 50,2%.

Our SVR rate was 96,9% (282 patients cured the infection): six patients did not cure the infection owing to lack of adherence, in two patients the treatment was stopped (acute renal failure and alveolar haemorrhage, respectively) and one patient had a relapse.
The elastography stiffness, AFP and transaminases decreased in a statistically significant manner comparing before and after treatment (Wilcoxon test).
Conclusions: Our results confirm in real life the efficacy of these DAA with improvement of fibrosis, hepatic cytolysis and AFP.

TUPEB0389

Daily cannabis use and reduced risk of severe steatosis in a population of patients co-infected with HIV and hepatitis C virus (HCV) (ANRS CO13-HEPAVIH)

S.E. Nordmann[1], A. Vilotitch[1], P. Roux[1], L. Esterle[2], B. Spire[1], F. Marcellin[1], D. Salmon-Ceron[3], F. Dabis[2], J. Chas[4], D. Rey[5], L. Wittkop[6], P. Sogni[7], P. Carrieri[1], ANRS CO13 HEPAVIH Study Group
[1]Aix-Marseille Université, SESSTIM U 912 - ORS PACA, Marseille, France, [2]Université Bordeaux, INSERM U 1219, Bordeaux, France, [3]Université Paris Sud, Université Paris Descartes, UMR-S 0669, Paris, France, [4]Hôpital Tenon-APHP, Infection Disease Department, Paris, France, [5]CHU Strasbourg, Le Ttrait d'Union, Strasbourg, France, [6]Université de Bordeaux, INSERM U 1219, Bordeaux, France, [7]Université Paris Descartes, Hôpital Cochin, INSERM U 567 & CNRS 8104, Paris, France
Presenting author email: dominique.salmon@aphp.fr

Background: Liver steatosis is common in HIV-HCV co-infected patients. Some recent studies have found that cannabis use is negatively associated with insulin resistance in the general population and in HIV-HCV co-infected patients. Given the causal link between insulin resistance and steatosis, we hypothesized that cannabis use is a protective factor for steatosis. Therefore, we aimed to study whether cannabis use in this population was associated with a reduced risk of severe steatosis, as measured by ultrasound examination.
Methods: The ANRS CO13-HEPAVIH cohort is a French nationwide multicenter of HIV-HCV co-infected patients. Medical and socio-behavioral data from clinical follow-up visits and annual self-administered questionnaires are prospectively collected. A cross-sectional analysis was conducted using data from the first visit where both the ultrasound examination data for severe steatosis (positive or negative diagnosis) and data on cannabis use (every day, regularly, never/sometimes) were available. A multivariable logistic regression model was used to evaluate the association between cannabis use and severe steatosis.
Results: Among study sample patients (n=838), 69.8% were men, 40.1% had severe steatosis and 14.0% reported daily cannabis use, 11.7% regular use and 74.7% never or sometimes. The percentage of patients with genotypes 1, 2, 3, 4, and 5 was 55.6%, 3.2%, 18.5%, 22.4%, and 0.3%, respectively. The percentage of patients with a BMI > 27 kg/m^2 was 17.4%. With regards to HIV transmission route, 64.7% of the patients had contracted the disease via intravenous drug use. Overall, 8.8% had hazardous alcohol consumption (AUDIT>8). Daily cannabis use was independently associated with a reduced risk of severe steatosis (adjusted odds ratio [95%]=0.60 [0.39;0.93]; p=0.02), after adjusting for hazardous alcohol consumption (adjusted odds ratio [95%]=1.82 [1.10;3.00] ; p=0.02), current or ever use of lamivudine/zidovudine (adjusted odds ratio [95%]=1.53 [1.14;2.06]; p=0.004) and elevated levels of alanine transaminase (adjusted odds ratio [95%]=1.46 [1.01;2.13]; p=0.05).
Conclusions: Daily cannabis use may be a protective factor against steatosis in HIV-HCV co-infected patients. As cannabis use was also shown to lower the risk of insulin resistance in a previous study in the same population, these findings confirm the need for a clinical evaluation of cannabis-based pharmacotherapies in co-infected patients.

TUPEB0390

Assessment of liver fibrosis in former injection drug users with HIV/HCV co-infection and alcohol use disorder

A. Sanvisens[1], F. Bolao[2], P. Zuluaga[1], D. Fuster[1], I. Rivas[3], J. Tor[1], R. Muga[1]
[1]Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, Internal Medicine, Badalona, Spain, [2]Hospital Universitari de Bellvitge, Universitat de Barcelona, Internal Medicine, L'Hospitalet de Llobregat, Spain, [3]Centro de Atención a las Drogodependencias (Centro Delta), IMSP, Badalona, Spain
Presenting author email: rmuga.germanstrias@gencat.cat

Background: High rates of Hepatitis C Virus (HCV) infection occur in individuals with substance use disorder. When HIV infection or HIV/HCV co-infection occur patients with alcohol use disorder (AUD) are at increased risk of liver disease. We aimed to assess Advanced Liver Fibrosis (ALF) in former injection drug users (IDUs) seeking treatment of AUD.
Methods: Cross-sectional study in patients admitted for hospital detoxification between 2000 and 2014 in metropolitan Barcelona, Spain. Substance use characteristics, blood samples for viral infections and liver function tests were collected at admission. Fibrosis of the liver was assessed by APRI, FIB-4 and Forns indexes. ALF was defined by APRI >1.5, FIB-4>3.25 and Forns>6.9.
Results: Among 1.313 patients admitted, 208 (80.3% M) were former IDU. Age at admission was 40 years (IQR: 36-44 years), age at starting alcohol use 19 years (IQR: 17-24 years) and the amount of alcohol consumption 210 g/day (IQR: 147-350 g/day). Prevalence of HCV infection was 83% (173/208) and 9% (15/173) had antecedent of HCV treatment. Forty percent (70/173) of patients were HIV/HCV-coinfected and median CD4 cell count at admission was 336 cell/µL (IQR: 175-579 cell/µL)
Table 1 shows prevalence of ALF according to indexes and viral infections:

	HIV-/ HCV- N=35 n (%)	HIV+/ HCV- N=101 n (%)	HIV+ / HCV+ N=70 n (%)	p value
APRI >1.5	7 (20.0)	36 (37.9)	30 (46.9)	0.031
FIB-4 >3.25	4 (11.4)	22 (23.2)	27 (42.2)	0.002
Forns>6.9	4 (11.8)	33 (35.1)	34 (55.7)	<0.001

[Table 1]

Table 2 shows the ORs for ALF in patients with HCV-infection and HIV/HCV co-infection with respect to those without viral infections:

	APRI OR (95%CI)	FIB-4 OR (95%CI)	Forns OR (95%CI)
HIV-/HCV- (n=35)	1	1	1
HIV-/HCV+ (n=101)	2.4 (1.0-6.2)	2.3 (0.7-7.3)	4.1 (1.3-12.5)
HIV+/HCV(+) (n=70)	3.5 (1.3-9.2)	5.6 (1.8-17.9)	9.4 (3.0-30.1)

[Table 2]

Conclusions: Risk of symptomatic, advanced fibrosis of the liver is high in AUD patients with HIV/HCV co-infection. Treatment of alcoholism and HCV infection with direct-acting antivirals should be prioritized in this population.

TUPEB0391

Validation and scale-up of Hepatitis B viral load on polyvalent open PCR platforms in West African and South East Asian countries. A study of the AC12 working group (ANRS 12327)

Presenting author email: draka3703@yahoo.fr

Background: Quantification of HBV DNA is critical for therapeutic decision, however access to affordable HBV DNA testing remains limited in resource-constrained countries. The ANRS AC12 Virology group is an international working group of clinical virologists promoting validation and scale up of molecular tests. In this multi-laboratory study we evaluated the performance of a new generic HBV PCR assay performed with automated open polyvalent platforms (OPP) and compared with proprietary classical assays.
Methods: The generic HBV viral load assay was based on an in-house PCR assay previously evaluated with different HBV genotypes. This assay uses the same thermocycling protocol as the ANRS generic HIV-1 assay, thus enabling HIV-1 RNA and HBV DNA testing during the same PCR run. Optimization, standardization and production of the PCR assay were done in collaboration with two private companies Omunis (Clapiers, France) and Biocentric (Bandol, France) that

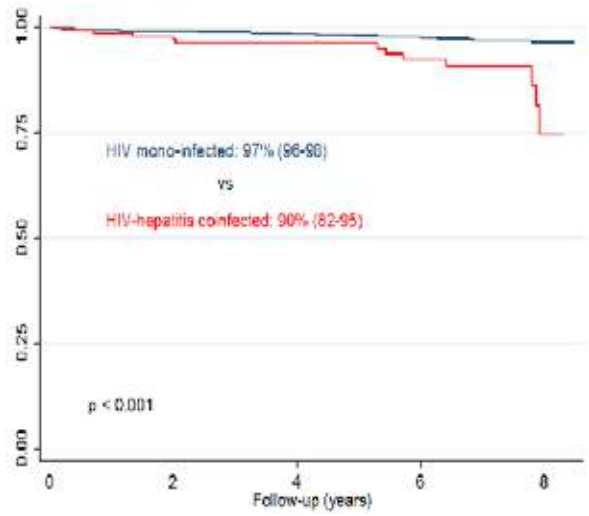
pursue regulatory approval of the "Generic HBV Charge Virale" assay. The PCR was evaluated in nine West/Central African and South East Asian countries. HBV DNA results were compared to Roche COBAS® HBV test version 2.0 and Abbott RealTime HBV PCR assays.
Results: Laboratories in France, Côte d'Ivoire, Burkina Faso and Cambodia provided intermediary results of HBV viral load using the generic HBV PCR versus Roche and Abbott PCR assays. Of 186 clinical samples with HBV DNA level over 1,000 IU/ml, 184 (99%) tested positive for HBV DNA with the generic PCR. High correlation (r >0.90, p >0.001) and good agreement between the Biocentric assay and the Roche and Abbott tests were obtained. The generic assay presents also a good specificity (100%) among 99 HBs Ag negative samples.
Conclusions: The use of this nucleic acid test with OPP could contribute to better implement HBV DNA testing and therapeutic decision-making in low- and middle income countries. Good agreement between the generic HBV PCR and Roche/Abbott assays was observed for samples collected from patients with chronic active hepatitis B. A higher input volume for DNA extraction would be useful to lower the limit of detection below 100 IU/ml and improve the quantification of HBV DNA in inactive carriers.

TUPEB0392

Factors associated with liver fibrosis progression from minimal (F0F1) to advanced liver fibrosis (F3F4) in HIV-infected patients with or without chronic hepatits coinfection: a prospective study

H. Perazzo Pedroso Barbosa, S. Cardoso, P. Luz, C. Yanavich, J. Fittipaldi, J.C. Soares, V. Veloso, B. Grinsztejn
Fundação Oswaldo Cruz, LAPCLIN-AIDS, Rio de Janeiro, Brazil
Presenting author email: perazzohugo@gmail.com

Background: Liver fibrosis progression might lead to cirrhosis and end-stage liver disease. This longitudinal study aimed to evaluate the risk factors for development of advanced fibrosis in HIV infected patients with no/minimal fibrosis at baseline.
Methods: 4,071 HIV patients were prospectively followed from 2007 to 2015. Liver fibrosis was estimated at baseline and at the last blood analysis by FIB-4 biomarker [FIB-4=(age*AST)/(platelet count*[sqrt(ALT)])].
Minimal (METAVIR=F0F1) and advanced fibrosis (METAVIR=F3F4) were defined by FIB-4 <1.45 and FIB-4 >3.25, respectively. The exclusion criteria were missing transaminases or platelet count (n=795); missing hepatitis serology (n=211); absence of follow-up (n=120) and FIB-4 > 1.45 at baseline (n=427).
Hepatitis coinfection was defined by positive HBsAg or anti-HCV. Age-gender-adjusted multivariate Cox proportional-hazards regression models were performed. Baseline and nadir CD4 cell counts and baseline HIV viral load were considered as confounders.
Results: 2,518 HIV patients [64% male, median age=37(IQR,29-44) years, 7% (N=158) with hepatitis coinfection)] were included. During a median of 5.1 years (IQR,2.7-6.9) of follow-up, 63 patients developed advanced fibrosis. The incidence rates (95%CI) of advanced fibrosis in HIV mono-infected and coinfected patients were 4.1 (3.1-5.4) and 16.0 (9.1-28.2) per 1000 person-year, respectively. The 7-year survival without advanced fibrosis [Kaplan Meier (95%CI)] was higher in HIV mono-infected compared to those with coinfection [97% (96-98) vs 90% (82-95; p<0.001] [Figure]



[Survival without progression to advanced fibrosis]

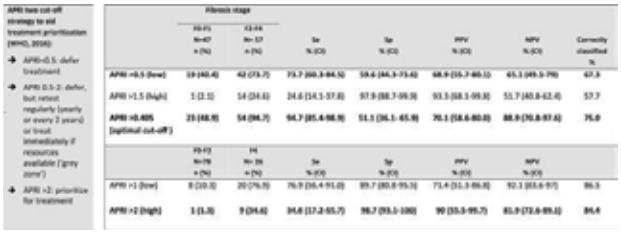
In multivariate Cox model [HR (95%CI)], age >45 years [1.86 (1.05-3.24), p=0.033]; CD4 count <200 cells [2.96 (1.51-5.77), p=0.002]; nadir CD4 <200 cells [4.48 (1.72-11.67), p=0.002] and hepatitis coinfection [2.62 (1.62-5.41), p=0.010] were independently associated with progression to advanced fibrosis. Considering HIV mono-infected patients (n=2,616), CD4 count <200 cells [2.51 (1.23-5.10), p=0.011]; detectable HIV viral load [2.43 (1.06-5.59), p=0.036] and nadir CD4 <200 cells [6.80 (2.20-21.05), p=0.001] were independently associated with fibrosis progression.
Conclusions: Hepatitis coinfection, low nadir CD4 and baseline CD4 count were independently associated with progression from minimal to advanced fibrosis in HIV-infected patients.

TUPEB0393

Usual APRI score thresholds lack sensitivity to prioritize for hepatitis C treatment in a HCV/HIV coinfected cohort in Cambodia

A. De Weggheleire[1], S. An[2], J. Buyze[1], S. Thai[2], S. Francque[3], L. Lynen[1]
[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Sihanouk Hospital Center of Hope, Phnom Penh, Cambodia, [3]University of Antwerp, Antwerp, Belgium
Presenting author email: adeweggheleire@itg.be

Background: The vast demand and limited resources justify in some contexts stepwise scale-up of hepatitis C treatment. We evaluated the Aspartate-to-platelet ratio index (APRI) threshold strategy for treatment prioritization, as proposed in the WHO guidelines, in the HCV/HIV coinfected cohort of Sihanouk Hospital Center of Hope in Cambodia.
Methods: Liver fibrosis was evaluated by Fibroscan (stageF0-F1: < 7.2 kPa, F2: 7.2-9.5, F3: 9.5-14.5, F4: ≥14.5). ROC curves for APRI to diagnose significant fibrosis (≥F2) and cirrhosis (F4) were established with area-under-curve (AUC) and 95% confidence interval. Performance of APRI low (>0.5, for ≥F2) and high (>2.0, for cirrhosis) cut-off was evaluated. The optimal cut-off was determined by weighing false negatives (FN) twice as harmful as false positives (FP).
Results: Hundred-seven coinfected were identified among 3046 HIV patients. Median age was 48.7 years. All, but three, were on ART (median duration 6.5 years); 97.7% had undetectable viral load. FibroScan was done for 104 coinfected; 47 staged F0-F1, 31 F2-F3 and 26 cirrhosis.
The AUC of APRI was 0.79 (95% CI 0.71-0.88) for ≥F2. At cut-off >0.5, sensitivity was 73.7% (60.3-84.5) and specificity 59.6% (44.3-73.6). For cirrhosis, AUC was 0.93 (0.88-0.98), with for cut-off >2.0 sensitivity 34.6% (17.2-55.7) and specificity 98.7% (93.1-100).
Applying the cut-off strategy, treatment would be prioritized for 10 patients and deferred in 43. Fifty-one would be in the grey zone. Thirty-one patients with advanced fibrosis, including 17 cirrhotics, would not be prioritized. A unique APRI cut-point for >F2 (=minimizing number FP + 2* number FN), 0.405 in our cohort, would identify 77 patients to treat, including 54 with significant fibrosis.



[APRI threshold strategy and performance]

Conclusions: The APRI two cut-off strategy lacked sensitivity in our coinfected cohort. A unique lower APRI cut-point (0.405) allowed more balanced and inclusive prioritization, and seems more adapted given the improving affordability of HCV treatment. Further validation in other cohorts is needed.

TUPEB0394

Comparative steatosis rates by liver biopsy and transient elastography controlled attenuated parameter (CAP) in hepatitis C (HCV) and HIV/HCV coinfection in a large U.S. hepatitis clinic: time to take notice

J. Martin[1,2], O. Adeyemi[1,2], K. Burke[2], I. Alvaraz[2], C. Winston[2], S. Markham[2], B. Go[2], G. Huhn[1,2]
[1]Rush University Medical Center, Infectious Diseases, Chicago, United States, [2]Ruth M. Rothstein CORE Center, Chicago, United States
Presenting author email: greghuhn@gmail.com

Background: Steatosis contributes to liver fibrosis in both HCV and HIV/HCV coinfection. Liver biopsy (LB) is the gold standard for grading steatosis and staging fibrosis, yet recent non-invasive staging modalities have largely supplanted LB in HCV, which may limit recognition of underlying steatosis. We compare steatosis rates in LB to transient elastography (TE) CAP among HCV and HIV/HCV patients in a U.S. hepatitis clinic.
Methods: Demographic information, fibrosis stage, and steatosis grade using standardized cutoffs were recorded among unique patients with chronic HCV during pre-treatment evaluation by LB (N=319, December 2001-December 2010) and TE CAP (N=822, May 2016-January 2017) at The CORE Center. Univariate analysis was performed, and p-values with α< 0.05 were calculated for comparisons of fibrosis and steatosis rates by LB and TE with CAP stratified by HCV versus HIV/HCV coinfection status.
Results: Steatosis was not reported in 26% of LBs (Table 1). Significant steatosis rates (≥S2) were greater by CAP compared to LB (26% versus 10%), and median CAP scores were significantly higher in HCV versus HIV/HCV coinfection (231 versus 216; p<0.0001)(Tables 1 and 2). Steatosis ≥S2 was significantly associated with greater fibrosis severity overall and in HCV monoinfection by CAP (Table 2).

[Table 2. Association between significant steatosis with severity of fibrosis by transient elastography (TE) with controlled attenuated parameter (CAP)]

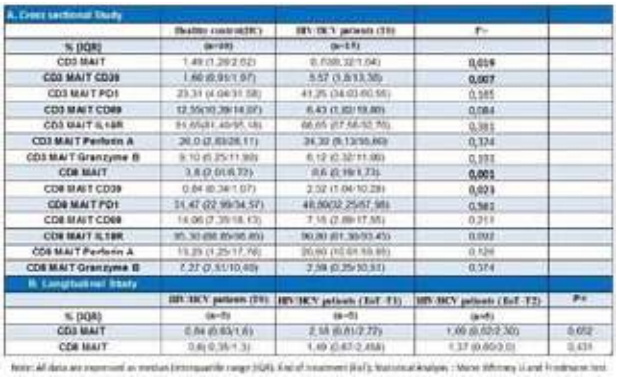
Conclusions: Steatosis was underreported by LB, and severity may be increasing in the modern HCV treatment era, particularly in HCV monoinfection. Without LB steatosis quantification requires advanced technology and may go unrecognized if soluble biomarkers are used exclusively for fibrosis staging. Improved biomarkers are needed to serially assess HCV patients with significant steatosis undergoing curative HCV therapy.

TUPEB0395

Circulating mucosal associated invariant T cells (MAITs) fail to be recovered by successful direct-acting antiviral therapy (DAA) in HIV/HCV co-infected patients

E.S. Cannizzo[1], M. Cerrone[1], E. Merlini[1], B. van Wilgenburg[2], L. Swadling[2], C. Tincati[1], A. De Bona[1], A. d'Arminio Monforte[1], P. Klenerman[2], G. Marchetti[1]
[1]University of Milan, Health Sciences, Milan, Italy, [2]University of Oxford, Peter Medawar Building for Pathogen Research, Oxford, United Kingdom
Presenting author email: stefania.cannizzo@gmail.com

Background: MAITs play a crucial role in innate immunity. A substantial reduction in MAITs has been described in untreated HIV, which is not restored by cART. Little is known about MAITs frequency/function in HIV/HCV co-infected patients and their fate after HCV elimination by DAA. We assessed MAITs in cART-treated HIV/HCV co-infected patients (pts) and the impact of anti-HCV therapy (both interferon and DAA-based).
Methods: We enrolled 15 HIV/HCV+ cART-treated pts [HIV-RNA< 40cp/ml; median CD4 527/mmc (IQR 409-780)] and 10 age-matched healthy controls (HC). All pts were treated with pegIFN-based anti-HCV treatment: 9/15 patients (60%) achieved a sustained virologic response (SVR), 6/15 patients (40%) failed to clear HCV infection (non responders-NR), 5/6 NR pts started DAA-based therapy (3 PI-based vs 2 with NS5A inhibitors)
We measured MAITs frequency (CD161++Va7.2+ CD3 or CD8), activation (CD69), exhaustion (CD39/PD-1), IL18R expression, cytolytic activity (granzyme B/perforin A) (flow cytometry) at baseline (T0), Interferon end-of-treatment (T1) and DAA end-of-treatment (T2). Statistical analyses: Mann-Whitney, Friedman.
Results: As compared to HC, HIV/HCV pts displayed substantially contracted total and CD8 MAITs (Table 1A). All MAIT subsets of HIV/HCV pts showed a trend towards higher CD39 expression, especially within the CD8 subset, but no differences in PD-1, IL-18R, granzyme B and perforin A expression were detected between HIV/HCV pts and HC (Table 1A). Following IFN-based therapy (T1), we found a non-significant increase in total and CD8 MAITs (Table 1B). Likewise, no significant recovery of total and CD8 MAITs frequency was shown following DAA treatment (T2) (Table 1B).
Conclusions: In HIV/HCV co-infected patients we show a profound depletion of the circulating MAITs compartment that is not recovered by anti-HCV treatment and HCV virus eradication, indicating a profound and irreversible virus-mediated depletion in MAIT cell subsets. Future research is needed to dissect molecular mechanisms governing the homeostasis of circulating and tissue MAIT cells upon viral clearance.



[Table 1. Phenotypes of circulating mucosal-associated invariant T cells (MAIT) in cross-sectional and longitudinal study]

TUPEB0396

Efficacy of ledipasvir/sofosbuvir (LDV/SOF) for 8 weeks in real life setting for patients with HCV/ HIV-1 co-infection

J. Berenguer[1], P. Buggish[2], A. Moreno[3], V. Isakov[4], L. Backus[5], D. Ain[6], S. Christensen[7], P. Ruane[8], J. Gonzales[9], S. Naik[10], S. Mehta[10], M. Mertens[11], F.E. Kucuksayrac[11], M. Natha[10], K. Kersey[12], A. Osinusi[12], K. Zhdanov[13], S. Zeuzem[14]
[1]Hospital General Gregorio Marañón, Madrid, Spain, [2]Liver-Centre Hamburg, Institute for Interdisciplinary Medicine/MVZ-Hamburg, Asklepios Hospital St. Georg, Hamburg, Germany, [3]API, Madrid, Spain, [4]Russian Academy of Sciences, Moscow, Russian Federation, [5]US Department of Vetereans Affairs, Palo Alto, United States, [6]Clinical Research at Ruane Medical and Liver Health Institute, Los Angeles, United States, [7]Center for Interdisciplinary Medicine, Muenster, Germany, [8]Ruane Medical and Liver Health Institute, Los Angeles, United States, [9]Hospital Universitario La Paz, Madrid, Spain, [10]Gilead Sciences, Medical Affairs, Foster City, United States, [11]Gilead Sciences, Medical Affairs, London, United Kingdom, [12]Gilead Sciences, Clinical Research, Foster City, United States, [13]Military Medical Academy, Department of Infectious Diseases, Saint Petersburg, Russian Federation, [14]JW Goethe University Hospital, Frankfurt, Germany
Presenting author email: ece.kucuksayrac@gilead.com

Background: The AASLD/IDSA/IAS-USA Guidance and EASL Recommendations on Treatment of Hepatitis C state that HIV/HCV coinfection should be treated the same as HCV monoinfection. Real world cohorts (RWC) have demonstrated excellent efficacy of LDV/SOF for 8 weeks in HCV monoinfected patients. The aim of this study was to describe the effectiveness of the single tablet regimen of LDV/SOF for 8 weeks in HCV genotype (GT) 1 patients with HIV/HCV coinfection in RWC.
Methods: Real world effectiveness data of LDV/SOF for 8 weeks in HIV/HCV coinfection is emerging from several prospective and retrospective cohorts. In this analysis, data from two prospective studies, one investigator sponsored (Ain et al.) and 1 registration trial (Isakov et al.), and three retrospective RWC (Deutsches Hepatitis C-Register, Madrid Coinfection Registry (Madrid-CoRe), and Veterans Affairs HCV Registry) of LDV/SOF for 8 weeks in HIV/HCV co-infected patients were compared. RWC were selected based on willingness to participate with at least 15 HIV/HCV co-infected patients. Baseline characteristics and efficacy were analyzed.
Results: The majority of the 279 patients included in analysis were GT 1, treatment naïve (TN), noncirrhotic (NC), and had HCV viral load < 6 million. The prospective cohorts enrolled 79 patients with the following baseline characteristics: mean age (43 years), male (74%), white (78%), and GT 1a (55%). The RWC studies assessed enrolled 200 patients with the following overall baseline characteristics: mean age (53 years) male (79%), white (98%), and GT 1a (82%) in those that reported demographics. The overall SVR12 from five diverse real world and post-marketing cohorts was 94% (263/279). The individual study results are presented in Table 1.

Clinical trials and RWC with LDV/SOF for 8 weeks in HIV/HCV coinfection				
Study	**Study Design**	**Treated (n)**	**SVR12 (n)**	**SVR 12%**
Ain et al.	Prospective LDV/SOF x 8 weeks	20	18	90
Russian cohort (Isakov et al)	Prospective LDV/SOF x 8 weeks	59	57	97
VA (Backus et al)	Retrospective LDV/SOF x 8 weeks	31	30	97
DHC-R (Buggish et al)	Retrospective LDV/SOF x 8 weeks	76	73	96
Madrid-CoRe	Retrospective LDV/SOF x 8 weeks	93	85	91

[Table 1]

Conclusions: This analysis of diverse cohorts from the EU and US yielded high SVR rates similar to SVR rates seen in multiple RW moninfected cohorts and supports the use of 8 weeks of LDV/SOF in TN, NC GT 1 HIV/HCV coinfected patients with a baseline HCV viral load <6 million.

TUPEB0397

Chronic hepatitis C and HIV co-infection among people who inject drugs along the Kenyan Coast

R.N. Shah[1,2], J. Kinyua[3], A. Kattammaiyo[3], K. Mandaliya[4], B. Langat[3], S. Bhagani[5], M. Thursz[2], E. Songok[3], M. Lemoine[2]
[1]Nottingham University Hospitals NHS Trust, Infectious Diseases, Nottingham, United Kingdom, [2]Imperial College, Medicine, London, United Kingdom, [3]Kenya Medical Research Institute, Centre for Virus Research, Nairobi, Kenya, [4]PathCare Kenya Ltd, Mombasa, Kenya, [5]Royal Free London NHS Foundation Trust, Genito-Urinary Medicine, London, United Kingdom
Presenting author email: rajiv_334@hotmail.com

Background: People who inject drugs (PWID) are a major driver of HCV spread worldwide. The use of injecting drugs is an emerging but neglected problem in Africa, particularly in East Africa. This study aimed to determine the prevalence and severity of chronic hepatitis C and HIV co-infection among a group of PWID in Mombasa, Kenya.
Methods: Participants were recruited at local drop-in centres supported by Kenya AIDS NGOs Consortium (KANCO). Epidemiological data and blood samples were systematically collected for liver function tests and virological analysis (HIV/HCV serology, RNA and genotyping). PathCare Kenya Limited as well as Kenya Medical Research Institute (KEMRI) provided support for processing and storage of blood samples. In the absence of a Fibroscan, liver fibrosis was assessed using the Aspartate Transaminase to Platelet Ratio Index (APRI) score according to the WHO guidelines.
Results: 400 PWID (85% Male) were recruited in Mombasa and Kilifi Counties. The mean (± SD) age was 34 years (± 7.5), 33% (130/400) admitted to sharing needles while injecting heroin. 95% (378/400) had spent time in or prison. 34% (137/400) were heavy drinkers. Only 1% of participants had completed secondary level education.
Only 8% (31/400) had previously been tested for HCV whereas all participants had been tested for HIV previously, with the majority receiving regular HIV care. The prevalence of positive HCV and HIV serologies were 36% and 17%, respectively. 72% (50/69) were HIV-HCV co-infected. More than 40% had a positive HCV RNA and the vast majority were infected with HCV genotype 1 or 4. Of the 143 infected with HCV, 14% (20/143) had an APRI score >1 and 6% (9/143) >2 suggesting the presence of cirrhosis.
Conclusions: PWID along the Kenyan Coast are at high risk of HCV infection and HCV-HIV co-infection but are not systematically screened for HCV although 14% might need urgent antiviral therapy. High rate of incarceration and low level of education might be potential barriers to implement screen-and-treat interventions in this key population.

TUPEB0398

Virtual elimination of hepatitis C in an Australian regional area: what a difference access to the new medications makes!

D. Russell[1,2], C. Gorton[1], R. Lewis[1], P. Fox[3]
[1]Cairns Sexual Health Service, Cairns, Australia, [2]James Cook University, School of Medicine, Dentistry and Pharmacy, Cairns, Australia, [3]Cairns and Hinterland Hospital and Health Service, Gastroenterology Service, Cairns, Australia
Presenting author email: darrenrussell@optusnet.com.au

Background: Australia has been estimated to have about 230,000 people living with hepatitis C virus (HCV). Approximately 10% of people living with HIV are coinfected with HCV. On 1 March, 2016, the Australian Government made new direct acting HCV medications (DAAs) available to all Australians with HCV, regardless of liver fibrosis, HIV status, or injecting drug use status. Cairns is a city in Far North Queensland and has a population of 160,000, though it services a vast area containing about 250,000 people.
Methods: A "Make Cairns Hep C Free by 2020" program was instituted with the input of the Cairns Sexual Health Service, the Liver Clinic at the Cairns Hospital, local General Practitioners (GPs), the Alcohol and Drug Service, and the 800-bed male prison in the region. Initial focus was on reducing the hospital waiting list for those awaiting the new DAAs, upskilling GPs, involving users of the Alcohol and Drug services, and rapidly clearing the prison of HCV. In addition, all HIV/HCV coinfected individuals were treated as a priority.
Results: After 9 months of access to new hepatitis C DAAs the majority of individuals already identified with HCV in Cairns and surrounding areas have been treated and cured of HCV. The hospital clinic waiting list has been reduced to zero, the prison is virtually free of HCV infection, and efforts to find a smaller number of individuals who have not yet been diagnosed or treated have been increased.
Conclusions: Easy and widespread access to new hepatitis C DAAs at a variety of sites throughout Cairns and the broader region has led to the virtual elimination of hepatitis C in this part of Australia. Involvement of local clinicians with the ability to prescribe these agents, along with the communities of those such as people living

with HIV, injecting drug users, and prisoners appears to have been successful and has allowed these results to occur within a matter of months. Cairns is on track to be "Hep C Free by 2020".

Presenting author email: sylvie.ronot@ap-hm.fr

Background: High efficacy of Direct Antiviral Agents (DAAs) lead us to consider that HCV cure is now the main challenge for HIV-HCV coinfected people. We report the results of a care program aimed to reduce prevalence of hepatitis C in a cohort of HIV-infected patients.
Methods: This program was initiated in February 2016 in an outdoor-HIV-clinical unit. According to French guidelines, the program included (i) HCV serology for patients with unknown or negative HCV antibodies evaluated for most than 12 months or whatever the date in case of risk factor (ii) HCV-RNA viral load for patients with positive HCV antibodies and for those with a negative HCV-RNA (spontaneous or post treatment) evaluated for more than 12 months. DAAs regimen was defined during multidisciplinary staff and nurse' intervention for compliance and education was planned during treatment. Tolerance was evaluated through questionnaires.
Results: At program initiation, the cohort included 622 HIV-monoinfected and 276 HCV-HIV co-infected patients. Among these last one, 116 had positive HCV-RNA (83 never treated), 140 were negative (36.6% after treatment) and 20 patients were under HCV-treatment. Up to now, HCV serology was controlled in 481 patients (89%) and two cases of acute hepatitis C were diagnosed. HCV-RNA was measured in 122 patients (58%) without reinfection diagnosis and 25 patients are still lost of follow-up. DAAs regimen (mostly: 59% with sofosbuvir /ledipasvir for 12 weeks) was started in 54 patients (70% males, HCV genotype 1/3/4 in 34/13/7; F0-F1/F2/F3-F4 in 35/7/12), recused in 18 cases for medical reason and refused by 7 patients. Among the 30 patients reaching 12 weeks post-end of treatment, 2 failed therapy: 1 breakthrough and 1 relapse (SVR rate=96%). Tolerance questionnaires were fulfilled by 37 patients. At 2 weeks (W2) of treatment, 64% declared at least one adverse events. They were 76% at W4, 81% at W8, 68% at W12 and 50% at W16. Detail of adverse events are presented in Graphic 1.
Conclusions: Despite a specific care program, HCV treatment uptake in our cohort was of 46%, highlighting that HCV cure in HIV-infected people will be not so easy to achieve in routine practice.

TUPEB0400

Untreated HCV-coinfection in HIV-infected patients induces additional CD4+ T-lymphocyte deficiency due to mobilization of naive cells into immune response resulting in their regeneration failure

K. Shmagel[1,2], E. Saidakova[1,2], L. Korolevskaya[1,3], N. Shmagel[3,4], V. Chereshnev[1,2]
[1]Institute of Ecology and Genetics of Microorganisms (UB RAS), Laboratory of Ecological Immunology, Perm, Russian Federation, [2]Perm State University, Department of Biology, Perm, Russian Federation, [3]Perm State University, Research Department, Perm, Russian Federation, [4]Perm Regional Center for Protection against AIDS and Infectious Diseases, Medical Assistance Department, Perm, Russian Federation
Presenting author email: radimira@list.ru

Background: One of the major immune discrepancies differing HIV/HCV-coinfection from HIV-monoinfection is the development of a deeper CD4+ T-cell deficiency that is mainly due to the naive cell loss. In HIV-infected subjects, the reasons for the naive CD4+ T-cell decline are well known: thymus productive function failure, and lymph nodes sclerosis that blocks lymphocyte access to IL-7 and disrupts their ability to regenerate. However, the role of HCV-coinfection in deepening the CD4+ T-cell deficiency induced by HIV-infection remains unknown.
Methods: Twenty ART-treated HIV/HCV-coinfected patients without interferon or anti-HCV drugs prescription were examined. ART-treated HIV-monoinfected subjects (n=21) and uninfected volunteers (n=20) served as controls. HCV viral load in the first group exceeded 1000000 copies/ml, HIV viral load in infected groups was < 50 copies/ml. On the basis of CD31 naive CD4+ T-cells were divided into recent thymic emigrants (CD4+ RTE: naive CD4+CD31+ T-cells) and mature naive T-lymphocytes (naive CD4+CD31- T-cells). IL-7R (CD127) expression by naive T-cells was determined. Cell proliferation was assessed by Ki-67 expression. Blood IL-2 and IL-7 concentrations were measured.
Results: Naive CD4+ T-lymphocyte content was reduced in the HIV+HCV+ group as compared to the HIV+HCV- group. In HIV-monoinfected subjects, naive CD4+ T-lymphocyte regeneration was characterized by two principles:
1) the less cells were presented, the more intensive their proliferation was;
2) mature naive CD4+ T-cell numbers were directly associated with the CD4+ RTE counts. In HIV/HCV-coinfected patients, both principles were disregarded. However, in that group the number of mature naive CD4+ T-lymphocytes was directly related both to blood HCV concentration and to hepatitis activity indices. IL-7 levels in two HIV-positive groups did not differ from each other but were significantly higher than in uninfected volunteers. CD127 expression on naive CD4+ T-cells in HIV/HCV-coinfected patients was reduced but corresponded to the level in HIV-monoinfected subjects. IL-2 concentration in HIV/HCV-coinfected individuals significantly exceeded the ones in people without infections and in HIV-monoinfected subjects.
Conclusions: Presented results demonstrate that active immune response to HCV antigens takes place in HIV/HCV-coinfection. It leads to the naive CD4+ T-cells' recruitment and, consequently, to their regeneration process failure.

Background: Blood transfusions remain a major challenge in resource-limited settings like Sub-Saharan Africa where sexually transmitted diseases mainly hepatitis B virus (HBV), hepatitis C virus (HCV), syphilis and HIV are hyper-endemic. HBV is ranks as the 7th leading cause of annual global deaths. There are 10 genotypes (A to J) that differ in >8% in genetic diversity and all show unique geographic distribution, response to treatment and prognosis. Genotype A, D and E are circulating in different African HBV-cohorts. There is limited data on this in Botswana. We aimed to determine the HBV prevalence and to molecularly characterize the HBV circulating genotypes among blood donors in Botswana.
Methods: This was a cross-sectional study of hepatitis B surface antigen positive (HBsAg+) allogeneic blood donations at National Blood Transfusions Services in Botswana (NBTS) confirmed using ELISA conducted in a 10 month period between 2014 and 2015. Nucleic acid extraction was done using UltraSense DNA/RNA Kit followed by polymerase chain reaction (PCR) reaction using SuperScript Platinum III Taq-polymerase covering 2.1kb surface antigen .Genotyping was done using Sanger sequencing.
Results: In the 10798 allogeneic donations done during study period, the prevalence of $HBsAg^+$ was 0.92% (75). Co-infections confirmed were of Syphilis 1.72%, 1.54% for HIV and 0.43% for Hepatitis C. The total population had normally distributed age with mean of 29 ±1.7 years and a range of 44 years. PCR was successful on 41 (82%) of which 87.8% were successfully sequenced and genotyped. Sub-genotype A1 (48%) serotype adw2 and D (52%) serotype ayw2 were found in the study population. Secondary escape mutations with high impact associated with failure to Immunoglobulin G therapy, vaccine and failure to HBsAg detection were noted on positions **A120L** and **130R** in genotype A with a frequency of 1 and 2 respectively. In sub-genotype D3, escape mutations were observed on positions **134H** and **144A.** The impacts of D3 mutations were similar to A1.
Conclusions: Predominant genotype amongst Botswana blood donors is D3 There are some escape mutations which are present in Botswana blood donors.HBV complications and its HIV co-infection is high in Africa and more analysis should be done in larger cohorts.

TUPEB0402

Prevalence of polymorphism within HCV NS5A gene in HCV-GT1A patients in Spain

V. Briz[1], C. Palladino[2], M. Sánchez Carrillo[1], X. Jiang[1], S. Vázquez Morón[1], M.A. Jiménez Sousa[1], S. Resino[1]
[1]Institute of Health Carlos III, Laboratory of Viral Hepatitis, National Center for Microbiology, Majadahonda, Spain, [2]University of Lisbon, Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Lisbon, Portugal
Presenting author email: veronica.briz@isciii.es

Background: Hepatitis C virus (HCV) resistance-associated substitutions (RASs) in the NS5A gene may limit the sustained viral response during antiviral therapy and lead to no cure. The objective was to evaluate the prevalence of RASs in the NS5A gene in HCV-GT1a infected patients from Spain.
Methods: A nationwide cross-sectional study of 617 treatment-naïve chronic HCV-GT1a infected patients (292 HIV/HCV-coinfected and 325 HCV-monoinfected) from 84 Spanish hospitals between October/2014-June/2016. Direct sequencing of the NS5A gene was performed. The prevalence of clinically-relevant RASs and degree of resistance to approved NS5A inhibitors was evaluated.
Results: Overall, 80.1% (n=494) of subjects were men and had a median of age of 50 years (IQR=47-53). A higher frequency of GT1a clade II [82.5% (n=509)] than clade I [17.5% (n=108)] was observed (p=0.0001). Clade I was more represented in HIV/HCV-group (22.9%) than HCV-group (12.6%) whereas clade II was less represented in HIV/HCV-group than HCV-group (77.1 vs 87.4%, respectively; p=0.001). Overall, the presence of RASs that confer a reduced susceptibility to NS5A inhibitors was observed in 7.9% (n=49) patients. Of them, 2.1% (n=13/617) had RASs that conferred resistance to all approved NS5A inhibitors (daclatasvir, ledipasvir, ombitasvir, elbasvir and velpatasvir) while 2.6% (n=16/617) harbored viruses that were possibly resistant to these drugs. The frequency of clinically relevant RASs was: 3.7% (n=23) M28A/T/V; 2.3% (n=14) Q30E/H/R; 0.6% (n=4) L31M; 0.3% (n=2) H58D and 2.3% (n=14) Y93C/H/N. RASs that conferred resistance to all NS5A inhibitors in 7 HIV/HCV-coinfected patients were: Y93C (n=4), Y93H (n=1) and double (Q30H or Q30R and Y93H) in two patients; in 6 HCV-monoinfected patients were: Y93C (n=1), Y93H (n=1) and double (Q30H or Q30R and Y93H) in four patients. The frequency of RASs was not uniform in Spain. Eight autonomous communities (CCAAs) had a prevalence ≥10% (e.g. Madrid: 16.1%. Murcia: 14.3%, Cantabria: 13.3%); four CCAAs had a prevalence of 5%-< 10%, and in three CCAAs was < 5%. Three CCAA did not show RASs isolates in the samples analyzed.
Conclusions: In Spain, the overall prevalence of NS5A RASs was low in HCV-GT1a infected patients, did not differ in HIV/HCV-coinfected or HCV-monoinfected subjects but showed a marked geographical variability.

TUPEB0403

Evolution of glomerular filtration rate in patients concomitantly treated with ledipasvir and tenofovir

M. Fabbiani[1], G. Lapadula[1], R. Gagliardini[2], A. Soria[1], D. Moschese[2], A. Muscatello[1], M. Rossi[1], N. Squillace[1], A. Bandera[1], A. De Luca[3], S. Di Giambenedetto[2], A. Gori[1]

Presenting author email: a.muscatello@asst-monza.it

Background: Since ledispavir can increase tenofovir plasma levels, there is concern about renal safety of these two drugs co-administered in HIV-infected patients. However, few data are available on the evolution of glomerular filtration rate(eGFR) in patients treated with ledipasvir and tenofovir in clinical practice.
Methods: We performed a retrospective study including patients treated for HCV with directly acting antivirals(DAA) at two reference centers in Northern and Central Italy. eGFR was estimated through CK-EPI at baseline(time of DAA start), at week 12 during DAA treatment(T1) and 12 weeks after DAA discontinuation(T2). Evolution of eGFR during follow-up was compared in patients concomitantly treated with ledipasvir-tenofovir or not.
Results: 302 patients (73% males, median age 55 years, 50% HIV-HCV co-infected) were enrolled. Sofosbuvir/ledipasvir was prescribed in 139(46.0%) patients; other DAA regimens were sofosbuvir+ribavirin(n=65,21.5%), sofosbuvir +daclatasvir(n=57,18.9%), sofosbuvir+simeprevir(n=41,13.6%). Among 151 HIV-infected patients, 104(68.9%) were treated with a tenofovir-containing regimen and 19(18.5%) also received a boosting agent (ritonavir or cobicistat). Overall, patients were classified in the following groups: 91 treated with ledipasvir only(group 1), 48 concomitantly treated with ledipasvir-tenofovir (group 2), 108 treated with tenofovir only(group 3) and 55 treated with none of the two drugs (group 4). At baseline, median eGFR was 95 mL/min/1.73m^2(IQR 78-103). No significant modification of eGFR was observed in group 1, whilst patients in group 2 showed a significant decrease of eGFR at all time points during DAA treatment, with a mean eGFR loss at week 12 of -6 mL/min/1.73m^2 (p<0.001). Only partial eGFR recovery was observed 12 weeks after DAA discontinuation (-4.6 mL/min/1.73m^2, p=0.002). In group 3, eGFR decreased during DAA treatment (week-12 change -6 mL/min/1.73m^2, p<0.001) but, after DAA discontinuation, a recovery to values similar that observed at baseline occurred (T2 versus baseline mean change -2 mL/min/1.73m^2, p=0.126).

	Week 4	Week 8	Week 12	12 weeks post-treatment
Ledipasvir (group 1)	-0.5 (9.4) 0.468	-0.1 (8.1) 0.981	+0.3 (7.8) 0.584	-1.4 (8.5) 0.1845
Ledipasvir+Tenofovir (group 2)	-6.2 (8.7) <0.001	-7.1 (7.7) <0.001	-6.0 (6.9) <0.001	-4.6 (7.1) 0.001
Tenofovir (group 3)	-1.6 (10.5) 0.452	-5.1 (12.1) 0.009	-6.2 (7.6) <0.001	-2 (9.2) 0.128
No tenofovir nor ledipasvir (group 4)	-1.8 (7) 0.013	-2.4 (6.9) 0.004	-1.4 (7) 0.024	-2.8 (6.2) <0.001

[Mean eGFR change in the 4 groups (SD)]

Conclusions: Patients concomitantly treated with ledipasvir and tenofovir showed a slight decrease in eGFR, which persisted also after DAA discontinuation. The clinical relevance of this finding should be verified over a long-term follow-up.

TUPEB0404

HCV genotype profile in Brazil among HIV-infected and uninfected individuals: a survey truly representative of an entire country

M. Nutini[1], J. Hunter[1], A.F. Pires[2], I. Kohiyama[2], M. Camargo[1], M.C. Sucupira[1], D. Ricardo[1]
[1]UNIFESP, Sao Paulo, Brazil, [2]Brazilian Ministry of Health, Brasilia, Brazil
Presenting author email: rsdiaz@catg.com.br

Background: In order to receive antiviral treatment, HCV infected patients need a genotype determination provided by the Brazilian government after initial diagnosis. We assessed the HCV genotype profile vis a vis Brazilian geographic region, gender, age and HIV co-infection.
Methods: We assessed 6,338 samples from HCV infected patients subjected to HCV genotype (Abbott RealTime HCV Genotype) collected from January 2016 to July 2016. 620 randomly selected samples were tested for HIV co-infection using the kit TR DPP HIV 1/2 Bio-Manguinhos. Descriptive statistical analyses were performed using the R statistical system and language.
Results: Overall median age was 53 years old (1 to 93); 57.4% being males. Overall HCV genotype distribution was 41.9% G1A, 28.5% G1B, 24.5% G3, 3.1% G2, 0.5% G4, and 1.5% mixed genotypes. Prevalence of G1A was 64.9% among males and 35.1 among females, and G1B, G2 and G3 were more prevalent in older ages than other genotypes. G3 was more prevalent in the far South (Rio Grande do Sul, 29.4%) than in other Brazilian States.
Among 620 samples tested for HIV co-infection, 18.4% were HIV+, with a median age of 46.5 among co-infected patients as compared to 54.0 among mono-infected individuals. 71.1% of co-infected patients were male as compared to 57.1% of mono infected individuals. G1B was less prevalent among HIV+ individuals as compared to mono-infected individuals (8.5% and 32.8% respectively). HIV co-infection was more prevalent Rio Grande do Sul State (23.4%), as compared to the next highest state, São Paulo (19.6%).
Conclusions: This is a report of the genotype HCV that is truly representative of the entire Brazil, which show a relatively high HIV overall co-infection prevalence. High prevalence of G3 in the south of Brazil poses an extra challenge related to HCV disease progression and treatment response, as well as the higher prevalence of G1A especially among males, a genotype with lower genetic barrier to resistance to protease inhibitors.

TUPEB0405

Outcomes after direct-acting antiviral therapy initiation in patients with cirrhosis

M.J. Vivancos Gallego, A. Moreno, M.J. Perez Elias, C. Quereda, C. Gomez Ayerbe, M. Sanchez Conde, J.L. Casado, S. Del Campo, S. Moreno
Ramón y Cajal Hospital. IRYCIS, Madrid, Spain
Presenting author email: mjesus.vivancos@gmail.com

Background: Virological responses are excellent with direct-acting antivirals (DAAs) in HIV/HCV cirrhotic patients but the longer term outcomes are unclear.
Methods: Prospective study of coinfected HIV/HCV patients with cirrhosis (N=181) who received oral direct-acting antivirals in a tertiary center in Madrid, Spain from April 2013 with overall follow-up data after DAAs initiation. Endpoints were sustained virological response, deaths, hepatocellular carcinoma (HCC), decompensation events or hospitalisations. All statistical analyses were conducted with IBM SPSS Statistics 15.0.
Results: Among 181 cirrhotic patients 82% men, GT1 (61%), peg-IFN/RBV pretreated (58%); median age 52 yo (IQR: 49-54), CD4 431 cs/mm^3 (IQR: 249-611), CHILD 6 (IQR: 5-7), MELD 9 (IQR: 7-11), there were 21% patients with prior decompensation events. Median DAAs duration was 3 months (IQR: 3-6) and median follow up from DAAs initiation was 21.3 months (IQR: 19.6-23.4). 30% (n=54) were admitted in the hospital for any reason. Twenty five (14%) had at least one admission for liver related disease (7 during therapy and 18 after DAAs) with a median time of 9.5 months (IQR: 5.1-14.7). Overall mortality was 5.5% (n=10), 3% liver-related deaths (n=6): 3 hepatocarcinoma, two with multicentric HCC „de novo" with rapid progression, 2 hydropic decompensation and 1 upper gastrointestinal bleeding. Median time to death was 2.8 months (IQR: 0-12.7). There were 5 HCC (2.8%), 2 of them in palliative care (multicentric HCC). Median time from DAAs initiation to HCC diagnosis was 8,1 months (IQR: 3,4-14,5). 154/181 (85%) patients achieved sustained virological response at 12 weeks post-treatment. On univariate analysis, the absence of SVR was associated with prior decompensations (69% vs 20% p=0,007), decompensations during follow-up (33% vs 8% p=0,001) and mortality (26% vs 2% p=0,0001).
Conclusions: Over 21 months of follow-up, 3% of liver-related deaths were found in patients with cirrhosis treated with DAAs. Four of 5 HCC were multicentric, early presentation and had poor prognosis.

TUPEB0406

Sustained virologic response (SVR) after hepatitis C virus (HCV) treatment does not lead to improved renal function in HIV/HCV coinfected patients

C. Rossi[1], E. Moodie[1], M. Hull[2], V. Martel-Lafferriere[3], M.-L. Vachon[4], C. Cooper[5], N. Pick[6], S. Walmsley[7], M. Klein[8], Canadian Coinfection Cohort
[1]McGill University, Epidemiology and Biostatistics, Montreal, Canada, [2]University of British Columbia, BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Centre Hospitalier de l'Université de Montréal, Notre-Dame Hospital, Montréal, Canada, [4]Centre Hospitalier Universitaire de Québec-Université Laval, Québec, Canada, [5]University of Ottawa, Ottawa, Canada, [6]University of British Columbia, Oak Tree Clinic, Vancouver, Canada, [7]University of Toronto, Toronto, Canada, [8]McGill University Health Centre, Medicine/Infectious Diseases, Montreal, Canada
Presenting author email: marina.klein@mcgill.ca

Background: Direct-acting antivirals for chronic HCV infection have improved cure rates and may have extrahepatic benefits for specific comorbidities linked to HCV infection. We assessed the effect of SVR on renal function in HIV/HCV co-infected patients.
Methods: We obtained data from the Canadian Coinfection Cohort, a prospective study which has recruited co-infected patients from 19 clinical centres since 2003. All patients with SVR after either interferon or interferon-free HCV treatment were matched using a 1:2 ratio, without replacement, to individuals chronically infected with HCV on calendar time (study visit +/- 30 days of the SVR index date) and the propensity score for receiving treatment using variables shown in the Table with a nearest-neighbor algorithm. We modeled differences in the annual rate of eGFR decline from the index date between SVR and comparable chronically infected patients using repeated-measures linear generalized estimating equations.
Results: Of 1,695 recruited patients, 424 were treated for HCV, of whom 332 developed SVR (78%). Interferon-free regimens were used in 45%. Baseline characteristics between SVR and chronically infected patients are shown in the Table. Patients were followed for a total of 1,491 person-years; median, 1.4 years (IQR 0.6, 3.6). The annual rate of eGFR decline (mL/min/1.73 m^2/year) did not differ between patients with SVR and those chronically infected: -1.2 (95% confidence interval [CI]: -1.7, -0.7) and -1.0 (95% CI: -1.5, -0.4), respectively. The principal factor associated with eGFR decline was injection cocaine use (adjusted eGFR decline: -2.3, 95% CI: -3.8, -0.8 and -1.9, 95% CI: -3.1, -0.7 in cocaine users with SVR and chronically infected, respectively).

Characteristic	Sustained Virologic Response (n=332)	Chronically Infected (n=664)
Median age (IQR), years	50 (45, 55)	50 (44, 55)
Female, n(%)	64 (19%)	128 (19%)
Black , n(%)	13 (4%)	25 (4%)
Aboriginal, n(%)	25 (8%)	51 (8%)
Median CD4$^+$ count (IQR), cells/μL	520 (360, 730)	510 (340, 720)
Detectable HIV RNA (> 50 copies/mL), n(%)	38 (11%)	69 (10%)
Previous AIDS diagnosis, n(%)	82 (25%)	146 (22%)
Current or past tenofovir exposure, n(%)	227 (68%)	433 (65%)
Current or past ATZ or LPV/r exposure, n(%)	158 (48%)	303 (46%)
Recent injection cocaine use, n(%)	35 (10%)	68 (10%)
Recent other injection drug use, n(%)	16 (5%)	25 (4%)
Current or past hypertension, n(%)	50 (15%)	112 (17%)
Current or past diabetes, n(%)	36 (11%)	71 (11%)
Past end-stage liver disease, n(%)	81 (24%)	167 (25%)
Median HCV viral load (IQR) prior to index date, IU/mL	2,430,000 (359,000, 7,520,000)	2,350,000 (315,000, 7,790,000)
Median eGFR (IQR), mL/min/1.73m^2	92 (75, 104)	93 (77, 106)

[Table 1. Baseline characteristics between SVR and chronically infected patients in the matched sample]

Conclusions: In HCV/HIV co-infected patients, SVR was not associated with improved eGFR over the short term suggesting HCV replication has a minimal impact on kidney function. Other modifiable factors such as cocaine use may be responsible for eGFR decline in this population.

TUPEB0407

Alanine aminotransferase level monitoring to detection hepatitis B virus reactivation in 170 HIV/hepatitis C virus-infected patients on direct-acting agent-based therapies

P. Colson, S. Mokhtari, H. Tissot-Dupont, C. Dhiver, I. Ravaux, L. Meddeb, A. Motte, C. Tamalet, S. Aherfi, P. Brouqui, A. Stein, A. Menard
IHU Méditerranée Infection, Marseille, France
Presenting author email: isabelle.ravaux@ap-hm.fr

Background: Hepatitis B virus (HBV) reactivation during therapy of chronic hepatitis C by direct-acting agents (DAA) has been recently reported. Such issue could be particularly relevant among HIV-infected patients because real-life HIV cohorts[PC1] are associated with high prevalence of positivity for HBV serological markers indicating either HBsAg-positivity or past resolved infection. In addition, immunosuppression is associated with a greater risk of HBV reactivation. We aimed to analyze retrospectively liver transaminases in HIV/HCV-co-infected patients under DAA-based therapies followed-up in Marseille university hospitals.
Methods: Alanine aminotransferase levels (ALT) and HBV serological patterns analyzed were those available in the Nadis database. ALT were analyzed retrospectively at baseline (or at the most recent assessment within the 12-month period prior treatment), at weeks 4, 8, and at end (week 12 or 24) of DAA therapies administered between May-2014 and September-2016 to HIV/HCV-co-infected patients followed-up in Marseille university hospitals, southeastern France.
Results: 170 HIV/HCV-co-infected patients were treated by DAA-based therapies during the 29-month study period. 76% were male. Mean age (±standard deviation) was 51±5 years. 5% and 69% had serological markers of on-going or past resolved HBV infection, respectively. HCV treatments included sofosbuvir+daclatasvir or ledipasvir in 91% of the cases. At baseline of DAA regimens, mean ALT was 65±49 IU/L (range, 9-352). These values were 31±21 IU/L (10-143) (n=148), 29±20 IU/L (10-126) (n=150), and 28±22 IU/L (9-189) (n=157) at weeks 4, 8, and 12/24 of treatment, respectively. Maximum ALT on HCV therapy was 189 IU/L. Mean reduction of ALT between baseline and maximal on-therapy values was 35±25 IU/L. Maximal increase was 35 IU/L. ALT >2x the upper normal value (90 IU/L) were only observed in 7 patients (4%; ALT=94-189 IU/L), and were greater than at baseline (of 16-23 IU/L) in only 3 of these cases. Overall, no HBV reactivation was identified based on liver cytolysis detection.
Conclusions: HBV reactivation appears to be a rare event in HCV/HIV-positive patients on DAA-based regimen, which may be due in part to administration of anti-HBV compounds as part of their combined antiretroviral therapy. Notwithstanding, previous observations warrant for HBV assessment at baseline of DAA-based treatment initiation and in case of ALT elevation.

TUPEB0408

Hepatitis E virus serological and molecular testing in 1979 patients followed-up in 2014-2016 in HIV reference centers of University Hospitals of Marseille, southeastern France

P. Colson, C. Dhiver, H. Tissot-Dupont, S. Mokhtari, A. Motte, I. Ravaux, C. Tomei, C. Tamalet, S. Aherfi, P. Brouqui, A. Stein, A. Menard
IHU Méditerranée Infection, Marseille, France
Presenting author email: philippe.colson@univ-amu.fr

Background: Hepatitis E virus (HEV) is an emerging cause of autochthnous hepatitis in developed countries. These infections can become chronic in severely immunocompromised patients, including those transplanted and HIV-infected. We studied results of HEV serological and molecular testing performed for patients followed-up in HIV reference centers of university hospitals of Marseille, southeastern France.
Methods: Serum or plasma samples analyzed were collected between December 2013 and November 2016 from patients followed-up in HIV reference centers of university hospitals of Marseille, the second largest French city, southeastern France. Anti-HEV IgG and IgM testing were performed using ELISA microplate assays (Wantai). HEV RNA detection, quantification was performed using in-house real-time PCR assays targeting ORF2 and 3 regions of the HEV genome. HEV genotype was determined based on sequences of ORF2 and ORF1 genes obtained by Sanger population sequencing by in-house protocols.
Results: Over the three-year period of the study, 2299 serum or plasma samples collected from 1979 HIV-positive patients were tested for the presence of IgG and IgM anti-HEV antibodies. These samples represented 20% of all those serologically-tested for HEV infection (N=11687). 1535 IgG/IgM testing (67%) were negative. 703 serum/plasma (31%) indicated past HEV exposure (IgG-positivity/IgM-negativity). 56 serum/plasma (2.4%) from 45 patients (2.3%) were IgM-positive, suggesting possible on-going or recent HEV infection; of these 56, 9 (16%) were IgG-negative/IgM-positive. Serum/plasma from 7 patients were HEV RNA-positive, which involved 0.3% of the patients tested serologically for HEV infection. Mean(+/-standard deviation) HEV RNA load was 5.5+/-5.7 log_{10}copies/mL (range, 2.3-6.1 log10). HEV genotype was 3, which is the one involved in autochthonous HEV infections, in six cases, and could not be determined due to a low viral load (2.3 log10) in the 7th case.
Conclusions: Almost one third of patients followed-up in 2014-2016 in Marseille HIV reference centers had serological evidence of past HEV exposure, and 0.3% were HEV infected with autochthonous viruses at time of testing.

TUPEB0409

Usefulness of high-risk Human Papillomavirus (hrHPV) detection despite non-pathologic cervical cytology in women living with HIV

A. Rodallec[1], C. Allavena[2], S. Sécher[2], E. Vaucel[3], S. Petiteau[1], S. Wylomanski[3], G. Aillet[4], F. Raffi[2], M. Coste-Burel[1]
[1]CHU Hôtel Dieu, University Hospital, Virology, Nantes, France, [2]CHU Hôtel Dieu, University Hospital, Infectious Diseases Department, Nantes, France, [3]CHU Hôtel Dieu, University Hospital, Department of Gynecology and Obstetrics, Nantes, France, [4]Anatomopathology Unit, Institut d'Histopathologie, Nantes, France
Presenting author email: audrey.rodallec@chu-nantes.fr

Background: Women living with HIV (WLwH) are at increased risk of persistent hrHPV infection, cervical dysplasia and cervical cancer. Detection of cervical hrHPV is recommended only in case of abnormal cytology. This study aimed to describe the prevalence of abnormal cervical cytologies and hrHPV infection, and associated factors with hrHPV infection in WLwH in France.
Methods: Monocentric, observational, prospective cohort study of adults WLwH followed in an HIV reference center in Nantes. At each cervical cancer screening, WLwH were examined for cervical hrHPV (HPV16, HPV18 and others hrHPV) and cytologic abnormalities (classified as non-pathologic, atypical squamous cells (ASC) and low-grade or high-grade squamous intraepithelial lesions (L/HSIL). Socio-demographic characteristics, HIV history and immuno-virological data were prospectively collected.
Results: From September 2012 to October 2016, 323 WLwH with at least one cervical cancer screening were included in the study (median age 38 years; IQR 31-44). At first screening, 95 WLwH were found with hrHPV+ (29%). Cervical cytology was non-pathologic in 82% (hrHPV + in 21%), ASC in 6% (hrHPV + in 28%), L/HSIL in 12% (hrHPV + in 90%). WLwH hrHPV + were younger (35 vs 38 years), had a lower median CD4 nadir (190 vs 248 cells/mm^3) and current CD4 ≤350 cells/mm^3 (36% vs 11%), no antiretroviral therapy (ART) (18% vs 9%) or a shorter median duration of ART (2.5 vs 5.9 years), and a detectable HIV viral load (28% vs 10%) than WLwH with no hrHPV (all p<0.05). Among the 55 WLwH with non-pathologic cytology hrHPV+, 32 had at least a second screening: viral clearance was observed in 8/32 cases (25%) within a median time of 14.5 months, cervical cytology progressed to ASC or L/HSIL in 8 cases (25%) within a median time of 12 months and no change in 16 cases (50%) with the same hrHPV genotypes detected within a median time of 10.5 months.
Conclusions: A quarter of WLwH with non-pathologic cytology but presence of hrHPV progress to a pathologic cytology within 14 months. High risk HPV screening seems more informative than annual cervical cytology to prevent cervical dysplasia in this French cohort of WLwH.

High-risk genital HPV infection , dysplasia and cancer of the cervix in a cohort of women infected with HIV in Senegal

S. Ba[1], P.S. Sow[1], M. Toure[2], B. Dembele[3], M.P. Sy[1], F. Traore[1], F. Sall[1], Q. Feng[2], G.S. Gottlieb[2], N.B. Kiviat[2], S. Hawes[4], for the University of Washington-Dakar HIV-2 Study Group
[1]Fann Hospital, Infectious Department, Dakar, Senegal, [2]University of Washington, Department of Medecine and Global Health, Seattle, United States, [3]Curie Institut Hospital Le Dantec, Dakar, Senegal, [4]University of Washington, Department of Epidemiology, Seattle, United States
Presenting author email: sellyba2003@yahoo.fr

Background: Screening programs to prevent development of cervical cancer in sub-Saharan African women with HIV infection are lacking. We have undertaken the study to determine the burden of HPV infection and dysplasia of the cervix in a cohort of HIV-positive women
Methods: atThis is an analysis of prevalence data from a the baseline visit of a prospective cohort study conducted from October 2005 to September 2011. Inclusion criteria included no pregnant woman aged 18 years and more, infected with HIV, who consented to participate in the study. Exclusion criteria included pregnancy and an abnormal cervical finding by cytology at baseline. Study visits visits were scheduled every four months with cervical Pap smear, HPV detection by PCR at all visits,and biopsy at the initial and final exit visit, as well as with abnormal cytologic findings.
Results: 209 women infected with HIV (HIV-1: 79% (n = 167); HIV-2: 14% (n = 29); HIV-1 and HIV-2: 7% (n = 13)) were enrolled. Median age was 41 years (range 20-66), 54% were married, and 84% reported no contraception during study follow-up. The median CD4 count was 375 cells/mm^3, 58% were on ART, and average length of follow-up was 2.45 years.
At baseline, HPV DNA was detected in 75% of HIV-1, 62% of HIV-2, and 77% of dually HIV-1 and HIV-2 infected subjects, respectively; p = 0.3), among them 118 (78%) were positive for multiple HPV types. High risk genital HPV types most commonly detected were HPV-52 (17%), HPV-58 (16%), HPV-35 (15%), HPV-16 (14%), HPV-51 (11%), HPV-18 (10%), and HPV-33 (10%).
At baseline, 30% (n = 62) had prevalent cytological abnormalities (HIV-1 (33%), HIV-2 (25%), dual HIV-1/HIV-2 (23%); p = 0.7), including 6% with ASCUS, 12% with low grade lesions, 4% with high grade lesions, 4% with carcinoma in situ (CIS), and 4% with invasive cancer (ICC).
Conclusions: In a cohort of HIV infected women in Senegal, there was a high burden of prevalent HPV infection and prevalent cervical abnormalities identified at baseline. Early detection of cervical abnormalities through cervical screening, or their prevention by HPV vaccination, is critical to prevent cervical disease among the HIV-positive women.

TUPEB0411

Prevalence of asymptomatic STI in HIV-positive MSM in Germany

C. Spinner[1,2], C. Jordan[1,2], S. Noe[3], C. Boesecke[2,4], C. Wyen[5], T. Kümmerle[5], G. Knecht[6], S. Scholten[7], A. Zink[8], I. Krznaric[9]
[1]University Hospital Klinikum rechts der Isar, Department of Medicine II, Munich, Germany, [2]German Center for Infection Research, Braunschweig, Germany, [3]Medical Center Karlsplatz, Private Practice, Munich, Germany, [4]University Hospital Bonn, Department of Medicine I, Bonn, Germany, [5]Praxis am Ebertplatz, Private Practice, Cologne, Germany, [6]Infektiologikum, Private Practice, Frankfurt am Main, Germany, [7]Praxis Hohenstaufenring, Private Practice, Cologne, Germany, [8]University Hospital Klinikum rechts der Isar, Department of Dermatology and Allergology, Munich, Germany, [9]ZIBP, Private Practice, Berlin, Germany
Presenting author email: christoph.spinner@tum.de

Background: Sexually transmitted infections (STI) occur frequently in high-risk populations such as HIV-positive men having sex with men (MSM). Rapid diagnosis is important for accurate treatment and reduction of onward transmission. However, the role of screening programs of asymptomatic STI carriers remains controversial as data on prevalence are conflicting to date.

Methods: We enrolled asymptomatic, sexually active, HIV-positive MSM (pts) in a prospective cross-sectional sentinel study from 23.02.2016 until 30.08.2016 at 7 German HIV care centers. All subjects (pts) were screened for Treponema pallidum infection, HIV RNA, HBV- and HCV-serology, as well as oral, rectal, and urethral colonization by Chlamydia trachomatis (CT) and/or Neisseria gonorrhea (NG), using a cartridge based nucleic acid amplification system (GeneXpert CT/NG®; Cepheid, Frankfurt,Germany). In addition, all patients completed a sexual risk questionnaire.
Results: In total, 296 pts with a median age of 43.5 (36,5-50) years were enrolled. 294 patients were on antiretroviral treatment for a median of 5.5 (2.5-11) years. HIV RNA was < 50 cps/ml in 94% of all pts. The majority of sexual contacts were unprotected (79% of oral, 61% of anal contacts and 68% of fisting). While 22% had unprotected intercourse with 1 partner, unprotected sex with 2-5, 6-10, 11-20, and >20 partners were reported by 23%, 10%, 9%, and 9% within the last 6 months, respectively. Active syphilis infection was found in 5% of all patients, while 55% had a history of syphilis infection. While only 2% had HBsAg-positive chronic Hepatitis-B infection, an unexpectedly high number of 29% had no detectable anti-HBs-antibodies in absence of anti-HBc-antibodies. 9% had active hepatitis C infection. 13% had positive CT/NG swabs (NG: 4% anal, 4% urethral and 2% pharyngeal; CT: 7% anal, 1% urethral, 2% pharyngeal). Statistically significant more STIs were found in pts with more than 1 sexual partner and a history of recreational drug abuse (14% vs. 2%, p=0.046).
Conclusions: We found a high number of asymptomatic syphilis-, HCV- and CT/NG-infections in HIV-positive MSM, especially in those reporting recreational drug use and a history of multiple sexual partners. Intensified screening and treatment strategies should be addressed especially to high-risk populations to curtail ongoing high numbers of STIs.

TUPEB0412

High prevalence and incidence of sexually transmitted infections and poor test-of-cure outcomes among HIV-infected pregnant women in Soshanguve Township, South Africa: what are the next steps?

A. Medina-Marino[1,2], M. Mudau[1], L. De Vos[1], D. Olivier[1], D. Joseph Davey[3], E. Mkwanazi[1], J.A. McIntyre[4,5], R.P.H. Peters[4,6], J. Klausner[7]
[1]Foundation for Professional Development, Research Unit, Pretoria, South Africa, [2]University of Pretoria, School of Health Systems and Public Health, Pretoria, South Africa, [3]University of Cape Town, School of Public Health, Department of Epidemiology, Cape Town, South Africa, [4]Anova Health Institute, Johannesburg, South Africa, [5]University of Cape Town, School of Public Health, Cape Town, South Africa, [6]University of Pretoria, Department of Medical Microbiology, Pretoria, South Africa, [7]University of California, David Geffen School of Medicine, Los Angeles, United States
Presenting author email: andrewm@foundation.co.za

Background: During pregnancy, Chlamydia trachomatis (CT), Neisseria gonorrhoea (NG) and Trichomonas vaginalis (TV) may lead to intrauterine death, preterm delivery, and may facilitate mother-to-child-transmission of HIV. Treatment of those infections is sub-optimal due to the syndromic approach to diagnosis and management. We determined the prevalence of those sexually transmitted infections (STI) among HIV-infected pregnant women, test-of-cure (ToC) outcomes and identified new infections post-delivery.
Methods: Participating HIV-infected pregnant women attending their first antenatal care (ANC) visit at two clinics in Soshanguve, a historically disadvantaged township, were interviewed and asked to self-collect two vaginal swab specimens for CT, NG and TV testing. STI-infected women were treated, provided a partner treatment pack, and asked to return in three weeks for ToC. All women were re-tested for CT, NG and TV at their first post-delivery visit. STI tests were performed by nurses in the clinic using Xpert® CT/NG and Xpert® TV assays [Cepheid, Sunnyvale, California].
Results: To date 214 women were tested for CT, NG and TV at first ANC, of which 106 (49%) had at least one infection (CT=39%, TV=25%, NG=7%). Of those, 57% were asymptomatic infections. Of those with ToC, 36/83 (43%) had a positive result (CT=39%, TV=26%, NG=0%). Overall, 67% of women reported sexual activity following treatment for their infection. ToC+ was associated with >1 partner at enrollment (+ToC=29% vs -ToC=7%; p=0.007) and less condom use at last sex (+ToC=17% vs -ToC=30%; p< 0.05). ToC+ women reported that 59% of partners accepted a take-home pill packet provided by study staff, 38% did not seek care and 3% sought care after disclosure. Currently, 48 of 214 enrolled women have returned for post-delivery services, of whom 35% (n=17) had at least one STI infection (new and re-infections; CT=31%, TV=6%, NG=6%).
Conclusions: HIV-infected pregnant women attending ANC in our study clinics have a high burden and infection rate of curable STIs. Given the high rate of asymptomatic infections, routine STI testing with ToC must be considered. Poor ToC outcomes may be associated with poor uptake of treatment by sex partners. Optimal impact of STI screening and treatment during pregnancy might require interventions to increase treatment uptake by partners.

TUPEB0413

Behavioral risk factors among HIV-infected pregnant women with a sexually transmitted infection in South Africa

D. Joseph Davey[1,2,3], A. Medina-Marino[4], M. Mudau[4], L. De Vos[4], D. Olivier[4], J.A. McIntyre[5], R.P. Peters[5], J.D. Klausner[3]
[1]University of Cape Town, School of Public Health and Family Medicine, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [2]University of Californa, Los Angeles, Fielding School of Public Health, Department of Epidemiology, Los Angeles, United States, [3]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, United States, [4]Foundation for Professional Development, Research Unit, Pretoria, South Africa, [5]Anova Health Institute, Cape Town, South Africa
Presenting author email: dvoradavey@gmail.com

Background: Sexually transmitted infections (STI) may increase the risk of vertical and horizontal HIV transmission. However, more knowledge is needed about risk factors associated with STIs among HIV-infected pregnant women to develop targeted diagnostic, treatment and STI and HIV transmission prevention interventions.
Methods: We conducted a study of HIV-infected pregnant women in antenatal care at two primary care facilities in Pretoria, South Africa to evaluate prevalence and risk factors for STIs. Participants were interviewed and self-collected vulvovaginal swabs which were tested for Chlamydia trachomatis (CT), Neisseria gonorrhoea (NG) and Trichomonas vaginalis (TV), Xpert® (Cepheid, Sunnyvale, USA). We report descriptive and multivariate logistic regression results of risk factors associated with any STI.
Results: To date we enrolled 214 HIV-infected pregnant women (median age=29y; median gestational age=20-weeks). Prevalence of any STI was 50%. Overall, 90% of pregnant women reported having sex during pregnancy (of whom 9% reported oral sex and 4% anal sex). Most (62%) had sex 7-days prior to study enrollment. Over 70% of women were not virally suppressed (>200 copies/mL). At last sex 75% reported condomless sex and 15% reported having >1 sex partner in the past 12 months. Of women 14% reported any alcohol use during pregnancy of whom 25% reported ≥5 drinks on a typical day. Twenty-two percent reported being in a serodiscordant relationship with father of the child; 27% seroconcordant relationship; and 51% didn't know their partner's serostatus. Odds of having any STI decreased as age increased (OR/year=0.93; 95%CI=0.88-0.98). Odds of having any STI increased with increased gestational age at time of testing (aOR=1.07; 95% CI=1.02-1.12) and recent sex (past 30 days vs. longer) (aOR=1.42; 95% CI=1.04-1.93). Trends toward increased odds of any STI included: >1 recent sex partner (aOR=2.36; 95% CI=0.96-5.84; p=0.06) and reporting ≥5 drinks on more than one occasion (aOR=3.61; 95% CI=0.77-35.7; p=0.09), adjusted for age.
Conclusions: Preliminary results demonstrate risk behaviors for HIV vertical and horizontal transmission including: high prevalence of STIs, frequent condomless sex, anal sex, heavy alcohol use and multiple sex partners. Interventions to diagnose, treat and prevent STIs and further HIV transmission among HIV-infected pregnant women are urgently needed.

Cancer

TUPEB0414

Cancer mortality among HIV-positive adults in British Columbia, Canada: a retrospective analysis

K. Salters[1,2], M. Ye[2], M. Lu[2], M. Hull[2,3], J. Shoveller[2,4], J.S. Montaner[2,4], R. Hogg[1,2]
[1]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]St. Paul's Hospital, Vancouver, Canada, [4]University of British Columbia, Vancouver, Canada
Presenting author email: ksalters@cfenet.ubc.ca

Background: Since the advent of modern combination antiretroviral therapy (cART), life expectancy for people living with HIV/AIDS (PLWH) has significantly improved, making way for a rise in comorbid conditions, including cancer. There is little known about how PLWH may be differentially impacted by cancer-related mortality in the modern cART era.
Methods: The Comparison of Outcomes and Service Utilization Trends (COAST) study is a population-based retrospective study that is inclusive of all PLWH in the province of BC, including those on and off cART, between April 1996 and March 2013. It utilizes demographic and clinical data from the BC Centre for Excellence in HIV/AIDS provincial Drug Treatment Program and administrative health data from Population Data BC.
We calculated crude and direct age-adjusted mortality rates for all-type cancers, by AIDS-defining malignancies (ADM) and Non-AIDS defining malignancies (NADM), and system-specific cancers among our sample of PLWH and a general

population sample using the age distribution for the 2011 Canadian standard population to adjust.
Results: Between 1996 and 2013, there were 1121 PLWH in BC diagnosed with cancer, of which, 155 (13.8%) were women, 384 (34.3%) had a Hepatitis C diagnosis, and the median age at cancer diagnosis was 47 years. Of the 1121 PLWH with a cancer diagnosis, 555 (49.5%) died during the follow-up period, inclusive of 11 (2.0%) deaths attributed to ADM and 222 (40.0%) attributed to NADM. The age-adjusted cancer-related mortality rate for PLWH was 63.1 (95% CI: 51.6, 74.6) per 1000 PY compared to 48.3 (95%CI: 46.7, 49.8) per 1000 PY in the general population sample. Mortality rates were higher among PLWH with NADM diagnosis (Rate Ratio: 1.3 (95% CI: 1.0, 1.5)), as well as for those with a lymphatic system cancer diagnosis (Rate Radio: 13.2, 95% CI: 8.4, 17.9), compared to the general population.
Conclusions: Age-adjusted cancer-related mortality rates are elevated among PLWH compared to the general population. It is important to consider confounding factors such as smoking status that could not be accounted for in this analysis. These findings suggest that the majority of cancer-related deaths are attributed to NADM in the modern cART era, highlighting future priorities for HIV-care.

TUPEB0415

Impact of cART and chemotherapy on lung function of HIV-infected individuals with pulmonary Kaposi sarcoma in Harare, Zimbabwe

F.D. Manyeruke[1], T. Makoni[1], M. Borok[1], T. Campbell[2]
[1]University of Zimabwe, Medicine, Harare, Zimbabwe, [2]University of Colorado Denver, Infectious Disease, Colorado, United States
Presenting author email: felixmanyeruke@yahoo.co.uk

Background: Pulmonary Kaposi sarcoma (pKS) in HIV positive patients is associated with impaired lung function and high mortality. While the combination of chemotherapy and combined antiretroviral therapy (cART) for pKS substantially improves survival, there is no evidence that there is concomitant improvement in lung function in HIV positive patients with pKS in response to cART and chemotherapy.
Methods: This was an observational longitudinal study of HIV positive patients with a diagnosis of pKS at Parirenyatwa hospital in Harare Zimbabwe. Chemotherapy naïve patients were enrolled after bronchoscopy confirmed pKS, which was classified as extensive (affected ≥2 lobes) or localised (affected only 1 lobe) and excluded if they had active tuberculosis. Spirometry, pulse oximetry (SpO_2), six minute walk test (SMWT) and Karnofsky performance status score were performed on patients every 3 weeks for 9 weeks. Chemotherapy was given according to the local standard of care. Chest X-rays were performed at baseline and at 9 weeks. Statistical analysis was performed using chi-square test, t-test and analysis of variance (ANOVA).
Results: Forty patients (mean age 37 years, 85% male) with a diagnosis of pKS on bronchoscopy were enrolled. 57% had extensive disease; baseline lung function tests (mean ± standard deviation): FVC 61.7±18.0, FEV_1% 59.9±18.5, SpO_2%91.3±3.7, SMWT 294.5±158.5. Treatment of pKS was associated with a statistically significant improvement in resting SpO_2 from baseline to 9 weeks (93%versus 96%; p=0.005), SMWT (347 m versus 449 m; p= 0.038) and Karnofsky score (70 versus 80; p= 0.013) but not FVC (73.3±25.0 versus 78.5±18.1; p=0.737) or FEV_1 (70.4±23.7 versus 79.0±15.9; p= 0.303). 71.4% of patients had significant radiological improvement. Mortality was 22.5% over 9 weeks of follow-up.
Conclusions: Extensive pKS is associated with impaired lung function. Current therapy for pKS is associated with significant improvement in the resting SpO_2, SMWT, radiological changes and Karnofsky score but no significant short term improvement in spirometry measures (FVC and FEV_1) was detected.

TUPEB0416

Real-world use of chemotherapy for Kaposi's sarcoma in a large community-based HIV health care network in Kenya

E. Freeman[1], N. Busakhala[2], F.C. Asirwa[2,3], S. Regan[4], M. Wenger[5], K. Chelidze[1,6], A. Semeere[5,7], I. Bassett[4], R. Walensky[4], K. Wools-Kaloustian[3], J. Martin[5]
[1]Massachusetts General Hospital, Department of Dermatology, Boston, United States, [2]AMPATH, Moi University, Eldoret, Kenya, [3]Indiana University, Indianapolis, United States, [4]Massachusetts General Hospital, Boston, United States, [5]University of California, San Francisco, United States, [6]Weill Cornell Medicine, New York, United States, [7]Makerere University, Infectious Diseases Institute, Kampala, Uganda
Presenting author email: esther.freeman@gmail.com

Background: Kaposi's sarcoma (KS) is one of the commonest HIV-associated malignancies in sub-Saharan Africa. In the current era, KS survival has improved largely due to antiretroviral therapy (ART). In resource-rich settings, survival has also benefited from chemotherapy. Little is known, however, about the epidemiology of chemotherapy for KS in resource-limited regions. We sought to determine the prevalence of indications for chemotherapy amongst patients with new HIV-associated KS, penetration of chemotherapy, and regimens used in a large community-based health care network in East Africa.
Methods: We identified all patients newly diagnosed with HIV-related KS from 2009-2012 in the 26-clinic AMPATH network in Kenya, a member of East Africa IeDEA. Through chart review, we ascertained disease severity at diagnosis and KS-specific treatment. Indications for chemotherapy were considered AIDS Clinical Trial Group (ACTG) T1 stage and/or "severe" disease defined by WHO KS treatment guidelines.
Results: Of 674 patients diagnosed with KS, charts were available for 599 (89%); 61% were men, median age was 35 years, and median CD4 at KS diagnosis was 184 cells/μl. At diagnosis, of 476 patients with evaluable ACTG T stage, 72% were T1 stage. Of 354 patients with evaluable WHO KS treatment guideline staging, at least 27% had documented "severe" disease. Among all patients, 49% received chemotherapy of any kind within 2 years of KS diagnosis. Of those receiving chemotherapy, median time to first chemotherapy was 28 days (IQR 4-57 days). Restricting to patients with a chemotherapy indication, for T1 disease, 57% received chemotherapy; for patients with WHO "severe" disease, 59% received chemotherapy. Initial regimens were bleomycin-vincristine (78%), adriamycin-bleomycin-vincristine (10%), etoposide (7%), gemcitabine (3%), and vincristine (1%).
Conclusions: A substantial fraction of patients with KS in East Africa are diagnosed at advanced disease stage. For patients with apparent chemotherapy indications, nearly half did not receive chemotherapy; prospective work is needed to understand why (e.g., poor access, inability to tolerate, sufficient response to ART alone, or patient preference). Liposomal anthracyclines, which are often first-line in resource-rich settings, are very expensive in this setting, and were not used as first line. These findings highlight challenges in East Africa in cancer care.

TUPEB0417

Epstein-Barr viral load predicts prognosis of AIDS-related Non-Hodgkin Lymphoma

J. Tanuma[1], S. Hagiwara[2], S. Oka[1]
[1]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [2]National Center for Global Health and Medicine, Department of Haematology, Tokyo, Japan
Presenting author email: jtanuma@acc.ncgm.go.jp

Background: Non-Hodgkin lymphoma (NHL) is still one of the important comorbidities among HIV-infected individuals and Epstein-Barr virus (EBV) reactivation is thought to be a risk factor for developing NHL. However, the role of EBV-DNA load in peripheral blood has yet to be established in the management of AIDS-related NHL. We aimed to evaluate the prognostic value of plasma EBV-DNA loads in AIDS-related NHL.
Methods: Data was retrospectively reviewed on HIV-infected individuals diagnosed as systemic NHL who received chemotherapy at National Center for Global Medicine in Tokyo, Japan since 2000 through 2015. Overall survival was defined as time from NHL diagnosis to death from any cause.
Results: Sixty-one AIDS-related NHLs were involved to the analysis, including 25 diffuse large B cell lymphomas (DLBCL), 21 Burkitt lymphomas (BL), 7 plasmablastic lymphomas and 8 primary effusion lymphomas. All were male and their median age was 42 years old (range 25-75). Thirty-five (57%) had detectable plasma EBV-DNA load (>198 IU/ml) at baseline. The proportion of patients in the international prognostic index (IPI) category of either low and low-intermediate or high-intermediate and high was not different by plasma ENV-DNA detection (31% vs 27%, p=0.97) and CD4 count at NHL diagnosis was higher in the detectable EBV-DNA group but not statistically significant (90 cells/μl vs. 186 cells/μl, p=0.06) During median 1.03 years of follow up (range 0.02-12.7), 33 patients died after median 0.54 years (range 0.02-11.8) and progression of NHL was attributable for 85% (28/33) of the deaths. Overall survival rate at 2 years were 48% in total [95% confidential interval (CI) 34-60], 36% (95% CI 21-58) in the detectable EBV-DNA group and 64% (95% CI 49-79) in the undetectable EBV-DNA group (p=0.04). Cox proportional hazard models revealed EBV-DNA detection was significantly predictive in mortality after adjustment for IPI category and baseline CD4 counts, which presented hazard ratios of 2.83 (95% CI 1.16-6.89), 2.59 (95% CI 1.05-6.38), and 3.15 (95% CI 1.28-7.77) with EBV-DNA load cut-off values of 198, 496, and 991 IU/ml respectively.
Conclusions: Our findings demonstrate the detection of plasma EBV-DNA is an independent indicator of poor prognosis of AIDS-related NHL.

TUPEB0418

Human herpes virus 8 (HHV8) in HIV-1-infected individuals receiving cancer chemotherapy and stem cell transplantation

L. Hogan[1], E. Hanhauser[1], K. Hobbs[1], C. Palmer[2], Y. Robles[3], S. Jost[4], A. LaCasce[5], J. Abramson[6], A. Hamdan[7], F. Marty[3], D. Kuritzkes[3], T. Henrich[1]
[1]University of California, San Francisco, San Francisco, United States, [2]Ragon Institute of MGH, MIT and Harvard, Boston, United States, [3]Brigham and Women's Hospital, Boston, United States, [4]Center for Virology and Vaccine Research, Beth Israel Deaconess Medical Center, Boston, United States, [5]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [6]Massachusetts General Hospital, Boston, United States, [7]Beth-Israel Deaconess Hospital, Boston, United States
Presenting author email: louise.hogan@ucsf.edu

Background: Little is known about the association between cancer chemotherapy or hematopoietic stem cell transplantation (HSCT), circulating HHV8 DNA levels, and clinical Kaposi Sarcoma (KS) in HIV-1-infected individuals with various malignancies. However, some targeted therapies (e.g. rituximab) are known to trigger HHV8 reactivation and the development of KS. Therefore, we examined the associations between chemotherapy, T-cell phenotypes, and circulating HHV8 DNA in 29 HIV-1-infected participants with KS or other malignancies.
Methods: We quantified HHV8 plasma and cell-associated DNA and determined the relationship between HHV8 DNA, T-cell counts, and markers of early and late T-cell activation, proliferation and exhaustion (CD69, CD38, HLA-DR, Ki67 and CD57, respectively) inHIV-1 infected individuals with KS (N=6), non-Hodgkin lymphoma (N=15), Hodgkin lymphoma (N=6), and other tumors (N=2).
Results: Twelve (41%) participants, including all individuals with clinical KS, had detectable anti-HHV8 antibodies; 83% of these participants with KS and 17% of participants with other malignancies had detectable circulating HHV8 DNA. Four additional participants were HHV8 DNA+ but antibody negative. Twenty three participants were on ART throughout the study, and no significant correlations were observed between circulating HHV8 DNA and plasma HIV-1 RNA.
Overall, there were no significant differences between baseline and post-chemotherapy HHV8 DNA levels, but two participants experienced increased circulating HHV8 DNA following treatment for KS or allogeneic stem cell transplantation for lymphoma. We also observed an approximately 2-$\log^{10}$ reduction in plasma HHV8 DNA in an individual with KS and multicentric Castleman disease following rituximab monotherapy.
Although, individuals with clinical KS had lower mean $CD4^+$ lymphocyte counts and percentages, there were no significant associations between $CD4^+$ T-cell counts and plasma HHV8 levels.
However, increased frequencies of $CD8^+$ and $CD4^+$ T-cells expressing CD69 and $CD4^+$ T-cells expressing CD57 were observed in participants with detectable HHV8 (P=0.01, P=0.04, and P=0.003, respectively).
Conclusions: Cancer chemotherapy and HSCT exhibit variable effects on HHV-8 reactivation. While CD4+ T-cell counts were not associated with circulating HHV-8, plasma HHV8 is positively correlated with early markers of T-cell activation and exhaustion. Overall, these results suggest that there is a complex relationship between circulating HHV8 DNA and tissue-based disease in HIV-1-infected individuals with malignancy.

TUPEB0419

AIDS related Kaposi Sarcoma in a cohort in Rio de Janeiro, Brazil: KSHV viral dynamics, immune response and clinical outcome

J. Netto[1], B. Grinsztejn[1], V. Veloso[1], A. Pacheco[2], T. Campbell[3], W. Miley[4], R. Viggiano[5], M. Zalis[6]

Presenting author email: juliananetto@gmail.com

Background: HIV-associated Kaposi Sarcoma (AIDS-KS) remains an important cause of morbidity and mortality in Brazil. It remains crucial to understand Kaposi Sarcoma herpes virus (KSHV) infection viral dynamics and immune response in our setting to develop serological and virological assays for monitoring clinical treatment response and as prognostic markers. We conducted a prospective study of individuals with AIDS-KS at INI/FIOCRUZ, a major referral center for HIV care in Rio de Janeiro, Brazil. We measured KSHV immune response and plasma KSHV DNA in individuals with AIDS- KS initiating treatment and assessed relationships to clinical outcomes.
Methods: We enrolled all patients diagnosed with HIV-KS at INI/FIOCRUZ. Blood samples collected at enrolment and the last visit during follow up, were used in the analysis. Plasma KSHV DNA was determined using real-time PCR; immune response to KSHV latent (ORF73) and lytic (K8.1) antigens were evaluated using ELISA; immune response to a panel of KSHV antigens was assessed by multiplex assay. Logistic regression was used to determine risk factors for death.
Results: From 2011-2013, 50 patients were enrolled; 2 were lost to follow-up and excluded from analysis. One patient also fulfilled criteria for KICS and another for MCD. Mean age at KS diagnosis was 32.7 (SD9.2) years. 47.9% were white, 10.4% were female. Plasma KSHV DNA was detected in 77.8% and seroreactivity to ORF73 and K8.1 were 75% and 90.9% respectively. 8 (16.7%) died, and 6 (75%) deaths were KS related. Women had significantly higher odds of dying (OR=11.4; 95%CI=1.516-85.72; p=0.018). Plasma KSHV DNA and seroreactivity to K8.1 and ORF73 were not associated with clinical outcome. Seroreactivity to ORF19 and ORF59 significantly correlated with death (OR=14.4; 95%CI=1.095-189; p=0.026 and OR=7.778; 95%CI=1.281-47.2; p=0.034, respectively), as well as the number of antigens for which the patient was seroreactive at the time of diagnosis, (OR=1.279; 95%CI=1.018-1.605; p=0.034).
Conclusions: Our study does not support the routine use of plasma KSHV DNA nor ELISA for ORF73 or K8.1 as monitoring or prognostic markers, but we know our study has a small number of patients. Further studies are necessary to better understand the role of the multiplex assay in clinical practice.

HIV-associated Kaposi sarcoma in the post-HAART era

C. Rodríguez-Olleros[1], A. Cabello[1], S. Carbajal[1], A. Úbeda[2], R. Pérez-Tanoira[1], R. Téllez[3], J. Fortes[2], N. Rallón[1], J.M. Benito[1], M.L. Fernández Guerrero[1], M. Górgolas Hernández-Mora[1]

Presenting author email: normaibon@yahoo.com

Background: After the introduction of High-Activity AntiRetroviral Therapy (HAART), incidence of AIDS-related events decreased significantly. Despite this fact, HIV-associated Kaposi Sarcoma (HIV-KS) remains as the most frequent neoplasm in this group.
Methods: An descriptive, retrospective, unicentric study of patients with HIV-KS diagnosis in a tertiary hospital in Madrid was performed from January 2001 to December 2016. Epidemiological, clinical and therapeutical characteristics, as well as evolution criteria, were analysed with SPPS 20.0.
Results: 124 patients with HIV-KS were studied, being most of them (98%) men who have sex with men (MSM), with a mean age of 39 years (21-70). 75% were caucasic (64% Spanish) and 22% Latin-American. 37% smoked or had smoked before, and 9% had hepatotropic viruses coinfection. In 82% (90 patients) KS was the reason to start HAART, being HIV diagnosis simultaneous in 58% (52p). Mean CD4 lymphocyte count at diagnosis was 294 ± 255 c/μ, being 43% < 200, and in 75% a CD4/CD8 ratio ≤ 0,4. In 5 patients, KS appeared in the context of an immune reconstitution syndrome (IRS) and in 15 patients (14%) it was diagnosed after virological control (mean 2,3 years after HAART; mean CD4 339± 140 cel/μ; 66% CD4/CD8 ≤ 0,4). In 88% HHV-8 was detected in the hystopathological exam. 66% had a cutaneous form exclusively, while 12,5% it was mucocutaneous, 9% in lymph nodes and 11% had visceral affection. 27% associated an oportunistic infection. Treatment depending on the type of affection was started, being 60% the HAART, while 32% required adjuvant chemotherapy with 11% of toxicity; two patients required radiotherapy and 5% surgery.
20% ha one or several relapses, requiring a second-line treatment. 5 patients died during treatment, 6 had Castleman disease, and two developed cavity lymphoma.
Conclusions: HIV-KS is a prevalent disease in MSM, with a high morbi-mortality in spite of HAART implementation. HIV control does not avoid its development nor its control in some cases. Abscense of immune recovery and immunoactivation persistence could be related factors.

Piloting very early infant diagnosis (VEID) of HIV in Lesotho: acceptability and feasibility among mothers, health workers and laboratory personnel

M.M. Gill[1], M. Mokone[2], V. Tukei[2], M. Nchephe[3], M. Phalatse[3], L. Guay[1,4], A. Tiam[1], L. Mofenson[1]

Presenting author email: mgill@pedaids.org

Background: Mortality associated with in-utero HIV infection rises rapidly within weeks after birth. Current guidelines recommend HIV testing at age six weeks, but very early infant diagnosis (VEID) - testing at birth-two weeks - followed by immediate initiation of antiretroviral therapy (ART) has potential to avert mortality associated with in-utero transmission. However, our understanding of acceptability and feasibility of VEID among mothers, health workers (HW) and laboratory staff is limited.
Methods: VEID was piloted in an observational prospective cohort of HIV-positive pregnant women and their infants in 13 Lesotho health facilities from July 2014 to October 2016. Semi-structured interviews were conducted March-July 2016 with 20 HIV-positive women attending 6-week or 14-week postnatal visits in eight study facilities in three districts. Counselors/study nurses (n=18) and district/central laboratory staff (n=9) involved in VEID were also interviewed. Interview themes included acceptability of birth and subsequent HIV testing and early treatment, perceived VEID challenges and HIV birth testing procedures and how well they were performed. Thematic analysis was conducted using MAXqda (V10).
Results: Nearly all mothers interviewed were happy to know their child's HIV status at birth. Mothers and HW did not indicate that birth testing affected subsequent acceptance of infant HIV testing or clinic attendance. No respondents expressed a challenge with early ART initiation (though only the perspective of HW was captured, as all mothers interviewed had HIV-negative children). Some women expressed concern about obtaining blood from newborns and stated they received limited counseling about HIV testing. HW and laboratory staff reported weak follow-up systems for mothers with home delivery, and concern regarding limited number of diagnostic machines, reagent stock-outs and increased workload associated with additional testing requirements. All groups reported turnaround time delays for all EID, and that sometimes results were never received, which would be exacerbated by adding a test to the algorithm.
Conclusions: While respondents found VEID acceptable and feasible, the study also highlighted challenges within the existing EID system that must be addressed for birth testing to be effective. These include strategies to strengthen counseling on infant HIV testing, improve turnaround time, increase the number of facility-based deliveries and improve client tracing procedures.

Evaluation of a pilot chain peer referral approach for HIV testing among adolescents in Kisumu County, Kenya

P. Ong'wen[1], C. Blat[2], N. Okoko[1], S. Awuor[1], J. Otieno[1], M. Mburu[1], E. Mugoma[1], M. Guze[2], E.A. Bukusi[3], C.R. Cohen[2], H. Wolf[4]
[1]Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya, [2]University of California, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [3]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [4]Georgetown University, Department of Pediatrics, Washington, United States
Presenting author email: hilarywolf@gmail.com

Background: In Kenya, it is estimated that 18,000 adolescents become infected with HIV annually. Yet they are among the least likely to access HIV testing. We sought to evaluate the feasibility of a chain peer referral approach to mobilize adolescents for HIV counseling and testing.
Methods: Index participants (IPs) were identified among adolescents ages 15 to 19 years seeking any health services from September through December 2016 (intervention period) at Rabuor Sub-County Hospital in Kisumu County, Kenya. IPs were offered testing and those willing to recruit age-group peers for HIV testing received 3 to 5 referral coupons, with a cash incentive of 100 Kenyan shillings (approximately US$1) for each referral tested.
Data were analyzed using Chi-square, Fisher's exact and Wilcoxon Rank-Sum tests. We compared the monthly rates of adolescent testing and HIV-positivity per number tested (yield) between the intervention and baseline (January-August 2016) periods.
Results: Of the 1,076 coupons issued to 293 IPs, 242 (22.5%) referrals were tested, which accounted for 28.5% of the total 850 adolescents tested at Rabuor during the intervention period. 113 (38.6%) IPs recruited one or more referrals for testing, with a mean of 0.8 [standard deviation 1.26] referrals per IP. Tested referrals were predominately male (63.5%) and friends (66.4%) or classmates (14%) of the IP. No referrals tested HIV-positive. IPs with ≥1 tested referrals were more likely to be older, male, single, in school, seeking HIV testing services, without children, and themselves referred by a peer for testing (all p<0.05). Overall, adolescent testing rates did not differ significantly during the intervention [median 182 per month; IQR 147-278] compared to before the intervention [median 154 per month; IQR 117-179; p=0.31). Yield was consistently low during and before the intervention (0.7% vs. 1.5%, respectively, p=0.11).
Conclusions: The chain peer referral approach to increase HIV testing among adolescents did not lead to an increased number of positive HIV test results. Males, adolescents in school, and those seeking testing were more likely to refer others successfully for HIV testing. This approach requires further evaluation, with efforts to specifically target girls and those with undiagnosed HIV infection.

Presenting author email: atiam@pedaids.org

Background: Universal antiretroviral treatment(ART) for HIV-positive pregnant women is anticipated to significantly reduce mother-to-child HIV transmission (MTCT). The World Health Organization recommends infant HIV testing at 4-6 weeks to capture in-utero/intrapartum/early breastfeeding transmission. In-utero infection is associated with high mortality of 20-30% by age 8-12 weeks. We conducted an implementation research study to determine the relative yield of HIV birth testing.
Methods: HIV-positive and negative pregnant women were enrolled in an observational cohort to evaluate effectiveness of universal maternal ART within 13 health facilities in Lesotho following introduction of Option B+. HIV birth testing (DNA PCR within two weeks of birth) was introduced at study sites in addition to routine six-week infant testing, per national guidelines. Dried blood spots were collected at birth for PCR testing (Roche CAP/CTM HIV v2) followed by routine six-week testing. Data were analyzed to identify HIV transmission rates at birth and six weeks.
Results: Among 602 women (median age, 29 years; median gestational age at first ANC visit, 24 weeks), 427/602 (70%) of their infants were tested at birth, 497/602 (83%) were tested at 6 weeks, and 363/422 (86%) of infants uninfected at birth were retested at 6 weeks. In utero HIV infection with positive birth PCR occurred in 5/427 (1.2%) infants. An additional 2 infants, one with a prior negative birth test and a second without a prior birth test tested positive at 6 weeks, for a cumulative MTCT incidence of 1.25% (95%CI: 0.5%-2.6%). The 6-week MTCT rate was 1/211 (0.5%) among women who initiated ART before pregnancy compared to 6/331 (1.8%) among women who started ART during pregnancy. Maternal HIV RNA levels were associated with transmission: median HIV RNA was 1.27 log10 copies/mL among non-transmitting women versus 5.03 log10 copies/mL among transmitting women.
Conclusions: Universal antenatal maternal ART resulted in very low 6-week MTCT (<1.5%); MTCT rates were lowest with pre-pregnancy ART initiation. Among infants, in contrast to pre-ART era, where ~30% of infections occurred in utero, most infections (5/7, 71%) were identified at birth, suggesting that introduction of birth testing, if accompanied by rapid infant ART initiation, could significantly impact the health of infected infants.

Rapid diagnostic tests ineffectively identify infants in need of definitive PCR testing

A. Ghadrshenas[1], B. Urick[1], Y. Fong[2], C. Okiira[3], N. Nabukeera-Barungi[4], D. Nansera[5], E. Ochola[6], J. Nteziyaremye[7], V. Bigira[1], I. Ssewanyana[3], P. Olupot-Olupot[7], T. Peter[1], L. Vojnov[1], C. Kiyaga[3]
[1]Clinton Health Access Initiative, Kampala, Uganda, [2]Fred Hutchinson Cancer Research Center, Seattle, United States, [3]Central Public Health Laboratories, Kampala, Uganda, [4]Makerere University, Kampala, Uganda, [5]Mbabara Regional Referral Hospital, Mbabara, Uganda, [6]St. Mary's Hospital Lacor, Gulu, Uganda, [7]Mbale Regional Referral Hospital, Mbale, Uganda
Presenting author email: anisaleyla@gmail.com

Background: HIV programs operationalize WHO recommendations for the use of Rapid Diagnostic Tests in infants by offering testing as a screening tool at sick-care visits or for wider screening of healthy infants, as well as within PMTCT programs for known HIV-exposed infants returning at 9 months of age. In all cases, the result of the RDT is used as a screening test to reflex to definitive PCR testing, but has not been formally evaluated for effectiveness in HIV diagnosis.
Methods: A cross-sectional prospective study of children younger than two years presenting at primary health facility entry points was conducted at four Ugandan hospitals. Infants were systematically sampled from five entry points at each facility: Immunization/EPI/well-child, pediatric outpatient, pediatric inpatient, nutrition ward, and outreach. All participants, regardless of HIV exposure status, received an RDT to determine exposure status and a PCR test to determine infection status. The samples were collected in parallel and PCR samples were run irrespective of the RDT outcome.
Results: The sensitivity of the RDT to accurately identify HIV-positive children in need of PCR testing was 61.7% (95% confidence interval: 51.1 - 71.5), while the specificity was 97.3% (95% CI: 96.6 - 97.8). The positive predictive value in this population was 42.3% (95% CI: 34.0 - 51.1), while the negative predictive value was 98.7% (95% CI: 98.3 - 99.1). We also examined performance of the RDT in different age groups in four-month intervals and found that for each age category under one year, the estimated sensitivity was less than 50%, including 8 - 12 months of age (47%). The median age of HIV-positive infants with a negative RDT was 8.5 months, while the median age of HIV-positive infants with a positive RDT was 14 months. Additionally, approximately 40% of HIV-positive infants identified were negative by RDT.
Conclusions: These data suggest that the use of RDTs to screen HIV-exposed infants or those in need of a definitive PCR test could result in a large proportion of vulnerable HIV-positive infants being sent home without receiving care and treatment. In order to improve identification and linkage of HIV-positive infants, PCR testing could instead be considered.

TUPEB0425

Status of early infant diagnosis and bottlenecks to paediatric ART services in heavy HIV burden districts in Malawi

J. Chipeta
University of Malawi, College of Medicine, Blantyre, Malawi
Presenting author email: jbchipeta@gmail.com

Background: Paediatric ART in Malawi is sub-optimal with coverage in 2016 of only 65%. A major problem is delayed HIV testing (HT) of infants and loss to follow up (LTFU). Interventions to improve paediatric ART initiation, coverage and retention include early infant diagnosis (EID), training and client follow-up models. Current management information systems aggregate service delivery data for 0-14 year olds. An assessment of the current status of HIV testing, ART initiation and retention among children aged 0-9 years was conducted to identify gaps that are critical to early diagnosis and enrolment in care and treatment.
Methods: Stratified random sampling was used to select 61 out of 276 health facilities in 8 high HIV burden districts. The sample included peripheral, district and tertiary level health facilities. Age-disaggregated data on EID and ART were abstracted from HIV service delivery registers and data analysis conducted using Excel.
Results: Of 11,401 children aged 0-9 years tested for HIV during July-September 2016, 10% were aged 0-11 months. Four percent of infants 0-2 months and fourteen percent of infants 3-11 months tested positive. Sixty-five percent of children aged 0-11 months who tested HIV-positive were started on ART. ART retention was lowest in the age group 0-11 months, at 76% and 74% at 3 and 6 months, respectively.
Conclusions: Reporting HTC and ART data for children aged 0-14 years masks inadequate HIV testing and ART retention in children 0-11 months. The increase in HIV positivity yield in infants 3-11 months suggests the need to aggressively promote HIV prevention among HIV negative mothers to prevent sero-conversion of mothers and infants during the breastfeeding period. Disaggregating paediatric data is critical to delivering appropriate HIV services to mothers and their children.

TUPEB0426

Intensified vertical HIV-1 transmission prevention influences the rate and eventual outcome of indeterminate HIV-1 PCR results

J.N. Maharaj[1,2], M.F. Cotton[3], W. Preiser[1,2], J. Maritz[1,2]
[1]University of Stellenbosch, Medical Virology, Cape Town, South Africa, [2]National Health Laboratory Service, Cape Town, South Africa, [3]University of Stellenbosch, Pediatrics and Child Health, Cape Town, South Africa
Presenting author email: maritzj@sun.ac.za

Background: Indeterminate HIV-1 PCR results obtained from testing HIV-exposed infants may represent very early HIV-1 infections, established infections with viral suppression by antiretroviral drugs, or non-specific amplification. Indeterminate PCR results are defined by laboratory criteria currently used across all public health laboratories in South Africa. We investigated rates of indeterminate PCR results and outcomes of subsequently obtained samples from the Western Cape province of South Africa, and hypothesised that the predictive value of an indeterminate PCR for a subsequent positive result has increased in the setting of intensified vertical HIV transmission prevention regimens.
Methods: Routine diagnostic PCR data of a public health laboratory from June 2009 to October 2014 was analysed and categorised by South African vertical HIV transmission prevention regimen. All included PCRs were performed with the Roche CAP/CTM HIV-1 Qualitative Version 1 test. First indeterminate HIV-1 PCRs in patients younger than 12 months were linked with follow-up HIV-1 PCRs (any age) and serological tests (when >18 months of age). Linked results sets were analysed for CAP/CTM amplification characteristics and subsequent sample outcome.
Results: The dataset comprised 38,043 infants tested at a median age of 45 days of life. Over intensified vertical transmission prevention regimens, the rate of indeterminate and positive PCRs decreased significantly (5.6% to 3.2%, 2.4% to 0.4%, respectively; both p<0.001). Most notably, significantly more patients with indeterminate PCRs had positive PCRs on subsequent samples during WHO Option B+ use compared to previously used vertical transmission prevention regimens (64.1% vs 14.7%, p<0.001) at a median 28 of days later.

VTP regimen	Numbers (%)			Indeterminate PCRs as % of non-negative results	% indeterminate PCRs positive on follow-up
	Negative	Positive	Indeterminate		
ART initiated at CD4<200 cells/mm3	5936 (92.0)	359 (5.6)	152 (2.4)	29.8%	7.4%
WHO Option A	19927 (95.5)	687 (3.3)	257 (1.2)	27.2%	18.9%
WHO Option B+	10343 (96.4)	338 (3.2)	44 (0.4)	11.5%	64.1%

[Frequency and outcome of indeterminate PCRs]

Conclusions: Indeterminate HIV PCRs, although decreasing in frequency with Option B+ use, should be regarded with a high index of suspicion for being representative of true HIV-1 infections. Intensified vertical HIV transmission prevention regimens as well as diagnostic assay software improvements may account for this finding. Infants with indeterminate PCR results should receive close follow up and additional virological tests to arrive at a definitive diagnosis.

TUPEB0427

Adolescents enrolling in HIV care in East Africa from 2000-2014

Presenting author email: john.m.humphrey@gmail.com

Background: The objective of this study is to understand the characteristics and outcomes, over time, of adolescents enrolling in HIV care in Kenya, Tanzania, and Uganda.
Methods: This retrospective cohort study utilizes patient-level data from six HIV care programs affiliated with the East African International epidemiologic Databases to Evaluate AIDS (EA-IeDEA) Consortium. The study population con-

sists of all individuals enrolling in HIV care at study facilities during adolescence (10-19 years) between 2000 and 2014. Adolescents were stratified into two groups based on age at time of enrollment: younger adolescents (YA [10-14 years]) and older adolescents (OA [15-19 years]). Descriptive analyses were used to compare groups at enrollment and antiretroviral therapy (ART) initiation across four time periods 2000-2004, 2005-2009, 2010-2012, and 2013-2014. The proportion of enrolling adolescents was compared to the total number of individuals ≥10 years enrolling during each period. Competing risk analysis was used to estimate 12-month retention, defined as the inverse of death/loss to follow-up (LTFU), after enrollment/pre-ART initiation; standard survival analysis was used to estimate 12-month retention after ART initiation.

Results: A total of 6,342 adolescents enrolled between 2000-2014, 56.4% were OA, and 54.3% of YA and 77.1% of OA were female (Table). Median CD4 at enrollment in 2000-2004 compared to 2012-2014 increased for YA (208 vs. 359 cells/mm^3, p<0.0001) and OA (155 vs. 431 cells/mm^3, p=0.0002). The proportions of YA and OA enrolling with WHO stage 1-2 disease, compared to stage 3-4 disease, increased over time (p<0.0001). Retention rates were: 89% (95% CI 88-90%) for YA and 78% (95% CI 77-80%) for OA at 12 months after enrollment; 83% (95% CI 81-84%) for YA and 72% (95% CI 70-74%) for OA at 12 months after ART initiation.

Period of Enrollment	2000-2004		2005-2009		2010-2012		2012-2014		
	Younger adolescent n (%)	Older adolescent n (%)	Younger adolescent n (%)	Older adolescent n (%)	Younger adolescent n (%)	Older adolescent n (%)	Younger adolescent n (%)	Older adolescent n (%)	P values For comparison across periods
Proportion of adolescents enrolled among all individuals ≥10 years of age enrolled	135 (1.4)	100 (1.1)	1451 (1.3)	1456 (1.3)	904 (1.4)	1224 (2.0)	274 (1.0)	798 (2.9)	YA< 0.0001 OA< 0.0001
Female sex	63 (46.7)	67 (67.0)	781 (53.8)	1086 (74.6)	503 (55.6)	949 (77.5)	155 (56.6)	656 (82.2)	YA< 0.0001 OA< 0.0001

WHO stage 1-2 at ART initiation	7 (8.6)	13 (20.0)	138 (13.7)	261 (36.3)	185 (23.0)	423 (51.8)	85 (28.0)	524 (72.7)	YA< 0.0001 OA< 0.0001
WHO stage 3-4 at ART initiation	15 (18.5)	14 (21.5)	196 (19.4)	314 (43.7)	132 (16.4)	206 (16.8)	43 (14.1)	97 (12.2)	YA< 0.0001 OA< 0.0001
CD4 at enrollment, median	208	155	268	304	313	379	359	431	YA< 0.0001 OA= 0.0002
CD4 at ART initiation, median	81	60	164	128	234	209	260	323	YA< 0.0001 OA< 0.0001

[Adolescent characteristics from 2000 to 2014]

Conclusions: Program retention is suboptimal for adolescents, particularly OA, in East Africa. Strategies to understand LTFU and promote retention are needed.

Presenting author email: ml2842@columbia.edu

Background: The ACT Initiative aimed to double the number of children on ART. We describe outcomes within the ICAP Columbia University program at 442 health facilities in five counties in Kenya.
Methods: Trained lay counselors were deployed to provide HIV testing at multiple facility entry points, linkage officers facilitated enrollment from testing to HIV care, and clinicians were trained on prompt ART initiation, and adherence support. Peer counselors were trained to provide SMS reminders for clinic appointments, call and trace clients' who missed visits, and provide adherence/psychosocial support. Routinely collected aggregate data was analyzed to describe progress towards 90-90-90 for younger (<10 yrs) and older children (10-14 yrs).
Results: Overall, 292,213 younger children and 178,551 older children received HIV testing between October 2015 and September 2016, a two-fold increase compared to the prior 12 months. Of these, 1,814 (0.6%) younger children and 735 (0.4%) older children tested HIV-positive, compared to 1,926 (1%) younger and 682 (0.8%) older children in the previous 12 months. Of those testing HIV-positive, 93% of younger and 81% of older children enrolled in HIV care. Between the first and last quarter, there was a 22% increase in ART initiation among younger children (341 to 415), and 195% increase among older children (110 to 325). By September 2016, the proportion of children on ART reached 99% of younger and 94% of older children and retention at 12 months after ART initiation for children <10 yrs was 81% and 79% for 10-14years. The proportion of children who received a viral load (VL) test 6 months after ART initiation increased from 67% to 89% for children <10yrs, and from 60% to 85% for 10-14 yrs. Among those with documented VL results at 6 months (<10 yrs: 63%; 10-14 yrs: 66%), the proportion with VL< 1000 copies/ml was 80% and 84% in younger and older respectively.
Conclusions: Intensified testing strategies resulted in a substantial increase in the number of children tested, however the yield was low. Although ART initiation, 12-month retention, and viral suppression were high, additional strategies are needed to identify, engage and successfully treat all children with HIV.

TUPEB0429

Population level assessment of HIV+ Ugandan/Kenyan children who remained viremic in the SEARCH test-and-treat study, which achieved 90-90-90 coverage of adults

T.D. Ruel[1], J. Ayieko[2], A. Owaraganise[3], F. Mwangwa[3], M. Kaur[4], T. Liegler[4], D. Black[4], L. Brown[4], V. Jain[4], C.R. Cohen[5], E. Bukusi[2], T.D. Clark[4], E.D. Charlebois[4], D. Kwarisiima[3,6], M.L. Petersen[7], D.V. Havlir[4], M.R. Kamya[3,8]
[1]University of California, Department of Pediatrics, Division of Pediatric Infectious Diseases and Global Health, San Francisco, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]University of California, Department of Medicine, Division of HIV, Infectious Diseases & Global Medicine, San Francisco, United States, [5]University of California, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [6]Makerere University Joint AIDS Program, Kampala, Uganda, [7]University of California, Berkeley School of Public Health, Berkeley, United States, [8]Makerere University College of Health Sciences, 8 School of Medicine, Kampala, Uganda
Presenting author email: theodore.ruel@ucsf.edu

Background: The SEARCH HIV test-and-treat study (NCT01864603) achieved the 90-90-90 target of 80% population-level virologic suppression among adults in rural Kenyan and Ugandan communities. The HIV-status of 89% of children was ascertained, but the probability of suppression at 2 years was only 62%. We sought to describe the characteristics of viremic children and identify population-level predictors of risk.
Methods: All HIV+ children in 16 intervention communities were offered ART in a streamlined-care model. Viral loads (VLs) were measured during annual community heath campaigns and at clinic visits. We assessed children aged 2-14 years with ≥1 VL measured (May 2013-November 2016). Using multivariable logistic regression, we evaluated potential predictors of viremia (most recent VL>500 copies/ml), including demographic characteristics, HIV care-status (never linked, linked but lost to follow-up [no visit in prior ≥9 months], or active), household wealth index, and presence of HIV+ mother with suppressed VL in the household.
Results: Overall, 700/739 (95%) HIV+ children living in SEARCH communities had ≥ one VL. They were 55% female, with 42% aged 2-6, 32% aged 7-10, and 26% aged 11-14 years. Among 262/700 (37%) viremic children, care-status varied: 43(16%) never linked to care, 54(21%) linked but were lost to follow-up and 165 (63%) were known to be in active care. Children aged 11-14 and 2-6 years had greater likelihood of viremia than those 7-10 years. Greater household wealth predicted viremia, while presence of an HIV+ mother with suppressed VL lowered risk.

Variable	Univariate OR (95% CI)	Adjusted OR (95%CI)
Female gender	1.29 (0.94-1.75)	1.21 (0.87-1.67)
Age (years), 11-14 vs. 7-10	2.63 (1.73-3.98)	2.45 (1.58-3.78)
2-6 vs. 7-10	1.71 (1.17-2.50)	1.90 (1.28-2.82)
Care status, never linked vs. active	2.35 (1.46-3.81)	2.00 (1.21-3.30)
LTFU vs. active	1.38 (0.93-2.05)	1.32 (0.88-2.00)
HIV+ mother with suppressed VL present in home	0.63 (0.46-0.87)	0.69 (0.49-0.98)
Kenya vs. Uganda	1.53 (1.08-2.17)	1.50 (1.04-2.18)
High household wealth*	1.73 (1.01-2.97)	1.78 (1.00-3.15)
Household wealth ranked in quintiles; Odds ratio (OR) for highest vs. lowest shown.		

[Predictors of viremia in children]

Conclusions: To address the gap in community-level HIV suppression in children, improved linkage and retention will be important, but the highest proportion of viremic children are already in care, underscoring problems of adherence and/or drug resistance. Multiple interventions, tailored to different regions, age groups and higher wealth households will likely be required to achieve 90-90-90 in children living in rural East Africa.

TUPEB0430

Risk and warning signs for loss to follow-up in a cohort of HIV-infected children on antiretroviral therapy in Thailand

S. Kawilapat[1,2], N. Salvadori[1], N. Ngo-Giang-Huong[1,3,4], C. Leroi[1], C. Ngampiyaskul[5], S. Kanjanavanit[6], P. Layangool[7], N. Lertpienthum[8], S. Hanpinitsak[9], A. Puangsombat[10], N. Akarathum[11], S. Le Coeur[1,3,4], M. Lallemant[1,3,4], P. Traisathit[1,2], G. Jourdain[1,3,4]
[1]UMI 174-PHPT, Faculty of Associated Medical Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]Biostatistics and Applied Statistics Laboratory, Department of Statistics, Faculty of Science, Chiang Mai University, Chiang Mai, Thailand, [3]Institut de Recherche pour le Développement (IRD), UMI 174-PHPT, Marseille, France, [4]Harvard T H Chan School of Public Health, Boston, United States, [5]Prapokklao Hospital, Chantaburi, Thailand, [6]Nakornping Hospital, Chiang Mai, Thailand, [7]Bhumibol Adulyadej Hospital, Bangkok, Thailand, [8]Buddhachinaraj Hospital, Pitsanuloke, Thailand, [9]Regional Health Promotion Centre 6, Khon Kaen, Thailand, [10]Samutprakarn Hospital, Samutprakarn, Thailand, [11]Sanpatong Hospital, Chiang Mai, Thailand
Presenting author email: suttipong.kawilapat@phpt.org

Background: Detecting signs associated with an increased risk of loss to follow-up (LTFU) may help maximize the effectiveness of antiretroviral therapy (ART) programs. Adolescence is a well-known factor contributing to the risk of LTFU but other information collected during follow-up may help clinicians focus on children at higher risk.
Methods: We used demographics and clinical data collected at ART initiation (baseline), 2 weeks, 1 month, 3 and 6 months, and every 6 months thereafter in children participating in the PHPT multicenter pediatric cohort in Thailand between January 1, 1999 and December 31, 2014. Children who did not come for follow-up >9 months after their last appointment were considered as LTFU. Discontinuation of ART was considered if >7 days. Baseline and time-updated variables associated with LTFU were identified using Fine and Gray competing risk regression models accounting for deaths and referrals to other clinics as competing events. We adjusted for characteristics of the Thai program: calendar years of enrollment (quartiles: before 2003, 2003-2004, 2005-2006 and after) and regions in Thailand (northern and others). Missing values of time-updated variables were imputed using linear interpolation within 1 year before and after the missing visit.
Results: 832 children (445 female, 53%) were included in the analysis. Baseline median age was 7.2 years (IQR 3.1-10.0); 67 (9%) were living in orphanage and 508 (61%) in northern Thailand. 255 (34%) had HIV-RNA load >400 copies/mL at 5 years after initiation and 99 (12%) discontinued ART at least once. Median follow-up was 8.2 years (4.1-10.3): 184 (22%) were LTFU (observed cumulative risk of LTFU: 7.6% at 5 years and 29.5% at 10 years). The estimated cumulative incidence of LTFU (considering 184 children referred elsewhere and 72 deaths as competing) was 6.9% (95%CI 5.3-8.7%) at 5 years and 22.8% (19.8-26.0%) at 10 years. In the multivariable analysis, factors associated with a higher risk of LTFU were: not living in orphanage (p=0.006); and, as time-updated, age ≥13 years (p<0.001), HIV-RNA load >400 copies/mL (p=0.001), and previous ART transient discontinuation (p=0.001).
Conclusions: Transient discontinuation of ART at any time during the follow-up should draw clinicians' attention to prevent definitive LTFU.

TUPEB0431

"*Not all Mogen Clamps are created equal*": standardising Mogen Clamp specifications for EIMC

G.N. Dean[1], S. Frade[2,3], D. Hill[4], D. Taljaard[1]
[1]Centre for HIV/AIDS Prevention Studies, Research, Johannesburg, South Africa, [2]University of the Witwatersrand, Demography and Population Studies, Johannesburg, South Africa, [3]Centre for HIV/AIDS Prevention Studies, Johannesburg, South Africa, [4]PrionTex, Johannesburg, South Africa

Background: According to the "WHO Manual for Early Infant Male Circumcision under Local Anaesthesia" there are 3 devices that have been pre-qualified to be used on infants; namely, the Gomco Clamp, Plastibell and Mogen Clamp. An EIMC pilot study in South Africa, which used the Mogen Clamp found that there are currently no standard specifications for Mogen Clamps for EIMC - except that the WHO guidelines state that there must be an aperture of 2 mm, but does not indicate where this aperture of 2 mm refers to on the Mogen Clamp. During the start-up phase of the pilot study on EIMC in South Africa, and after several AEs due to low quality Mogen Clamps, it was found that standard specifications are required to ensure the safety of infants circumcised using the Mogen Clamp.
Methods: CHAPS, together with the supplier, measured the dimensions of the Mogen Clamps from three different suppliers to compare. The 3 different products are "Product A" (the Mogen Clamp found to be of the best quality and with the most appropriate specifications for EIMC), "Product B" and "Product C". Dimensions were taken from 7 different points on the Mogen Clamp.
Results: After several qualitative discussions with the clinicians, and the supplier in South Africa, it was determined that the best point of reference for determining a "good" quality Mogen Clamp was on dimension A (maximum opening width) given that it is at this point that the foreskin is pulled through before the crushing action (table 1).

Clamp Dimensions (mm)	Product A	Product B	Product C
A -Maximum opening width	2.35	3.39	3.10
B- Middle opening width	1.40	2.01	1.70
C- Inner hinge opening width	0.43	0.53	0.45
D- Clasp diameter	10.88	12.70	12.79
E- Back hinge width	0.40	0.45	0.45
F- Working surface length	< 0.04 (Length = 43.71)	< 0.04 (Length = 44.40)	< 0.04 (Length = 44.00

[Table 1: Mogen Clamp Dimensions]

Conclusions: This research will assist in establishing the parameters for the Mogen clamp in order for them to comply to WHO guidelines.

TUPEB0432

Pharmacokinetic (PK) modelling and simulation to support weight-based dosing of maraviroc (MVC) in paediatric subjects when co-administered with potent CYP3A inhibitors

L. McFadyen[1], B. Weatherley[1], P.L.S. Chan[1], M. Vourvahis[2], K. Moore[3], S.F. Marshall[1]
[1]Pfizer, Pharmacometrics, Sandwich, United Kingdom, [2]Pfizer, Clinical Pharmacology, New York, United States, [3]ViiV Healthcare, Clinical Pharmacology, Research Triangle Park, United States
Presenting author email: lynn.mcfadyen@pfizer.com

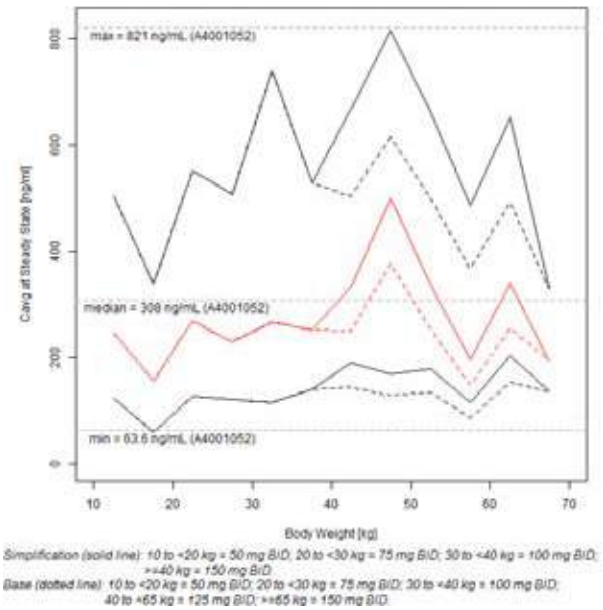
Background: A4001031 is a PK and safety study of MVC in treatment-experienced HIV-1-infected paediatric subjects. Initial MVC dose was adjusted on body surface area (BSA) and co-administered potent CYP3A inhibitors or inducers. Most subjects (90/103) took MVC with CYP3A inhibitors (i.e. protease inhibitors) in optimized background therapy. The objectives were to describe the PK of MVC with potent CYP3A inhibitors and determine weight-based dosing by simulation for paediatric subjects.
Methods: MVC PK data from 85 paediatric subjects were combined with adult data from Phase1-4 studies. Nonlinear mixed effects modelling was used to fit a 2-compartment model with first-order absorption; covariates (See Table) were assessed in stepwise modelling.

	Paediatric Study (A4001031)	Adult Phase 2b/3/4	Adult Phase 1
Number of subjects (males/females)	85 (43/42)	125 (112/13)	56 (45/11)
Weight (kg) : Median (Range)	28.9 (10.2-69.8)	76.7 (50.2-120.0)	71.0 (46.0-92.2)
BSA (m2) : Median (Range)	1.05 (0.48-1.83)	1.93 (1.50-2.44)	1.87 (1.39-2.19)
Age (years) : Median (Range)	11 (2-17)	45 (28-69)	29.5 (20-55)
Race: White/Black/Asian/Other (N)	13/58/11/3	96/20/4/5	24/5/26/1
Subjects/PK Sampling Occasions/Samples (N)	Intense: 38/67/468 Sparse: 84/0/648	Intense: 0/0/0 Sparse: 125/0/861	Intense: 56/74/628 Sparse: 0/0/0
Protease Inhibitors: ATV/ATV/r /FPV/r /LPV/r /DRV/r (N)	0/2/1/68/14	5/33/0/79/8	0/12/0/19/25
Food Status for Samples: Fasted/Fed/Not Known (N)	Profiles: 0/460/8 Sparse: 0/491/157	Profiles: 0/0/0 Sparse: 152/539/170	Profiles: 628/0/0 Sparse: 0/0/0
Baseline Estimated Creatinine CL (mL/min): Median (Range)	Under 12 years: 111 (57-180) 12 years and over: 135 (42-189)	107 (53-240)	108 (68-172)

[Covariates and Populations]

The paediatric covariate dataset was bootstrapped with replacement to produce a simulation dataset (N=1000) to determine concentrations for various dosing scenarios, using the PK model.

Results: The 2-compartment model was satisfactory. Statistically significant covariates were: weight (Central and Peripheral CL and Volumes); dose nonlinearity (Relative Bioavailability); CYP3A inhibitor groups, CYP3A inducer & creatinine CL (all on CL); Race (central Volume).
The Figure shows 5th, 50th and 95th percentiles of MVC average concentration (Cavg) simulations for two dosing scenarios (Base=5 weight bands for BSA-to-weight translation and Simplification=4 weight bands with flat adult dose for subjects >40 kg) compared with median and range MVC Cavg for 150 mg BID with DRV/r in adult Study A4001052.



[Simulations for Paediatrics vs Adult Data]

Conclusions: Using modelling and simulation, MVC dosing in paediatric subjects with the simplified, 4 weight bands across 10-70 kg achieves comparable exposures (Cavg) to adults on MVC 150 mg BID with potent CYP3A inhibitors.

TUPEB0433

Maraviroc pharmacokinetics and dosing recommendations in CCR5-tropic HIV-1-infected children aged 2 to < 18 years

M. Vourvahis[1], L. McFadyen[2], S.R. Valluri[1], A. Fang[1], K. Moore[3], J. Heera[4]
[1]Pfi, New York, United States, [2]Pfizer, Clinical Pharmacology, Sandwich, United Kingdom, [3]ViiV Healthcare, Research Triangle Park, United States, [4]Pfi, Groton, United States
Presenting author email: lynn.mcfadyen@pfizer.com

Background: Maraviroc (MVC) is a CCR5-antagonist approved to treat adults, and recently children/adolescents, infected with CCR5-tropic HIV-1.
Methods: A4001031 is an open-label, two-stage (stage-1: dose-finding, stage-2: safety/efficacy), non-comparative, multicenter study of MVC plus optimized background therapy in treatment-experienced children aged 2 to < 18 years. Participants were dosed twice-daily according to body surface area and concomitant medications (i.e., presence of CYP3A inhibitors and/or inducers). Intensive and sparse MVC pharmacokinetics (PK) up to Week 48 were determined in subjects to assess dose or modify dose in stage-1, if required, to achieve average concentration (C_{avg}) ≥100ng/mL.
Results: A total of 97 subjects were treated with MVC tablet or oral solution with/without food in stage-2 including the 50 subjects who also participated in stage-1 (MVC dosed with food).

Concomitant Medications	MVC dosed with potent CYP3A inhibitors (with or without a CYP3A inducer)	MVC dosed with non-interacting drugs	MVC dosed with a potent CYP3A inducer (without a potent CYP3A inhibitor)
Number of subjects (males/females)	85 (43/42)	10 (4/6)	2 (0/2)
Weight (kg) : median (range)	28.9 (10.2-69.8)	32.1 (16.2-40.3)	32.8 (17.0-48.5)
BSA (m2) : median (range)	1.05 (0.48-1.83)	1.1 (0.67-1.30)	1.0 (0.69-1.41)
Age (years) : median (range)	11 (2-17)	11.5 (3-17)	9 (4-14)
Race (White/Black/Asian/Other)	13 / 58 / 11 / 3	2 / 6 / 0 / 2	0 / 2 / 0 / 0

[Table 1]

MVC PK in children/adolescents based on body weight (kg)-bands and concomitant medication fell within the ranges observed in adults on approved doses.
Children receiving non-interacting drugs required greater mg/kg MVC dose compared to adults in order to achieve target exposures. Regulatory approval in US was achieved for children ≥30kg receiving non-interacting concomitant medications and for children 10kg to ≥40kg receiving concomitant CYP3A inhibitors (with/without CYP3A inducers). EU approval is pending and submissions in other regions are planned. Insufficient PK data are available to make dose recommendations for children receiving MVC in combination with potent CYP3A inducers (without CYP3A inhibitor).

Observed MVC Geometric Mean PK Parameters in TE Children and Adolescents Receiving MVC with Other Concomitant Medications (not Potent CYP3A Inhibitors and/or CYP3A Inducers)						
Weight (kg)	***MVC Dose***	***AUC12 (ng.h/mL)***	***Cavg (ng/mL)***	***Cmax (ng/mL)***	***Cmin (ng/mL)***	
10 to <20 kg (n=2)	No recommendation*	1941	162	746	16.0#	***# arithmetic mean (geometric mean could not be calculated as one value was zero)***
20 to <30 kg (n=1) α	No recommendation*	2498	208	751	44.1	***α - Two observations from 1 subject***
≥30 kg (n=5)β	300 mg twice daily	1998	167	413	50.6	***β - Nine observations from 5 subjects***
Simulated MVC Geometric Mean PK Parameters in TE Children and Adolescents Receiving MVC with Potent CYP3A Inhibitors (with or without a Potent CYP3A Inducer)^						
10 to <20 kg	50 mg twice daily	2349	196	324	78	***^model-predicted steady-state PK parameters***
20 to <30 kg	75 mg twice daily	3020	252	394	118	
30 to <40 kg	100 mg twice daily	3229	269	430	126	
≥40 kg	150 mg twice daily	4044	337	563	152	

[Table 2]

CYP3A=Cytochrome P450 3A; kg=kilogram; mg=milligram; TE=treatment-experienced
[a]Two observations from 1 subject;
[b] Nine observations from 5 subjects;
*PK following MVC 200mg (10kg to < 20kg) and 300mg twice daily (20 to <30kg), respectively;
arithmetic mean (geometric mean could not be calculated as one value was zero);
^model-predicted steady-state PK parameters
Conclusions: MVC exposures in pediatric subjects, with MVC dosing based on body weight and concomitant medication, were similar to those observed in adults at approved doses and serve as the basis for MVC dose recommendations in children 2 to <18 years of age weighing ≥10kg.

[1]Centre Pasteur du Cameroun, Service d'Epidémiologie et de Santé Publique, Yaounde, Cameroon, [2]Centre Hospitalier d'Essos, Pédiatrie, Yaoundé, Cameroon, [3]Centre Mère et Enfant, Fondation Chantal Biya, Unité Pédiatrique de Jour, Yaoundé, Cameroon, [4]Hôpital Laquintinie de Douala, Département de Pédiatrie, Douala, Cameroon, [5]Université de Douala, Faculté de Médecine et des Sciences Pharmaceutiques, Douala, Cameroon, [6]Centre Pasteur du Cameroun, Service de Virologie, Yaoundé, Cameroon, [7]Assistance Publique des Hôpitaux de Paris, Hôpital Robert Debré, Pédiatrie Générale, Paris, France, [8]INSERM UMR 1123, ECEVE, Paris, France, [9]Université Paris Diderot, Sorbonne Paris Cité, Paris, France, [10]Assistance Publique des Hôpitaux de Paris, Hôpital de Bicêtre, Le Kremlin Bicêtre, France, [11]CESP - INSERM U1018, Equipe VIH et IST, Le Kremlin Bicêtre, France, [12]Université Paris Sud, Paris, France
Presenting author email: temacy@yahoo.fr

Background: Negative serological test in early treated HIV-infected children is no more a rare phenomenon. However, the host factors determining the absence of HIV antibodies are not completely understood. Here, we explored characteristics associated with the absence of HIV-antibodies in early treated children followed-up during five years in the ANRS-Pediacam cohort.
Methods: From November 2007 to December 2011, HIV-infected children <7 months were included in the ANRS-PEDIACAM cohort in Cameroon after parental consent, treated and followed-up during five years. HIV serology was carried out

with a fourth-generation ELISA as from fifteen months of age, and was repeated during follow-up. Retrospectively, we defined using serological test and viral load result and compared two groups of children: seronegative group (children with at least one negative serological test during follow-up) and control group (children with positive serological test who maintained HIV viral load under 1000 copies/ml during follow-up).
Results: Of 210 children enrolled in the study, 144 performed at least one HIV serology and were considered in the analysis. Median age at cART initiation was 4.1 months [IQR: 3.2-5.6] and the median duration of cART was 4.7 years (IQR: 4.5-4.8). Median age at first HIV serology was 20.3 months [Interquartile range (IQR): 18.3-22.8]. Of the 144 children, 28 (19%) children were seronegative and 26 (18 %) fulfilled the control group criteria. Age at cART initiation, duration from cART initiation to first HIV suppression, and pre-term birth were significantly associated with absence of HIV-antibodies (Table 1).
No difference was observed between the two groups concerning gender, PMTCT prophylaxis, mode of delivery, cART regimen at initiation, and other social and economic characteristics of the mothers.

Characteristics	Seronegative group N=28	Control group N=26	p
Age at treatment initiation less than 3 months	11 (39 %)	3 (12 %)	0.04
Duration from cART initiation and first viral load <1000 copies/ml	3.31 [2.97 - 6.46]	5.27 [3.17 - 6.06]	<0.001
Duration from cART initiation and first CD4 lymphocytes >35%	3.13 [2.95 - 13.98]	6.03 [5.14 - 12.69]	<0.001
Preterm birth (gestational age <38 weeks)	11 (39 %)	4 (15 %)	0.04

[Table 1: Significant characteristics between the 2 groups]

Conclusions: These results underscore the interest of early cART, and highlight the fact that lack of children maturation could influence the production of HIV-antibodies. There is a need to continue this exploration in order to gather convincing data for families to maintain adherence in case of seronegativity

TUPEB0435

Longer-term safety of maraviroc in paediatric patients with R5 HIV: follow-up data from study A4001031

Presenting author email: elnavanderryst@live.com

Background: Study A4001031 evaluated the pharmacokinetics (PK), safety and efficacy of maraviroc (MVC) in treatment-experienced (TE) paediatric patients with R5 HIV. Week 48 data demonstrated that MVC exposures achieved were in the same ranges as those seen in adults. MVC was safe and well-tolerated with a similar safety profile and efficacy compared to adults. Based on this data MVC was recently approved in the USA (with doses based on body weight and concomitant medication) for the treatment of children (2-18 years) with R5 HIV. Safety and efficacy data from the longer-term post Week 48 follow-up of patients remaining in study are described.
Methods: This open-label, age-stratified, non-comparative, multicenter study of MVC plus optimized background therapy (OBT) had a primary endpoint analysis conducted at Week 48, but is continuing to 5 years to assess long-term safety. Patients were enrolled into one of four age/formulation cohorts and received twice daily doses of MVC, selected based on body surface area and adjusted for potential interactions with OBT.
Results: One-hundred and three patients were enrolled, of whom 52% were female. The majority (68.9%) were black, with 15.5% White and 10.7% Asian. As of 19 February 2016, all patients remaining in study (n=65) have reached 96 weeks, and 18 have reached the 5 year endpoint. Fifty patients discontinued from treatment, with insufficient clinical response (n=32) being the main reason for discontinuation. Of patients remaining in study, 52/65 (80%) and 47/55 (85%) had HIV-1 RNA <48 copies/mL at Weeks 96 and 144, respectively, compared to 49/72 (68%) at Week 48. CD4 cell count increases (absolute and percentage) were maintained after Week 48. Three patients discontinued due to adverse events (AEs). AEs occurring in >10% (diarrhoea, vomiting, pyrexia, bronchitis, upper respiratory tract infection and cough) are common in this population. The frequency and nature of AEs remained similar to what was seen at Week 48, and consistent with MVC's safety profile in adults.
Conclusions: Long-term follow-up data from study A4001031 confirmed the safety and tolerability of MVC in paediatric patients with no new safety concerns observed. Virologic responses were maintained in the majority of patients remaining in study.

TUPEB0436

Pediatric long-term outcomes following enrollment in an HIV perinatal clinical trial

K. Nielsen-Saines[1], Y. Bryson[1], C. Moreira[2], P.R. Soni[1], M.I. Gouvea[3], M.D.L. Teixeira[3], M.L.S. Cruz[2], I. Gomes[4], J.H. Pilotto[5], E. Joao[2], NICHD/HPTN 040 Neonatal Study
[1]UCLA - David Geffen School of Medicine, Pediatric Infectious Diseases, Los Angeles, United States, [2]Hospital Federal dos Servidores do Estado, Rio de Janeiro, Brazil, [3]Hospital Federal dos Servidores do Estado e Fiocruz, Rio de Janeiro, Brazil, [4]Hospital Geral de Nova Iguacu, Nova Iguacu, Brazil, [5]Oswaldo Cruz Foundation/Fiocruz & HGNI, Rio de Janeiro, Brazil
Presenting author email: psoni@mednet.ucla.edu

Background: Early diagnosis of HIV infection followed by ART initiation among infants who participate in perinatal trials for prevention/identification of infection are often associated with improved outcomes. We evaluated the clinical/laboratory status of HIV- infected children identified in an early trial 5 to 11 years later.
Methods: We offered study participation to HIV-infected children previously enrolled in the NICHD/HPTN 040 neonatal study between 2004-2011 from Brazil. Medical history, timing of infection (in utero/ intrapartum), time of ART initiation and number of regimens were evaluated along with anthropometric measures, plasma virus load, T- cells, and viral reservoir studies.
Results: 77 of 140 HIV-infected infants (55%) from the original trial came from 3 sites; 37/77 (48%) were available for study follow-up. The median age was 8 years (range: 5.3-11.8 years). Twelve children (16%) died in the first 6 months of age; 4 (5%) died subsequently; 20 (26%) were lost to follow-up and 4 (5%) could not be enrolled. Of 37 children, 19 (51%) were infected in utero (IU) and 18 (49%) intrapartum (IP). The median age of ART initiation was 11 months, range: 9 days to 6 years [IQR: 5-19.5]. Twenty-three children (62%) had undetectable plasma virus load (53% IU vs. 72% IP, p =0.37); 5 (14%) had sustained virologic suppression since the first ART regimen [0/19 IU vs. 5/18 (28%) IP, p=0.02]. The median number of ART cycles was 2 (range: 1-8). Thirty-one children (83%) had normal CD4 cell counts. Eight children (22%) had past or present findings of HIV disease, 7/19 (37%) IU vs. 1/18 (5.6%) IP. Two children had abnormal weight/height Z-scores for age. Presence of symptomatic HIV disease was associated with IU infection (p=0.04). No children had negative HIV-1 EIAs or Western Blots secondary to early treatment initiation. Early ART for prophylaxis in the first month of life (single, double, triple ART) was not associated with viremia at present.
Conclusions: Despite early HIV recognition and careful follow-up in perinatal trials, adverse outcomes (mortality, loss in retention) are frequent. Among children retained in care, virologic suppression was achievable in 2/3. Symptomatic HIV disease and initial ART failure was more frequent in IU infection.

Presenting author email: carole.devaux@lih.lu

Background: Effectiveness of early antiretroviral therapy (ART) in young children needs to be evaluated. We assessed the virological suppression (VS) in West-African children on a LPV/r based-ART over 25 months and the impact of drug resistance mutations.

Methods: From 05/2011 to 01/2013, 156 HIV-infected children < 2 years of age were initiated in an initial LPV/r based-ART cohort for 12 months before being enrolled at 13-month for those in VS in a randomized simplification trial, assessing LPV/r vs EFV-based ART, in Ouagadougou, Burkina Faso, and Abidjan, Côte d'Ivoire. Viral load (VL, Biocentric) were measured three-monthly. VS (HIV RNA < 500 copies/mL) was determined after 12 months and 25 months of LPV/r-ART. HIV-1 genotypic resistance testing was performed before ART initiation and when VL was ≥1000 copies/mL.
Results: At 12-month of LPV/r-based ART, 13/156 children have died (8%), 5 were lost-to-follow-up/withdrew (3%) and 106/138 of children alive/followed (77%) achieved VS. Following randomisation, 86 children were further maintained on LPV/r therapy (54 in VS and 32 in virological failure, VF). At 25 months of therapy, 3 additional children were lost-to-follow-up: 57/83 children (69%) were virologically supressed (46/54 of children in VS at 12 month and 11/29 of children in VF at 12 month). HIV genotyping at 12-month showed that 21/28 viruses (75%) with a VL≥1000cp/mL had ≥1 drug resistance mutation (DRM) (61% to lamuvidine; 29% to efavirenz, 4% to zidovudine and lopinavir/ritonavir): 11 (52%) were transmitted drug resistance (TDR) with 5 viruses exposed to a maternal PMTCT intervention. 5/19 viruses genotyped from children in VF at 12-month showed the emergence of DRM to lamivudine between 12 and 25 months and 3/19 viruses pursued to accumulate other DRM after 12 months of LPV/r-based therapy (one to LPV/r). For children in VS at 12-month, 5/7 viruses with a VL≥1000cp/mL harboured ≥1 DRM to lamivudine or EFV, 3/5 were TDR from exposure to a maternal/PMTCT intervention.
Conclusions: These data highlighted the high prevalence of DRM in LPV/r-based treated HIV-1 children compromising long-term VS. A high frequency of HIV-TDR (54%) was detected in children in VF. The majority of DRM emerged before 12 months of LPV/r-based therapy.

HIV+ve adolescents differ depending on infection mode. Implications for service from the Mzantsi Wakho cohort in South Africa

L. Sherr[1], L. Cluver[2,3], E. Toska[4,5]
[1]UCL, London, United Kingdom, [2]University of Oxford, Dept of Social Policy and Intervention, Oxford, United Kingdom, [3]University of Cape Town, Dept of Psychiatry and Mental Health, Cape Town, South Africa, [4]University of Oxford, Oxford, United Kingdom, [5]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa
Presenting author email: l.sherr@ucl.ac.uk

Background: HIV+ve adolescents are the fastest growing group, with little insight into their different needs and service requirements. They include adolescents infected at birth (vertical infection) and those infected during adolescents - most commonly from sexual exposure (horizontal infection).
Methods: This study examines the world's largest community based study of HIV+ve adolescents (n=1060) drawn from the Eastern Cape, South Africa. From detailed records at all 53 health district clinics 1060 ever-ART initiated adolescents were tracked and interviewed (representing an inclusion rate of 90.1%. Ethical approval, informed consent and data collector training preceded data gathering on a detailed inventory providing validated measures of mental health, adherence , drug and alcohol use, cognitive abilities and disability, opportunistic infections, overall health, and clinic attendance.
Results: Vertically infected adolescents (n=713, 67% of the sample) were significantly (p=.001, OR .59 CI .43-,81) less likely to be non-adherent to cART, yet they were significantly more likely to miss clinic appointments (p<0.05, OR 1.6 CI 1.0-2.5). In terms of mental health horizontally infected adolescents were more likely to be depressed (p<0.001, B -.10) and express suicidal ideation (p<0.001, B -.11) - linked to the fact that they were older and greater likelihood of girls in the group. Vertically infected adolescents were half as likely to record drug and alcohol use in the past few months (p<0.012, OR.49, CI .29-.86). They performed significantly lower on cognitive tasks (p<0.008, OR 1.5 CI 1.1-2.1), and were more likely to have a disability on the WHO physical index (p=.001, OR 1.6, CI 1.2-2.1). The vertically infected group, despite better adherence than the horizontally infected, had 1.5 times higher risk of TB (p<0.03, OR 1.6, CI 1.1-2.1).
Conclusions: There are notable differences between these two groups of adolescents. Studies that conflate the groups may blur the findings. Clinic provision, if it is to be effective, needs to adapt and adjust to the different groups, take their needs into account and tailor services to them to ensure optimal adherence, development and wellbeing.

TUPEB0439

Lopinavir hair concentrations predict viremic episodes in HIV-infected Asian children and adolescents on second-line ART

J. Pintye[1], C. Koss[2], P. Bacchetti[3], S. Teeraananchai[4], S. Kerr[4,5], W. Prasitsuebsai[4,6], T. Singtoroj[7], K. Kuncze[2], C. Jin[3], A. Louie[2], H. Horng[2], A. Sohn[7], M. Gandhi[2]

Presenting author email: monica.gandhi@ucsf.edu

Background: Children and adolescents have suboptimal antiretroviral therapy (ART) adherence and virologic outcomes compared to adults. For children who require second-line ART, objective measures of adherence could help explain virologic outcomes and guide subsequent treatment decisions. Hair concentrations of antiretrovirals reflect drug exposure and adherence, and predict viral suppression in adults. However, hair measures (collected noninvasively) have not been examined longitudinally in pediatric populations or in the context of second-line ART.
Methods: We examined predictors of viremia (HIV-1 RNA >400 copies/ml) at least 24 weeks after switch to lopinavir-based second-line ART in a cohort of HIV-infected Asian children and adolescents. Participants were followed between 2011 and 2013. Small hair samples, HIV-1 RNA, and self-reported adherence by 30-day visual analogue scale (reported by parent/guardian when appropriate) were collected every 6 months. Hair concentrations of lopinavir were measured via liquid chromatography-tandem mass spectrometry using validated methods in the UCSF Hair Analytical Laboratory. Time to first viremic episode was examined using discrete-time Cox models.
Results: Among 244 participants, 44.7% were female; 11.1% were from Indonesia, 34.4% Thailand, 54.5% Vietnam. At switch to second-line, median CD4 percentage was 12.6% (IQR 7.0-19.0%); median HIV RNA was 103,000 copies/ml (IQR 22,300-357,000). At enrollment in the cohort, median age was 10.0 years (range 1.7-18.0); median time on lopinavir-based ART was 1.9 years (IQR 0.7-3.9). Median time of study follow-up was 48 weeks and a median of 3 (range 1-5) hair samples was collected from each participant. In a model including age, self-reported adherence, country, and CD4 percentage and HIV-1 RNA at switch, hair concentrations of lopinavir were the strongest independent predictor of a lower risk of viremia (odds ratio 0.44 for every doubling in hair level, 95% CI 0.32-0.62, p< 0.001).
Conclusions: In this longitudinal cohort of children and adolescents on second-line ART, we show for the first time that higher lopinavir hair concentrations more strongly predicted a lower risk of viremia than self-reported adherence, age or CD4. Monitoring hair antiretroviral concentrations may be useful for this vulnerable population at risk of virologic failure with limited future treatment options.

Presenting author email: sirinya.t@hivnat.org

Background: There are limited data on the long-term durability of protease inhibitor (PI)-based second-line antiretroviral therapy (2nd-ART) regimens after virologic failure (VF). We aimed to identify factors associated with repeated VF in a cohort of perinatally HIV-infected Asian children and adolescents on 2nd-ART.
Methods: HIV-infected children who switched to PI-based 2nd-ART after first-line failure and had a history of ≥1 episode of VF (HIV-RNA ≥1000 copies/mL) after prior suppression on 2nd-ART were followed every six months over two years (2014-2015). Adherence was measured by self/guardian-report (visual analogue scale;

VAS), pill counts, and hair concentrations; therapeutic drug monitoring (TDM) via plasma levels and genotypic resistance testing were performed upon repeat VF. Generalized estimating equation approach was used to assess factors associated with VF.
Results: A total of 56 perinatally HIV-infected children were followed at sites in Thailand (N=12) and Vietnam (N=34); 65% male, 51 (91%) taking lopinavir-based regimens. At enrollment, 43% (24/56) had ≥2 prior episodes of VF while on 2nd-ART. At the first 6-monthly follow-up visit, median age was 12.3 (IQR 10.2-14.5) years, and median CD4 count was 689 (IQR 386-1,096) cells/mm3. Although 54% (30/56) remained resuppressed, 46% (26/56) had at least one subsequent occurrence of VF during study follow-up, and 34% (19/56) had persistent VF at their next 6-monthly visit with a median 2nd-ART duration of 2.7 (2.0-3.7) years. In a multivariate model, additional episodes of VF were associated with lower lopinavir hair concentrations, CD4 count < 350 cells/mm3 and adherence < 95% by VAS. Two (2/26, 8%) developed high-level resistance to both lopinavir and atazanavir, and 3 (3/26, 11.5%) exhibited major PI mutations (M46I, I54V, V82A, N88NS). At the first occurrence of VF after enrollment, 43% (10/26) of children had random lopinavir plasma levels by TDM that were lower than the lower limit of quantification.
Conclusions: Half of children with a single episode of viremia while on PI-based second-line ART resuppressed their virus, but the other half had repeated episodes related to poor adherence (by report and objective measures) and immunologic status. While few developed high-level PI resistance, mutation accumulation will increase without more effective interventions to improve adherence in this population.

TUPEB0441

Profiling adolescents and youth in HIV care in Tanzania by age, sex, pregnancy status, ART initiation and retention

G. Antelman[1], G. Somi[2], M. Mukaminega[1], J. van ,t Pad Bosch[1], P. Njau[3], R. van de Ven[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [3]Ministry of Health, Community Development, Gender, Elderly and Children, PMTCT Unit, Dar es Salaam, Tanzania, United Republic of
Presenting author email: ga_zzz@yahoo.com

Background: Adolescents and young adults with HIV (AYHIV) have unique needs and circumstances. This retrospective analysis aims to describe age, sex, ART initiation and pregnancy status among current-in-care AYHIV, and factors associated with one-year retention in care among a recently enrolled cohort.
Methods: Electronic medical records (national HIV care/treatment database) from 135 HIV clinics across three regions were analyzed using descriptive and logistic regression methods. AYHIV (n=7538) who were enrolled from 2005-2015, received care and were ages 10-24 years at their last visit (in 2015) contributed to the current-in-care profile. One-year retention in care (i.e. enrollment) was explored in the AYHIV cohort enrolled from January 2013 to December 2014 (n=4379), with observed visits through March 2015.
Results: The proportion of female AYHIV increases from 52%, 62% to 83% in the age groups 10-14Y, 15-19Y and 20-24Y, respectively (p<0.0001). One-third of all female AYHIV were either pregnant at enrollment (23%) or became pregnant in care (10%), but even non-pregnant female AYHIV aged 15-24Y out-numbered males more than 3-fold. AYHIV starting ART did not differ by sex (73% male [M]; 72% female [F], p=0.13), but ART initiation was higher among pregnant (81%) compared to non-pregnant females (66%, p<0.0001). One-year-retention in care was higher for males, overall (49% M; 42% F, p=0.002), and among males starting ART (63% M; 55% F, p=0.002). In multivariable analysis, one-year retention in care was positively associated with being under 15Y at enrollment (AOR:1.90, 95%CI:1.44,2.49) and ART initiation (AOR:14.8, CI:11.5,19.1). Retention was lower among those enrolled who were pregnant (AOR:0.73, CI:0.63,0.86).
Conclusions: Gender imbalances among AYHIV in HIV care, and the high prevalence (one-third) of pregnancy among young women are important considerations when designing clinical and psychosocial support models of HIV care for adolescents/youth. While Option B+ has increased ART access for female AYHIV, those enrolled during pregnancy are at significant risk of non-retention. Differentiated and gender-sensitive service models should offer targeted services, depending on need and circumstances, that incorporate sexual and reproductive health education, family planning services, partner HIV testing, and efforts to support newly-diagnosed and newly ART-initiated pregnant women.

Presenting author email: florence.buseyne@pasteur.fr

Background: Cumulative exposure to viral replication has been consistently associated with morbidity and mortality in HIV-infected patients under successful combined antiretroviral treatment (cART) over several years. Long-term maintenance of adherence and viral control can be challenging, particularly in children and adolescents.
We previously described associations between cumulative viremia, cell-associated HIV-DNA, and naïve CD4 T-cell levels in perinatally infected youths over the age of 15 years. Here, we assessed whether cumulative viremia was associated with treatment history and biomarkers of inflammation and T-cell function.
Methods: The ANRS-EP38-IMMIP study included youths who acquired HIV during the perinatal period. Cumulative viremia was defined as the area under the curve of HIV RNA load over the last 10 years before the study. Plasma inflammatory markers were quantified using ELISA or Luminex technology. SEB-specific cytokine production by CD4 T cells was assessed by flow cytometry. Linear regression was used for univariate and multivariate analysis of cumulative viremia.
Results: The present analysis focused on the 57 patients with undetectable plasma HIV RNA at the time of the study. Their median (interquartile range) age was 18 (16-19) years and their CD4 T-cell count was 642 (522-949) cells/µl. Cumulative viremia was negatively associated with the duration of the last period of uninterrupted cART (estimate [95% confidence interval]: -315.6 [-569.1;-62.1], P=0.01) and positively with the number of cART interruptions (708.26 [34.2;1382.3], P=0.04), but not total duration of cART (-327.0 [-728.3;74.3], P=0.11).
It was positively associated with current CD8 T-cell count (2.5 [0.1;4.9], P=0.04), neopterin (511.7 [70.6; 952.8], P=0.02), and soluble tumor necrosis receptor 2 (3424.9 [741.5;6108.3], P=0.01) levels.
It was negatively associated with the percentage of polyfunctional CD4 T cells (-3281.3 [-4820.5;-1742.1], P<0.0001). These associations were significant in multivariate analysis including age, sex, and CD4 T-cell count.
Conclusions: Lower cumulative viremia was associated with reduced immune activation and improved T-cell function in youths with long-term HIV infection and suppressed viral replication. However, cART interruptions were associated with higher cumulative viremia. Our data support the importance of adherence to treatment in HIV-infected youths.

TUPEB0443

Decreasing risk of short-term virological failure with the more recent period of early cART initiation in HIV-infected infants in France

Debré, AP-HP, Paris, France
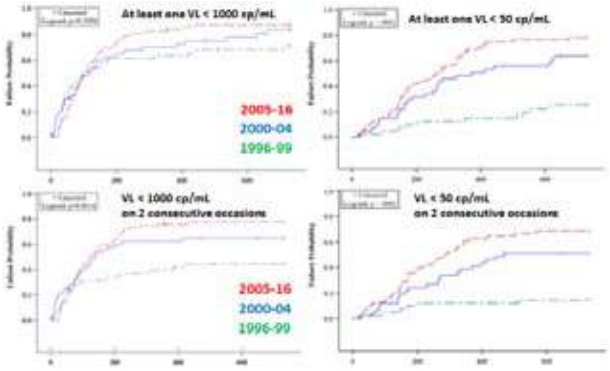
Presenting author email: pierre.frange@aphp.fr

Background: Several studies have reported virological responses to be weakest in children under the age of two years. Since 2008, WHO guidelines have recommended systematic early cART initiation in infants, due to its demonstrated clinical benefits. Early ART started to be administered in France since the end of the 1990s. We estimated the probability of achieving viral suppression within two years of early cART initiation and studied trends associated with the period of initiation.
Methods: All neonates included in the national ANRS-EPF CO10 cohort from 1996 to 2016, followed since birth, and with cART initiation before one year of age were included in this analysis. The primary outcome was viral suppression (50 and

1000 cp/mL thresholds) on at least one occasion. The secondary outcome was viral suppression on two consecutive occasions. Probabilities were estimated with the Kaplan-Meier method.
Results: Overall, 148 children initiated cART at a median age of three months (IQR: 1- 5). The proportion of cART regimens including a PI increased from 65% in 1996-99 to 72% in 2000-04 and 83% in 2005-16. Three infants died during the first 24 months of cART, all beginning treatment before 2005. The probability of viral suppression increased significantly over time. For children born after 2005, the probability of having at least one viral load below 1000 or 50 copies/mL was 87% [79-95] and 78% [67-89], respectively (Fig 1). The probability of virological suppression on two consecutive occasions was 77% [67-88] and 68% [56-80], respectively.
Conclusions: The virological failure of early cART decreased over time, but the probability of not achieving sustained viral suppression below 50 cp/mL remained around 30% two years after initiation of treatment.



[Figure 1. Probabilities of achieving viral load suppression at two years of cART initiated during first year of life (Kaplan-Meier method) - The ANRS-EPF CO10 / 1996-2016]

Retention in ART care amongst adolescents attending an urban clinic in Durban, South Africa

C. Kindra[1,2], G. Kindra[1], M. Archary[1,2], R. Bobat[1,2]
[1]Nelson Mandela School of Medicine/University of KwaZulu-Natal, Paediatrics, Durban, South Africa, [2]King Edward VIII Hospital, Paediatrics, Durban, South Africa
Presenting author email: chirjeevkindra@gmail.com

Background: Adherence and retention in care are critical in attaining the UNAIDS 90-90-90 goals. Adolescents are particularly challenging and a recent systematic review reported a retention rate of 83% (95%CI 68%-93%) amongst adolescents on ART. It is imperative to identify good practices which aid retention in care in an African context.
The adolescent clinic at King Edward VIII Hospital functions within a combined Paediatric and Adult HIV clinic, with dedicated adolescent-friendly days. Each adolescent is managed by a multidisciplinary team, including a doctor, lay counsellor, social worker and nurses and is seen by the same staff at each visit to allow continuation of care and bonding. Facilitated group counselling is also provided.
Methods: A retrospective chart review of all adolescents (10 years-19 years) attending the clinic between January 1996 - December 2015 was conducted. Analysis was conducted using STATA12.O; Mantel-Haenszel estimates were calculated and multivariate logistic regressions performed.
Results: Amongst the 357 eligible patients were identified, 343 files were available for analysis and the remaining 14 files were incomplete. All patients were black African of Zulu ethnicity and 43.7% are female. Most were WHO stage 3 at ART initiation (67.4%). Median age at diagnosis and ART initiation were 97 months and 102.4 months respectively. Most adolescents (62.6%) had lost one or both parents. Almost 87% of the adolescents were still being actively followed-up at the time of this analysis; with 28 (8.2%) being transferred; 16 (4.7%) lost to follow-up and 1 (0.3%) death.
Predominantly, 256 (74.6%) were still on their 1st line ART regimens (EFV based ART); 86 (25.1%) on 2nd line (Protease-inhibitor based ART); and 1 (0.3%) on 3rd line. Current or past history of TB was present in 228 (66.5%) of the adolescents. On multivariate analysis, controlling for current age, being on a once daily combination pill was almost 80 times protective for retention in care (OR 0.05; 95%CI 0.01-0.39; P=0.004).
Conclusions: Provision of adolescent-friendly days with dedicated staff results in a 90% retention in-care of adolescents, even in a busy urban clinic in South Africa. Once daily fixed dose preparations can further improve retention in adolescents.

Presenting author email: ddahourou@gmail.com

Background: Long-term viral load (VL) suppression on antiretroviral therapy (ART) in children is challenging. We described the dynamic of the virological response among children ART-treated before the age of two over 25 months in West-Africa, and investigated its association with adherence.
Methods: Between 5/2011 and 2/2013, HIV-1-infected children < 2 years were initiated on ART and followed-up over 25 months in Ouagadougou, Burkina Faso and Abidjan Côte d'Ivoire. Adherence to ART was assessed at each scheduled monthly visit, using a 4-day recall of missed doses questionnaire and adherence to medical appointments. VL was measured quarterly (success < 500copies/mL). We used a clusterwise linear regression (R package kmlcov) to adjust the logarithm of VL on the visit timing, 4-day recall of missed ART and delay between the theoretical visit and the effective visit to cluster our study population.
Results: Among the 156 children enrolled, 63% were from Abidjan; 53% were females, 67% have had access to tap water at home, and mother was the main caregiver (81%). We identified four different longitudinal profiles of VL response over 25 months (Figure 1): 66% had a good profile, with consistent VL success (purple); 9% had a longitudinal VL failure profile (blue); 16% had an initial VL failure profile, then were suppressed beyond 19 months (green); 9% had a "boom and bust" profile ending with virological failure (red). The good profile was characterized in children having more often access to tap water, females, and in those with the smallest number of missed ART doses, and days of delay. In the VL failure profile, caregiver was less often the mother, and the average number of missed doses and visit' delays were significantly highest.
Conclusions: Different virological profiles can be identified in HIV-infected children. Interventions targeting children at risk for treatment failure will be helpful in optimizing virological success.

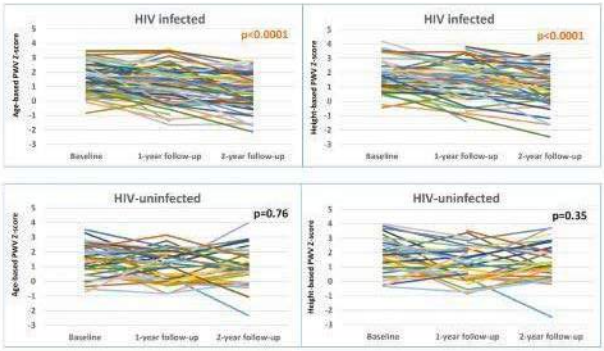
Premature vascular stiffness in children slowly resolves following early ART: data from post-CHER trial cohort

S.E.V. Innes[1], M.F. Cotton[1], K. Otwombe[2,3], B. Laughton[1], S.H. Browne[4,5]
[1]Childrens' Infectious Diseases Clinical Research Unit (KID CRU), Stellenbosch University & Tygerberg Children's Hospital, Paediatrics and Child Health, Cape Town, South Africa, [2]University of the Witwatersrand, Paediatrics, Soweto, South Africa, [3]Perinatal HIV Research Unit, Faculty of Health Sciences, Soweto, South Africa, [4]Divisin of Infectious Diseases, Department of Medicine, University of California San Diego, San Diego, United States, [5]AntiViral Research Center, University of California San Diego, San Diego, United States
Presenting author email: innes@sun.ac.za

Background:
• Cross-sectional data suggests increased vascular disease in HIV+ children on antiretroviral therapy (ART) adjusting for traditional risk factors
• Thus far, pediatric studies have focused on children initiating ART after 3 months of age
• Whether very early ART will prevent HIV-related premature vascular disease is unknown
• Aorto-femoral pulse wave velocity (PWV) is a sophisticated and sensitive measure of elevated arterial wall stiffness, typically due to atherosclerosis or subclinical arteritis
• Reduced arterial wall elasticity leads to faster propagation of the arterial pulse wave
• PWV elevations strongly predict subsequent cardiovascular events in asymptomatic adults.
Methods:
• Baseline, 1-year and 2-year follow-up PWV measurements in perinatally-HIV-infected primary-school-age children who initiated lopinavir/ritonavir, zidovudine and lamivudine very early in infancy with minimal HIV disease and normal CD4 counts; and in HIV-uninfected controls (HIV-exposed uninfected, HEU, and HIV-unexposed, HU) from the same communities and socio-economic background
• Raw PWV, height-based PWV Z-scores (PWVZ-ht) and age-based PWV Z-scores (PWVZ-age) compared by ANOVA followed by pairwise T-test, and adjusted using multivariable regression for body mass index, fasted glucose, total and low density lipoprotein cholesterol, triglycerides and serum cotinine.
Results:
• 87 HIV+ (median age 7.7 [IQR: 7.6-8.5] years) who initiated ART at median 9 (7-12) weeks of age, with cumulative time on ART of median 7.1 (6.7-7.5) years and normal CD4 counts
• 53 uninfected (31 HEU; 22 HU), median age 8.5(IQR:7.8-8.7) years, with similar anthropometric Z-scores (p>0.10)
• Baseline PWV metrics in HIV+ and HEU were higher than HU and this difference persisted in HIV+ after adjustment (p≤0.04). (HEU not adjusted due to limited n)
• PWVZ-ht and PWVZ-age improved substantially over two years in HIV+ (p≤0.0001) and moderately in HEU (p≤0.05), whereas HU remained unchanged.



[Figure 1. Prospective changes in pulse wave velocity (PWV), a sophisticated measure of arterial wall softness]

Conclusions: In children initiating ART soon after birth, early PWV abnormalities gradually improve with accumulating time on ART.

TUPEB0447

Longitudinal changes in lipids after switch to boosted atazanavir or darunavir in children/adolescents with perinatally acquired HIV on older line protease inhibitors: results from the PHACS Adolescent Master Protocol Study

J. Jao[1], W. Yu[2], K. Patel[3], T. Miller[4], M. Geffner[5], L. DiMeglio[6], A. Mirza[7], J. Chen[8], M. Silio[9], B. Karalius[3], E. McFarland[10], R. Van Dyke[9], D. Jacobson[2], Pediatric HIV/AIDS Cohort Study (PHACS) Adolescent Master Protocol (AMP) Study

Presenting author email: jennifer.jao@mssm.edu

Background: Dyslipidemia is common in perinatally HIV-infected (PHIV) youth receiving Protease Inhibitors (PIs). Few studies have evaluated longitudinal lipid changes in PHIV youth after switch to newer PIs.
Methods: We compared longitudinal changes in fasting lipids [Total Cholesterol (TC), Triglycerides (TG), Low Density Lipoprotein-C (LDL), High Density Lipoprotein-C (HDL), and TC/HDL] between PHIV youth enrolled in the U.S.-based PHACS AMP cohort who switched to either atazanavir/ritonavir (ATV/r) or darunavir/ritonavir (DRV/r) - based antiretroviral therapy (ART) from an older PI-based ART vs. those remaining on an older PI. Lipids were measured prior to switch or at first lipid measure, in the comparison group, and annually thereafter for three years. We excluded youth without lipid measurements, with ATV or DRV use prior to baseline, or who switched to ATV/r or DRV/r-based ART comprised of ≥ 3 classes of antiretrovirals. Generalized estimating equation models were fit to assess the association of switch to ATV/r or DRV/r-based ART with the rate of change in lipids, adjusted for potential confounders.
Results: From 2007-2014, 47 PHIV youth switched to ATV/r (n=27) or DRV/r (n=20) while 120 remained on an older PI. Of the latter, 72% received lopinavir/r and 24% nelfinavir. Baseline age ranged from 7-21 years with 73% non-Hispanic black. Compared to youth remaining on an older PI, those who switched were older (median age 14 vs. 11 years, p< 0.001) and reported receiving ART for longer at baseline (median 11.9 vs. 8.3 years, p< 0.001). At baseline, median TC was lower in the switch group (158 vs. 177 mg/dL, p=0.042). Overall, lipid profiles improved in both groups during follow-up. After adjusting for age, Tanner Stage, race/ethnicity, and HIV RNA level, switch to ATV/r or DRV/r was associated with a more pronounced rate of decline in the ratio of TC/HDL (ß= -0.12, p=0.039) over time. On average, TC declined 4.57 mg/dL/year (p=0.057) more in the switch group. There was no association between a switch to ATV/r or DRV/r and the rate of increase in HDL or decline in LDL and TG.
Conclusions: Switch to newer-line PIs may result in more rapid improvement in TC and TC/HDL in PHIV youth.

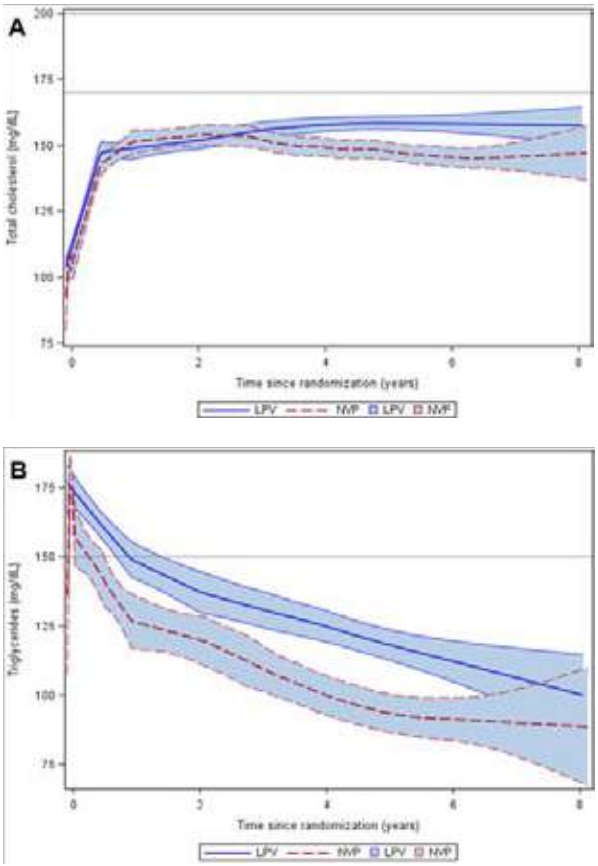
TUPEB0448

Long-term metabolic implications of initiating lopinavir/ritonavir-based regimens for infants and children: a follow-up study of IMPAACT P1060

K. Patel[1], J. Lindsey[2], M. Hernán[1], K. Angelidou[2], G. Aldrovandi[3], P. Palumbo[4], IMPAACT P1060 Study Team
[1]Harvard T H Chan School of Public Health, Epidemiology, Boston, United States, [2]Harvard T H Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]Keck School of Medicine of USC, Pediatrics, Los Angeles, United States, [4]Dartmouth-Hitchcock Medical Center, Infectious Diseases and International Health, Lebanon, United States

Background: A lopinavir/ritonavir (LPV/r)-based regimen is recommended as first-line therapy for HIV-infected children <3 years of age. The long-term implications of using LPV/r-based regimens among young children on lipid parameters are unknown.
Methods: 451 HIV-infected children, enrolled at 2-36 months of age from six African countries and India and randomized to initiate zidovudine, lamivudine, and either nevirapine (NVP) or LPV/r in the P1060 trial were included. Linear and

log-binomial regression models estimated differences by randomized arm in mean cholesterol and proportions of participants with high/borderline cholesterol (≥170 mg/dL) and high triglyceride (>150 mg/dL) measures, respectively. An intention to treat approach was used.
Results: Median duration of follow-up was 5.7 and 5.6 years for LPV/r and NVP, respectively. After treatment initiation, total cholesterol increased dramatically for up to 6 months, followed by more gradual trends over the rest of follow-up, while triglycerides continually decreased over follow-up (Figure). No difference was observed between LPV/r and NVP in total cholesterol during the first year, but total cholesterol was significantly higher with LPV/r between 4 and 6 years of follow-up (relative difference (95% confidence interval (CI)): Year 4: 13.5 (5.8, 21.2), Year 5: 8.4 (1.4, 15.3), Year 6: 16.6 (8.2, 25.0)). There were significantly higher risks for high/borderline cholesterol with LPV/r compared to NVP between 4 to 6 years of follow-up (relative risk (95% CI): Year 4: 1.8 (1.2, 2.7), Year 5: 1.7 (1.2, 2.4), Year 6: 2.4 (1.5, 3.9)). Significantly higher risk of high triglycerides with LPV/r compared to NVP was only observed during years 1 and 4 of follow-up.
Conclusions: Initiating LPV/r was associated with higher total cholesterol after prolonged follow-up compared to initiation of NVP. Our results are consistent with known effects of protease-inhibitors on hyperlipidemia and suggest monitoring for lipid parameters over time among children who initiate LPV/r globally.



[Figure. LOESS fit plots with 90% confidence bands for total cholesterol (A) and triglycerides (B) over follow-up randomized treatment]

Presenting author email: julie.jesson@isped.u-bordeaux2.fr

Background: We assessed growth evolution and its associated factors among adolescents enrolled in the paediatric IeDEA West African cohort (pWADA), and explored the association between growth and adverse outcomes using a joint modeling approach.
Methods: We included all HIV-infected children aged 10-15 years, with at least one available measure of weight and height, and initiated on ART before 10 years. Growth was described using Body-Mass-Index (BMI)-for-age Z-score (BAZ), according to the WHO Child Growth Standards. Correlates of growth evolution were studied using a linear mixed model (1) and a survival model (2) described time to death or lost-to-follow-up (LTFU, last contact>6 months) since age 10 (baseline time). We assessed the effect of BAZ value and slope over time on the risk of death and LTFU among HIV-infected adolescents using a joint model combining models 1 and 2.
Results: Between 2005 and 2015, 1860 children were included. Median age at last visit was 12.3 years (InterQuartile Range [IQR] = 10.9-14.3). At baseline, 54% were boys, 18% were wasted (BAZ< -2 SD), 26% stunted, 16% had severe immunodeficiency (CD4 cell count< 350 cells/mL), and 62% initiated ART between ages 5 and 10. Between 10 and 15 years, 4% died and 11% were LTFU. BAZ decreased significantly, of -0.06 SD by month, with a more important decrease for males, non-wasted and stunted children at baseline (model 1). Probability of death was higher for severely immunodeficient and malnourished children at baseline (model 2). In the joint model, probability of death was higher when BAZ value decreased by one unit (associated Hazard Ratio [aHR] = 2.2, Confidence Interval [CI] 95% = 1.7-2.9) and when BAZ slope decreased (p=0.011). However, probability of LTFU was not associated with growth evolution.
Conclusions: Malnutrition was associated with a higher risk of death among ART-treated adolescents, independently of their HIV-disease progression. A joint modelling approach could investigate association between growth and other adverse events (CD4 drop or viral rebound). Growth needs to be monitored in the absence of viral load, and a decrease of growth could be a marker for guiding pediatric HIV care in resource-limited settings.

TUPEB0450

High-risk of liver fibrosis among HIV-infected youth with chronic viral hepatitis B coinfection despite receiving tenofovir-containing antiretroviral regimen

L. Aurpibul[1], T. Puthanakit[2,3], S. Kanjanawanit[4], A. Leerapun[5]
[1]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]The Netherlands, Australia, Thailand Research Collaboration (HIVNAT), Bangkok, Thailand, [3]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand, [4]Nakornping Hospital, Chiang Mai, Thailand, [5]Chiang Mai University, Division of Gastroenterology, Department of Internal Medicine, Chiang Mai, Thailand
Presenting author email: lindaa@rihes.org

Background: HIV and Hepatitis B (HBV) coinfection is associated with risk of progression to chronic liver disease. This study aims to determine the risk of liver fibrosis and long-term treatment outcomes of tenofovir (TDF)-containing antiretroviral therapy (ART) regimens in HBV/HIV coinfected youth.
Methods: A cross-sectional study was conducted among HIV-infected youth between 15-25 years. Inclusion criteria were
1) chronic HBV-HIV infection, and
2) received a TDF-containing ART regimen for ≥96 weeks.
Measurements included HBV DNA by Abbott® real-time PCR assay, HBV serolo-

gy profiles, liver function tests, and transient elastography (TE). The cut-off for TE results included ≥5.9 Kpa for F2-moderate fibrosis, ≥7.4 KPa for F3-severe fibrosis, and ≥ 9.6 KPa for F4-cirrhosis. AST-to-platelet ratio index (APRI) and FIB-4 index were calculated as markers of liver fibrosis.
Results: From March-December 2016, 15 HBV-HIV-infected adolescents with median (interquartile range, IQR) age of 23.0 (19.8-24.4) years were enrolled. At a median (IQR) duration on TDF of 172 (136-200) weeks, 14 (93%) achieve HBV DNA levels <200 IU/mL. Five of the 6 (40%) patients who hadd HBV DNA <10 IU/ml became HBsAg and HBeAg seronegative; all five had normal ALT; none had liver fibrosis. There were 5 patients (33%) had significant liver fibrosis: 3 (20%) had F2-moderate fibrosis, 1(6%) had F3-advanced fibrosis, and 1(6%) had cirrhosis. Only the one with cirrhosis had high ALT (110 IU/L), and abnormal APRI and FIB-4. Characteristics of study participants are shown in Table1.

[Table 1. Comparison of characteristics between groups of patient with HBsAg seroconversion, HBsAg serpositive without liver fibrosis, and presence of liver fibrosis]

Conclusions: One-third of Thai HIV/HBV-infected youth on TDF-containing ART for ≥96 weeks had significant liver fibrosis. TE to evaluate risk of liver fibrosis/cirrhosis should be advised for youth with co-infection, in particular, for those who did not achieve HBV <10 IU/ml on TDF-containing ART, or had abnormal liver biomarkers. More intensive monitoring and consultation with hepatologist might be warranted.

TUPEB0451

Insulin resistance in South African perinatally HIV-infected adolescents on antiretroviral therapy: a cross-sectional study

L. Frigati[1], J. Jao[2], S. Mahtab[3], N.-A. Asafu-Agyei[3], L. Myer[4,5], H. Zar[6]
[1]Stellenbosch University, Pediatrics and Child Health, Cape Town, South Africa, [2]Icahn School of Medicine at Mount Sinai, Department of Medicine, Department of Obstetrics, Gynecology, and Reproductive Science, New York, United States, [3]University of Cape Town, Cape Town, South Africa, [4]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [5]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [6]University of Cape Town, Paediatrics and Child Health, Cape Town, South Africa
Presenting author email: landon.myer@uct.ac.za

Background: Access to antiretroviral therapy (ART) has reduced morbidity and mortality in perinatally HIV-infected (PHIV) children, but metabolic complications of ART including insulin resistance (IR) in adolescents are poorly understood.
Methods: We evaluated IR in a cross-sectional analysis of PHIV and HIV-uninfected adolescents enrolled in the Cape Town Adolescent Antiretroviral cohort (CTAAC). Adolescents 9-14 years old and on ART for >6 months were eligible. The Homeostatic Model Assessment (HOMA) was used to assess IR calculated from fasting insulin and glucose measurements at enrollment. IR was defined as HOMA >2.5 for pre-pubertal and >4.0 for pubertal adolescents. Multiple linear regression was used to examine adjusted associations between HOMA and both HIV-related and traditional cardiovascular risk factors.
Results: Of 403 adolescents, 356 were PHIV. Median age was 12.1 (IQR:10.7-13.3) years for PHIV and 11.5 (IQR:9.9-13.1) for uninfected adolescents. 49% of PHIV and 60% of uninfected adolescents were female. Median duration on ART was 7.5 (IQR:4.7-9.2) years with 123 (35%) of PHIV adolescents starting ART between 0 -2 years of age, 97 (27.6%) between 3-5 years and 131 (37.3%) between 6-14 years of age. The most common regimens included Abacavir (72%) and Lopinavir/ritonavir (59%). Median triglycerides were 79.7 mg/dl (IQR: 62.0-106.3) in PHIV and 62.0 mg/dL (IQR:44.3-70.9) in uninfected controls (p< 0.0001). Median waist circumferences were 61cm (IQR:58-66) and 62.5cm (IQR: 57-70) for PHIV and uninfected adolescents. Overall, 20.1% had IR, but rates of IR did not differ between groups or by duration of ART exposure. Among PHIV adolescents, waist circumference (ß=0.007, p=0.035), hypertriglyceridaemia (ß=0.074, p=0.013), and ever use of Abacavir (ß=0.071,p=0.022), were associated with increased HOMA, while viral load >1000 copies/mL (ß= -0.062, p=0.013) was associated with decreased HOMA after adjusting for age, gender, body mass index and Tanner stage.
Conclusions: : In a South African cohort of PHIV adolescents, IR did not appear significantly different from uninfected adolescents.In addition to traditional risk factors such as waist circumference and hypertriglyceridaemia, Abacavir exposure may be associated with increased HOMA, and this finding needs further exploration.

TUPEB0452

Malnutrition, growth response and metabolic disorders within the first 24 months of ART initiation in HIV-infected children treated before the age of two years in West Africa

J. Jesson[1], D.L. Dahourou[2,3,4], M. Amorissani-Folquet[5], K. Malateste[2], C. Yonaba[6], M.-S. N'Gbeche[7], S. Ouégraogo[8], V. Méa-Assande[9], C. Amani-Bossé[9], S. Blanche[10], M. Timité-Konan[11], V. Leroy[1], MONOD ANRS 12206 Study Group
[1]INSERM U 1027, University Paul Sabatier Toulouse 3, Toulouse, France, [2]INSERM U 1219, Université de Bordeaux, Institut de Santé Publique, d'Epidémiologie et de Développement (ISPED), Bordeaux, France, [3]MONOD Project ANRS 12206, Centre de Recherche International pour la Santé, Ouagadougou, Burkina Faso, [4]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [5]Centre Hospitalier Universitaire of Cocody, Paediatric Department, Abidjan, Cote D'Ivoire, [6]Centre Hospitalier Universitaire Yalgado Ouédraogo, Paediatric Department, Ouagadougou, Burkina Faso, [7]Centre de Prise en Charge de Recherche et de Formation, CePReF-enfants, Abidjan, Cote D'Ivoire, [8]Centre Hospitalier Universitaire Charles de Gaulle, Paediatric Department, Ouagadougou, Burkina Faso, [9]PACCI Programme, Site ANRS, Projet MONOD, Abidjan, Cote D'Ivoire, [10]EA 8, Université Paris-Descartes, Immunology, Hematology, Rhumatology Unit, Hôpital Necker Enfants Malades-Assistance Publique, Hôpitaux de Paris, Paris, France, [11]Centre Hospitalier Universitaire de Yopougon, Paediatric Department, Abidjan, Cote D'Ivoire
Presenting author email: julie.jesson@isped.u-bordeaux2.fr

Background: Healthcare of HIV-infected children in resource-limited settings faces several challenges, which one of them is malnutrition. We described baseline malnutrition, growth evolution and metabolic disorders within the first 24 months of antiretroviral therapy among children initiated on ART < 2 years in Burkina Faso (BF) and Côte d'Ivoire (CI).
Methods: HIV-1-infected children < 2 years were initiated on a LPV/r based-ART for 12 months, before randomization in a simplification trial. Weight-for-age, Height-for-age and Weight-for-height Z-scores (WAZ, HAZ, WHZ) defined malnutrition (Z-score < -2 Standard Deviations [SD]), using WHO growth references. Malnutrition at baseline was studied using a multivariate logistic regression and growth evolution within the first 24 months of ART using linear mixed models. Biological data were collected every 6 months and MacNemar and students tests for paired samples were used to compare rates between ART initiation (baseline) and 6, 12 and 24 months of ART.
Results: Between 2011 and 2013, 161 children were enrolled: 64% were from Abidjan, 54% were girls. At baseline, median age was 13.6 months [IQR 7.7; 18.4], 53% were underweight (WAZ), 51% stunted (HAZ), and 36% wasted (WHZ). Overall, malnutrition at baseline was more likely for children living in BF vs CI, those never breastfed, the oldest (12-24 months), and with a low birth weight. Growth improvement occurred mainly within the first 6 months on ART and was greater for the most severely malnourished children at baseline, but 8% (wasting) to 32% (stunting) remained malnourished after 24 months. ART initiation was associated with an increase of hypercholesterolemia (38% at 24 months vs 8% at baseline, p< 0.001) and a decrease of anemia (21% at 24 months vs 74% at baseline, p< 0.001) and hypoalbuminemia (0% at 24 months vs 50% at baseline), with no difference according to the initial nutritional status.
Conclusions: Prevalence of malnutrition was high at ART initiation. Even if growth improved, a part of children remained malnourished after 2 years on ART, highlighting the need of nutritional supplementation. Lipid disorders were observed, which is concerning and need to be monitored carefully to reduce the long-term cardiovascular risk, especially among children in a lifelong therapy process.

TUPEB0453

Case report: disseminated histoplasmosis in an HIV-infected child in the southern highlands zone of Tanzania

L. Campbell[1,2,3], J. Bacha[1,2,3], R. Bradsher[4], V. Mng'ong'o[3], G. Shutze[1,2], C. Kovarik[5]
[1]Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Pediatrics, Houston, United States, [3]Baylor College of Medicine Children's Foundation, Pediatrics, Mbeya, Tanzania, United Republic of, [4]University of Arkansas for Medical Sciences, Dermatology, Little Rock, United States, [5]Hospital of the University of Pennsylvania, Dermatology, Philadelphia, United States
Presenting author email: lianec@bcm.edu

Background: Histoplasmosis is an uncommon opportunistic infection in HIV positive children. The most common form is primary disseminated histoplasmosis, characterized by persistent fever and failure to thrive. We present a case of disseminated histoplasmosis with a unique presentation of ulcerated skin lesions and a violaceous facial rash.
Methods: Retrospective chart review of patient´s medical file.
Results: A 10 year old HIV positive girl presented to the inpatient malnutrition ward at Mbeya Zonal Referral Hospital in Mbeya, Tanzania with ulcerated scalp lesions, facial rash and subcutaneous nodule (Figure 1). She had persistent fevers, severe acute malnutrition and severe anemia. At diagnosis, the patient was failing first line antiretroviral therapy (ART) with a CD4 of 24 cells/μL and VL of 196,658 cp/mL. The patient was changed to a second line ART regimen (ABC-3TC-LPV/r), received nutritional support, blood transfusions, multiple antibiotics and meticulous wound care.
Biopsy of a lesion showed intracytoplasmic organisms consistent with histoplasmosis. The patient was treated with conventional amphotericin B and received a total of 20mg/kg. Amphotericin B infusions. Following amphotericin, a repeat biopsy showed clearance of organisms and the patient was transitioned to oral itraconazole. However, after 3 weeks of oral itraconazole, the patient had clinical and histological relapse. She resumed amphotericin B and received an additional 30mg/kg with clinical improvement of the scalp wounds at which point she was again transitioned to itraconzole with ongoing slow improvement. After 3 months of second line ART, her CD4 was 160 cells/μL and VL of 35 cp/mL.

[Figure 1]

Conclusions: We describe a case of disseminated histoplasmosis presenting with large scalp wounds which was treated with amphotericin B and itraconazole. Diagnosis of histoplasmosis is difficult in the resource limited setting and histopathology support is essential. Histoplamosis should be considered in the differential diagnosis of the immunocompromised host with unusual skin manifestations and persistent fever.

Background: Infectious morbidity in HIV-exposed uninfected (HEU) infants has been described. Few studies have evaluated this in HEU infants born to perinatally HIV-infected (PHIV) women.
Methods: HIV-infected and -uninfected pregnant women were enrolled in a prospective cohort in the U.S. between September 2009-2015. We evaluated the prevalence of hospitalization due to an infectious cause during the first year of life (HDIC) in HEU and HIV-unexposed uninfected (HUU) infants of these women. Maternal HIV status was categorized as PHIV vs. non-perinatally HIV-infected (NPHIV) vs. HIV-uninfected. Data on socio-demographics, maternal HIV clinical markers, antiretroviral therapy during pregnancy, mode of HIV acquisition, infant birth outcomes, and HDIC were collected. Generalized Estimating Equation modeling was used to evaluate the effect of maternal HIV status on infant HDIC.
Results: Of 205 evaluable infants, 28 were HEU born to PHIV women (HEU-P), 112 HEU born to NPHIV women (HEU-N), and 65 HUU. PHIV women were younger compared to NPHIV and HIV-uninfected women (median age 22 years vs. 29 and 23 respectively, p< 0.01). Amongst HIV-infected women, PHIV women were more likely to have a CD4 nadir < 50 cells/mm^3 during pregnancy (25% vs. 1%, p< 0.01). HEU-N infants were more likely to be in the custody of someone other than the biological mother in the first year of life compared to HEU-P and HUU infants (17% vs. 14% and 2%, p< 0.01). Overall, 18% of HEU-P, 4% of HEU-N and 12% of HUU infants had HDIC (p< 0.01). After adjusting for maternal age, education, black race, substance use during pregnancy, infant small-for-gestational age, prematurity, infant custody by someone other than biological mother, and infant outpatient visits during the first year of life, HEU-P infants were at increased risk for HDIC compared to HEU-N infants [adjusted odds ratio (aOR)=3.97, 95% Confidence Interval (CI):1.02-16.39]. In sub-group multivariable analysis of HEU infants, this relationship persisted after additional adjustment for maternal CD4 and HIV RNA level (aOR=7.73, 95% CI:1.67-63.30).
Conclusions: In our small cohort, HEU-P infants were at increased risk for HDIC. Differences in intrauterine environments, social factors, or access to care may be important factors to assess in future larger studies.

TUPEB0455

Long-term developmental outcomes and *in utero* antiretroviral exposure in HIV-exposed uninfected (HEU) children born to mothers living with HIV in British Columbia (BC), Canada

M. Piske[1], M.A. Budd[1], A.Q. Qiu[2], E.J. Maan[2], L.J. Sauve[2,3], A. Alimenti[2,3], J.C. Forbes[2,3], P. Janssen[4,5], H.F. Côté[1,5], CIHR Team grant on Cellular Aging and HIV Comorbidities in Women and Children (CARMA)
[1]UBC, Department of Pathology and Laboratory Medicine, Vancouver, Canada, [2]Oak Tree Clinic, BC Women's Hospital and Health Centre, Vancouver, Canada, [3]UBC, Department of Pediatrics, Vancouver, Canada, [4]School of Population and Public Health, UBC, Vancouver, Canada, [5]Women's Health Research Institute, Vancouver, Canada
Presenting author email: hcote@pathology.ubc.ca

Background: Over 1.4 million children worldwide and more than 200 children in Canada are born annually to mothers living with HIV, with an increasing proportion exposed to ARVs in utero during early development. Concerns exist on potentially adverse immunological, neurodevelopmental and mitochondrial effects from long-term ARV treatment; sociodemographic factors and adverse childhood experiences may also be involved. We previously reported a concerning prevalence of autism spectrum disorder in HEUs within the CARMA cohort. Here, we aimed to compare frequencies of neurodevelopmental disorders among HEU children born in BC and examine possible associations with exposure to maternal ARVs.
Methods: Data on 446 HEU children and 1323 HIV-unexposed uninfected (HUU) children (matched ~1:3 for age, sex and geocode) born between 1990 and 2012 were collected by Population Data BC from several data holdings including the BC Ministry of Health's Medical Services Plan (ICD9/ICD9-CM), Perinatal Services BC, and ARV treatment information housed at Oak Tree Clinic.
Results: One or more of the following developmental disorders: autism spectrum disorder, disturbance of emotions, hyperkinetic syndrome, developmental delay, intellectual disability, and/or epilepsy were diagnosed in 30% of our HEU cohort compared to 13% in the matched HUU cohort ($p< 0.0001$). Of 369 HEUs with any ARV exposure in utero, 101 (27.4%) had a disorder: a lower proportion ($p< 0.01$) than expected assuming no association between in utero ARV exposure and developmental disorders. Compared to HUUs, HEU children had higher relative risks of autism spectrum disorder (RR=2.97, p=0.02), disturbance of emotions (RR=2.76, $p< 0.0001$), hyperkinetic syndrome (RR=2.97, $p< 0.0001$), and developmental delay (RR=3.08, $p< 0.0001$), but no increased risk of medical conditions such as asthma (RR=1.01, p=0.89) or neoplasms (RR=0.68, p=0.06). The HEU cohort showed higher proportions of exposure to maternal smoking ($p< 0.0001$) and alcohol consumption ($p< 0.0001$) during pregnancy.
Conclusions: Our data suggest a possible reassuring association between ARV exposure in utero and neurodevelopmental disorders within our HEU cohort. HEU children in BC may be at a nearly three-fold higher risk for several neurodevelopmental disorders compared to matched HUUs. Our results highlight the need for careful developmental monitoring and access to early interventions to optimize neurodevelopment for at-risk HEUs.

TUPEB0456

The population effect of HIV exposure without HIV-infection on infant hospitalizations and mortality in Botswana and South Africa

A. Slogrove[1,2], L. Johnson[2], K. Powis[3,4]
[1]Stellenbosch University, Department of Paediatrics & Child Health, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Disease and Epidemiologic Research, Cape Town, South Africa, [3]Harvard University, Departments of Pediatrics and Medicine, Massachusetts General Hospital, Boston, United States, [4]Harvard University, Botswana Harvard AIDS Institute Partnership, Gabarone, Botswana
Presenting author email: slogrove@gmail.com

Background: With successful prevention of maternal-child HIV transmission but stagnant antenatal HIV prevalence, the population of HIV-exposed uninfected (HEU) infants accounts for >20% of the infant population in Botswana and South Africa. HEU infants are at greater risk of mortality and morbidity than HIV-unexposed (HU) infants, with these trends persisting despite maternal antiretroviral therapy and uptake of safer breastfeeding. We aimed to quantify the contribution of excess HEU infant morbidity and mortality at a population-level in Botswana and South Africa.
Methods: The attributable fraction (AF), population attributable fraction (PAF) and annual excess hospitalizations and mortality due to HIV-exposure without infection were estimated using published estimates of relative risk (RR) for infant hospitalization and meta-analysis estimates of RR for mortality in HEU compared to HU infants. 2013 UNICEF infant mortality rate (IMR) estimates for Botswana and South Africa were used to calculate excess infant mortality.
Results: At a RR of 1.5 for hospitalization in HEU relative to HU infants, AF in HEU infants was 33.3% and PAF at an HIV exposure prevalence of 23% in South Africa and 26% in Botswana were 10.3% and 11.5% respectively. In South Africa, an excess 13,660 of 132,000 hospitalizations in HIV-uninfected South African infants annually could be due to HIV-exposure after removing baseline risk for hospitalizations in all HIV-uninfected infants. Similarly, in Botswana 683/5,935 hospitalizations annually could be excess hospitalizations in HEU infants. At a RR of 1.70 for mortality in HEU compared to HU infants, AF of mortality in HEU infants was 41.2% and PAF was 13.9% in South Africa and 15.4% in Botswana. At an IMR of 33/1000 in South Africa and 36/1000 in Botswana, assuming 8% of infant mortality is associated with infant HIV-infection, HIV-exposure without HIV-infection could increase the IMR by 4.2/1000 in South Africa and 5.1/1000 in Botswana.
Conclusions: With the high prevalence of infant HIV-exposure in Southern Africa, at a population level the contribution of HIV exposure without infection to mortality is possibly exceeding that of infant HIV-infection. This threatens achievement of optimal health and well-being of Southern African infants despite tremendous efforts to avoid HIV-infection in this population.

Moving beyond PMTCT: HIV, ART and adverse birth outcomes in a Zambian pregnancy cohort

J. Price[1], B. Vwalika[1,2], J. Winston[1], M. Castillo[1], L. Njobvu[3], N. Sindano[3], M. Kasaro[1,3], N. Fuseini[1], J. Stringer[1]
[1]University of North Carolina at Chapel Hill, Obstetrics and Gynecology, Chapel Hill, United States, [2]University of Zambia School of Medicine, Obstetrics and Gynaecology, Lusaka, Zambia, [3]University of North Carolina Global Projects, Lusaka, Zambia
Presenting author email: joan_price@med.unc.edu

Background: HIV and its treatment have been associated with adverse birth outcomes (ABOs), however, many studies lack ultrasound dating and do not account for important obstetrical risk factors, including cervical length. We present data from an ongoing prospective cohort study of preterm birth in Lusaka, Zambia.
Methods: We used logistic regression to assess the association between HIV and several ABOs: preterm birth <37 weeks (PTB); low birthweight <2500g (LBW); small-for-gestational age (SGA; <10th percentile); *composite* of PTB, LBW, stillbirth (SB) and SGA; very PTB <34 weeks (VPTB); very LBW <1500 g (VLBW); very SGA (VSGA; <3rd percentile) and *severe composite* of VPTB, VLBW, SB, and VSGA. All women had early ultrasound for dating and an evaluation of cervical length in the mid-trimester. HIV+ women received ART (predominately TDF/FTC/EFV). We treated timing of ART commencement (before/after conception) as a covariate.
Results: Between August 2015 and December 2016, we enrolled 962 women, of whom 410 have delivered. Characteristics are as follows: median age 27 yrs (IQR: 23, 32); median BMI 24.4 kg/m2 (IQR: 21.6, 27.9); 134 (34%) were nulliparous; 225 (24%) were HIV+; 29 (2.9%) had twins gestation; 11 (2.8%) had cervical length <20mm ("short cervix"). The following were associated with the **composite outcome** in multivariable analysis: prior PTB (AOR:1.9; 95%CI: 1.0, 3.8), twin gestation (AOR: 6.0; 95%CI: 1.5, 24), and short cervix (AOR: 7.4; 95%CI 1.7, 32). HIV infection trended toward association (AOR: 1.7; 95%CI: 0.73, 4.1). The factors were associated with the *severe composite outcome* in multivariable analysis: twin gestation (AOR: 7.2; 95%CI: 1.7, 31), vaginal bleeding at enrollment (AOR: 3.2; 95%CI: 1.2, 8.1), and short cervix (AOR: 9.2; 95%CI 2.1, 33). HIV infection trended toward association (AOR: 2.5; 95%CI: 0.86, 7.4). Among the HIV+ women, timing of ART commencement was not associated with any individual outcome or either composite outcome.
Conclusions: The known risk factors of prior PTB, short cervix, and twin gestation are associated with ABOs in this population. There is also a worrying trend between HIV and ABOs. Timing of ART commencement does not appear to affect PTB or other ABOs in this cohort.

TUPEB0458

Risk of mortality and hospitalization among HIV-exposed uninfected Ugandan infants in the setting of Option B+

T. Andra Ochieng[1], T. Ruel[2], P. Natureeba[1], C. Koss[2], P. Jagannathan[3], A. Kakuru[1], M. Muhindo[1], J. Okiring[1], E.D. Charlebois[2], G. Dorsey[2], M.R. Kamya[1,4], D.V. Havlir[2], C. Marquez[2], PROMOTE II Study Group
[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco, United States, [3]Stanford University, Palo Alto, United States, [4]Makerere University, Kampala, Uganda
Presenting author email: carina.marquez@ucsf.edu

Background: V-exposed uninfected children (HEU) have an increased risk of mortality compared to HIV-unexposed uninfected children (HUU). It remains unclear whether this risk persists in the setting of the Option B+. In parallel birth cohorts of HEU and HUU from Uganda, we assessed the association between HIV-exposure and mortality and hospitalizations.
Methods: We evaluated children enrolled in the PROMOTE II birth cohorts from 0-12 months who were participating in a trial on dihydroartemisinin-piperaquine (DP) for malaria chemoprevention. Outcomes assessed were: mortality, hospitalization, and a composite of hospitalization and death. We excluded death and hospitalizations within 48 hours of life, and outcomes attributed to malaria. All HIV-infected mothers received combination antiretroviral therapy (cART) per Option B+, and were advised to breastfeed for at least 1 year. Generalized estimating equation regression models were used to assess risk. Models were adjusted by preterm birth (<37 weeks) age and wealth tertiles, unless specified. Models were not adjusted for breastfeeding, due to insufficient non-breastfeeding person time.
Results: 196 HEU (181 person-years) and 287 HUU (278 person-years) were included, and accrued from October 2014-December 2016. 9.1% of the HEU and 7.7 % of HUU children were preterm, p=0.60. By 1 year of age 99.6% of HEU and 98.5% HUU were breastfeeding. Among HIV-infected mothers, at delivery the median CD4 count was 571 (IQR 403-776) and 96% were virally suppressed (HIV RNA <500 copies/ml). There were 4 (2%) deaths among HEU and 2 (1%) among HUU (RR 2.9, 95% CI: 0.6-16.3, p=0.21, adj. for age). Death and hospitalization was associated with preterm birth (RR 4.4, 95% CI: 1.7-11.3, p<0.01) and there was a trend towards a decreased risk of the composite outcome among HEU (RR 0.4, 95% CI:0.2-1.2, p=0.1) compared to HUU. Hospitalization was associated with HIV exposure (RR 0.2, 95%CI:0.05-0.7, p<0.01), preterm birth (RR 4.6, 95% CI:1.6-12.9, p<0.01).
Conclusions: Contrary to findings from studies conducted prior to Option B+, in this cohort, the risk of mortality and hospitalization was not worse in HEU compared to HUU. Maternal cART, extended breastfeeding, and infant cotrimoxazole prophylaxis may narrow gaps between the health outcomes of HEU and HUU.

TUPEB0459

Neonatal outcomes of pregnancies complicated by HIV: preliminary results of a retrospective matched cohort study from 2004 to 2014

R.K. Scott[1], C. Moore[2], S. Fernandez[3], J. Davitt[4], H. Al-Kouatly[4]
[1]MedStar Health Research Institute and Washington Hospital Center, Womens' and Infants' Services (WIS), Washington, United States, [2]Georgetown University, Washington, United States, [3]MedStar Health Research Institute, Washington, United States, [4]Washington Hospital Center, Womens' and Infants' Services (WIS), Washington, United States
Presenting author email: rachelkscott@hotmail.com

Background: Pregnancy in HIV-positive women is complicated by medical and psychosocial comorbidities. Despite the breadth of the HIV crisis in the developed world, relatively little is known about these pregnancies in resource rich settings. There is an urgent need to identify the adverse outcomes for which HIV-exposed neonates are at risk.
To test the hypothesis that there would be higher neonatal morbidity associated with HIV-positive pregnancies, we conducted a retrospective matched cohort study of neonatal outcomes of HIV-positive pregnancies at MedStar Washington Hospital Center (MWHC).
Methods: We included all pregnancies complicated by HIV and delivered at MWHC from 2004-2014. We excluded multiple gestations and abortions. For each HIV-exposed neonate, we identified two HIV-unexposed neonates, propensity score matched on gestational age at delivery, maternal race, parity, zip-code, and insurance status within a calendar year of delivery.
Data collection is still ongoing. We used chi-squared and fisher's exact tests for categorical variables and t-tests for continuous variables.
Results: We identified 433 HIV-exposed neonates and 866 controls. 433 HIV-exposed neonates and 514 HIV-unexposed neonates were included in this preliminary analysis. Mean maternal age was 27 years; mean gestational age was 38 weeks. The majority were African-American (88%). Mother-to-child transmission of HIV was 2.5% (80.1% in-utero).
In HIV-exposed neonates, we found more intra-uterine growth restriction on prenatal sonogram (7.4 vs. 1.5%, p<0.001) and low birth weight (12.1 vs. 6.4%, p=0.005) compared to controls. There were increased neonatal intensive care unit (NICU) admissions (27.8 vs. 14.7%, p<0.001) among HIV-exposed neonates. We observed increased neonatal respiratory distress syndrome (9.2 vs. 5.2%, p=0.027), need for continuous positive airway pressure (8.4 vs. 4.6%, p=0.027), and intubation (7.1 vs. 3.1%, p=0.009) in HIV-exposed neonates. Although proportions of jaundice were similar, HIV-exposed neonates were more likely to require phototherapy (11.6 vs. 8.5%, p=0.037). We also observed increased hypoglycemia (15 vs. 6.7%, p<0.001).
Conclusions: This is the largest single-site cohort of HIV-exposed neonates in the United States. Our study found that HIV-exposed neonates had increased NICU admission, low birth weight, respiratory morbidity, hypoglycemia, and jaundice requiring phototherapy. Further analysis is needed to explore associations with maternal comorbidities, such as substance abuse and HIV disease status, and prenatal maternal antiretroviral therapy.

TUPEB0460

Readiness of youth living with HIV for long-acting antiretrovirals

E.D. Weld[1], R. Dallas[2], A. Camacho-Gonzales[3], S. Rana[4], L. Thomas-Seaton[2], A. Gaur[2], P. Ryscavage[5], C. Flexner[6], R. Chakraborty[3], A. Agwu[7]
[1]Johns Hopkins University School of Medicine, Clinical Pharmacology & Infectious Disease, Baltimore, United States, [2]St. Jude Children's Research Hospital, Pediatric Infectious Diseases, Memphis, United States, [3]Emory University, Pediatric Infectious Diseases, Atlanta, United States, [4]The Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [5]University of Maryland School of Medicine, Infectious Disease, Baltimore, United States, [6]Johns Hopkins University School of Medicine, Clinical Pharmacology, Baltimore, United States, [7]Johns Hopkins University School of Medicine, Pediatric Infectious Disease, Baltimore, United States
Presenting author email: eweld@jhmi.edu

Background: Youth 13 to 24 years old comprise 26% of all incident US HIV infections, and are a high-risk group for non-adherence to antiretrovirals (ARV). Long-acting parenteral nanoformulated ARV (LA-ARV), now in phase-3 studies, may improve clinical outcomes in this group. However, little is known about the readiness of youth living with HIV (YLHIV) to adopt and adhere to LA-ARV technologies. We examined attitudes to LA-ARV in a mixed cohort of youth with perinatally- and non-perinatally-acquired HIV (PHIV and NPHIV, respectively).
Methods: A cross-sectional survey study of a purposive sample of 256 YLHIV followed at 4 HIV clinics in Baltimore, MD, Atlanta, GA, and Memphis, TN, to determine interest level in LA-ARV. A modified survey instrument previously used in adults was employed. Interest level across groups was compared using Mantel-Haenszel c^2 tests. Multivariable logistic regression was used to determine the impact of various characteristics on interest and enthusiasm level for LA-ARVs.
Results: Respondents were 67% male, 3% male to female transgender; 87% African-American, 8% Hispanic, and 5% Caucasian. The median age and number of years living with HIV was 22 (range 13-24) and 3 years (range 1 month to 24 years), respectively. The most common modes of HIV acquisition were male-to-male sexual contact (148/252 (58.7%) and PHIV (64/252 (25.4%). The proportion of YLHIV that probably/definitely would try LA-ARV regularly injected intramuscularly was 87% [219/252 overall; 56/64 (87.5%) PHIV vs. 148/172 (86%) NPHIV]. Willingness to use increased with lower frequency of injections. The proportion of YLHIV who would probably/definitely try a surgically-placed subdermal implant of slow-release LA-ARV was 77.1% [192/249 overall; 50/64 (78.1%) PHIV vs. 128/169 (75.7%) NPHIV]. There were no significant differences in probable or definite willingness to use by route of infection, age, or gender.
Conclusions: YLHIV at 4 urban US pediatric/adolescent HIV clinics had a high level of enthusiasm for LA-ARV. These observations may be important given the high rates of attrition in care and nonadherence of this vulnerable group. LA-ARV should be given high priority as a potentially viable treatment option to improve clinical outcomes in HIV-infected youth.

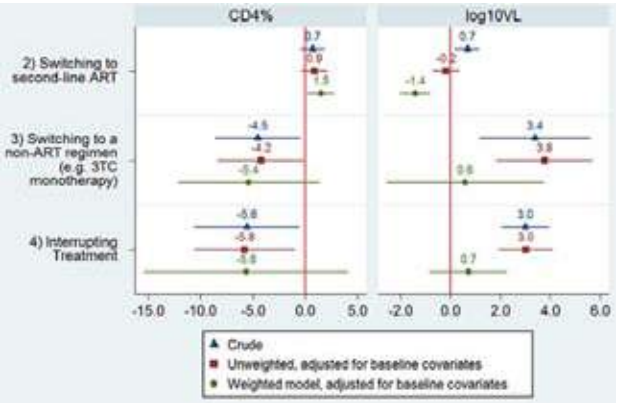
Presenting author email: gem.patten@uct.ac.za

Background: Virologic failure (VF) in HIV-infected children is difficult to manage in resource-limited settings, given limited availability of alternative drugs and concerns around adherence and the development of viral resistance. We aimed to evaluate four management strategies for children following their first episode of VF by comparing their immunologic and virologic outcomes.
Methods: Children (age < 16 years at cART start) with VF, defined as having ≥2 consecutive unsuppressed viral loads (>1000 copies/ml) ≥1 month apart after ≥6 months on cART (at least 3 anti-retroviral drugs from at least 2 drug classes), were followed from their first episode of VF, starting from their second unsuppressed viral load (VL). Children from 8 IeDEA-SA cohorts initiating ART between 2004-2010, with recorded CD4% at VF, and with ≥1 subsequent CD4% were included. Children with VF followed one of four management strategies: 1) Continuing on their failing regimen with at most 1 same-class drug substitution; 2) Switching to a new cART regimen based on guidelines or resistance testing; 3) Switching to a holding regimen, either lamivudine monotherapy or other non-cART regimen; 4) Discontinuing all anti-retrovirals. We compared the effect of management strategy choice, relative to strategy 1, on both the 52-week change in CD4% and $\log_{10}$VL from VF, using the inverse probability weighting of a marginal structural linear model.
Results: We followed 982 patients over 54168 patient-weeks, during which 73%, 24%, 1% and 2% was spent on strategies 1, 2, 3 and 4 respectively. All patients started on strategy 1, 557 remained on strategy 1, 335 switched to strategy 2, 25 to strategy 3 and 65 to strategy 4.



[Figure 1. Estimating change in CD4% and log viral load at 12 months after virologic failure compared with continuing on a failing regimen, from crude, unweighted and weighted generalised linear models]

Conclusions: Consideration should be given to switching children failing first-line ART to a new regimen early, given the improved virologic and immune responses when compared with all other strategies. These results should guide clinicians when managing VF in children.

TUPEB0462

Prevalence, factors and preferred HIV-diagnosis disclosure methods among adolescents living with HIV: a mixed methods study

C.P. Namisi[1,2], G. Wanjala[3], H. Wanzira[4], R.L. King[5], R. Parkes-Ratanshi[6,7], M. Nannyonga[2]
[1]Infectious Diseases Instutite College of Health Sciences Makerere University, Ugandan Academy for Health Innovation and Impact, Kampala, Uganda, [2]St. Francis Hospital Nsambya, Home Care Department, Kampala, Uganda, [3]Hoima Regional Referral Hospital Ministry of Health, Paediatrics, Kampala, Uganda, [4]Ministry of Health, Department of Epidemiology, Kampala, Uganda, [5]University of California (UCSF), Global Health Sciences, San Francisco, United States, [6]Infectious Diseases Institute College of Health Sciences Makerere University, Ugandan Academy for Health Innovaton and Impact, Kampala, Uganda, [7]Univserity of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom
Presenting author email: charlespcn@gmail.com

Background: To date, low-resource settings have no substantive method of disclosure of HIV-diagnosis for adolescents. The study objective was: to measure, characterize and use adolescents' living with HIV (ALHIV) perspectives to derive a preferred method of disclosure of HIV-diagnosis among adolescents attending St Francis Hospital Nsambya Home Care, Kampala, Uganda.
Methods: A mixed method research design was used: a cross-sectional study was conducted among 341 randomly selected ALHIV using interviewer-administered questionnaires on sociodemographic and HIV-related characteristics. The relationship between sociodemographic and HIV-related characteristics, and dependent variable ALHIV disclosure status was analyzed in univariate and logistic regression using odds ratios: 95 % confidence interval and p-value at 0.05. To explain the important quantitative results, we conducted six focus groups each of five purposively selected ALHIV, caregivers and health care providers, total 30 participants. The interview guide had questions on "how disclosure of HIV-diagnosis ALHIV should be carried out?" We used line-by-line coding, labelled concepts from content, defined and developed categories based on their properties and dimensions to interpret the disclosure methods.
Results: Overall 341 ALHIV were enrolled: 51.2% females, mean age 15 years (SD+/-3yrs), 73.4% (248 of 338) who responded to disclosure questions, knew their HIV-diagnosis. Adolescents who knew their own HIV-diagnosis were: older (aOR 7.20, 95% CI: 3.58-14.51) p =0.000), orphans (aOR 2.5, 95% CI: 2.21 (1.15-4.24)p =0.016), self-medicating (aOR 0.39, 95% CI: 0.16-0.92, p=0.03), and had attended adherence-related workshop (aOR 4.30, 95% CI: 2.17-8.53, p =0.000). The emerging themes on method of disclosure were: adolescent's psychological age, address caregiver's emotional readiness and a supportive by health care system.
Conclusions: The prevalence of ALHIV who knew their own HIV-diagnosis was high compared to the figures in other low-income countries. Factors favouring disclosure were adolescent's individual and facility level characteristics. Our findings support the following method of disclosing HIV-diagnosis to adolescents: the healthcare provider should screen the ALHIV for disclosure using: age, orphan-hood, self-medication, and attendance of adherence-related workshop. Then identify and address caregiver's fears and communication skills, and the healthcare provider should be ready to support the disclosure process.

First line antiretroviral treatment outcomes and durability in HIV-infected children treated through the universal coverage health program in Thailand

S. Teeraananchai[1,2], T. Bunupuradah[2], T. Puthanakit[2,3,4], S.J. Kerr[2], K. Ruxrungtham[2,5], S. Chaivooth[6], S. Bhakeecheep[6], M.G. Law[1], K. Chokephaibulkit[7]
[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand, [4]Research Unit in Pediatric Infectious Diseases and Vaccines, Chulalongkorn University, Bangkok, Thailand, [5]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [6]The HIV/AIDS, Tuberculosis and Infectious Diseases Program, National Health Security Office (NHSO), Nonthaburi, Thailand, [7]Siriraj Hospital, Mahidol University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand
Presenting author email: sirinya.t@hivnat.org

Background: The universal coverage health care program (UC), managed by the National Health Security Office (NHSO) since the end of 2007, has been providing HIV treatment and care for more than 70% of the Thai HIV-infected population. In 2014, 4,502 HIV children were receiving antiretroviral therapy (ART) through UC. We assessed the treatment outcomes on first-line antiretroviral therapy (ART), and factors associated with switching regimen in HIV-infected children treated through the UC in Thailand.

Methods: Children aged <15 years at ART initiation who had been receiving ART for at least 6 months between 2008 and 2014 through UC were included in the analysis. The Kaplan-Meier method was used to estimate immunological recovery (IMR), immunologic failure (IMF) and virologic failure (VF). Cox models were used to assess predictors of IMR and VF. Competing risk models were used to assess factors associated with switching to a second-line regimen, with death considered as a competing risk.
Results: A total of 4,120 children initiated ART at a median (IQR) age of 9.3 (5.8-12.0) years. The median duration of ART was 3.7 years with 17,950 person-years of follow up. 2,805 children achieved IMR and the probability of IMR increased to76% by 3 years after ART initiation. Among 1,054 children switched to second-line regimens; 84% had VF and 19% had IMF. The cumulative rate of switching regimen increased from 4% to 20% from 1 to 3 years after treatment. Children aged ≥12 years at ART initiation (≥ 12 vs 5-<9 years, aSHR 1.33, 95%CI 1.12-1.57), starting with NNRTIs (NNRTIs vs PI years, aSHR 1.61, 95%CI 1.23-2.12), and baseline CD4% <10% (<10% vs ≥16%, aSHR 1.48, 95%CI 1.22-1.79) had an increased risk of switching to second-line regimens.
Conclusions: Children receiving ART through UC had good treatment outcomes, although a fifth required switching regimen by 3 years. Earlier treatment initiation and avoiding NNRTIs first-line regimens in high risk children may prevent treatment failure.

High proportion of virological failure and drug resistance among adolescents on first-line ART in Chiradzulu district, Malawi

B. Schramm[1], A. Dublineau[1], A. Rakesh[2], T. Munyenyembe[2], S. Nicholas[1], J. Kandulu[3], L. Salumu[4], E. Pasquier[4], R.N. Keango[5], E. Poulet[1], L. Serrano[6], M. Peeters[6], E. Szumilin[4]
[1]Epicentre, Paris, France, [2]Medecins Sans Frontieres, Chiradzulu, Malawi, [3]Ministry of Health, Lilongwe, Malawi, [4]Medecins Sans Frontieres, Paris, France, [5]Medecins Sans Frontieres, Lilongwe, Malawi, [6]Institut de recherche pour le développement-University of Montpellier, UMI 233, Montpellier, France
Presenting author email: birgit.schramm@epicentre.msf.org

Background: Adolescent are a growing proportion of the HIV-infected population in sub-Saharan Africa, mostly comprised of perinatally infected children who survived on ART. Nonadherence and drug resistance development are considered a particular challenge to this patient-group. We assessed virological response to first-line ART and drug resistance among adolescents receiving treatment in a decentralized HIV-programme supported by Médecins Sans Frontières in rural Chiradzulu District, Malawi. Routine VL monitoring was implemented in this programme by end of 2013.
Methods: Between May-November 2016 a cross-sectional assessment was conducted among HIV+ patients (10-19 years) receiving standard first-line ART for ≥ 6 months. Participants were recruited from five decentralized health centers and the district hospital outpatient-clinic. Plasma viral load (VL) was assessed with SAMBA-VL test (semi-quantitative, 1000 HIV RNA copies/ml) and by quantitative VL-method (Biocentric). Resistance-genotyping was performed if VL ≥500 copies/ml, and sequences interpreted by Stanford algorithms for drug resistance mutations.
Results: 409 adolescents (median age 13 years, 57% females) were included after a median time of 6.7 years (IQR: 3, 14.3) on ART (85% AZT/3TC/NVP, 10% TDF/3TC/EFV). One-hundred-and-twenty-nine (31.5%) had SAMBA VL detectable (≥ 1000 copies/ml), with a median CD4 of 552 cells/ml (IQR: 350, 785) among virological failures and 776 (IQR: 636, 1029) among non-failures (p< 0.001), and 98% current clinical stage 1. Currently available resistance results (46/129) revealed 87% (40/46) dual drug-class resistance, 87% 3TC, 96% NVP and 76% EFV resistance (all major). Seventy-six percent remained susceptible to TDF, and 63% to AZT. Complete VL and resistance data will be presented.
Conclusions: Nearly one-third of adolescents on first-line ART had virological failure. Overall clinical condition was good, though CD4 counts were significantly lower among failures. Currently available resistance data indicate that most were on a failing regimen equivalent to a mono-therapy, requiring prompt switch to second-line. Early and regular VL-monitoring and a robust once-per-day first-line should be considered to prevent major resistance accumulation in children and adolescents.

TUPEB0465

Reproductive health, social life and future plans of adolescents born with HIV: a case-control study in Thailand

L. Rolland-Guillard[1,2], E. de La Rochebrochard[2,3], W. Sirirungsi[4], C. Kanabkaew[5], D. Breton[1,2], S. Le Coeur[2,4,5]
[1]Strasbourg University, Demographic Institute of the University of Strasbourg, Strasbourg, France, [2]Institut National d'Etudes Démographiques (INED), Paris, France, [3]Paris-Sarclay University, Univ. Paris-Sud, UVSQ, CESP, INSERM, Villejuif, France, [4]Faculty of Associated Medical Sciences, Chiang Mai University, Chiang Mai, Thailand, [5]Institut de Recherche pour le Developpement (IRD), IRD174-PHPT, Chiang Mai, Thailand

Background: Thanks to antiretroviral treatment (ART), perinatally HIV-infected children now survive into adolescence. This is a period when young people experience puberty, shape their sexual identity, initiate their own social life, and may experiment with sex. Several studies indicate pubertal delay in HIV-infected children. However, few have compared the broad experience of adolescence among HIV-positive and HIV-negative youth. The aim of our analysis was to compare the reproductive health, social life and plans for the future of adolescents born with HIV with a matched control group from the general population.
Methods: We used data from the Teens Living with Antiretrovirals (TEEWA) survey carried out from March 2010 to July 2012 in Thailand among perinatally HIV-infected adolescents aged from 12 to 19, living in family settings. Adolescents completed a self-administered questionnaire focusing on family, schooling, reproductive health and social life. Each adolescent born with HIV (Case) was matched on sex, age and place of residence with a randomly selected adolescent from the general population (Control). Descriptive analysis was stratified by age (above or below 15 years) and performed separately for boys and girls, using McNemar's test for paired comparison.
Results: A total of 1,142 adolescents (571 pairs) were included in the analysis: 666 (58.3%) girls and 476 (41.7%) boys. Compared to the controls, significantly fewer cases had experienced puberty before age 15 (p<0.001). At the time of the survey, they did not differ in terms of sex education, sexual intercourse, romantic relationships or friendships. However, at all ages, cases were less likely to have plans for higher education (p=0.016), marriage (p=0.011) or parenthood (p<0.001).

	Boys				Girls			
	Cases <15 yrs	Controls <15 yrs	Cases ≥15 yrs	Controls ≥15 yrs	Cases <15 yrs	Controls <15 yrs	Cases ≥15 yrs	Controls ≥15 yrs
Experienced puberty	41.2%	64.0% (p<0.001)	79.2%	74.5% (p=0.411)	55.2%	82.6% (p<0.001)	93.1%	98.8% (p=0.013)
Had sex education	78.7%	82.3% (p=0.446)	89.2%	85.3% (p=0.433)	87.8%	87.8% (p=1.000)	95.7%	93.8% (p=0.467)
Had sexual intercourse	0.8%	0.8% (p=1.000)	15.7%	18.5% (p=0.439)	0.6%	0.6% (p=1.000)	7.5%	9.8% (p=0.317)
Had a boy/ girl friend	11.8%	15.4% (p=0.369)	30.4%	39.2% (p=0.149)	9.9%	16.3% (p=0.101)	38.8%	38.5% (p=0.908)
Hang out with friends	53.8%	50.7% (p=0.541)	78.0%	82.2% (p=0.433)	47.1%	51.7% (p=0.352)	70.0%	77.0% (p=0.172)
Plan for high education	31.6%	53.7% (p<0.001)	50.0%	67.7% (p=0.016)	49.4%	75.6% (p<0.001)	65.8%	86.3% (p<0.001)
Plan to marry	26.5%	41.2% (p=0.011)	17.7%	59.8% (p<0.001)	8.1%	22.1% (p<0.001)	17.4%	39.1% (p<0.001)
Plan to have children	15.4%	40.4% (p<0.001)	13.7%	57.8% (p<0.001)	5.2%	17.4% (p<0.001)	12.4%	34.8% (p<0.001)

[Characteristics: cases vs. controls differences]

Conclusions: As WHO is now recommending ART to all HIV-infected children, pubertal delay should be reassessed. For the current generation, additional counselling and psychological support is needed to allow them envision a future with more options.

A clinical and neuroradiological study of apathy in HIV-infected South African children

C.J. Wedderburn[1], J.P. Fouche[2], N.J. Phillips[2], S.D. Lawn[1], D.J. Stein[2,3], J. Hoare[2]
[1]London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [3]MRC Unit on Anxiety & Stress Disorders, Cape Town, South Africa
Presenting author email: catherine.wedderburn@gmail.com

Background: Apathy is a well-recognised neuropsychiatric symptom in adults with HIV, but there is no research on the phenomenology, neuropsychology and neuroimaging of this symptom in HIV-infected children. The aim of this study was to

examine apathy in HIV-infected children in South Africa and the association with HIV disease progression, cognition and white matter microstructure.
Methods: We investigated apathy in 76 perinatally HIV-infected children in South Africa aged 6 to 16 years, including 63 on antiretroviral therapy (ART) and 13 ART-naïve slow progressors within a cross-sectional study design. We used the Children's Motivation Scale (CMS) to assess apathy severity, a battery of validated neuropsychological tests to assess cognition and diffusion tensor imaging (DTI) to examine white matter microstructure in specific frontostriatal regions-of-interest.
Results: CMS scores were associated with DTI metrics in specific brain regions using bivariate analyses including the anterior limb of the internal capsule, superior corona radiata and the cingulum. Fractional anisotropy, a measure of white matter microstructural integrity, in the anterior limb of the internal capsule remained a significant predictor of apathy when controlling for age, gender and ART use in multiple linear regression analyses (right side beta = -0.32, p=0.02; left side beta = -0.29, p=0.04). Children on ART exhibited less motivation than ART-naïve slow progressors (p=0.02), but CMS scores were not associated with laboratory markers of disease progression or cognition.
Conclusions: Apathy may be an important neurobehavioural symptom in perinatally HIV-infected children, and may reflect changes in white matter microstructure in specific frontostriatal brain regions. As growing numbers of perinatally HIV-infected children progress into adolescence and adulthood, long-term neuropsychological sequelae are becoming increasingly important and apathy may have implications in planning appropriate care.

TUPEB0467

A study of non-disclosure and associated factors among perinatal HIV-infected children and adolescents in Bangkok, Thailand

W. Kingkaew[1], S. Anugulruengkitt[2,3], W. Jantarabenjakul[2,3], S. Phonphithak[1], N. Kasipong[1], S. Bureechai[1], S. Thamsala[1], J. Sophonphan[1], T. Bunupuradah[1], T. Puthanakit[1,2,3]
[1]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand, [3]Chulalongkorn University, Research Unit in Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Bangkok, Thailand
Presenting author email: waraporn_k@trcarc.org

Background: Disclosure of HIV status to children is essential for disease management but is not well characterized in resource-limited setting. This study aimed to describe the prevalence of disclosure/non-disclosure and associated factors of non-disclosure in a cohort of perinatal HIV-infected children and adolescents.
Methods: We conducted a cross-sectional study of HIV disclosure status in all perinatal HIV-infected children age ≥ 6 years at HIV-NAT, the Thai Red Cross AIDS Research Centre, Bangkok, Thailand. HIV disclosure status of each child and caregiver were collected by pediatricians by interview children and their caregivers in each scheduled clinic visits during January-December 2016. Descriptive statistics and disclosure prevalence were calculated. Univariate analysis and multivariate logistic regression were performed to assess the association of non-disclosure.
Results: Two hundred thirty six children were enrolled, current median (IQR) age was 18.5 (15.8-20.6) years, 51.6% were female, median CD4 was 663 (491-917) cells/mm^3. Two hundred thirty four (99%) children were using antiretroviral therapy and 78% had plasma HIV RNA <50 copies/ml. One hundred fifty four (65%) children had at least 1 of parents alive and 33 (14%) live in orphanage house.
Prevalence of HIV disclosure was 91% (214/236). Median age at disclosure was 12.1 (10.7-13.7) years. Twenty two (9%) children were HIV non-disclosure. The reasons of non-disclosure were caregiver felt that the child is too young 10 (45%), child had delayed cognitive development (i.e. from HIV encephalopathy) 9 (41%), caregiver is not ready to disclose i.e. not know how to do 2 (9%), and caregiver fear of HIV stigma 1 (5%).
In multivariate regression, factors associated with non-disclosure were age ≤15 years (aOR 22, 95%CI 6.8-70.9, p<0.001), and living in orphanage vs. community (aOR 6.5, 95%CI 1.6-25.7, p=0.01). Other variables such as parent alive and current CD4 were not significantly associated with non-disclosure.
Conclusions: One-tenth of perinatal HIV-infected children and adolescents were non-disclosure in our pediatric cohort. Younger age and living in orphanage were significantly associated with non-disclosure. Health care provider should give more psychosocial support to these children and caregiver in disclosing process.

TUPEB0468

Behavioral and mental health outcomes in the Cape Town Adolescent Antiretroviral Cohort

J. Hoare[1], N. Phillips[2], J. Joska[2], L. Myer[2], H. Zar[2], D. Stein[2]
[1]University of Cape Town, Department of Psychiatry, Groote Schuur Hospital, Cape Town, South Africa, [2]UCT, Cape Town, South Africa
Presenting author email: hoare.jax@googlemail.com

Background: The impact of HIV together with antiretroviral therapy (ART) on long term mental health in perinatally infected children has not been well studied.
Methods: The aim of this study was to comprehensively investigate a wide range of mental health outcomes including depression, anxiety, attention deficeit hyperactivity disorder, apathy, disruptive behaviour and functional competence in perinatally infected adolescents stable on ART as part of a prospective cohort study, the Cape Town Adolescent Antiretroviral Cohort. 204 perinatally HIV-infected adolescents (mean age 10.38 years; mean duration of ART 9.11 years; mean CD4 952 cells/mm$^{3;}$ mean viral load of 5205 cells/mL) and a convenience sample of 44 uninfected matched controls aged 9 to11 years were studied. The Beck Youth Inventories, Children's Motivation Scale, Conner's Parent's Rating Scale, Child Behaviour Checklist and Columbia Impairment scale were administered by trained mental health study staff.
Results: The HIV infected group of adolescents were more likely to have had repeated grades at school, caregiver depression, the loss of both biological parents and shorter stature. HIV infected adolescents had poorer functional competence (p=.006), self concept (p=.009), motivation (p=.000), and higher levels of depressive (p=.003) and ADHD symptoms (p=.018), compared to uninfected controls. HIV infected adolescents also had higher rates of clinically significant anger and disruptive behaviour (p=.047 and p=.00) Within the HIV infected group the loss of both biological parents was associated with higher levels of disruptive behaviour (p=.08).
Conclusions: HIV-infected adolescents well controlled on ART have poorer mental health and functional competence with potential impact on learning, school performance and adult health.

TUPEB0469

Psychiatric disorders among HIV-infected adolescents in Montreal, Canada

F. Kakkar[1], S. Valois[1], V. Lamarre[1], C. Renaud[2], N. Lapointe[3]
[1]CHU Sainte-Justine, University of Montreal, Infectious Diseases, Montreal, Canada, [2]University of Montreal, Microbiology and Immunology, Montreal, Canada, [3]CHU Sainte-Justine, University of Montreal, Immunology, Montreal, Canada
Presenting author email: fatima.kakkar@umontreal.ca

Background: The incidence of psychiatric disorders among perinatally HIV infected children who are on effective antiretroviral therapy (ART) is not well known, despite the neurotropic effects of the virus, and concerns about the potential ART associated neurotoxicity. The objective of this study was to document the incidence of psychiatric disorders among perinatally HIV infected children in Montreal.
Methods: Clinical records and the database of the Centre Maternel et Infantile sur le SIDA (CMIS) (Montreal) cohort (1988-2015) were reviewed to identify all children who were diagnosed with a psychiatric disorder according to DSM IV criteria. Patients were excluded if they were followed at CMIS less than 5 years, were non-perinatally infected, were less than 13 years of age at the time of study, or died before the age of 18.
Results: Out of a total of 184 HIV infected children followed at CMIS, 93 met the inclusion criteria. Of these, 8.6% were diagnosed with a psychiatric disorder (psychoses with hallucinations=2, psychosis without hallucinations=1, major depression with suicide attempt=2, major depression without suicide attempt, n=3). Mean age at psychiatric diagnosis was 14 (range 10-17 years). The majority (62.5%) were on effective ART at the time of their diagnosis, with sustained viral suppression. There was a higher proportion of psychiatric diagnosis among children born during the era of cART availability (2000-2014), vs. those for whom only sequential ART was available (1980-2000) (14% vs. 8.2%), though not statistically significant. The overall incidence of psychosis (4.3%) and suicide (2.1%) was higher that reported in the general Canadian population of adolescents (0.5% and 0.001% respectively).
Conclusions: In this cohort of perinatally infected children, the incidence of psychiatric disorders was 8.6% in adolescence, and appears significantly higher than among the general population of Canadian adolescents. These findings and specific causative factors need to be confirmed in larger studies.

TUPEB0470

Children and HIV in Nigeria: prevalence, patterns and correlates of emotional and behavioral comorbidity

O. Adejumo[1], K. Malee[2], S.J. Hunter[3], R.E. Oladokun[4], B. Brown[4], O. Omigbodun[1,5], A. Ogunniyi[6], K. Robertson[7], B. Taiwo[8]

Presenting author email: radejumo@yahoo.com

Background: With effective treatment, children with perinatally acquired HIV are reaching adolescence and adulthood in increasing numbers. Emotional and behavioural problems (EBPs) are observed among children and adolescents with perinatally-acquired HIV infection (paHIV youth) across cultures. We characterized EBPs and their correlates in a cohort of paHIV youth in South-West Nigeria, in comparison to a non-infected, unexposed (HUU) group.
Methods: Data were collected from 102 paHIV and 101 HUU at entry into the Ibadan Cohort Study on NEUROAIDS in Children (ICONIC), a longitudinal cohort (aged 8 to 15 years) at the University College Hospital, Ibadan. The paHIV and HUU groups had similar age and socioeconomic status, and resided in two communities within Ibadan. EBPs, defined as borderline and/or clinically significant problems on the caregiver-reported Child Behavior Checklist (CBCL) were assessed using age-and gender-standardized norms from the CBCL multicultural supplement. Clinical and sociodemographic variables were obtained using a structured parent interview and patient records and caregiver depression was assessed using the Centre for Epidemiological Studies Depression Scale Revised (CESD-R). CBCL problem and syndrome scale mean scores were compared using independent t tests, and univariate and multivariate analyses of EBP correlates were conducted with logistic regression.
Results: Among paHIV youth, 10.8% had EBPs in the borderline or clinical range, compared to 3.9% of comparison youth (p=0.014). Significant differences were detected in the Attention problems and Aggressive Behaviour subscales (7.8% vs 1.0%, p=0.001) and (12.7% vs 2.0%, p<0.001) for paHIV and HUU respectively. Compared to paHIV youth between 8 and 11 years (N=76/102), more of those above 11 years (N=26/102) had Social Problems (19.2% vs 3.9%; p=0.024) and Thought Problems (15.4% vs 2.6%; p=0.036). Among biomedical and psychosocial variables, caregiver depression only was associated with CBCL Total Problem Scores in the borderline and clinical range for paHIV youth (OR 1.1, 95% CI 1.02-1.14; p=0.013).
Conclusions: EBPs, especially externalizing problems, are more prevalent among paHIV than HUU children in Nigeria and are associated with caregiver depression. With ongoing access to cART, paHIV children in Nigeria require comprehensive health care, early diagnosis of existing EBPs, and family focused, evidence-informed mental health treatment and prevention programmes.

TUPEB0471

A diagnostic prediction model for tuberculosis treatment decision in smear and Xpert-negative HIV-infected children

O. Marcy[1,2], M. Tejiokem[3], N.L. Nguyen[4], B. Nacro[5], V. Ung[6], L. Borand[2], P. Msellati[7], G. Carcelain[8], S. Godreuil[9], S. Blanche[10], C. Delacourt[11], ANRS 12229 PAANTHER 01 Study Group

Presenting author email: oliviermarcy@gmail.com

Background: WHO recommends assessing for tuberculosis HIV-infected children presenting with fever, cough, weight loss, or contact history. Tuberculosis diagnosis is very challenging in this population where microbiological confirmation is seldom reached. We aimed to develop a diagnostic model for tuberculosis treatment decision in smear and Xpert MTB/RIF (Xpert)-negative HIV-infected children.
Methods: HIV-infected children aged ≤13 years with a suspicion of tuberculosis were enrolled in the ANRS 12229 PAANTHER 01 study in Burkina Faso, Cambodia, Cameroon, and Vietnam. Children underwent full medical history and clinical assessment, bacteriological samples for smear microscopy, Xpert, and culture, chest radiograph (CXR), and abdominal ultrasound (AUS). The NIH classification was used as reference standard considering both confirmed and unconfirmed tuberculosis. We developed a multivariable prediction model for tuberculosis diagnosis in Xpert and smear-negative children, using logistic regression with a 0.15 significance threshold. We assessed area under the receiver operating characteristics curve (AUROC) of the model.
Results: Of 438 children enrolled, 53 were Xpert or smear-positive and 385 were considered in this analysis. Of these, 310 had full data available for all predictors, including 170 classified as tuberculosis. Hemoptysis (OR 5.39; 95%CI 0.95 - 30.76), sleep disorder >2 weeks (OR 2.84; 95%CI 1.02 - 7.93), fever >2 weeks (OR 3.45; 95%CI 1.95 - 6.09), contact with smear-positive tuberculosis (OR 10.61; 95%CI 2.10 - 53.70), tachycardia (OR 2.99; 95%CI 1.05 - 8.53), abdominal distension (OR 1.91; 95%CI 0.87 - 4.21), alveolar opacities (OR 2.84; 95%CI 1.60 - 5.05), miliary or macronodules (OR 2.30; 95%CI 0.88 - 6.03), and lymphadenopathies on CXR (OR 2.30; 95%CI 1.28 - 4.13), and abdominal lymphadenopathy on AUS (OR 5.67; 95%CI 2.85 - 11.27) remained in the model (AUROC 0.842). Selecting an individual probability threshold of 0.460, sensitivity of the model was 75.7% and specificity 66.9%.
Conclusions: A model integrating easily collectable signs and symptoms, CXR and AUS findings has good predictive performance for tuberculosis diagnosis in children without immediate microbiological confirmation by smear microscopy and Xpert. It could be used as manual or automated diagnostic score to help prompt tuberculosis treatment decision in these children. Internal and external validation is needed to refine the model.

TUPEB0472

Human genomic DNA concentration is significantly reduced among children and adolescents on antiretroviral therapy

C. Onwuamah[1], D. Idowu[2], R. Aworunse[2], P. Odeigah[2]
[1]Nigerian Institute of Medical Research, Human Virology Laboratory, Lagos, Nigeria, [2]University of Lagos, Department of Cell Biology and Genetics, Lagos, Nigeria
Presenting author email: chikaonwuamah@yahoo.com

Background: Documented adverse effect of antiretroviral therapy (ART) include incorporation into chromosomal DNA, loss of heterozygosity, altered cell cycles, centrosomal amplification and aneuploidy, these increases genomic instability. Genomic instability has been implicated in several cancers and among HIV-positives, cancer indices are higher than in the general population. Can increased genomic instability induced by ART exposure be implicated? We thus determined human genomic DNA concentration and damage among children/adolescents exposed to ART to ascertain if genomic instability is increased.
Methods: We obtained ethical approval and informed consent. Study groups include HIV-negative children presenting for other illness (control group), children born to HIV-positive women exposed to ART possibly in utero and/or via PMTCT (exposed group), and HIV-positive children/adolescents on ART (therapy group). Human genomic DNA was extracted from venous blood. DNA concentration and damage (fragmentation and nicks) was quantified using fluorometric methods. Glutathione S-transferase (GST) T1 and M1 genotypes, crucial for xenobiotics detoxification, were determined by PCR. Kruskal-Wallis statistical test was used.

Variables	Options	Control (n=26)	Exposed (n=71)	Therapy (n=46)
Time on ART	Median (Months)	-	8.0 (IQR: 7.0 - 9.0)	74.0 (IQR: 26.0 - 90.0)
T1 Genotype&	Homozygote/ Heterozygote	10 (38.5%)	30 (42.3%)	25 (54.3%)
	Null	15 (57.7%)	37 (52.1%)	20 (43.5%)
M1 Genotype&	Homozygote/ Heterozygote	16 (61.5%)	58 (81.7%)	29 (63.0%)
	Null	9 (34.6%)	9 (12.7%)	16 (34.8%)
#DNA Content	Median (µg/mL)	10.0 (IQR: 6.9 - 23.4)	10.3 (IQR: 7.7 - 13.7)	3.7 (IQR: 2.6 - 6.3)
#Intact DNA	%	74.2 (IQR: 40.4 - 100.0)	100.0 (IQR: 100.0 - 100.0)	100.0 (IQR: 100.0 - 100.0)
Un-nicked DNA	%	88.3 (IQR: 38.0 - 98.9)	79.7 (IQR: 36.8 - 91.4)	82.8 (IQR: 67.5 - 90.0)
#Statistically Significant; &One, four and one participants' PCR failed and thus not determined for control, exposed and therapy groups respectively				

[Table 1: Group values for different variables]

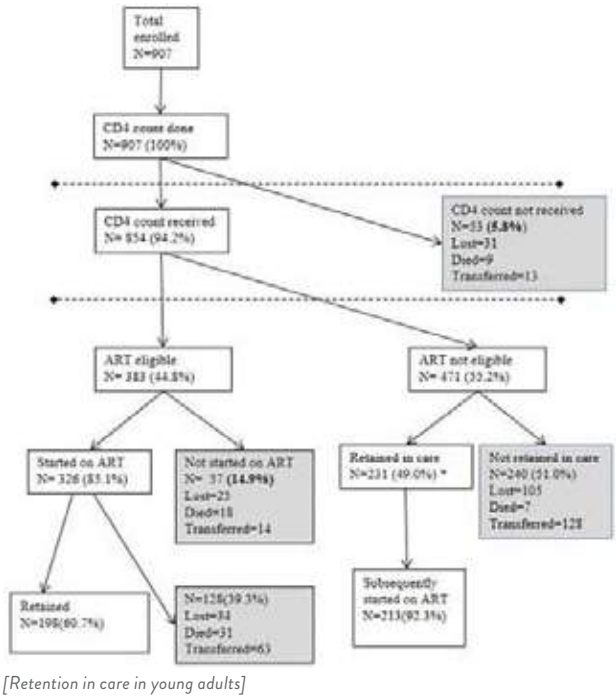
Results: Proportions of T1 and M1 null genotypes was varied (Table 1). DNA concentration analyzed by time on ART was significant (p=0.0001), becoming greatly reduced after >24 months on ART. Without correction, T1 null genotype had significantly lower DNA concentration (p=0.043) among the therapy group. Thereafter, we compared DNA concentration by GST genotypes, weighting for time on ART. Among the exposed group, M1 null genotypes (3.7µg/mL; p<0.0000) had lower DNA concentration while the T1 null genotypes had higher DNA concentration (10.3µg/mL; p=0.013). Conversely among the therapy group, the T1 null genotype (3.5µg/mL; p<0.0000) had lower DNA concentration.
Conclusions: Human genomic DNA concentration was significantly reduced among HIV-positive children/adolescents on ART compared to HIV-negative ART-naïve children and those children with minimal ART exposure. The possible effect of GST-T1 and M1 genotypes on DNA concentration needs to be clarified.

TUPEB0473

Describing the continuum of care in young adults who transition from adolescent to adult care

B. Castelnuovo, F. Mubiru, R. Musomba, S. Nakalema, A. Twimukye, A. Kiragga
Infectious Diseases Institute, Research, Kampala, Uganda
Presenting author email: bcastelnuovo@idi.co.ug

Background: In sub-Saharan Africa there is an increasing number of adolescents and young adults entering care due to reduction of mortality in HIV positive infants, and high incidence of new infections in this age group. We aimed to investigate the continuum of care in young adults (18-25 years).
Methods: We included all patients 18-23 years (to allow 2-years follow-up) at enrolment at the Infectious Diseases Institute, Kampala, Uganda, from 2010 to 2014. We describe the number of patients who were lost along the steps of the cascade 1) enrolment 2) CD4-count measurement 3) ART assessment (reception of CD4 count) 4) Follow up stratified by ART eligibility. We carried out survival analysis for time to being lost to program (LTP) at any stage by gender, WHO stage and ART eligibility. We performed Cox regression analysis to identify patients at the highest risk to be LTP defined as being dead or not have returned to the clinic for >90 days.
Results: . 907 young adults were enrolled in care, 784 (82.47%) female, median age 21 years (IQR: 20-22), 26.9% were in WHO stage 3&4, median CD4 count at enrolment was 400 cells/µL (IQR 170-612). A total of 260 were LTP (see figure).



[Retention in care in young adults]

In survival analysis we did not find any difference in LTP by gender and ART eligibility; the probability was higher in patients in WHO stage 3&4 as compared to 1&2 (0.52, CI:0.14-0.64 versus 0.31, CI:0.26-0.36, P< 0.001). Similarly in the multivariate analysis we found that the only risk factor associated with LTP was WHO stage 3&4 (adjusted HR: 1.72 (CI: 1.32-2.26, P< 0.001).
Conclusions: One quarter of young adults, especially those presenting in advance stage of disease were LTP; there is need for tracking studies to evaluate the true viral status of LTP in this group since it is likely that deaths were underestimated.

Transition of perinatally HIV-infected adolescents into adult care: lessons learned and new challenges

F.K. Ndiaye[1], H. Mbodj[1], S. Diop[2], M.B. Diallo[2], N.A. Ndiaye[3], A. Diop[1], C. Cames[4], A. Diack[1]
[1]Centre Hospitalier National d'Enfants Albert Royer, Dakar, Senegal, [2]Centre Hospitalier Universitaire de Fann, Service des Maladies Infectieuses et Transmissibles, Dakar, Senegal, [3]Centre Hospitalier Universitaire de Fann, Centre Regional de Recherche et de Formation à la Prise en Charge Clinique, Dakar, Senegal, [4]Institut de Recherche pour le Developpement, Montpellier, France
Presenting author email: fknsamb@yahoo.fr

Background: With improvements in antiretroviral (ART) access, a growing population of perinatally HIV-infected adolescents go through adulthood. Adolescents should start the transition into adult care around 15 years of age. This transition raises concerns of retention in care and long-term adherence to ART. From 2011 to 2016, a transition support process (TSP) was implemented in a pediatric HIV hospital in Dakar. We described retention in care and changes in virologic suppression (VS) in patients who received TSP or a standard transition process (STP).
Methods: Perinatally HIV-infected adolescents ≥15 year-old, on ART, and autonomous in their care were identified for transition into adult care. Patients were referred to TSP or STP according to their own preference. STP consisted of preparation sessions in the pediatric hospital followed by direct transfer to the adult care facility. For patients receiving TSP, transfer to adult care was preceded by a 2 year-period of joint visits with a physician and the attending pediatrician, as well as community support groups.
Results: Of 47 adolescents eligible for transition, 32 consented to enter the TSP. For those opting for the STP, 4 were pregnant, 3 about to start university and 8 were at an advanced age who had previously refused to enter transition (Table 1). Patients in both groups remained in care during the study. The percentage of VS patients at the end of transition increased following TSP (p=0.01) and those with VS at enrollment maintained it at the end of the process. By contrast, the rate of VS decreased in patients receiving the STP.

Characteristics	TSP n=32	STP n=15
Female, %	39	80
Age in years, (median IQR)	18.3 (17.1-19.7)	20.4 (18.4-22.1)
Age at HIV disclosure in years, (median IQR)	15.9 (14.5-17.5)	16.3 (15.3-18.0)
VS patients at enrollment, %	61	73
VS patients at exit, %	81	60
Transition duration in months, (median IQR)	27.1 (17.3-39.7)	6.5 (5.7-7.6)

[Table 1: Characteristics of HIV-infected Senegalese adolescents enrolled in a transition process.]

Conclusions: We report encouraging results suggesting TSP helps maintain and possibly improves VS in adolescents transitioning into adult care. However, late HIV disclosure, and reluctance to leave their pediatrician, dramatically delayed transition in many adolescents. Transition should be tailored to fit the adolescents' specific needs, including early pregnancy prevention and monitoring.

TUPEB0475

Sexual satisfaction: determining unique clinical needs of the first generation of young women living with HIV since childhood through the Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS)

A. Underhill[1], V.L. Kennedy[1], J. Brophy[2], M. Loutfy[1,3], W. Wu[1], A. Carter[4], K. Proulx-Boucher[5], K. Webster[4], A. de Pokomandy[5], A. Kaida[4], on behalf of the CHIWOS Research Team
[1]Women's College Hospital, Women's College Research Institute, Toronto, Canada, [2]The Children's Hospital of Eastern Ontario, Department of Pediatrics, Ottawa, Canada, [3]University of Toronto, Faculty of Medicine, Toronto, Canada, [4]Simon Fraser University, Vancouver, Canada, [5]McGill University Health Centre, Montreal, Canada
Presenting author email: jbrophy@cheo.on.ca

Background: The profiles of young women living with HIV are becoming more diverse, now including those with HIV since childhood (YWLHC) and those who acquired HIV in late adolescence/early adulthood (YWLH). Clinicians are tasked with identifying the unique needs of YWLHC compared to YWLH, including their sexual and reproductive health (SRH) needs. We aimed to identify if YWLHC differed from YWLH regarding sexual satisfaction and pleasure.
Methods: Baseline data from CHIWOS were used (n=1425). Women between 18 and 29 who responded yes (YWLHC, n=38) or no (YWLH, n=94) to an item inquiring if they had received pediatric HIV care were included in the analysis (total

n=132). Sexual satisfaction was measured amongst all participants using 6 items from the Sexual Satisfaction Analysis scale (scores ranged from 6-30, higher=more satisfaction). Additional items measured the importance of sexual activity, pleasure from sexual activity in the past month, and sexual relationship satisfaction (SRS) in the past month (exclusive to participants who reported sexual activity in past 6 months). Bivariate analyses and linear regression were used to compare the sexual outcomes between groups.
Results: YWLHC were younger (median=22.5 years, IQR 21-25) than YWLH (median=26, IQR 23-28, p< .001). Most YWLHC (92%) and YWLH (95%) had experienced consensual sex. Ratings of sexual satisfaction were similar in both groups, and low (median=18.5 for YWLHC; median=20 for YWLH, p=0.15). No statistically significant differences were found regarding the importance of sexual activity, pleasure from sexual activity, or SRS. 69% of YWLHC and 63% of YWLH felt sexual activity was somewhat/very important, 53% of YWLHC and 50% of YWLH usually/always felt pleasure, and 94% of YWLHC and 85% of YWLH were very/somewhat satisfied in their sexual relationship.
Conclusions: While previous literature has captured the unique clinical needs of YWLHC, our findings suggest YWLHC may mirror YWLH in terms of sexual satisfaction and sexual pleasure. Although overall sexual satisfaction appears to be low, this may be related to lower levels of recent sex given particpants' reports of high SRS in the past month. This is an important clinical consideration as we support the SRH of all women living with HIV.

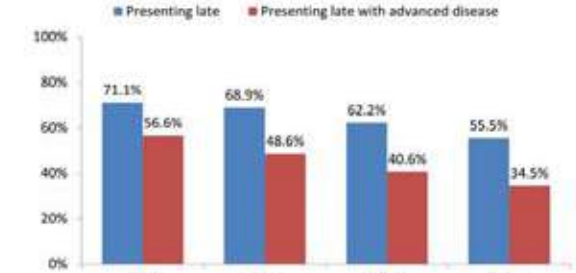
Epidemiology and Modeling of the HIV Epidemic

TUPEC0725

Late presentation of HIV infection in the country of Georgia: 2012-2015

N. Dvali[1], N. Chkhartishvili[1], O. Chokoshvili[1], N. Bolokadze[1], M. Tsinstadze[1], L. Sharvadze[1,2], P. Gabunia[1], A. Abutidze[1], T. Tsertsvadze[1,2]
[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia, [2]Ivane Javakhishvili Tbilisi State University (TSU), Tbilisi, Georgia
Presenting author email: nc@aidscenter.ge

Background: Late presentation for HIV care has important individual and population implications. The objective of this study was to explore the problem of late presentation in the country of Georgia.
Methods: Data on adult persons newly diagnosed with HIV in Georgia between 2012 and 2015, where extracted from the national AIDS Health Information System. Late presentation was defined as a person diagnosed with HIV with a CD4 count <350 cells/mm^3 or an AIDS defining illness regardless of the CD4 count. Late presentation with advanced disease was defined as a person diagnosed with HIV with a CD4 count <200 cells/mm^3 or an AIDS defining illness, regardless of CD4 cell count. Mortality rates were calculated as number of events divided by the number of total person-years of follow-up.
Results: A total of 1987 persons were included in the analysis, among them 509 (25.6%) were women, 1260 (63.4%) were classified as late presenters and 870 (43.8%) as late presenters with advanced disease. Women and men had similar prevalence of late presentation (64.2% and 63.1% respectively, p=0.65). The proportion of late presenters declined from 71.1% in 2012 to 55.5% in 2015 (p<0.0001); presentation late with advanced disease decreased from 56.6% in 2012 to 34.5% in 2015 (p<0.0001). Late presentation was most common among people who inject drugs (77.7%). Overall 186 patients died over the studied period. Mortality was higher both among late presenters (6.74 per 100 person-years vs. 1.08 per 100 person-years, p<0.0001) and late presenters with advanced disease (8.93 per 100 person-years vs. 1.34 per 100 person-years, p<0.0001).



[Late presentation in Georgia: 2012-2015]

Conclusions: High prevalence of late presentation in Georgia reflects insufficiencies in HIV testing services. Better testing strategies are needed to improve earlier diagnosis and disease outcomes.

TUPEC0726

HIV-1 viral control in a large cohort of African adults with incident HIV infection

K. Wall[1], W. Rida[2], E. Ruzagira[3], S. Lakhi[4], E. Karita[5], M. Inambao[6], E. Sanders[7], O. Anzala[8], E. Hunter[9], A. Kamali[3], S. Allen[9], J. Tang[10], P. Fast[11], J. Gilmour[11], M. Price[11], The IAVI African HIV Research Network
[1]Emory University, Epidemiology, Atlanta, United States, [2]Biostatistics Consultant, Arlington, United States, [3]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda, [4]Rwanda Zambia Emory HIV Research Group, Lusaka, Zambia, [5]Rwanda Zambia Emory HIV Research Group, Kigali, Rwanda, [6]Rwanda Zambia Emory HIV Research Group, Ndola, Zambia, [7]Kenyan Medical Research Institute, Kilifi, Kenya, [8]Kenya AIDS Vaccine Initiative, Nairobi, Kenya, [9]Rwanda Zambia Emory HIV Research Group, Atlanta, United States, [10]University of Alabama at Birmingham, Department of Medicine, Birmingham, United States, [11]International AIDS Vaccine Initiative, New York, United States
Presenting author email: kristin.wall@gmail.com

Background: Few HIV-infected persons are able to maintain viral replication at low levels without therapeutic intervention. We report on a large cohort of African adults with incident HIV infection, describing viral control, subsequent loss of control, and evaluating predictors of control.
Methods: Volunteers from well-defined HIV-incidence cohorts in Kenya, Rwanda, South Africa, Uganda, and Zambia joined an HIV+ cohort within one year of their estimated date of infection (EDI). Plasma viral load (VL) was measured and antiretroviral treatment (ART) history was taken monthly for 3 months post EDI, quarterly for 2 years, and every 6 months thereafter. Viral subtyping was based on pol sequencing. Viral control was defined as ≥2 consecutive VL ≤2,000 copies/mL beyond 74 days post-EDI with no subsequent, consecutive visits with VL >2,000 in the absence of ART. Plasma from volunteers was tested for ART if their VL dropped to ≤2,000 copies/mL but they self-reported no ART use. Multivariable logistic regression characterized predictors of viral control.
Results: Of 590 volunteers, 44 (7%) experienced viral control and 68 (12%) controlled but later lost control. Median ART free follow-up time since EDI was 3·7 years (range: 31·0 days to 9·7 years). Factors associated with control were HIV-1 subtype A versus C infection (adjusted odds ratio [aOR]: 3·1 [95%CI: 1·4-7·0]) and having the human leukocyte antigen (HLA) class I variant B*57 (aOR: 3·7 [1·6-8·1]). Women (aOR: 2·6 [1·2-5·9]) and men who have sex with men (aOR: 2·8 [1·1-7·1]) were also more likely to control versus heterosexual men. These associations persisted when excluding controllers who later lost control.
Conclusions: We confirm associations with HLA type and viremic control, and demonstrate novel, strong associations between control and infecting viral subtype and sex/HIV risk group, even after controlling for demographics and host genetics. Our work builds on increasing evidence that HIV-1 infecting subtype has an impact on transmission and disease course, and this may be relevant for the development of vaccines, therapeutics, and other new prevention technologies.

TUPEC0727

Late Presentation Among Patients with Human Immundeficiency Virus Infection in Turkey

H. Kumbasar Karaosmanoglu[1], B. Mete[2], D. Yildiz Sevgi[3], F. Sargin[4], O. Altuntas Aydin[1], A. Gunduz[3], B. Durdu[5], S. Bolukcu[5], I. Dokmetas[3], F. Tabak[2], ACTHIV-IST (Action Against HIV in Istanbul)
[1]Bakırkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey, [2]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [3]Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey, [4]Istanbul Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey, [5]Bezm-i Alem University, Istanbul, Turkey
Presenting author email: drhayat1@hotmail.com

Background: Turkey is among low-prevalance countries in Europe in HIV infection. The characteristics of late presentation among HIV-positives have not been previously studied. We aimed to analyze the status of late presentation among HIV-positive patients in Turkey.
Methods: The HIV-positive patients were enrolled in this study by ACTHIV-IST (Action against HIV in Istanbul) Study Group, which consists of five centers to follow up HIV-positive patients in Istanbul. Demographic data including age, sex, transmission routes, education level, marital status, and history of imprisonment, CD4+ counts, and HIV RNA were collected from medical records. Late presentation was defined as presentation for care with a CD4 count below 350 cells/ml

or presentation with an AIDS-defining event, regardless of the CD4 cell count. Advanced HIV disease was defined as presentation for care with a CD4 count below 200 cells/mm^3 or presentation with an AIDS-defining event, regardless of the CD4 cell count

Results: The cohort included 1,673 patients (1440 male, median age was 35 years). The characteristics of the patients were given in Table 1. Among them, 847 (50.6%) had an early diagnosis, with a CD4 count of more than 350 cells/mm^3. The remaining 826 were late-presenters (Table 2). Among late presenters, 427 (25.5% of all, 51.7% of late presenters) presented with advanced HIV disease.

The characteristics of late and non-late, "early" presenters are given in Table 2. Late presenters were more elderly and less educated. The gender seemed comparable between groups. Late presenters were more likely among married patients. Early presenters were more likely among homosexuals, those diagnosed on screening studies, and in lower HIV-RNA viral load category. There has been a trend in decreasing late presenters in 2011-2016 when compared to 2003-2011 period.

Conclusions: In our cohort, those presented late were more elderly, less educated, married and had heterosexual intercourse.

Efforts to reduce the proportion of late presentation are essential for almost every country. The countries should identify the risk factors of their late presenters and should use targeted public health interventions to improve early diagnosis and presentation for HIV care. Improvements in HIV testing policies, emphasizing vulnerable groups are crucial.

TUPEC0728

Determination of AIDS- and non-AIDS-related causes of death reported in death certificates as compared to physicians' reviews in a tertiary referral hospital in Vancouver, British Columbia

A.C. Ulloa Baez[1], M. Pedromingo[2], C. Stanley[3], S. Stone[3], S. Guillemi[1,3], B. Yip[1], W. Zhang[1], V. Dias Lima[1,4], N. Gataric[1], R. Dutta[1], R. Barrios[1,5], J.S.G. Montaner[1,4]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Nuestra Señora de Sonsoles Hospital, Ávila, Spain, [3]John Ruedy Immunodeficiency Clinic, Vancouver, Canada, [4]University of British Columbia, Faculty of Medicine, Department of Medicine, Division of AIDS, Vancouver, Canada, [5]University of British Columbia, Faculty of Medicine, School of Population and Public Health, Vancouver, Canada
Presenting author email: aulloa@cfenet.ubc.ca

Background: Reliability of death certificates in Vancouver, British Columbia (BC) for assessing causes of death (CoD) for HIV-infected individuals remains uncertain. We examine the reliability of underlying CoD as reported in death certificates for individuals enrolled in a hospital-based immunodeficiency clinic (IDC) in Vancouver, BC.

Methods: All deaths occurring between 01-Jan-2004 and 31-Dec-2015 for HIV-infected individuals aged ≥19 years enrolled in the IDC were included in the study. Patients' medical histories were obtained from the clinic's database and individual medical records. Underlying CoD were obtained from BC's Vital Statistics Agency, which registers all deaths in the province. Two physicians, using patients' medical histories, independently reviewed CoD; these were then adjudicated and recorded utilizing a previously validated algorithm. Agreement rate was assessed for AIDS-, non-AIDS-related and unknown CoD between physicians' reviews and death certificates. Cohen's kappa coefficient was used to measure the magnitude of agreement.

Results: There were 271 deaths included in the analyses. Agreement rate was 77% between physicians' reviews and death certificates (Table 1). Kappa coefficient was 0.56, indicating moderate agreement. Deaths were classified as AIDS-related (27.31% vs. 35.42%), non-AIDS-related (70.11% vs. 55.35%) and unclassifiable/unknown (2.58% vs. 9.23%) by physicians and death certificates respectively. Using more detailed categories, the most common CoD ascertained by physicians were AIDS-related (n=74, 27.31%), non-AIDS-related malignancies (n=44, 16.24%), substance abuse (n=44, 16.24%) and chronic viral hepatitis (n=16, 5.90%). As per death certificates, these were AIDS-related (n=96, 35.42%), non-AIDS-related malignancies (n=44, 16.24%), substance abuse (n=32, 11.81%) and unknown causes (n=25, 9.23%).

Vital Statistics	Physicians´ Reviews	Frequency	Percent
AIDS-related	**AIDS-related**	**65**	**23.99**
AIDS-related	Non-AIDS-related	30	11.07
AIDS-related	Unclassifiable/Unknown	1	0.37
Non-AIDS-related	AIDS-related	5	1.85
Non-AIDS-related	**Non-AIDS-related**	**142**	**52.4**
Non-AIDS-related	Unclassifiable/Unknown	3	1.11
Unclassifiable/Unknown	AIDS-related	4	1.48
Unclassifiable/Unknown	Non-AIDS-related	18	6.64
Unclassifiable/Unknown	**Unclassifiable/Unknown**	**3**	**1.11**

[Table1: Cross-Tabulation: CoD in the IDC 2004-2015]

Conclusions: While providing moderate reliability when compared to physicians' reviews, death certificates overestimated AIDS-related and unknown/ill-defined causes of deaths in this sample of patients from a hospital-based immunodeficiency clinic. As trends in cause-specific mortality continue to shift from AIDS- to non-AIDS-related CoD, it is critical to be able to more reliably capture mortality statistics.

TUPEC0729

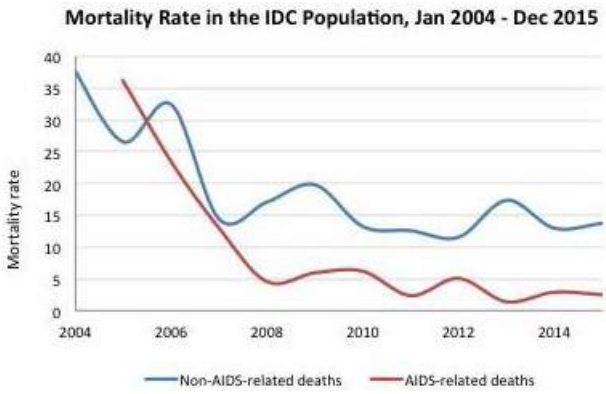
Examining differences in cause-specific mortality among patients enrolled in a hospital-based HIV care clinic in a Canadian setting

A.C. Ulloa Baez[1], M. Pedromingo[2], C. Stanley[3], S. Stone[3], S. Guillemi[1,3], B. Yip[1], W. Zhang[1], V. Dias Lima[1,4], N. Gataric[1], R. Dutta[1], R. Barrios[1,5], J.S.G. Montaner[1]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Nuestra Señora de Sonsoles Hospital, Ávila, Spain, [3]John Ruedy Immunodeficiency Clinic, Vancouver, Canada, [4]University of British Columbia, Faculty of Medicine, Department of Medicine, Division of AIDS, Vancouver, Canada, [5]University of British Columbia, Faculty of Medicine, School of Population and Public Health, Vancouver, Canada
Presenting author email: aulloa@cfenet.ubc.ca

Background: Engagement in care and access to highly active antiretroviral therapy (HAART) have significantly decreased morbidity and mortality among people living with HIV/AIDS. Here we examine differences in cause-specific mortality for individuals enrolled in a comprehensive, hospital-based immunodeficiency clinic (IDC) in Vancouver, British Columbia.

Methods: A retrospective study was conducted on HIV-infected individuals aged ≥19 years enrolled in the IDC between 01-Jan-2004 and 31-Dec-2015. Patients' medical histories and laboratory data were obtained from the clinic's database, individual medical records and death certificates. Causes of death were independently reviewed by two physicians and recorded utilizing a previously validated algorithm. A Poisson regression model was used to examine trends for AIDS- and non-AIDS-related mortality and a Chi-squared test was used to compare differences between the two groups.

Results: Out of 2244 patients enrolled in the IDC, there were 271 deaths (12%), 264 of them with known causes of death, during the study period. AIDS-related mortality rate decreased from 36.18 per 1000 person-years (PY) in 2005, to 2.49 per 1000 PY in 2015 (p< 0.001). Non-AIDS-related mortality rate decreased from 37.38 per 1000 PY in 2004, to 13.72 per 1000 PY in 2015 (p=0.01) (See Figure 1). The most frequent underlying causes of death were AIDS-related events (n=74, 27%), causes related to substance abuse (n=44, 16%), and non-AIDS-related malignancies (n=44, 16%). Significant differences were observed between patients who died of AIDS-related and non-AIDS-related causes of death for age at first visit, baseline CD4, baseline VL, CD4 before death, VL before death, depression status (ever), IDC utilization and medication adherence after first clinic visit (p≤0.017).



[Figure 1: Mortality Rate in the IDC, 2004 - 2015]

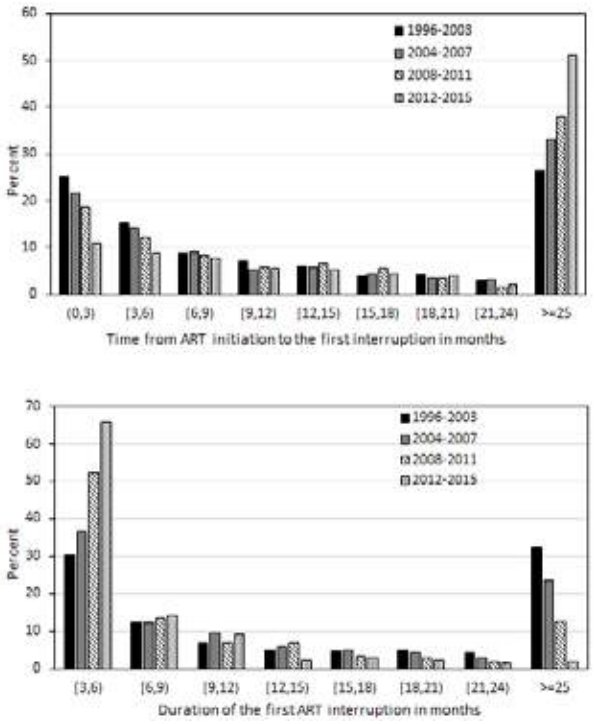
Conclusions: We observed a significant decreasing trend for AIDS- and non-AIDS-related mortality over the study period. Advances in treatment are showing significant benefits for people living with HIV/AIDS; Differences between AIDS- and non-AIDS-related deaths assert the need for better management of non-AIDS-related morbidities.

TUPEC0730

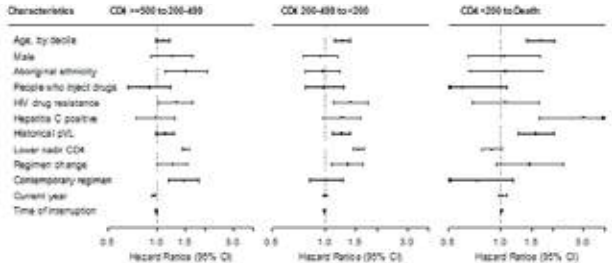
Characterizing HIV antiretroviral therapy interruption and the following disease progression using population-level data in British Columbia, Canada: 1996-2015

L. Wang[1], J.E. Min[1], X. Zang[1], P. Sereda[1], P.R. Harrigan[1,2], J.S.G. Montaner[1,2], B. Nosyk[1,3]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Division of AIDS, Faculty of Medicine, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada

Background: Sub-optimal retention is among the biggest challenges to realize benefits of antiretroviral therapy (ART). We aim to describe ART interruption patterns and identify determinants of disease progression while off-ART in British Columbia (BC).
Methods: With population-level data on ART utilization and laboratory testing in BC, Canada (1996-2015), we described the time, frequency and duration of ART interruptions (a gap of ≥90 days in ART dispensation records). A four-state continuous-time Markov model was implemented to estimate disease progression and identify its associated determinants during individuals' first ART interruption episode. Disease progression was measured according to CD4-based state transitions (≥500 cells/mm^3 to 200-499; 200-499 to < 200; ≥500 to death; 200-499 to death; and <200 to death).



[Figure 1. Distributions of the time and duration of the first ART interruption by year of interruption (N=3129)]



[Figure 2. Adjusted hazard ratios associated with disease state transition intensities during the first ART interruption episode among 2212 individuals]

Results: Over a median eight-year follow-up [(IQR):4.3, 13.5], 3129 (38.1%) interrupted ART. The study population had a median of one interruption [1.0, 3.0], with the first interruption occurring 12.8 months [4.0, 36.1] after ART initiation, lasting for 7.5 months [4.1, 20.3]. The time from ART initiation to first interruption increased over time, while the duration of the first ART interruption decreased (Figure1). Model-estimated average probabilities of all-cause mortality after one-year ART interruption was 2%, 4% and 19% for individuals with a CD4 count of ≥500, 200-499, and < 200 cells/mm^3 respectively at ART dropout. In the multivariable analysis, age, historical plasma viral load, and ART regimen changes prior to interruption were associated with increased hazard of CD4 decline and death during interruption (Figure2).
Conclusions: Despite observed improvement over time, further efforts to develop ART re-engagement interventions are warranted.

TUPEC0732

HIV mediated immunosenescence in young adults infected at birth

S. Fastenackels[1], D. Sauce[1], C. Vigouroux[2], C. Rouzioux[3], L. Nailler[4], E. Azeres[4], J. Warszawski[4], J.P. Viard[3], V. Appay[1,5], ANRS Co19 COVERTE
[1]CIMI Paris, Inserm U1135, UPMC UMRS CR7, Hôpital Pitié Salpêtrière, Paris, France, [2]Inserm UMRS 938, UPMC Hôpital Saint Antoine, Paris, France, [3]Laboratoire de Virologie, EA7327 Hôpital Necker, Paris, France, [4]CESP 1018 Inserm, Service d'Epidémiologie - Santé Publique, Hôpital Bicêtre, Le Kremlin Bicêtre, France, [5]International Research Center for Medical Sciences, Kumamoto University, Kumamoto, Japan
Presenting author email: victor.appay@upmc.fr

Background: Young adults infected with HIV since birth represent a small yet very important group of the HIV infected population. Immunological evolution studies in these young adults compared to patients infected with HIV later during adulthood is needed to understand the consequences of the infection at this early stage of life onwards. In particular, HIV-infected patients usually develop a premature immunosenescence profile, linked to chronic immune activation. In the context of young HIV-infected adults, these anomalies could be balanced by their robust immune resources and capacities for lymphocyte regeneration. We thus assessed the impact of HIV infection on the immune system of young adults infected by HIV at birth.
Methods: We performed a comprehensive immunomonitoring on PBMCs of patients from the ANRS Co19 COVERTE Cohort, including young adults aged between 18 and 25 years, infected by HIV either since birth or during childhood. We assessed the frequency and phenotype of circulating CD34$^+$ hematopoietic progenitor cells, as well as lymphocyte subpopulations (NK, B and T cells), in comparison to patients infected with HIV in adulthood.
Results: Young HIV-infected patients displayed a general lymphopenia with a decrease of CD4$^+$ T cells, B-lymphocytes and NK cells. They also presented altered resources, with decreased numbers of progenitor cells and naïve T cells, reminiscent on the whole of immune alterations found in patients infected in adulthood. This highlights the strong impact of HIV on the immune system despite patient young age. However, alterations were particularly obvious in a high proportion of patients (nearly 1/3) presenting high viral loads together with increased frequency of memory senescent CD8$^+$ T cells and chronic activation markers.
Conclusions: In virally controlled COVERTE patients, there was a trend towards less affected primary immune resources, supporting robust lymphopoiesis of a young immune system in the face of HIV infection. However, a significant number of HIV-infected young adults had increased markers of immune activation and senescence, related to uncontrolled viral replication. This highlights the issue of non-observance to antiretroviral therapy of young patients, resulting in loss of viral control, premature immunosenescence, and potentially irreversible damage of their lymphopoietic system.

TUPEC0733

Cascading the HIV epidemic in Kenya from national to county level for county programme planning and evaluation: a modelling study

K. Mutai[1], J. Stover[2], R. Ombam[1], N. Kilonzo[1]
[1]National AIDS Control Council, Nairobi, Kenya, [2]Avenir Health, Glastonbury, United States
Presenting author email: kkmuttai@gmail.com

Background: To ascertain areas of remaining high HIV transmission (‚epidemic strongholds'), UNAIDS recommends that countries progressively utilize available data and focus on programs tailored to the local needs. Kenya has redefined its HIV epidemic by cascading the HIV estimates from national to county level for county programme planning and evaluation.
Methods: Two approaches to model the Kenyan HIV epidemic for the 2015 HIV estimates were used. First, data collected from sentinel surveillance, routine program, surveys and census from 1970 to 2015 were entered into the Spectrum software for each of the former eight provinces. Smooth prevalence curves were fitted to surveillance and survey data for each province using AIM model in Spectrum. Incidence implied by prevalence curves were combined with information on age structure of incidence and program coverage to estimate indicators of interest. Second, county estimates were produced by disaggregating the provincial totals per indicator, generated from AIM model, to the counties within each former province based on county prevalence. The county prevalence were obtained by examining surveillance and survey cluster data from 2003 to 2015. The estimates of each indicator were adjusted so that the total across all counties in a province would equal the provincial total. Estimates were validated for reliability by comparing mortality estimates with vital statistics and estimated prevalence with survey estimates.
Results: The county models showed heterogeneity in HIV epidemic in the 47 counties (see Table). For instance, whereas Nyanza province had a prevalence of 16.1%, cascading to counties within the province showed a prevalence as low as 4.7% in Kisii County (11.5% lower than the province estimate) to a high prevalence of 26.0% in Homabay County (9.9% higher than the province estimate).

Indicator	Province Estimate	County Estimates (Lowest/Highest)	
Prevalence	Nyanza; 16.1%	Kisii; 4.7% (11.5% lower)	Homa Bay; 26.0% (9.9% higher)
Adult ART coverage	Central; 51.3%	Kiambu; 39.8% (11.4% lower)	Nyeri; 87.8% (36.5% higher)
Children ART coverage	Rift Valley; 68.8%	Turkana; 33.6% (35.2% lower)	Kericho; 99.8% (31.0% higher)
PMTCT coverage	North Eastern; 22.7%	Wajir; 2.8% (19.9% lower)	Garisa; 54.7% (32.0% higher)
MTCT coverage	Eastern; 9.0%	Meru; 5.9% (3.1% lower)	Makueni; 22.4% (13.4% higher)

[Table 1: HIV Estimates 2015]

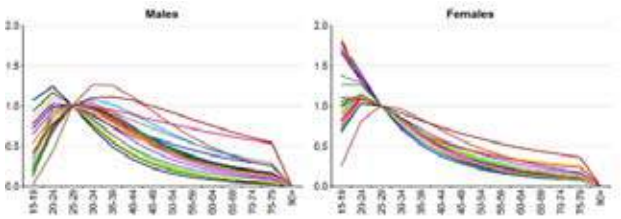
Conclusions: The county-level estimates better reflect differences in HIV epidemic in Kenya and thereby provide valuable information for county programme planning, evaluation and decision making. Nonetheless, validity and reliability of such estimates depends on the amount and quality of data available at the sub-national level.

TUPEC0734

How does the distribution of new HIV infections by age and sex vary by location and time in sub-Saharan Africa?

R. Glaubius, J. Stover
Avenir Health, Modeling and Analysis, Glastonbury, United States
Presenting author email: rglaubius@avenirhealth.org

Background: National AIDS programs in Sub-Saharan Africa (SSA) produce annual estimates of key epidemic indicators, including the need for ART and PMTCT services, using the Spectrum/EPP model. Trends in HIV incidence among all adults aged 15-49 are estimated from antenatal clinic surveillance and survey data. These trends are disaggregated by sex and age according to standard patterns derived from cohort studies. These patterns are assumed to be the same in all countries in SSA and constant over time. The resulting projections generally match age and sex patterns of prevalence as measured by national surveys but often underestimate prevalence among 15-34 year-old women. This may cause Spectrum to underestimate the number of women needing PMTCT services and consequently overestimate PMTCT coverage.
Methods: We estimated age and sex patterns of incidence by country and time period by fitting the Spectrum model projections to prevalence data from national surveys in 26 countries. We modeled age-specific incidence rate ratios (IRRs) as shifted log-normal densities, calibrated using a Bayesian framework informed by incidence patterns from cohort studies. We quantified goodness-of-fit to prevalence data using a binomial likelihood. For countries with more than one survey we compared the performance of static and dynamic IRR patterns using the Akaike Information Criteria (AIC).
Results: Fitted static IRRs matched prevalence data more closely, compared to default patterns in Spectrum, for 25 of 26 countries. Fitted dynamic IRRs improved on static IRRs in 11 of 20 countries with more than one survey, but were preferred by AIC in only three: South Africa, Swaziland, and Zimbabwe. In 22 countries the estimated need for PMTCT was higher with the fitted patterns.
Conclusions: National surveys provide information that can be used to fit HIV incidence patterns by age and sex, leading to improved estimates of prevalence by age and need for PMTCT services.



[Figure 1. Fitted static incidence rate ratios (IRR)]

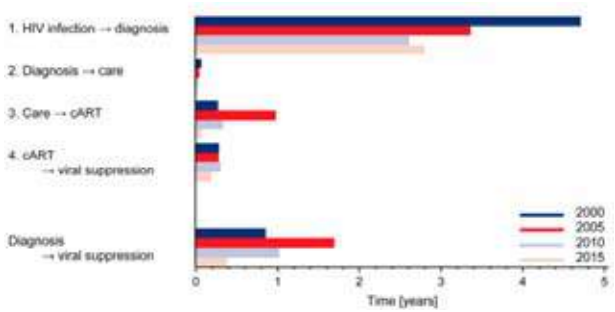
From HIV infection to HIV suppression: improvements in the time to reach successive stages in the HIV care continuum in the Netherlands

A. van Sighem[1], E. Op de Coul[2], T.S. Boender[1], B. van Benthem[2], J. Bouwhuis[3], K. Brinkman[4], P. Reiss[1,5,6], on behalf of the ATHENA National HIV Cohort
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [3]Isala, Zwolle, Netherlands, [4]OLVG, Department of Internal Medicine, Amsterdam, Netherlands, [5]Academic Medical Centre of the University of Amsterdam, Department of Global Health and Division of Infectious Diseases, Amsterdam, Netherlands, [6]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands
Presenting author email: a.i.vansighem@amc.uva.nl

Background: The HIV care continuum summarises engagement in various stages of HIV care but does not provide information on the time to reach these stages. Here we aimed to estimate changes in the time to reach successive stages of the HIV care continuum in the Netherlands since 2000.
Methods: Data from all HIV-1-positive individuals in care aged ≥18 years at the time of diagnosis were selected from the Dutch ATHENA national observational HIV cohort. Time between HIV infection and diagnosis was estimated with the European Centre for Disease Prevention and Control HIV Modelling Tool. Survival methods were used to estimate time between HIV diagnosis, entry into care, start of combination antiretroviral treatment (cART), and viral suppression, i.e. the first HIV RNA measurement <100 copies/ml. Patients who did not start cART or reach viral suppression were censored at their last follow-up visit.

Results: Of the 23,376 HIV-1-positive individuals in ATHENA, 17,053 (73%) were diagnosed in 2000 or later. Between 2000 and 2015, the estimated median time from infection to diagnosis decreased from 4.7 (interquartile range [IQR], 2.3-8.4) to 2.8 (1.3-5.1) years reflecting an increase in CD4 counts at the time of diagnosis from 260 (IQR, 78-460) to 370 (150-560) cells/mm^3. Meanwhile, the median time from diagnosis to viral suppression decreased from 0.85 (IQR, 0.41-3.66) to 0.38 (0.22-0.75) years (see Figure). This decrease was mainly a consequence of shorter time to start of cART, being 0.07 (0.04-0.13) years in 2015, and, to a lesser extent, shorter time to viral suppression after starting cART, 0.18 (0.08-0.32) years in 2015.



[Time to reach successive stages]

Conclusions: Time from acquiring HIV to reaching viral suppression has declined, but continues to be dominated by the duration of undiagnosed HIV infection. To further improve access to care and treatment ensuring earlier diagnosis by expanding testing for HIV will be key.

TUPEC0736

Potential impact of implementing pre-exposure prophylaxis (PrEP) among young women in combination with scaling-up antiretroviral therapy and male circumcision on HIV incidence in Shiselweni region, Swaziland: a modelling study

S. Blaizot[1,2], B. Riche[1,2], R. Teck[3], I. Ciglenecki[3], B. Kerschberger[4], M. Pasipamire[5], N. Lukhele[5], C. Jamet[3], D. Maman[6], R. Ecochard[1,2]
[1]Hospices Civils de Lyon, Service de Biostatistique, Lyon, France, [2]Université Lyon 1, CNRS UMR 5558, Equipe Biostatistique-Santé, Laboratoire de Biométrie et Biologie Evolutive, Villeurbanne, France, [3]Medecins Sans Frontieres, Geneva, Switzerland, [4]Medecins Sans Frontieres, Mbabane, Swaziland, [5]Swaziland National AIDS Program (SNAP), Mbabane, Swaziland, [6]Epicentre, Médecins Sans Frontières, Paris, France

Background: Swaziland is one of the countries most affected by HIV. The HIV prevalence and incidence in Shiselweni region (south of Swaziland) were estimated respectively at 31% and 2.8 per 100 person-years among adults in 2011. Young women continue to be at high risk of HIV infection, with incidence levels estimated at 3.7 per 100 person-years among 18-24 years.
Our aim was to assess the potential impact of pre-exposure prophylaxis (PrEP) use among young HIV-uninfected women, in combination with antiretroviral therapy (ART) and voluntary medical male circumcision (VMMC), on HIV spreading over four years in this region.
Methods: A mathematical model was used to compare the impacts on the HIV incidence rate of extending ART eligibility to all HIV-infected individuals, increasing VMMC, and implementing PrEP use among HIV-uninfected women. This model used sex- and age-specific data on adults (18-49 years) from the 2011 Swaziland HIV Incidence Measurement Survey. Baseline ART coverage among all HIV-infected individuals was 36%. Baseline VMMC coverage among HIV-uninfected men was 12%. Circumcision was assumed to reduce female-male transmission by 60% and PrEP to reduce male-female transmission by 65%.
Results: With no additional interventions (i.e. ART at CD4 <350 and baseline VMMC), incidence would decrease by 24% over 4 years compared to the baseline level. Reaching 65% ART coverage, the decrease in incidence would be 38% over 4 years. The decrease under PrEP among 18-29-year-old HIV-uninfected women at 60% coverage or VMMC at 35% coverage would be close to this level. However, increasing ART coverage in accordance with the 90-90-90 UNAIDS target would be the most effective intervention in reducing overall and sex-specific incidence rates. Combining ART at 65% coverage with the VMMC and PrEP interventions would be even more impactful: the incidence rate would be halved after 4 years compared to the baseline rate.
Conclusions: Extending ART eligibility to all HIV-infected individuals was adopted in Swaziland in 2016; achieving high levels of ART coverage could lead to high decrease in HIV incidence. However, in this hyper-endemic setting, combining these guidelines and PrEP among young women (and VMMC) could be an effective strategy in reducing the incidence to low levels.

TUPEC0737

Mortality trends in HIV-infected hispanic during the cART era

A.M. Mayor, E.J. Santiago Rodriguez, E. Rios-Olivares, R.F. Hunter-Mellado
Universidad Central del Caribe, Internal Medicine, Bayamon, Puerto Rico
Presenting author email: amayorb@hotmail.com

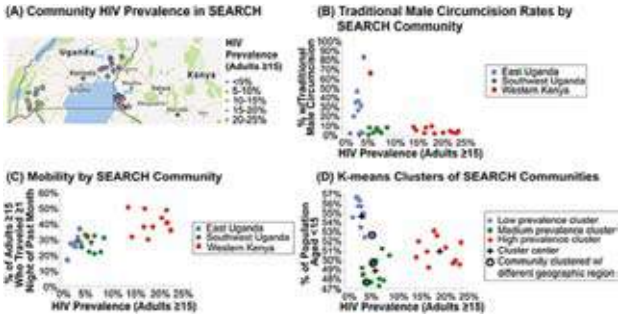
Background: The introduction of multiple spectrum antiretroviral therapy (ART) and the availability of combination ART (cART) have led to a dramatic improvement in the immunological function and to mortality profile changes among HIV infected patients. Our study evaluates and describes changes of the mortality rates and cause of death in a Hispanic HIV cohort during the cART era in Puerto Rico.
Methods: The database of 3,194 HIV infected adults followed in the Retrovirus Research Center at Bayamon, Puerto Rico was matched with the Puerto Rico Mortality Registry to establish the date of death and the cause of death as describe in the death certificates between 2000 and 2015. We have analyzed and compared the time periods of: 2000-2004, 2005-2009, and 2010-2015.
Results: A total of 997 cases died, with a significant mortality rate reduction throughout the study periods (19.3%, 15.0% and 9.7% respectively). Of them 71.6% were men, 52.3% injecting drug users, 19.5% men reported sex with another man, and the overall mean age at death was 47 ± 10 years. The most prevalent causes of death were: HIV (66.0%), pulmonary conditions (36.8%), septicemia (25.3%), cardiovascular conditions (21.2%), liver conditions (11.6%), renal conditions (8.8%), cancer (8.7%), viral hepatitis (7.1%), injury-poisoning (6.6%), hematological conditions (6.3), and psychoactive substance use (5.3%). When analyzed by time periods the distribution was: HIV (72.4%, 61.9%, 61.0%), pulmonary (40.1%, 37.5%, 30.1%), septicemia (24.4%, 27.6%, 23.3%), cardiovascular (17.8%, 19.9%, 28.8%), liver (11.5%, 10.2%, 14.0%), renal conditions (8.6%, 9.7%, 8.1%), cancer (7.1%, 8.5%, 11.9%), viral hepatitis (7.6%, 5.1%, 9.3%), injury-poisoning (6.8%, 4.8%, 8.9%), and psychoactive substance use (2.0%, 4.8%, 11.9%). Increment in injury-poisoning was seen only in men, while the increments of the other causes were observed simultaneously in women and in men. Contrary, HIV and pulmonary mortality decreased specially in men.
Conclusions: Availability of cART in this Hispanic HIV cohort is associated to an incremental higher mortality related to potentially preventable conditions, including cardiovascular, liver, cancer, and accidents. Aggressive prevention strategies targeting environmental agents and risky lifestyle behaviors are required, especially in young HIV infected population. Supported by NIH grants # U54MD007587, G12MD007583, and U01AI069918.

TUPEC0738

Understanding epidemic contexts within the cluster-randomized SEARCH trial: a clustering approach to grouping rural communities in East Africa according to epidemic characteristics

B. Jewell[1], A. Akullian[2], C. Camlin[3], M. Kaur[3], T. Clark[3], E. Charlebois[3], M. Kamya[4], M. Petersen[1], D. Havlir[3], A. Bershteyn[2]
[1]UC Berkeley, Berkeley, United States, [2]Institute for Disease Modeling, Seattle, United States, [3]UCSF, San Francisco, United States, [4]Makere University, Kampala, Uganda
Presenting author email: britta.jewell@ucsf.edu

Background: SEARCH is a community-randomized trial of the "test-and-treat" strategy for HIV prevention (NCT01864603) spanning three geographic regions - Southwest Uganda, East Uganda, and Western Kenya. Using baseline HIV prevalence and household census data (N=146,874 adults ≥15), we investigated the geospatial distribution of factors potentially driving community-level HIV prevalence.
Methods: We explored community-level adult HIV prevalence and factors including demographic structure, mobility (proportion of adults spending ≥1 night away from home in the past month), and traditional male circumcision (TMC). K-means clustering was used to categorize communities (N=32) according to epidemic context and identify which communities differed from others in their region.
Results: High HIV prevalence in Western Kenya occurred in the context of low TMC and high population mobility. The only Kenyan SEARCH community with a majority of men circumcised had one-third the HIV prevalence of other regional communities. In contrast, TMC rates were low in Southwest Uganda despite far lower HIV prevalence, and there was no relationship between TMC and community HIV prevalence in East Uganda despite wide variation in TMC. East and Southwest Uganda had similar mobility, but East Uganda had a younger population and lower prevalence than Southwest Uganda. Demographic structure and HIV prevalence clustered the communities into three distinct groups, mostly corresponding to geographic region. Three communities clustered with different regions, including the lower prevalence community in Western Kenya, which clustered with Southwest Uganda.



[Figure 1]

Conclusions: Consistent with findings from DHS and AIS surveys, HIV prevalence in Western Kenya was substantially lower in a community where a majority of men are traditionally circumcised. This inverse relationship between TMC and prevalence was not observed in Uganda. Western Kenya was also distinct in its high mobility; in contrast, East and Southwest Uganda had similar mobility but different demographic structures. These factors make it possible to cluster SEARCH communities into distinct epidemic patterns.

TUPEC0739

Health-related quality-of-life of people living with HIV in Zambia and South Africa: a comparison with HIV-negative people in the baseline survey of the HPTN 071 (PopART) trial

R. Thomas[1], R. Burger[2], A. Harper[3], S. Kanema[4], L. Mwenge[4], N. Vanqa[3], P.C. Smith[5], R. Hayes[6], S. Fidler[5], H. Ayles[4], N. Beyers[3], P. Bock[3], S. Floyd[6], A. Young[7], D. Donnell[7], K. Hauck[1]
[1]Imperial College London, School of Public Health, London, United Kingdom, [2]Stellenbosch University, Stellenbosch, South Africa, [3]Desmond Tutu TB Centre, Cape Town, South Africa, [4]Zambart, Lusaka, Zambia, [5]Imperial College London, London, United Kingdom, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]SCHARP, Seattle, United States
Presenting author email: k.hauck@imperial.ac.uk

Background: Life expectancy of HIV-positive individuals receiving antiretroviral therapy (ART) is approaching that of HIV-negative persons. However, little is known about the health-related quality-of-life (HRQoL) of HIV-positive individuals at different stages of disease and treatment, and how it compares to HIV-negative individuals in resource-constrained settings.
Methods: Data on 38,691 adults aged 18-44 years were gathered between October 2013 and March 2015 in cross-sectional surveys of random samples of the general population in 21 communities in Zambia and South Africa as part of the HPTN 071 (PopART) study. In Zambia 21% and in South Africa 22% were HIV-positive. HRQoL information was gathered with an instrument similar to the EuroQol Group's EQ-5D-5L that measures health in five domains. Responses were scaled into scores taking values between 0 (representing death) and 1 (representing perfect health). Beta-distributed multivariable models were used to analyse differences in HRQoL scores between HIV-positive and HIV-negative individuals unaware of their status, aware but not in care, in care but not on ART, and on ART for less or more than 5 years, adjusted for treatment status, sociodemographic and lifestyle variables.
Results: 19,637 (99%) of 19,750 participants in Zambia and 18,429 (97%) of 18,941 participants in South Africa had complete EQ-5D-5L information. Multivariable regression models show in both countries individuals on ART for at least 5 years reported similar levels of quality-of-life as those HIV-negative. In Zambia, individuals on ART for less than 5 years had a small reduction in score (-0.006, 95% CI -0.009 to -0.003) compared to HIV-negative individuals. In both countries, a large proportion of the sample (44% in Zambia and 53% in South Africa) were unaware of being HIV-positive, but reported good health, showing no significant difference in HRQoL compared to HIV-negatives.
Conclusions: ART is successful in restoring HRQoL of HIV-positive individuals to that of HIV-negative individuals in this general population sample. Individuals in this study who were unaware of being HIV-positive also report good health-related-quality-of-life. The direct health benefits of early diagnosis and ART in preventing losses in health-related-quality-of-life provide support to international advocacy efforts for scale-up of testing and expansion of treatment to all HIV-positive individuals.

TUPEC0740

Unraveling the geographic and population heterogeneity of the HIV epidemic in Belgium

L. Marty[1], D. Van Beckhoven[2], J. Deblonde[2], C. Ost[2], D. Costagliola[1], A. Sasse[2], V. Supervie[1], HERMETIC Study Group
[1]INSERM, UMR S 1136, Paris, France, [2]Scientific Institute of Public Health, OD Public Health and Surveillance, Brussels, Belgium
Presenting author email: lise.marty@iplesp.upmc.fr

Background: Increasing our knowledge about the geographic areas and key populations the most affected by HIV is essential to improve HIV prevention and care and to ensure a more focused HIV response. However, in most settings, our understanding of the HIV epidemics, and thus HIV programs, have relied on epidemiological estimates produced at the national level.
Methods: We used Belgian surveillance data on newly diagnosed HIV cases from 2006 to 2015 and a previously developed back-calculation model to estimate three key epidemiological indicators: HIV incidence, distribution of times from HIV infection to diagnosis, and the number of undiagnosed HIV infections in 2015. Estimates were obtained at national and subnational levels and by HIV exposure group.
Results: We estimated that, in Belgium, in 2015, around 1000 (95% confidence interval: 800-1200) new HIV infections occurred and 2800 (95% CI: 2200-3500) individuals were living with undiagnosed HIV. Median time from infection to diagnosis was 22 months (inter-quartile range: 2-33) in the 2010-2015 period. More than 50% of the new infections and undiagnosed infections occurred among individuals living in two areas: the Brussels-Capital Region and the province of Antwerp. These areas had also the highest HIV incidence and undiagnosed HIV prevalence rates (Figure 1a and b). Median time from infection to diagnosis were longest in the provinces of Antwerp and Hainaut (Figure 1c). In the province of Antwerp, undiagnosed prevalence rates were highest among heterosexual women from sub-Saharan African countries (SSA), followed by MSM and heterosexual men from SSA, while in the Brussels-Capital Region, it was MSM, followed by heterosexuals from SSA (first women, then men).
Conclusions: Our findings show that, in Belgium, heterogeneity exists in how geographic areas and exposure groups are affected by HIV and thus emphasizes the need for subnational surveillance to tailor prevention programs and develop a comprehensive HIV testing strategy.

Is MPHIA survey a validation method for HIV spectrum estimates in Malawi?

N. Wadonda-Kabondo[1], M. Nzima[2], A. Jahn[3], B. Matatiyo[4], E. Noelle[5], G. Bello[3], D. Payne[1], S. McCracken[6], A. Voetsch[7], A. Auld[8], MPHIA Study Team
[1]Centres for Disease Control, Lilongwe, Malawi, [2]UNAIDS, Lilongwe, Malawi, [3]Ministry of Health, Lilongwe, Malawi, [4]National AIDS Commission, Lilongwe, Malawi, [5]ICAP at Colombia University, New York, Malawi, [6]Centers of Disease Control, Atlanta, United States, [7]Atlanta, City, Malawi, [8]Centers for Disease Control, Lilongwe, Malawi
Presenting author email: vzn7@cdc.gov

Background: Malawi has been monitoring their HIV epidemic by combining antenatal clinic surveys among pregnant women with population demographic and HIV program data in a Spectrum mathematical model to produce population level estimates, with national household surveys incorporated into the model since 2006. This abstract seeks to determine whether indicators from Spectrum modelling are reproducible by another population-based survey, the 2015-2016 Malawi Population-Based HIV Impact Assessment (MPHIA).
Methods: MPHIA, a cross sectional household survey, was conducted for the first time between November 2015 and August 2016 in all districts in Malawi. The survey assessed HIV incidence, prevalence and viral load suppression and targeted both adults and children. Home-based HIV testing using the national rapid test algorithm with Geenius confirmation at satellite labs was conducted. HIV positive samples were centrally tested for viral load suppression and recency of infection using Lag_Avidity EIA. In 2015, antenatal clinic sentinel surveillance, MDHS, and national program data were entered into Spectrum software, which incorporated evidence-based assumptions about HIV program effectiveness and patterns of HIV transmission and disease progression to estimate HIV prevalence, incidence, and mortality in 2015, as well as future projections (unpublished).
Results: Spectrum estimated HIV incidence in 2015 to be 0.38% (95%CI:0.27-0.52%) among adults aged 15-49 years. This same model projected HIV incidence for 2016 at 0.34% (0.40% in females, 0.29% in males). The MPHIA survey estimate for HIV incidence was 0.32% (95%CI:0.16-0.48%). MPHIA found that HIV incidence was higher in females (0.39%, 95%CI:0.15-0.63%) than men (0.24%, 95%CI:0.03-0.46%).
Spectrum projected 2016 HIV prevalence for adults aged 15-49 as 9.2% (11.3% females, 7.2% males). The MPHIA estimate for HIV prevalence was 10.0% (95%CI:9.4-10.7%), with higher prevalence among women (12.4%, 95%CI:11.4-13.4%) than men (7.5%, 95%CI:6.8-8.3%)). In children aged 0-14 years, Spectrum projected 2016 HIV prevalence at 1.03%. MPHIA survey results were 1.6% (95%CI:1.2-2.0).
Conclusions: The HIV incidence and prevalence results from the 2015/2016 population-based survey in Malawi are consistent with the 2015/2016 estimates generated by Spectrum modelling, except for children. This supports the reliability of Spectrum model in estimating adult indicators and its use to inform HIV programming in Malawi.

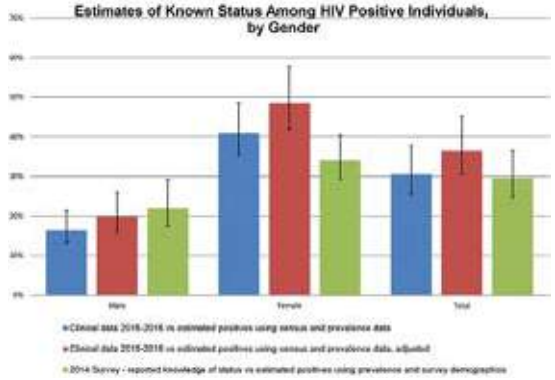
Measuring the first 90: comparing estimation methods for "Known HIV Status"

M.-S. Kang Dufour[1], S.A. Lippman[2,3], C.W. Kabudula[3,4], A. Julien[3,5], F.X. Gómez-Olivé[3], N. Masilela[3], K. Kahn[3,6], A. Pettifor[3,5]
[1]University of California, Division of Prevention Science, San Francisco, United States, [2]University of California, Department of Medicine, San Francisco, United States, [3]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Agincourt, South Africa, [4]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom, [5]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, United States, [6]Umea Centre for Global Health Research, Division of Epidemiology and Global Health, Umea University, Public Health and Clinical Medicine, Umea, Sweden
Presenting author email: mi-suk.kangdufour@ucsf.edu

Background: UN goals propose that 90% of HIV positives know their status, 90% of known positives be on treatment and 90% of those treated achieve viral suppression. The second two goals can be monitored using clinical and laboratory records. However, measuring the first "90" is less straightforward. Given underreporting of status and expanding test options, both the number of positives and known status can be challenging to estimate.
Methods: Data were collected in rural northeast South Africa. Three estimates of the first "90" were generated using multiple data sources: two used an estimate of HIV positive individuals calculated using age and gender stratified 2014 census data and previous seroprevalence survey data compared to individuals with a record of either HIV testing or HIV care in a clinical data capture system covering all clinics in the community. The first estimate was unadjusted, the second used clinic register data to adjust for HIV testing potentially missed by the data capture system. The third estimate compared population based survey self report to estimated HIV positives applying seroprevalence data to survey demographics.
Results: The study area includes 34,009 individuals ages 18 to 49. Estimates of HIV+ with known status are shown in Table 1. In all methods, estimates for women (41%, 49% and 34%) were much higher than those for men (16%, 20% and 22%). Estimates for men were highest in self report, and estimates for women were highest using clinical data capture.



[Known Status Among HIV Positives Individuals]

Conclusions: Although none of the estimation methods are ideal, all methods showed levels of known status far from the UN goal of 90%, particularly for men who are half as likely to know their status compared to women. Comparison of self report and clinical data based estimates differed by gender, suggesting gendered differences in either reporting bias, clinic utilization or both.

TUPEC0743

Evidence from the Zimbabwe population HIV impact assessment on 90-90-90: a national and provincial call to action for the first 90

B. Tippett Barr[1], H. Dube[2], M. Mhangara[3], L. Ruangtragool[4], S. Munyati[5], A. Hakim[6], A. Nwankwo-Igomu[7], J. Justman[8], E. Radin[8], O. Mugurungi[3], A. Mpofu[9], B. Parekh[10], D. Voetsch[11]
[1]Centers for Disease Control and Prevention, CGH/DGHT, Harare, Zimbabwe, [2]Columbia University, ICAP, Harare, Zimbabwe, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]ASPPH/CDC Allan Rosenfield Global Health Fellow, U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe, [5]Biomedical Research and Training Institute, Harare, Zimbabwe, [6]Centers for Disease Control and Prevention, Atlanta, United States, [7]Centers for Disease Control and Prevention, Harare, Zimbabwe, [8]Columbia Universitty, ICAP, New York, United States, [9]National AIDS Commission, Harare, Zimbabwe, [10]Centers for Disease Control and Prevention, CGH/ILB, Atlanta, United States, [11]Centers for Disease Control and Prevention, CGH/DGHT, Atlanta, United States
Presenting author email: hkc5@cdc.gov

Background: The UNAIDS 90-90-90 objectives have gained a lot of momentum globally and are considered the key measures against which countries gauge their progress towards HIV epidemic control. The Zimbabwe population HIV impact assessment (ZIMPHIA), implemented in 2015/16, included population estimates for each of the 90-90-90 objectives. Here we explore progress towards 90-90-90 at national and provincial levels, and relevance to programmatic decision-making.
Methods: Consenting participants provided demographic, behavioral and clinical information and blood samples for household HIV testing using the national serial rapid test algorithm. HIV+ results were confirmed in a central laboratory and viral load was performed on all HIV+ samples. Viral load suppression (VLS) was defined as HIV RNA < 1000 c/ml.
Results: 22,496 adults (>15 years) consented to participate and 3,503 (15.6%) were confirmed HIV-positive. Of all HIV-infected adults, 73.9% (95% CI 72.0-75.8) knew their HIV status; of those who knew their status, 86.5% (95% CI 85.0-88.0) reported being on ART, and 86.2% (95% CI 84.5-87.9) of those reporting to be on ART were virally suppressed (Figure 1). At provincial level, known-positive HIV status ranged from 70.4% to 78.9% (95% CI 64.5-76.3 and 74.5-83.4 respectively); HIV-positives self-reported on ART ranged from 82.2-92.3% (95% CI 76.4-87.9 and 88.3-96.3 respectively), and VLS ranged from 82.6-91.6% (95%CI 77.1-88.1% and 87.3-96.0% respectively).
Conclusions: Zimbabwe has made remarkable progress towards 90-90-90. Notably however, the first of the three 90's is under 80% in every province. The Zimbabwe Ministry of Health reported 19-59% of patients receiving care had an HIV test at the point of service. In order to ensure the three 90's are achieved in this widely

generalized epidemic, it is critical that Zimbabwe ensure that routine opt-out HIV testing is aggressively rolled out beyond antenatal care and tuberculosis clinics to include all patients at all points of service.

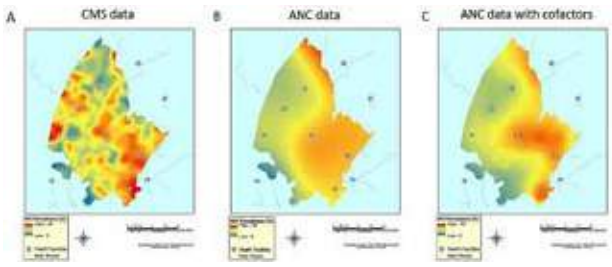
Could clinic-based antenatal HIV prevalence data be used for geographical targeting of resource allocation? Insights from an HIV hyper-endemic rural community in South Africa

D. Cuadros[1], B. Sartorius[2], A. Akullian[3], F. Tanser[2,4]
[1]University of Cincinnati, Geography and Geographic Information Science, Cincinnati, United States, [2]University of KwaZulu-Natal, School of Nursing and Public Health, Durban, South Africa, [3]Institute for Disease Modeling, Seattle, United States, [4]Africa Health Research Institute, Mtubatuba, South Africa
Presenting author email: diego.cuadros@uc.edu

Background: Large geographical variation of the HIV epidemic in sub-Saharan Africa calls for geographically targeted resource allocation where burden is greatest. However, data available for mapping the geographic variability of HIV prevalence is scarce, and community surveillance (CMS) data are not always available. Here, we evaluated the accuracy of using clinic-based antenatal HIV prevalence data (ANC), which are routinely collected and commonly available, for capturing the desired resolution of the spatial variation of HIV.
Methods: CMS individual-level HIV data from more than 7,000 households, as well as routinely ANC data from ten health facilities located in a rural community in KwaZulu-Natal, South Africa were mapped using Kernel interpolation techniques. To assess the use of cofactors to improve spatial HIV prevalence accuracy using ANC data, cofactors such as population density and distance to main roads were included using cokriging methods. Maps were compared using Local Indicators of Spatial Autocorrelation (LISA), and Pearson Correlation Coefficient (PCC).
Results: ANC data (Figure 1A) captured large scale geographic heterogeneity described by CMS data (Figure 1B), but failed to detect some pockets of high prevalence. LISA analysis indicated that ANC data could accurately predict the spatial distribution of HIV prevalence in ~50% of the study area. ANC data with cofactors (Figure 1C) improved the resolution and accuracy of the prevalence map (PCC= 0.50; 95% CI 0.44 - 0.55), compared to the map without the inclusion of cofactors (PCC= 0.27; 95% CI 0.20 - 0.34).
Conclusions: ANC data are able to capture the spatial structure of HIV prevalence in an acceptable manner, particularly in areas where the burden of the infection is concentrated. The inclusion of cofactors may improve model estimates of HIV prevalence based on ANC data. HIV data collected from health facilities may provide valid spatial prevalence estimates for geographical targeting where resources are needed the most.



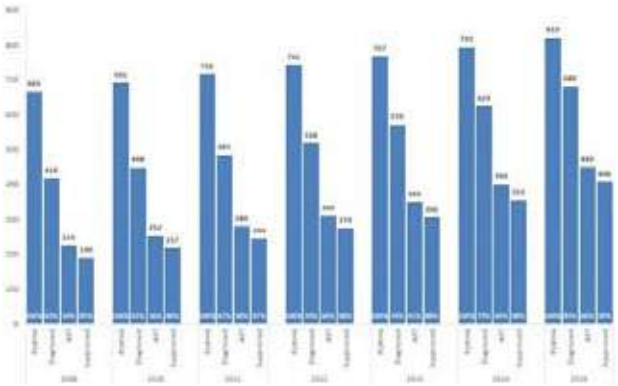
[Figure 1. Spatial distribution of HIV prevalence]

TUPEC0745

The HIV care continuum in Brazil, from 2009 to 2015

A.R. Pati Pascom[1], C. Habckost Dutra de Barros[1], V. Dias Lima[2], M. de Araújo Freitas[3], J. S. G. Montaner[4], M. Meireles[1], F. Mesquita[5], A. Schwartz Benzaken[1]
[1]Ministry of Health, Department of STI, HIV/AIDS and Viral Hepatitis, Brasília, Brazil, [2]University of British Columbia, Vancouver, Canada, [3]University of Columbia, Maputo, Mozambique, [4]British Columbia Centre for Excellence in HIV/AIDS, St. Paul's Hospital, Vancouver, Canada, [5]WHO, Jacarta, Indonesia
Presenting author email: ana.roberta@aids.gov.br

Background: The care continuum became a key tool for quantitative monitoring and evaluation of the HIV care and treatment. We aimed to characterize the cascade of HIV care in Brazil from 2009 to 2015.
Methods: We used surveillance data and programmatic individual-level information on HIV viral load(VL), CD4 and antiretroviral therapy (ART) for people living with HIV (PLWH) aged 18+, between 2009 and 2015. Four stages of the cascade were defined: PLWH; diagnosed; on ART; and virologically suppressed. Individuals who had at least one CD4, VL or ART dispensation between 2009 and 2015 were included in the analysis. We modelled trends of the cascade of care indicators by fitting generalized additive models.
Results: In 2009, HIV prevalence was 665K (0·50% of the adult population), and 418K individuals were diagnosed, (63% of the infected). 224K individuals were receiving ART (34% of the HIV infected). 190K individuals had VL < 1000 copies/mL, (29% of the infected and 85% of those on ART).
In 2015, the HIV prevalence was 0·58%(819K). 680K individuals were diagnosed (83% of the infected). 449K individuals were on ART (55% of the HIV infected). 406K individuals had VL< 1000 copies/mL (50% of the infected and 91% of those on ART).
Between 2009 and 2015, the estimated absolute HIV prevalence increased 23%, the diagnosis increased by 63%, the number of PLWH on ART was two times higher, and the number of virally suppressed increased by 114% (all p-values< 0·0001).
Conclusions: The results demonstrated significant changes in the Brazilian care continuum between 2009 and 2015. These results may be related to the important decrease in late diagnosis and the maintenance of the high percentage of viral suppression among PLWH on ART. However, innovative strategies are still required to diminish the largest leakage in the cascade of care, between diagnosis and ART.



[Care continuum. Brazil, 2009-2015]

TUPEC0746

Partner age and risk of HIV acquisition in rural Kwazulu Natal, South Africa

A. Akullian[1], A. Bershteyn[1], D. Klein[1], A. Vandormael[2], T. Bärnighausen[3], F. Tanser[2]
[1]Institute for Disease Modeling, HIV/TB, Seattle, United States, [2]Africa Centre for Population Health, Durban, South Africa, [3]Harvard University, Global Health and Population, Cambridge, United States
Presenting author email: aakullian@idmod.org

Background: Recent empirical evidence from South Africa has challenged the notion that older male sexual partners increase the risk of HIV transmission to young women. Whether specific partner-age pairings are associated with increased risk of HIV acquisition in men and women is unknown. We test for non-linear effects of self-reported partner age on HIV incidence and report on high risk partner age pairings in both men and women.
Methods: We conducted a population-based cohort study among women 15-49 and men 15-55 years of age using data collected between 2004-2015 from the Africa Health Research Institute (AHRI) surveillance system in Kwazulu-Natal,

South Africa. Smoothed HIV incidence rates were estimated by age pairings with most recent sexual partner using generalized additive models (GAM). Cox proportional hazards regression was used to estimate the relative risk of HIV by age pairings.
Results: A total of 882 new HIV infections were observed in 15,935 person-years for women, IR = 5.7 (95% CI, 5.3 - 6.1) and 270 new HIV infections were observed in 9,372 person-years for men, IR = 2.9 per 100 person-years (95% CI, 2.6 - 3.2). Age-adjusted risk of HIV was elevated in women who reported male partners aged 25-29 (aHR = 1.44, 95% CI, 1.02 - 2.04) and 30-34 (aHR = 1.50, 95% CI, 1.08 - 2.09) relative to those reporting male partners aged 35+. HIV risk was elevated among men who reported female partners aged 25-29 (aHR 1.72, 95% CI, 1.02-2.90) and 30-34 (aHR 2.12, 95% CI, 1.03-4.39) compared to men who reported partnerships with women aged 15-19.
Conclusions: Partner age pairings play an important role in driving the cycle of HIV transmission. Interventions targeted at vulnerabilities in the age-specific HIV transmission cycle have the potential to greatly reduce HIV incidence in high burden areas.

TUPEC0747

Is condom use different across three sexual identities of men who have sex with men from Myanmar?

K. Soe Lin[1,2], F. Fowkes[2,3], J. Anne Simpson[2], K.K. Than[1], Z.M. Oo[1], B. Draper[3], V. Veronese[3], M. Stoové[3,4]
[1]Burnet Institute, HIV, Yangon, Myanmar, [2]Melbourne University, Population Health, Melbourne, Australia, [3]Burnet Institute, HIV, Melbourne, Australia, [4]Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia
Presenting author email: khinesoelin07@gmail.com

Background: The most recent prevalence estimates clearly demonstrate HIV prevalence in the men who have sex with men (MSM) population is higher than in the general population in Myanmar; 11.6% in MSM compared to 0.59% in general population in 2015. Due to the challenges of early diagnosis and treatment of HIV, consistent condom use is still crucial for HIV prevention.
As has been demonstrated elsewhere in South East Asia, variations in self-identified sexuality among MSM in Myanmar can pose challenges for the uptake of condom use. In Myanmar, there are three MSM sexual identities:
1) Apone (hidden MSM)
2) Apwint (open MSM) and
3) Thange (heterosexual identified MSM).
Since sexual behaviours are diverse among them, it is valuable to understand their variation of consistent condom use.
Methods: The current study is a cross sectional study conducted in two cities: Yangon and Mandalay of Myanmar, surveying 520 MSM. The participants were recruited by time-location-based recruitment of a convenience sample alongside snowballing. In the current data analysis, the association of MSM sexual identity and inconsistent condom use with regular male partners versus casual male partners were explored by multivariable logistic regression method controlling for potential confounders.
Results: The research found that the reported inconsistent condom use was not significantly different across three sexual identities regardless of partner type. The adjusted odds ratio of inconsistent condom use with regular or casual male partners was 1.30 (0.71- 2.40) in Apwint and 1.10 (0.52- 2.18) in Thange compared to Apone. Those who were confident to negotiate with regular male partners for condom use were less likely to use condom inconsistently (adjusted odds ratio: 0.20, 95% CI: 0.06- 0.72).
Conclusions: Condom promotion should extend to the Apone and Thange in addition to the Apwint who usually focused on. The condom promotion should be tailored message relevant to each sexual identity of MSM, especially for MSM who live in heterosexual life. Condom promotion message should highlight the importance of consistence condom use with not only casual male partners but also with regular male partners. Condom negotiation skills training should be included as a part of condom promotion for MSM.

TUPEC0748

Factors associated with condom use at first sexual intercourse among high school students and apprentices in Benin

C.E. Zinsou[1], G. Guèdégbé[2], Y. Djamba[3]
[1]Association Béninoise de Marketing Social (ABMS/PSI), Research Monitoring Evaluation, Cotonou, Benin, [2]Association Béninoise de Marketing Social (ABMS/PSI), Cotonou, Benin, [3]PSI/WCA, Yaoundé, Cameroon
Presenting author email: cyprienzinsou@yahoo.fr

Background: In January 2013, the Benin Social Marketing Association (ABMS) launched a youth project to increase condom use among sexually active high school students and apprentices. In December 2014, a study was conducted to identify factors associated with condom use at first sex in project areas.
Methods: A representative sample of 2516 students and 1923 apprentices aged 15-24 was drawn and interviewed in project areas located north and south of Benin. Univariate analysis and logistic regression were used to describe and to identify factors associated with condom use at first sexual intercourse among these young people.
Results: The proportion of unmarried youth aged 15-24 who are sexually active is 53.2% (CI : 51.7-54.7).
• The age at first intercourse is 15.7 years among students and 16.1 years for apprentices. It is 16.2 years for girls and 15.6 years for boys.
• At first sexual intercourse, only 39.8% of respondents (33.1% of boys and 43.7% girls) used condoms with their sexual partners.
• Key factors associated with condom use at first intercourse are: knowledge of condom effectiveness against STIs/HIV/AIDS (OR = 1.45), knowledge of correct condom use (OR = 1.50), being a girl (OR = 1.79), and having an older sexual partner (OR = 1.37).
Conclusions: The study shows that in the survey areas, entry into sexual life is earlier for boys than girls and that girls seem more demanding of condom use at first intercourse. In addition, knowing the benefits of condoms against HIV contributes to its use at first sex.

TUPEC0749

HIV acquisition risks among sex working men who have sex with men in Jamaica

C.H. Logie[1], K. Kenny[2], P.A. Newman[1], K. Levermore[3], N. Jones[3], A. Neil[3], T. Ellis[3], A. Marshall[4]
[1]University of Toronto, Toronto, Canada, [2]University of North Carolina at Chapel Hill, Chapel Hill, United States, [3]Jamaica AIDS Support for Life, Kingston, Jamaica, [4]University of the West Indies, Kingston, Jamaica
Presenting author email: carmen.logie@utoronto.ca

Background: There are global reports of widespread rights violations and violence toward sex workers. Sex working men who have sex with men (MSM) are a uniquely marginalized population, experiencing exacerbated violence and social exclusion through the intersection of multiple marginalities. In Jamaica, there is a paucity of research investigating sex work among MSM, including its association with HIV risks. The study objective was to understand social ecological and HIV risk factors associated with sex work among MSM in Jamaica.
Methods: We implemented a cross-sectional survey using respondent-driven sampling with 556 MSM in Kingston, Ocho Rios, and Montego Bay, Jamaica. Sex work included sex exchanged for money, shelter, food, transportation, or drugs/alcohol in the past 12 months. We estimated associations of correlates selected based on their a priori hypothesized relationship with sex work. Bivariable regression assessed the strength of associations between potential factors with sex work. Logit-link models were used to estimate a final multivariable model.
Results: Among 556 MSM, 67 (13.5%) were HIV-positive and 182 (32.7%) reported sex work involvement in the past 12 months. In the final multivariable model, sex work was associated with social ecological and HIV risk factors, including: higher odds of forced sex (odds ratio [OR] 2.60, 95% confidence interval [CI]: 1.55-4.38); unstable housing (OR 1.94, 95% CI: 1.14-3.29); food insecurity (OR 2.18, 95% CI: 1.30-3.68); social support (OR 1.07, 95% CI: 1.02-1.11); perceived sexual stigma (OR 1.12, 95% CI: 1.04-1.21); no regular health care provider (OR 2.59, 95% CI: 1.50-4.47) and higher number of lifetime sexual partners (OR 1.04, 95% CI: 1.01-1.07). Sex work was associated with lower odds of safer sex self-efficacy (OR 0.82, 95% CI: 0.74-0.91), lower income (OR 0.87, 95% CI: 0.77-0.98) and residing in Ocho Rios or Montego Bay (versus Kingston) (OR 0.19, 95% CI: 0.06-0.63).
Conclusions: Findings highlight associations between sex work and structural (food and housing insecurity, lower income, reduced health care access), social (sexual stigma, forced sex) and sexual risk (lower safer sex self-efficacy, higher sex partners) factors among MSM in Jamaica. HIV prevention strategies should address social and economic marginalization to reduce HIV vulnerabilities among sex working MSM in Jamaica.

TUPEC0750

Financial hardship, condomless anal intercourse and HIV risk among men who have sex with men in Paris, France

D. Duncan[1], S.H. Park[1], J. Schneider[2], Y. Al-Ajlouni[1], B. Elbel[1], J. Morganstein[1], Y. Ransome[3], K. Mayer[4]
[1]New York University School of Medicine, New York, United States, [2]University of Chicago School of Medicine, Chicago, United States, [3]Harvard T H Chan School of Public Health, Boston, United States, [4]Fenway Health/ Harvard Medical School, Boston, United States
Presenting author email: dustin.duncan@nyumc.org

Background: Few studies have examined financial hardship among sexual and gender minorities, who may experience financial hardship (when one has insufficient financial resources to adequately meet household's needs) due to social discrimination. The objective of this exploratory study was to examine the association between financial hardship, condomless anal intercourse, engagement in transactional sex and sexually transmitted infectious (STIs), including HIV, among a sample of gay, bisexual and other men who have sex with men (MSM) in Paris France because MSM continue to be the group most at risk of HIV infection in Western Europe.
Methods: Users of a popular geosocial networking application in Paris France (n=580) were shown an advertisement with text encouraging them to complete an anonymous web-based survey, including financial hardship, condomless anal intercourse, engagement in transactional sex, HIV status as well as other STIs and socio-demographics. The log-binomial model was used to assess association between financial hardship, condomless anal intercourse, engagement in transactional sex, and HIV infection as well as infection with other STIs, with adjustment for socio-demographics. The adjusted risk ratio (aRR) with 95% confidence intervals (CIs) were calculated.
Results: Approximately half (45.5%) of the sample reported high financial hardship. In multivariate models controlling for socio-demographic variables, high financial hardship (compared to low financial hardship) was associated with any comdomless anal intercourse (aRR: 1.28; 95% CI: 1.08, 1.52), condomless receptive anal intercourse (aRR: 1.34; 95% CI: 1.07, 1.67), condomless insertive anal intercourse (aRR: 1.30; 95% CI: 1.01, 1.67), engagement in transactional sex (aRR: 2.36; 95% CI: 1.47, 3.79) and infection with STIs other than HIV (aRR: 1.50; 95% CI: 1.07, 2.10).
Conclusions: Financial hardship was associated with condomless anal intercourse, engagement in transactional sex, and STIs among MSM in Paris. Our study therefore confirms the results in the literature, and is the first to examine a sample of European MSM, as previous research regarding financial hardship has largely focused on US-based populations and MSM other from geographic locations. This study suggests that interventions to reduce financial hardships (e.g., income-based strategies for ensuring that people have basic necessities) could promote sexual health in this high-risk population.

TUPEC0751

Injection of prescription opioids: a significant threat to HIV and hepatitis C virus (HCV) prevention among people who inject drugs (PWID)

E. Roy[1,2], P. Leclerc[3], C. Morissette[3], C. Blanchette[4], K. Blouin[5], N. Arruda[1], M. Alary[4]
[1]University of Sherbrooke, Addiction Research and Study Program, Faculty of Medicine and Health Sciences, Longueuil, Canada, [2]Institut national de santé publique du Québec, Montréal, Canada, [3]Direction de la Santé Publique du CIUSSS du Centre-Est-de-l'Île-de-Montréal, Montréal, Canada, [4]Centre de Recherche du CHU de Québec, Université Laval, Québec, Canada, [5]Institut National de Santé Publique du Québec, Montréal, Canada
Presenting author email: elise.roy@usherbrooke.ca

Background: Non-medical use of prescription opioids (PO) has reached epidemic levels in North America. This phenomenon has been observed among PWID in the province of Québec, Canada. Our ethnographic work has shown that PWID who inject PO tend to inject frequently which might impact the capacity of harm reduction programs to insure full coverage of PWID needs in terms of clean injection material.
This study aimed to quantitatively examine the association between PO injection and high injection frequency in a sample of PWID.
Methods: PWIDs are participants of an ongoing surveillance system of HIV and HCV infections. PWID (past 6 months) are recruited in 2 urban and 6 semi-urban/rural sites, mainly in harm reduction programs. Each visit includes a structured interview addressing drug use behaviors. Analyses were carried out using GEE methods. Frequent injection (FI) was defined as ≥120 injections, previous month. Five categories of injected drugs (previous month) were created: 1) PO only, 2) PO + crack/cocaine, heroin or other drugs, 3) heroin ± crack/cocaine or other drugs, 4) crack/cocaine ± other drugs and 5) other drugs only.
Results: Overall 1,651 participants (77.5% male; median age 37.0 years) made 2,829 visits between 2011-2015. FI was reported in 30.1% of visits. Category 1 of injected drugs was observed in 14.9% of visits, category 2 in 41.6%, category 3 in 7.3%, category 4 in 35.6%, and category 5 in 0.6%. Compared to category 4, proportion of FI was higher in category 2 [adjusted PR 3.73; 95%CI: 2.94-4.73], 1 [aPR 2.84; 95%CI: 2.14-3.77] and 3 [aPR 1.73; 95%CI: 1.20-2.50] controlling for age, gender, homelessness, income and crack smoking.
Conclusions: Frequency of injection was the highest among PWID who injected PO. Injection of PO has become a significant threat to HIV and HCV prevention among PWID. This poses a major challenge for public health authorities in the endeavor to fully cover needs in safe injection equipment.

TUPEC0752

Which sexual behavioural profiles are more associated with seronegative MSM becoming HIV-infected in West Africa? (CohMSM ANRS 12324 - Expertise France)

P.-J. Coulaud[1], B. Mmadi Mrenda[1], L. Sagaon-Teyssier[1], G. Maradan[1], B. Dembélé Keita[2], C. Anoma[3], E. Ter Tiero Dah[4], E. Mensah[5], C. Couderc[6], A. Bernier[7], C. Laurent[6], B. Spire[1], The CohMSM Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]ARCAD-SIDA, Bamako, Mali, [3]Espace Confiance, Abidjan, Cote D'Ivoire, [4]Association African Solidarité, Ouagadougou, Burkina Faso, [5]Espoir Vie Togo, Lomé, Togo, [6]TransVIHMI, IRD UMI 233, INSERM U 1175, Université de Montpellier, Montpellier, France, [7]Coalition Internationale Sida, Pantin, France
Presenting author email: pierre-julien.coulaud@inserm.fr

Background: High HIV incidence in men who have sex with men (MSM) has been reported in sub-Saharan Africa. However, the heterogeneity of this group may hide specific high-risk sexual behaviours. We aimed to evaluate how sexual behavioural profiles are predictive of HIV infection among MSM in a prospective cohort.
Methods: HIV-negative participants have been recruited from a community-based cohort in four West-African countries since 2015 (Mali, Cote d'Ivoire, Burkina Faso, Togo). MSM are followed quarterly for HIV-testing and counselling. Socio-behavioural data are collected every 6 months using standardised face-to-face questionnaires. For the present intermediate analysis, HIV-seroconversions were observed over a 12-month period after enrolment. A cluster analysis helped determine specific sexual behavioural profiles at enrolment using data on sexual practices over the previous 6 months: condomless oral sex (COS); condomless anal sex (CAS); position during anal intercourse (exclusively insertive vs. receptive or both); multiple partnerships. Factors associated with sexual behavioural profiles were estimated using logistic regression.
Results: 418 MSM were recruited (median age: 24 years [Interquartile Range = 22-28]), 49% of them were employed. Three sexual behavioural profiles were identified: very high-risk (P1) (52%), high-risk (P2) (18%) and moderate-risk (P3) (30%). P1 MSM reported a high proportion of CAS (60%), multiple partners (65%), and all were receptive. Similar results were found among P2 MSM although all were exclusively insertive. All P3 MSM reported systematic condom use for oral sex, 32% were receptive, 45% practiced CAS, and 53% had multiple partners. P1 MSM showed the highest level of HIV-incidence in the first 12 months (11.5 cases/100 person-years vs. 4 in P2 and 1.6 in P3). They were more likely to define themselves as homosexual/gay (P1/P2: adjusted Odds Ratio (aOR):0.35, 95% Confidence Interval (CI)=0.17-0.70; P1/P3: aOR:0.43, 95%CI=0.24-0.76), to report multiple gender identities (P1/P2: aOR:0.10, 95%CI=0.05-0.22; P1/P3: aOR:0.17, 95%CI=0.09-0.31), and to search for partners on the internet (P1/P3: aOR: 0.55, 95%CI=0.31-0.96). P2 and P3 MSM were more likely than P1 to be bisexuals and identify themselves exclusively as men.
Conclusions: Sexual behavioural profiles may influence HIV-incidence. These findings can help prevention programs to better tailor risk-reduction interventions to reduce the dynamic of HIV-infection in MSM in West-Africa.

Presenting author email: sabriya.linton@emory.edu

Background: Racial/ethnic assortative sexual partnerships may partly explain racial/ethnic disparities in HIV infection among people who inject drugs (PWID). The potential impacts of racial and ethnic housing discrimination and residential segregation on racial/ethnic assortative sexual partnerships remains underexplored.
Methods: Multilevel modeling was used to assess cross-sectional associations of county-level racial and ethnic housing discrimination and ZIP code-level racial and ethnic residential segregation with self-reported racial/ethnic assortative sexual partnerships among 7,934 PWID recruited from 19 U.S. cities for CDC's 2012 National HIV Behavioral Surveillance. Racial/ethnic assortative sexual partner was last sexual partner in past year who was the same race/ethnicity. Housing discrimination and residential segregation variables were created using administrative data (e.g., U.S. Census). Racial housing discrimination and ethnic housing discrimination were separate exposures denoting the odds that black (or Hispanic/Latino) applicants were denied mortgage loans as compared to white applicants with similar characteristics in a given county. Racial residential segregation and ethnic residential segregation were separate exposures comparing concentrations of white residents to black (or Hispanic/Latino) residents in a given zip code.
Results: There were racial/ethnic differences in associations of racial and ethnic housing discrimination and racial and ethnic residential segregation with racial/ethnic assortative sexual partnerships. For example, racial housing discrimination was associated with more racial/ethnic assortativity among white and black PWID, but less assortativity among Latinos. Tables present standardized adjusted odds ratios.

Housing discrimination by race and ethnicity	Adjusted odds ratio (95% confidence interval)	p-value
Racial housing discrimination (White)	1.31 (1.07, 1.61)	0.009
Racial housing discrimination (Black)	1.25 (1.00, 1.58)	0.052
Racial housing discrimination (Latino)	0.82 (0.67, 1.00)	0.047
Ethnic housing discrimination (White)	0.93 (0.81, 1.08)	0.352
Ethnic housing discrimination (Black)	0.79 (0.67, 0.94)	0.008
Ethnic housing discrimination (Latino)	1.19 (1.02, 1.38)	0.024

[Housing discrimination and assortative partners]

Residential segregation by race and ethnicity	Adjusted odds ratio (95% confidence interval)	p-value
Racial residential segregation (White)	0.61 (0.51, 0.73)	<0.001
Racial residential segregation (Black)	1.91 (1.63, 2.24)	<0.001
Racial residential segregation (Latino)	1.10 (0.90, 1.32)	0.367
Ethnic residential segregation (White)	0.81 (0.69, 0.96)	0.016
Ethnic residential segregation (Black)	0.81 (0.68, 0.98)	0.032
Ethnic residential segregation (Latino)	1.77 (1.50, 2.09)	<0.001

[Residential segregation and assortative partners]

Conclusions: Institutional racism may differentially impact HIV transmission among racial/ethnic groups of PWID by differentially impacting sexual network assortativity. Extending this research to other key populations and identifying mechanisms behind these associations can inform housing-based HIV prevention strategies.

TUPEC0754

Characteristics associated with risky sexual behaviors reported by internet recruited MSM in the United States, eSTAMP 2015

R.J. MacGowan[1], P.R. Chavez[1], C.B. Borkowf[1], W.D. Johnson[1], A.D. McNaghten[1], P.S. Sullivan[2]
[1]Centers for Disease Control and Prevention, NCHHSPT/DHAP, Atlanta, United States, [2]Emory University, Atlanta, United States

Background: Men who have sex with men (MSM) account for >60% of new HIV infections each year in the US. The internet has become a mechanism for meeting sex partners. We report baseline characteristics associated with "risky sex" from the 12-month internet-based Evaluation of HIV Self-Testing among MSM Project (eSTAMP).
Methods: In 2015, we recruited MSM through online banner advertisements. Eligibility included: HIV-negative or unknown status, ≥18 years old, had a male sex partner in the past year, and not taking HIV antiretroviral medications. Participants provided information on demographic characteristics, HIV testing, and sexual behaviors in the past 3 months. For this analysis "risky sex" is defined as anal sex without condoms with an HIV-positive or unknown-status male partner. Odds ratios (ORs) for associations with risky sex were computed.
Results: The 2665 MSM were 58%-white, 23%-Hispanic, 10%-black; 17%-never tested for HIV, 41%-untested in past year; 43%-college degree; 85%-employed part or full-time; 57%-recruited from internet dating sites; 63%-reported ≥2 male sex partners, and 32%-reported engaging in "risky sex". "Risky sex" was associated with being black or Hispanic, ≤high school education, never tested for HIV, recruited from dating site, unemployed, and reporting ≥2 male sex partners.

Characteristic	Proportion	Odds Ratio	95% CI	P-value
NH** Black vs. NH** White	0.38 vs. 0.30	1.46	1.11-1.92	<0.01
Hispanic vs. NHb White	0.37 vs. 0.30	1.36	1.12-1.66	<0.01
≤ High School vs. Post HS education	0.37 vs. 0.31	1.31	1.06-1.62	<0.01
Never tested HIV vs. Tested	0.39 vs. 0.31	1.43	1.16-1.77	<0.01
Dating site vs. Not Dating site	0.35 vs. 0.29	1.34	1.14-1.59	<0.01
Not employed vs. employed	0.42 vs. 0.31	1.67	1.34-2.07	<0.01
***≥2 male partners: Yes vs. No	0.43 vs 0.15	4.20	3.44-5.13	<0.01
Risky sex*: anal sex without a condom with an HIV positive or unknown HIV status male partner in the past 3 months, **NH : non-Hispanic, ***≥2 male partners: 2 or more male sex partners in the past 3 months				

[Characteristics associated with risky sex]*

Conclusions: The internet may be useful in recruiting MSM who have never or not recently been tested for HIV. Contrary to previous research, "risky sex" was more prevalent among black and Hispanic MSM than white MSM. Online studies of MSM who engage in higher-risk sexual behaviors may consider recruiting more men of lower socio-economic status, minority populations, and from dating sites.

TUPEC0755

Association between internalized stigma and depressive symptoms: a cohort study in rural Uganda

A. Kembabazi[1], L. M Bebell[2,3], N. Musinguzi[1], J. N Martin[4], P. W Hunt[5], J. E Haberer[6], B. M Bwana[1], M. J Siedner[7], D. R Bangsberg[8], A. C Tsai[9]
[1]Mbarara University of Science and Technology, Mbarara, Uganda, [2]Massachusetts General Hospital Center for Global Health, Boston, United States, [3]Division of Infectious Diseases, Massachusetts General Hospital, Boston, United States, [4]University of California, Epidemiology and Biostatistics, San Francisco, United States, [5]University of California, Department of Medicine, San Francisco, United States, [6]Massachusetts General Hospital, Center for Global Health, Boston, United States, [7]Massachusetts General Hospital, Boston, United States, [8]Oregon Health & Science University, Portland, United States, [9]Harvard Center for Population and Development Studies, Boston, United States
Presenting author email: akembabazi2005@yahoo.com

Background: Depression affects>40% of people living with HIV (PLHIV) in low- and middle-income countries, and, >50% of all PLHIV report HIV-related stigma, a principal driver of depression. However, few longitudinal studies have examined the relationship between HIV stigma-related depression and antiretroviral therapy (ART). We sought to estimate the association between HIV, stigma, and depression among individuals initiating ART.
Methods: Data were obtained from the Uganda AIDS Rural Treatment Outcomes (UARTO) cohort of treatment-naïve PLHIV starting ART between 2007-2013 in rural Mbarara district. Eligible patients were ART-naïve, ≥18 years, and lived within 60km of clinic. Our primary outcome was depression, measured usingHopkins Symptom (HSS) checklist;our primary exposure was stigma score, measured using Internalized AIDS-Related Stigma Scale (IASS). Both scores weremeasured at en-

rollment and follow-up visits. We fit a linear generalized estimating equations (GEE) regression model to estimate the association between stigma and depression as continuous variables.We also fit a logistic regression model, dichotomizing stigma as any stigma (IASS score >0) and probable depression(HSS score ≥1.75). Estimates were adjusted for age, sex, education, marital status, household asset wealth, CD4 count, cohort entry date to account for secular trends in HIV stigma over time.
Results: The analysis included 454 participants (68% female) with mean age of 34 (SD 9.6) years; 54% were married. Mean baseline CD4 count increased from 169 for participants enrolled 2007-2009 to 310 for those enrolled 2010-2013 (P<0.001). Our GEE model demonstrated that both lower stigma (coefficient 0.032, P<0.001) and increased duration of ART (coefficient -0.0090, P<0.001) were associated with lower depression scores. Logistic regression models indicated that any stigma was associated with increased odds of probable depression (OR 2.6, 95% CI 2.0-3.5, P<0.001). The relationship between stigma and depression was similar after controlling for potential confounders (OR 2.6, 95% CI 2.0-3.3, P<0.001).
Conclusions: Higher degree of internalized stigma was longitudinally associated with higher depression scores in this large cohort of PLHIV initiating ART. Consistent with previous findings, longer duration of ART therapy was independently associated with lower depression scores. Our findings underscore the need for stigma-reduction interventions early in treatment for PLHIV.

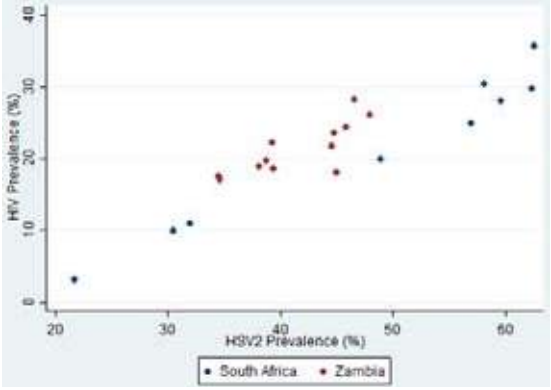
Sexually transmitted bedfellows: exquisite association between HIV and HSV2 in 21 communities in Southern Africa in the HPTN 071 (PopART) study

R.J. Hayes[1], J. Bradley[1], S. Floyd[1], E. Piwowar-Manning[2], A. Young[3], S. Fidler[4], N. Beyers[5], H. Ayles[6,7], HPTN 071 (PopART) Study Team
[1]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [2]HPTN Laboratory Center, Johns Hopkins University, School of Medicine, Baltimore, United States, [3]HPTN Statistical & Data Management Center, SCHARP, Seattle, United States, [4]Imperial College, HIV Clinical Trials Unit, London, United Kingdom, [5]Desmond Tutu TB Centre, Stellenbosch University, Cape Town, South Africa, [6]Zambart, Lusaka, Zambia, [7]London School of Hygiene & Tropical Medicine, Clinical Research, London, United Kingdom
Presenting author email: richard.hayes@lshtm.ac.uk

Background: Many studies have identified associations between HIV and Herpes simplex virus type-2 (HSV2), the commonest viral sexually transmitted infection, although the exact role of HSV2 as a cofactor in HIV transmission is unknown. A large community-randomised trial of an HIV preventive intervention afforded an opportunity to re-examine this association at individual and community levels.
Methods: The HPTN071(PopART) trial is measuring the impact of a combination prevention intervention on HIV incidence at population-level in 21 urban communities in Zambia and South Africa. To measure impact, a population-cohort of approximately 2,000 adults aged 18-44 was selected randomly from each community. Baseline data were collected on socio-demographic characteristics and sexual behaviour, and serological tests performed for HIV and HSV2 infection. Logistic regression was used to examine the association between HIV and HSV2 after adjustment for confounders. At community-level, HIV prevalence was plotted against HSV2 prevalence.

	HIV+ve/Total			
	HSV2-ve	HSV2+ve	OR (adj for age, community)	OR (adj for age, cty, partners, other)
Males	372/7,657 (4.9%)	834/2,401 (34.7%)	6.28 (p<0.001)	5.76 (p<0.001)
Females	790/11,380 (6.9%)	5652/13,305 (42.5%)	7.40 (p<0.001)	6.38 (p<0.001)

[Association between HIV and HSV2 in 21 communities]



[HIV and HSV2 prevalence in 21 communities]

Results: 38,691 adults were enrolled in the cohort. Overall HSV2 prevalence in men and women was 22% and 50% in Zambia, and 26% and 59% in South Africa. At individual level (Table) a six-fold higher odds of HIV was seen in HSV2-infected individuals in both sexes, even after adjustment for other risk factors including lifetime number of sex partners. At community-level there was a strong linear relationship between HIV prevalence and HSV2 infection (Figure).
Conclusions: These data show the exquisite association between these two infections, seen at both individual and community levels. While both viruses are sexually transmitted, the associations remained strong after adjustment for measures of sexual behaviour. This association is likely due at least partly to a powerful biological cofactor effect of HSV2 on HIV acquisition. Effective control tools for HSV2 could make an important contribution to HIV prevention.

Adolescent girls and young women's knowledge of sex partners' HIV status in Tanzania

D. Boyee[1], A. Exavery[1], C. Casalini[1], F. Rweikiza[2], N. Jonas[1], G. Kessy[3], G. Lija[4], T. Lennemann[1], A. Komba[1], K. Curran[5]
[1]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [2]EngenderHealth, Dar es Salaam, Tanzania, United Republic of, [3]Tanzania Commission for AIDS (TACAIDS), Dar es Salaam, Tanzania, United Republic of, [4]National AIDS Control Programme (NACP), Dar es Salaam, Tanzania, United Republic of, [5]Jhpiego, Washington, United States
Presenting author email: dorica.boyee@jhpiego.org

Background: Because 80% of HIV infections occur sexually in Tanzania, knowledge of sex partner's HIV status is vital to inform appropriate prevention strategies for individuals and couples, for example condom use or treatment as prevention. This analysis examines factors associated with unawareness of sex partner's HIV status among adolescent girls and young women (AGYW) in Tanzania.
Methods: We analyzed routine program data from the PEPFAR/USAID-funded Sauti Project that provides comprehensive, community-based biomedical, behavioral and structural prevention services to AGYW and key populations in Tanzania. Between November 2015 and March 2016, a vulnerability index tool was administered to out-of-school AGYW aged 15-24 years. Data analysis involved cross-tabulations with a Chi-square test for associations. Multivariate analysis was performed using mixed-effects logistic regression to identify factors associated with lack of awareness of sex partner's HIV status.
Results: Of 2,832 sexually active AGYW analyzed, 73% were not aware of the HIV status of their current sexual partners. Among the AGYW unaware of their partner's HIV status, 44% did not use condoms in all of their last three sex acts and 47% reported three or more sexual partners in the last 12 months. Multivariate analysis showed that lack of awareness of partners' HIV status was positively associated with food insecurity (OR=1.55%, 95% CI 1.23-1.94), increasing age difference between AGYW and her oldest sex partner (e.g. 10+yrs: OR=1.57, 95% CI 1.07- 2.29), having only some primary education or lack of formal education (OR=1.59, 95% CI 1.28-1.97), concurrency of sexual partners (OR=1.61, 95% CI 1.27-2.06), lack of an adult in the community that the AGYW could go to for emotional/financial support (OR=1.29, 95% CI 1.04-1.60) and being single/unmarried (OR=2.40, 95% CI 1.90-3.02).
Conclusions: Lack of awareness of sexual partner´s HIV status and inconsistent condom use are pervasive and constitute a significant risk for HIV acquisition among AGYW in Tanzania. Structural factors such as food insecurity, lack of adult support and limited education were associated with lack of awareness of partner's HIV status in our analysis, and highlight the potential role of structural interventions in reducing HIV acquisition risk.

TUPEC0758

Child sexual abuse, adolescent pregnancy and early substance use associated with underage entry to sex trade and HIV/STI infection in the Mexico - U. S. Border region

A.E.N. Servin Aguirre[1,2], E. Reed[3], C. Magis-Rodriguez[4], H. Staines-Orozco[5], S. Strathdee[2], K. Brouwer[2], J. Silverman[6]
[1]University Xochicalco, School of Medicine, Tijuana, Mexico, [2]University of California, Division of Global Public Health, San Diego, United States, [3]San Diego State University, Health Promotion and Behavioral Science, San Diego, United States, [4]Centro Nacional para la Prevencion y el Control del VIH y SIDA, Prevencion, Mexico, Mexico, [5]Universidad Autonoma de Ciudad Juarez, Departamento de Ciencias Medicas, Ciudad Juarez, Mexico, [6]University of California, Center for Gender Equity and Health, San Diego, United States
Presenting author email: argentinanoelle@gmail.com

Background: Forced or underage entry to sex trade has been linked to serious health and social impacts including enhanced risk of HIV infection, sexually transmitted infections (STIs), substance use and mental health disorders among youth. However, there is limited data about the risk factors that create vulnerability for underage entry, especially in Latin America, a region that is believed to be one of the largest sources of persons moved across international borders for the purposes of sexual exploitation.
Methods: This mixed methods study surveyed 603 female sex workers (FSWs) selected through modified time-location sampling within both indoor and street venues in two cities located on the Mexico-U.S. border region. Additionally, 30 in-depth interviews (15 in each city) were conducted with FSWs screening positive for underage entry to sex trade.
Results: One fourth of participants reported entering sex trade prior to age 18, among whom HIV and any STI (e.g., chlamydia, syphilis, gonorrhea, hepatitis B and/or C, HPV) prevalence were 5.9% and 49.6%. One in 8 participants (12.4%) reported child sexual abuse (forced sex prior to age 13), 54.5% reported an adolescent pregnancy (prior to age 18), 14.1% reported substance use prior to age 13 and 7.1% injected drugs prior to age 18. In multivariate analyses, child sexual abuse (adjusted odds ratio [AOR]= 1.9; 95% confidence interval [CI] 1.2-2.9), adolescent pregnancy (AOR=2.3; 95%CI 1.4-3.6), and substance use prior to age 13 (AOR=4.6; 95%CI 2.7-8.1) remained significant predictors for underage entry to sex trade. Qualitative data illustrates how sexual violence as a child can make girls vulnerable to adolescent pregnancy, early substance use and subsequent underage entry to sex trade.
Conclusions: Experiences of child sexual abuse, adolescent pregnancy and early substance use were associated with underage entry to sex trade. Further, FSWs who entered underage had a higher prevalence of HIV/STIs than those who did not. These results underscore the importance of targeting abused and otherwise vulnerable youth for prevention of sex trafficking in Mexico.

TUPEC0759

How changes in substance use affect psychological wellbeing and quality of life among people living with HIV/AIDS in South China?

X. Li[1], S. Qiao[1], Y. Zhou[2], Z. Shen[2]
[1]University of South Carolina, SC SmartState Center for Healthcare Quality, Columbia, United States, [2]Guangxi CDC, Institute of HIV/ATD Prevention and Control, Nanning, China

Background: Reductions in tobacco, alcohol, and other substance use may improve wellness of people living with HIV/AIDS (PLWH), but more empirical evidence is needed to inform interventions in diverse settings. This study aims to describe changes in substance use since HIV diagnosis, and explore whether and how the changes are associated with psychological wellbeing and quality of life among PLWH in China.
Methods: A cross-sectional survey was conducted among 2987 PLWH from 12 cities/counties in Guangxi, China to assess their health behaviors and outcomes. Data on substance use behaviors were collected from those who had ever engaged in tobacco, alcohol or other drug use. We conducted descriptive analysis and a series of multivariate regressions. Data analysis was stratified by gender.
Results: Men who were married, older, with higher education attainment and shorter period since HIV diagnosis were more likely to reduce or abstain from tobacco use. No demographic variables were related to the changes in either alcohol use or drug use among men. Similarly we did not identify any demographic variables were associated with changes of substance use among women.
For male participants, change in smoking was positively associated with perceived social support (αβ=.074, 95%PI= [.036, .210], p=.025) and self-efficacy (αβ=.055, 95%PI= [.003, .160], p=.04); reducing or abstaining from alcohol was associated with lower quality of life (αβ=-.076, 95%PI=[-.159, -.019], p=.013); reducing or quitting drug use was significantly decreased depression (αβ=-.163, 95%PI= [-.435, -.137], p<0.0001) and improved perceived social support (αβ=.160, 95%PI= [.166, .536], p<0.0001), self-efficacy(αβ=.120, 95%PI= [.072, .421], p=.006), resilience (αβ=.117, 95%PI= [.075, .474], p=0.007), and quality of life(αβ=.101, 95%PI= [.023, .289], p=0.022).
Among female participants, those reduced or quitted tobacco use reported lower self-efficacy (3. 22 vs. 3.50); those reduced or stopped drinking were more likely to show lower quality of life(αβ=-.146, 95%PI=[-.311, -.009], p=.038), self-efficacy (αβ=-.163, 95%PI=[-.477, -.040], p=.021) and resilience (αβ=-.176, 95%PI=[-.514, -.063], p=.012).
Conclusions: Abstaining from smoking, alcohol and drug may not always improve psychological wellbeing or enhance quality of life among PLWH. Psychological counseling services that assist PLWH in adaptation during post-abstaining period should be integrated into HIV care and management practice.

TUPEC0760

Prevalence and correlates of receptive anal intercourse among out of school adolescent girls and young women in Tanzania

T. Lennemann[1], C. Casalini[1], E. Majani[1], F. Hezwa[1], M. Ndolichimpa[1], E. Mlanga[2], N. Makyao[3], C. Chipere[4], A. Komba[1]
[1]Jhpiego Tanzania, Sauti Project, Dar es Salaam, Tanzania, United Republic of, [2]USAID Tanzania, Dar es Salaam, Tanzania, United Republic of, [3]National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [4]Pact, Sauti Project, Dar es Salaam, Tanzania, United Republic of
Presenting author email: albert.komba@jhpiego.org

Background: The risk of contracting HIV through receptive anal intercourse (RAI) is up to 18 times higher than through vaginal intercourse. Qualitative research suggests an increased acceptability of condomless anal sex (AS) among young women and their sexual partners in Tanzania. This abstracts investigates prevalence and correlates of RAI in out-of-school adolescent girls and young women (AGYW) aged 15-24 reached by the USAID-funded Sauti program in Tanzania.
Methods: Data were collected August 2015 to June 2016 in 5 regions of Tanzania. Univariate and multivariate comparisons used Chi square and multivariate logistic regression respectively.
Results: Of 6,678 AGYW who had ever been sexually active, 37% were 15-19, and 63% were 20-24 years of age. Twelve percent (n=900) reported AS. Multivariate analysis showed that having no adult support (OR 1.4, p <0.01), food insecurity (OR 2.8, p <0.001), exchanging sex for cash (OR 1.8, p <0.001), having multiple sexual partners (OR 2.1, p <0.001), partners with age difference >10 years (OR 1.8, p <0.001), lifetime experience of sexual violence (SV) ≥2 (OR 2.5, p <0.001), belonging to AGYW social groups (OR 1.8, p <0.01), and first pregnancy younger than 17 or older than 20 years (OR 1.6, 2.6 p <0.001) were positively associated with the likelihood of practicing AS.
On the other hand, AGYW with primary education or more were less likely to practice AS (OR 0.4 p <0.001). Though significant on univariate model, knowledge of partner HIV status, use of contraceptives, and age of sexual debut and exchange of sex for gifts were not associated with AS.
Conclusions: RAS is a relevant risk factor for HIV acquisition in out of school AGYW in Tanzania. Programs should invest in combination prevention services that offer condom promotion, GBV screening, and support along with cash transfer, gender transformative behavior change education and caregivers mentoring to protect from HIV acquisition through AS. Furthermore, use of mapping tools to better understand the communities where the AGYW live would play a crucial role to assess safety of existing social groups and institutions and therefore to design programmatic responses to that.

TUPEC0761

Latent substance use profiles and associations with condomless anal intercourse among a sample of young black men who have sex with men and transgender women in the United States

S. LeGrand[1], K. Muessig[2], R. Simmons[3], N. Blackburn[2], S.K. Choi[2], L. Hightow-Weidman[4]
[1]Duke University, Duke Global Health Institute, Center for Health Policy and Inequalities Research, Durham, United States, [2]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Department of Health Behavior, Chapel Hill, United States, [3]Duke University, Duke Global Health Institute, Durham, United States, [4]University of North Carolina at Chapel Hill, School of Medicine, Division of Infectious Diseases, Chapel Hill, United States
Presenting author email: sara.legrand@duke.edu

Background: Substance use has been associated with engagement in sexual risk behaviors among young black men who have sex with men and transgender women (YBMSM/TW), however additional research is needed to understand how patterns of substance use are associated with risk. We identified profiles of substance use among a sample of YBMSM/TW and examined associations with condomless anal intercourse (CAI).
Methods: Baseline data from 474 participants in the randomized controlled trial of healthMpowerment, a mobile-phone-optimized, Internet-based intervention to reduce sexual risk behaviors among HIV-positive and negative YBMSM/TW, ages 18-30, were examined. Latent profile analysis was used to approximate substance use profiles based on last 90 days use of alcohol, marijuana, crack, cocaine, heroin, methamphetamine, club drugs, opiates and inhalants. A zero-inflated Poisson model was used to predict mean episodes of CAI in the last 30 days based on substance use profiles and to compare CAI across profiles.
Results: Three distinct profiles of substance use were identified: low users (73% of sample; mean 11.98 days of alcohol use, 4.31 of marijuana use; low to no use of other substances); heavy marijuana users (25% of sample; mean 73.60 days of marijuana use, 20.34 of alcohol, 2.05 of cocaine; minimal use of other substances) and poly-substance users (2% of sample; mean 24.50 days of methamphetamine use, 36.40 of marijuana, 22.20 of alcohol, 9.10 of inhalants, 8.30 of club drugs, 3.90 of crack, 2.60 of cocaine and low use of other substances). Mean CAI was highest among poly-substance users (8.96, 95% CI: 7.03, 10.90), followed by heavy marijuana users (6.31: 95% CI: 5.64, 6.98) and low users (5.94: 95% CI 5.40, 6.48). CAI was significantly higher among poly-substance users compared to low users (IRR: 1.51; 95% CI: 1.20, 1.82) and heavy marijuana users (IRR: 1.42 95% 1.12, 1.72). There was no significant difference between heavy marijuana users and low users (IRR: 1.06; 95% CI 0.98, 1.15).
Conclusions: Patterns of substance use among this population were differentially associated with CAI. Although the proportion of poly-substance users was low, higher CAI in this group warrants targeted substance abuse interventions to reduce the likelihood of HIV acquisition or onward transmission.

TUPEC0762

Using exploratory factor analysis to guide the development of an HIV risk index for adolescent girls and young women in Tanzania

H. Han[1], S. Ketende[1], S. Baral[1], G. Urassa[2], C. Chipere[3], M. Bangser[4], S. Kaganda[5], A. Kinemo[6], A. Akridge[7], A. Komba[2], T. Lennemann[2]

Presenting author email: hhan19@jhu.edu

Background: Improved strategies to address the disproportionate burden of HIV and sustained HIV acquisition risks remains as a crucial component of an effective HIV response. To better tailor HIV prevention interventions, the USAID-funded Sauti program aims to develop and evaluate a risk stratification tool and determinants of HIV acquisition risk among adolescent girls and young women (AGYW) in Tanzania.
Methods: A 20-item index was developed and administered by trained peers to 6,526 out-of-school AGYW aged 15-24 in five regions of Tanzania August 2015 to June 2016. Based on the composite score received on the index, AGYW were categorized into four different risk groups (Low, Middle, High, and Very High). Principal factor analysis with polychoric correlation and promax oblique rotation was used to describe an underlying latent variable for the vulnerability of HIV acquisition. Factors included in the final scale were selected based on Kaiser's criterion, eigenvalues, scree plots, Horn's test, and interpretability with items selected based on factor loading estimates greater than 0.3.
Results: Thirteen items were selected in the final scale. Inter-item correlation identified four factors: sexual behavior, psychosocial vulnerability, transactional sex, and reproductive health. A Cronbach's alpha of 0.74 suggested high reliability of the tool. Although stratification by region and age (15-19 vs. 20-24) showed slightly different item combinations, the 13 items in the final scale are measuring the same risk construct. Risk groups were significantly associated with increased odds of multiple concurrent partners and compensated sex across all risk levels compared to the low-risk group (Table 1).

Risk Group	Have had three or more concurrent partners in the past 12 months		Have had sex in exchange for cash in the past 12 months	
	Odds ratio	95% CI	Odds ratio	95% CI
Low	-	-	-	-
Medium	1.6*	(1.5, 1.8)	1.7*	(1.6, 1.9)
High	2.4*	(2.2, 2.6)	2.6*	(2.4, 2.8)
Very High	3.0*	(2.8, 3.2)	3.0*	(2.8, 3.2)

* p-value significant at 0.01 level

HIV Risk Assessment Tool Domains and Questions

Domain	Question	
Sexual Behavior	Ever had Sex (Vaginal/Anal)	
	Age at Coital Debut	More than one sexual partner in the same month
	Sex in the last 12 Months	Compensated Sex
Transactional Sex	Condom Use during last three Vaginal Sexual Acts	
	Intergenerational Sex	
	Serodiscordant Partnerships	
Reproductive Health	Pregnancy	
	Relationship Status	
Psychosocial Vulnerability	Sexual Violence	
	Food Security	
	Emotional and/or Financial Support	

[Table 1. Logistic regression assessing the relationship between HIV-related risk groups assigned by the HIV risk assessment tool and surrogate parameters of HIV acquisition risk]

Conclusions: The Sauti AGYW HIV Risk Index reliably stratifies out-of-school AGYW in Tanzania based on individual and structural HIV risks. Scaling implementation of this risk stratification tool may support better HIV prevention specification for AGYW in Tanzania ranging from enhanced counseling and education, addressing structural risk determinants, and HIV pre-exposure prophylaxis.

TUPEC0763

Relationship between sexually transmitted infections (STIs) and HIV transmission among female sex workers (FSWs) in Nigeria

G. Emmanuel[1], A. Yusuf[2], P. Umoh[3], A. Ojeimiri[3], B. Ochonye[4], A. Kalaiwo[5], C. Law-Maduka[6], L. Torjir[7], R. Abang[8], K. Osisami[9], S. Ngene[9], V. Bassey[10], T. Zakka[11], J. Eze[12], B. Aiwonodagbon[3]
[1]Heartland Alliance International, Programmes, Abuja, Nigeria, [2]Heartland Alliance International-Nigeria, Programmes, Abuja, Nigeria, [3]Heartland Alliance International, Monitoring and Evaluation, Abuja, Nigeria, [4]Heartland Alliance International, Chief of Party, Abuja, Nigeria, [5]USAID, Abuja, Nigeria, [6]Heartland Alliance International, Akwa Ibom, Nigeria, [7]Heartland Alliance International, Benue, Nigeria, [8]Heartland Alliance International, Cross Rivers, Nigeria, [9]Heartland Alliance International, Abuja, Nigeria, [10]Heartland Alliance International, Lagos, Nigeria, [11]Heartland Alliance International, Nasarawa, Nigeria, [12]Heartland Alliance International, Rivers, Nigeria
Presenting author email: ayusuf@heartlandalliance.org

Background: STIs is a known predisposing factor to acquiring HIV. The Integrated Biological and Behavioural Surveillance Survey conducted in Nigeria in 2014 reported a high prevalence of HIV (19.4%) among brothel based female sex workers (BBFSW); with 21% and 7.2% of the BBFSW reporting unusual vaginal discharge and genital ulcers/sore respectively in the past 12 months prior to the survey.
Methods: Through the PEPFAR and USAID Integrated MARPs HIV Prevention Program (IMHIPP) in Nigeria, Heartland Alliance International works with female sex workers led community based organizations (CBOs) in 8 states of Nigeria (Akwa Ibom, Benue, Cross Rivers, Federal Capital Territory, Lagos, Kaduna, Nasarawa and Rivers) to mitigate the impact of HIV among sex workers of ages 15-49 through the provision of comprehensive HIV services. A total of 112,355 BBFSWs were reached with comprehensive HIV services across eight states in cohorts over a period of twenty months (April 2015-Novemebr 2016).
Each cohort of ten FSWs held cohort sessions weekly for six weeks. A total of 81,519 FSWs were provided HIV Testing Services (HTS) and also screened for STIs by trained providers. HTS and STI data were collected using client intake forms with each BBFSW given a unique ID. IBM SPSS statistical software 23 was used to analyze data and to ascertain the proportion of BBFSW with dual STIs and HIV infection.

Results: 3847 out of 81, 519 FSWs tested positive for HIV (4.7%). 1171 out of the 3847 FSWs (30.44%) that tested positive for HIV also had STIs. The most common STI were vaginitis (47.61%), lower abdominal pain (30.98%) and cervicitis (21.41%). There was statistical significance with a P value of 0.01. In addition, the Pearson's r was 0.947 which also indicates a very strong positive relationship.
Conclusions: The presence of STIs such as vaginitis and cervicitis increases the risk of HIV infection among BBFSWs in Nigeria. It is therefore essential that HIV prevention strategies targeting BBFSWs includes a full range of STI screening and treatment.

TUPEC0764

Comparison of HIV risks and HIV prevalence between poppers, amphetamine-type substance (ATS) and polydrug using Thai men who have sex with men and transgender women

T. Anand[1], C. Nitpolprasert[1], J. Jantarapakde[1], S. Pengnonyang[1], T. Sungsing[1], P. Rodbamrung[1], S.J. Kerr[2,3,4], T. Nakpor[5], W. Champa[6], D. Linjongrat[7], S. Janyam[8], R. Meksena[2], P. Phanuphak[1,2], N. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]Academic Medical Center, University of Amsterdam, Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands, [5]Sisters Foundation, Chon Buri, Thailand, [6]Caremat Organization, Chiang Mai, Thailand, [7]Rainbow Sky Association of Thailand, Bangkok, Thailand, [8]Service Workers In Group Foundation, Bangkok, Thailand
Presenting author email: tarandeepsinghanand@gmail.com

Background: Substance use has emerged as a part of the HIV syndemic among Thai men who have sex with men (MSM) and transgender women (TG). We compared HIV risks and prevalence between poppers, amphetamine-type substance (ATS) and polydrug users.
Methods: As part of community-based Test and Treat and Adam's Love study, MSM and TG received HIV testing and completed socio-demographic and risk behavior questionnaires. Participants were categorized on the basis of their substance use (regardless of alcohol use) into three groups: (1) 'only poppers users'; (2) 'only ATS users'; and (3) 'polydrug users'. Logistic regression analyses examined the association of each group with sexual behaviors and HIV infection.
Results: From May 2015 to December 2016, a total of 2,855 participants (75.4% MSM and 24.6% TG) were enrolled, and mean age was 26.5 (SD=7.1). There were 4.7% poppers, 3.6% ATS and 9.7% polydrug users. When compared with ATS and polydrug users, popper users were more likely to be MSM (98.5% vs. 65.1% vs. 83.8%, p<0.001), to have obtained a bachelor's degree or higher (51.9% vs. 20.4% vs. 34.9%, p<0.001), and were least likely to be bisexual (22.2% vs. 33% vs. 42.5%, p<0.001) or have only one sexual partner in the past 6 months (5.2% vs. 6.8% vs. 6.5%, p<0.001). ATS users included higher number of TG (35% vs. 16.2% vs. 1.5%, p<0.001), had less than high school education (43.7% vs. 27.7% vs. 7.4%, p<0.001), had monthly income ≤ 500 USD (63.1% vs. 49.6% vs. 42.2%, p=0.001) and had never previously tested for HIV (45.6% vs. 36.7% vs. 29.6%, p=0.001) as compared with polydrug and popper users. In multivariate regression model, using ATS was associated with unprotected anal sex (AOR 3.11, 95% CI 1.49 - 6.49, p=0.002) and testing HIV-positive (AOR 1.92, 95% CI 1.08 - 3.39, p=0.02).
Conclusions: Our study identified unique HIV vulnerabilities of distinct substance-using MSM and TG groups, ATS-users being at higher risk. Putting prevention tools such as pre-exposure prophylaxis (PrEP) and condoms into the hands of substance-users seeking clinical services, and implementing innovative models to identify those ‚unreached' for early interventions remains a critical priority.

Regional Office for the Western Pacific, Manilla, Philippines
Presenting author email: ferradinil@who.int

Background: In late 2014 in a rural village in Cambodia, a surge in HIV infections was reported and a rapid investigation identified 114 among 915 Roka commune residents being HIV infected (12.4%).
Methods: A case-control study was performed in December 2014 to identify risk factors associated with recently diagnosed HIV positive cases in Roka commune.
Results: The results provide strong evidence that unsafe medical injection practices were associated with HIV cases. Recent exposure to medical injections (AOR=4.9 [2.2 - 10.8]), intravenous infusion (AOR=4.3 [2.1 - 8.9]) or blood draw (AOR=5.6 [2.5 - 12.2]) within the past six months were found independently associated with HIV infection. No other factors examined were significantly associated with recent HIV infection, including other invasive procedures, injection drug use and sex-related risk behaviour usually associated with HIV transmission.
Conclusions: In countries with low HIV prevalence like Cambodia, healthcare-associated HIV transmission may continue to represent substantial HIV risk and compromise HIV control. Such a risk should be closely monitored with appropriate tools and alert systems, actively prevented by improving healthcare providers' injection practices, both in the public and private sectors, and reducing the demand for unnecessary medical injections by raising awareness of both the public and medical practitioners.

TUPEC0766

Alcohol use, substance use, and risk of HIV transmission among female sex workers in Kampala, Uganda

K. Ortblad[1], D. Kibuuka Musoke[2], T. Ngabirano[3], A. Nakitende[2], G. Taasi[4], A. Bazzi[5], T. Barnighausen[6], C. Oldenburg[7]
[1]Harvard T H Chan School of Public Health, Global Health and Population, Boston, United States, [2]International Research Consortium, Kampala, Uganda, [3]Uganda Health Marketing Group, Kampala, Uganda, [4]Uganda Ministry of Health, Kampala, Uganda, [5]Boston University School of Public Health, Department of Community Health Sciences, Boston, United States, [6]Heidelberg University, Heidelberg, Germany, [7]Francis I. Proctor Foundation, University of California San Francisco, San Francisco, United States
Presenting author email: kibuukamd@sfg-group.com

Background: Alcohol and substance use decrease inhibition and are thought to be associated with risk behaviors for HIV transmission. Key populations, including female sex workers (FSW), have historically high risk of HIV acquisition as well as alcohol and substance use. We investigate the association between alcohol use, substance use, and HIV-related risk behaviors among FSW in Kampala, Uganda.
Methods: HIV-naïve or perceived uninfected (no testing < 3 months) Kampala-based FSWs (n= 963) completed quantitative questionnaires in October - November 2016. Participants were asked how often they drank alcohol just before or during sex work (5-point scale, past month) and if they had used any intoxicating substances or drugs (past 12 months). HIV-related behavioral outcomes included 1) condom use with clients and 2) HIV testing (past 6 months). Multivariable logistic regression models adjusting for sociodemographic variables assessed associations between alcohol and substance use and the two behavioral outcomes.
Results: Participants had a median age of 28 years (IQR: 24-32 years) and the majority were literate (822, 85.7%) and reported monthly income < 250,000 UGX/~USD $70 (527, 55.1%). Almost half reported alcohol use before or during sex work "most times" or "every time" (435, 45.2%) and 374 participants (38.8%) reported past 12-month substance use. Inconsistent condom use was reported by 388 participants (40.4%) and 353 participants (33.7%) reported past 6-month HIV testing. Alcohol use (most or every time) before/during work and past 12-month substance use were both associated with increased odds of inconsistent condom use with clients (alcohol: aOR 1.98, 95% CI: 1.51-2.58; substance use: 1.89, 95% CI: 1.44-2.47) and decreased odds of past 6-month HIV testing (alcohol: aOR 0.85, 95% CI: 0.65-1.11; substance use: aOR 0.51, 95% CI: 0.38-0.67); the association between alcohol use and HIV testing, however, was not significant.
Conclusions: Alcohol and substance use are prevalent in this key population of Kampala-based FSWs and strongly associated with inconsistent condom use with clients and reduced HIV testing, behaviors that increase risk of HIV transmission and delay linkage to treatment and care. Interventions that reduce alcohol and substance use in the sex work environment should be developed for FSW in Kampala, Uganda.

TUPEC0767

Recent incarceration and risk of hepatitis C and HIV transmission amongst people who inject drugs: a systematic review and meta-analysis

J. Stone[1], M. Hickman[1], A. Lim[1], H. Fraser[1], J. Walker[1], L. MacGregor[1], A. Trickey[1], S. Abbott[1], Z. Ward[1], N.K. Martin[1,2], P. Vickerman[1]
[1]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom, [2]University of California San Diego, Division of Global Public Health, San Diego, United States
Presenting author email: jack.stone@bristol.ac.uk

Background: Recent modelling has suggested that incarceration could be a significant driver of HIV and hepatitis C virus (HCV) transmission amongst people who inject drugs (PWID), primarily due to an elevated risk of HIV and HCV acquisition following recent release. We conducted a systematic review to assess the degree to which recent incarceration elevates the risk of HCV or HIV transmission amongst PWID.
Methods: MEDLINE, EMBASE and PSYCHINFO databases were searched for epidemiological studies assessing HCV (both primary infection and reinfection) or HIV incidence amongst community PWID. Studies published since January 2000 were retrieved for review without language restriction. Studies were included if they reported the association between recent incarceration and HCV or HIV incidence. Authors of incidence studies which did not report on this outcome, but may have collected data regarding recent incarceration were contacted to obtain additional data. Data were extracted and pooled in meta-analyses using a random effects model.
Results: Sixteen published studies that examined the impact of recent incarceration on HIV or HCV transmission met criteria for inclusion; 11 studies of HCV transmission (10 primary infection and 1 reinfection) and 5 of HIV transmission. Recent incarceration was associated with a 56% increase in the risk of HCV infection (rate ratio 1.56, 95% confidence interval (95%CI) 1.15-1.98; P< 0.001) and a doubling in the risk of HIV infection (rate ratio 1.99, 95%CI 1.21-2.77; P< 0.001) among PWID. There was evidence of heterogeneity between studies in the HIV analysis (I-squared = 72.3%, chi(2)=14.46, P=0.006) but not in the HCV analysis (I-squared = 32.9%, chi(2)=14.70, P=0.144).
Conclusions: Recent incarceration is associated with an increased risk of both HCV and HIV transmission amongst PWID. Because of the high rates of incarceration experienced by PWID in most settings, incarceration is likely to be a significant driver for HCV and HIV epidemics amongst PWID. To help develop future interventions, research is needed to determine the precise mechanism by which incarceration elevates HCV and HIV transmission risk amongst PWID, and so whether prison-based harm reduction and structural interventions could reduce this elevated risk and the burden of HCV and HIV.

Evaluating the HIV prevention and treatment needs among male clients of female sex workers in Senegal

K. Coly[1], F.M. Drame[2], D. Diouf[2], C. Toure Kane[3], S. Ketende[1], C. Lyons[1], B. Liestman[1], O. Ndiaye[3], G. Turpin Nunez[1], A. Rao[1], F.M. Sy[2], P. Dieng[2], D. Diagne Gueye[3], S. Schwartz[1], S.D. Baral[1]
[1]Johns Hopkins School of Public Health, Center for Public Health and Human Rights, Baltimore, United States, [2]Enda Santé, Dakar, Senegal, [3]LBV/IRESSEF, Dakar, Senegal
Presenting author email: kcoly1@jhu.edu

Background: Consistent data support the concentration of HIV risks in Senegal. Specifically, burden of HIV in Senegal, is highly concentrated among specific key populations with specific HIV acquisition and transmission risks. Characterizing the HIV transmission dynamics in Senegal can support continued implementation of increasingly specific HIV prevention and treatment programs. While the prevalence of HIV among female sex workers (FSW) appears to have fallen in recent years, there has been limited study of the HIV prevention and treatment needs of the clients of FSW.
Methods: Using time location sampling we visited 56 sites in Dakar, sampled 602 clients of FSW defined as men who pay money to have sex with FSW between 11/2015 and 05/2016. The survey included a structured instrument combined with biological testing for HIV and syphilis.
Results: 602 clients participated in the study, the median age of included men is 34 (IQR: 27-42) 23.0%(140/602) went to koranic school, 19.6%(118/602) did not finish high school, and 7.1% (43/602) are university students. 49.3%(297/602) are single, 40.5 %(244/602) are married , 8.4%(51/602) are widowers, with 68.1%(169/602) of participants reporting not living with their partners. The median income per week (CFA) was 75000 (IQR: 36000-150000), 31.9%(192/602) were skilled workers, and 4.5%(27/602) were unemployed. 37.4%(225/602) reported always using condoms with sex workers though 96.8%(583/602) reported using health services designed for FSW and their clients within the past year. HIV-1 prevalence was 1.2 % (7/602) with 2.3% found to have active syphilis (14/602). While 33.4%(201/602) reported having tested for HIV, none of the participants that tested positive to HIV declared knowing their status before the study.
Conclusions: These data highlight male client engagement in sex work-oriented services, but limited history of HIV testing and consequently limited awareness of HIV status among those living with HIV. Given the significant risk of onward transmission among those unaware of their HIV status to other female partners, these unmet needs are significant. Moreover, understanding the HIV acquisition and transmission risks among all people including non-FSW partners of male clients provides further insight into the distributions of HIV risks and ultimately national investments needed to address these risks.

TUPEC0769

"I've finally deleted Jack'd (for good)": in-group HIV, sexuality and racial stigma within geospatial networking apps and sexual networking websites

S. LeGrand[1], D. Pulley[2], N. Blackburn[2], M. Barry[2], G. Sallabank[3], W. Dong[2], G. Harper[4], L. Hightow-Weidman[5], J. Bauermeister[6], S.K. Choi[2], K. Muessig[2]
[1]Duke University, Duke Global Health Institute, Center for Health Policy and Inequalities Research, Durham, United States, [2]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Department of Health Behavior, Chapel Hill, United States, [3]University of Michigan, Center for Sexuality and Health Disparities, Ann Arbor, United States, [4]University of Michigan, School of Public Health, Department of Health Behavior and Health Education, Ann Arbor, United States, [5]University of North Carolina at Chapel Hill, School of Medicine, Division of Infectious Diseases, Chapel Hill, United States, [6]University of Pennsylvania, School of Nursing, Department of Family and Community Health, Philadelphia, United States
Presenting author email: sara.legrand@duke.edu

Background: Geospatial networking apps (e.g., Grindr, Jack'd) and sexual networking sites (e.g., Adam4Adam, Manhunt) are often used by young black men who have sex with men (YBMSM) in the USA to identify sexual partners. Use of these online tools has been associated with increased sexual risk behavior. Experiences of HIV, sexuality and racial stigma within these sites may negatively impact sexual risk, mental health outcomes and uptake of HIV prevention and care services.
Methods: 232 YBMSM completed the intervention arm of a 12-month randomized controlled trial of healthMpowerment (HMP), an Internet-based intervention to reduce condomless anal intercourse. Intervention components included a discussion forum (The Forum) where participants could post about a variety of new and predefined topics such as coming out, HIV disclosure, and relationships. We used qualitative software to assist in systematically coding and thematically analyzing participant contributions about experiencing, anticipating, perpetuating and challenging in-group HIV, sexuality and racial stigma within geospatial networking apps and sexual networking site contexts.
Results: At baseline, 68.9% of participants reported searching for sexual partners on sexual networking sites in the last 3 months; 26.2% indicated at least daily use. The Forum participants discussed the strong emphasis on sex seeking in sexual networking apps and websites, sharing numerous examples of stigmatizing language describing HIV status, race, and sexuality. Participants debated the acceptability of expressing "preferences" regarding femininity vs. masculinity, sexual position, and body image and connected these preferences to an online culture that condoned stigmatization within the gay community. YBMSM recognized the stigma they experienced or anticipated in these virtual environments and articulated links to decisions about sex, condom use, and HIV status disclosure. Nevertheless, several participants felt unable to delete their app/website profiles because they served as a primary connection to the gay community.
Conclusions: YBMSM experience multiple layers of externally imposed stigma, impeding connection with other MSM for sexual or nonsexual relationships. Geospatial networking apps and sexual networking sites facilitate these connections, but in-group stigma within these virtual environments may contribute to increased risky sexual behaviors. Stigma reduction interventions that address in-group stigmas within sexual networking apps and websites may reduce sexual risk and HIV transmission.

TUPEC0770

Longitudinal analysis of sexual risk behavior, alcohol misuse and mental health disorders associated with STIs among U.S. military personnel across a shipboard deployment

J. Harbertson[1,2,3], B. Hale[1,4], N. Michael[2], P. Scott[2]
[1]Naval Health Research Center, San Diego, United States, [2]Walter Reed Army Institute of Research, US Military HIV Research Program, Rockville, United States, [3]Leidos, San Diego, United States, [4]University of California, San Diego, United States
Presenting author email: judith.harbertson.ctr@mail.mil

Background: Longitudinal sexually transmitted infection (STI) risk behavior data in mobile populations is difficult to obtain. Rates of sexual risk, alcohol misuse, mental health disorders, and other factors influencing STI acquisition may change significantly during a military deployment cycle; more accurate data on these factors may improve STI prevention. We examine factors associated with STIs before, during and after a U.S. military shipboard deployment.
Methods: Data were collected from 2012 through 2014 among active-duty U.S. Navy and Marine Corps personnel assigned to 11 deploying ships. Consenting participants completed an anonymous, paper-based survey assessing three months before deployment (T1), during the deployment (T2), and three months after deployment (T3). Questions included demographics, military history, sexual risk behavior, alcohol (AUDIT-C) and drug use, and mental health screening tools (CES-D and PCL-C). STI diagnosis was defined as a healthcare provider-diagnosed STI (chlamydia, gonorrhea, trichomoniasis, and/or syphilis). Descriptive and bivariate associations with STIs are reported for T1-T3 using t-tests and chi-square tests with statistical significance defined as p-value <0.05. Data were analyzed using SAS version 9.4. (SAS Institute, Cary, North Carolina, USA).
Results: Among participants, n=2,421(T1), n= 1,930 (T2), and n=1,444 (T3) completed the survey and reported age and sex. After excluding individuals who were not sexually active, the sample size for analysis was n=2,232 (T1), n= 649 (T2) and n=1,200 (T3). The STI prevalence was 1.5%, 6.8% and 2.3% for T1, T2 and T3 respectively among sexually active participants. Among participants reporting 2 or more sexual partners, 3% (T1), 7.7% (T2) and 5.8%(T3) of individuals also reported an STI. Among participants reporting engaging in transactional sex, 12.6% (T1), 19.9% (T2) and 22.2% (T3) also reported an STI in those respective time periods.
Conclusions: The proportion of sexually active individuals dropped to approximately 33% of all participants during T2, although those still engaging in sex during T2 had significantly higher STI rates compared to before or after deployment. Individuals who choose to remain sexually active during deployment face much higher risk of acquiring STIs and could be targeted for enhanced STI prevention and screening during this time period.

TUPEC0771

HIV risk factors and associated health outcomes among sexual minority women in the United States

J. Sherwood, A. Sharp, B. Honermann, S. Blumenthal, G. Millett
amfAR, The Foundation for AIDS Research, Washington, United States
Presenting author email: jennifer.sherwood@amfar.org

Background: Female-to-female sexual contact is an inefficient route of HIV transmission; and as such, sexual minority women have not been prioritized for HIV prevention programs. However, previous research has found high rates of sexual violence victimization, injection drug use, and lower healthcare access among sexual minority women, suggesting underlying vulnerabilities. This analysis examines sexual health outcomes and HIV risk factors among a population-based sample of sexual minority women in the United States.
Methods: 2013-2015 National Survey of Family Growth data from female respondents aged 15-44 (weighted n = 61,021,314) were analyzed. Multivariate logistic regression modeled associations between:
1) women reporting sex with women (WSW) and;
2) women identifying as lesbian, bisexual or gay (LBG), with a set of HIV and sexual health risk factors.
Results: 17.6% of U.S women (n = 10,757,319) report a same-sex experience. In adjusted analysis, WSW had increased odds of forced sex by a male, involuntary first sex, induced abortion, use of emergency contraception, and injection drug use, compared to other women.
Similar results were found among LBG women (8.5% of survey sample). WSW are more likely to have had a recent STD test, but no more likely to have HIV tests, pelvic exams, or pap smears compared to other women.

	WSW	WSW vs. non-WSW	
	%	cOR (95% CI)	aOR (95% CI)*
Ever forced sex by male	28.9	3.29 (2.59 - 4.19)	2.60 (2.03 - 3.32)
Involuntary first sex	9.7	1.82 (1.28 - 2.56)	1.67 (1.15 - 2.42)
Ever had an HIV test	80.9	1.63 (1.20 - 2.21)	1.04 (0.71 - 1.52)
STD test in past 12 months	44.5	2.11 (1.69 - 2.63)	1.51 (1.18 - 1.94)
Ever had induced abortion	32.1	2.54 (1.87 - 3.47)	2.12 (1.50 - 2.98)
Ever used emergency contraception	31.3	1.87 (1.48 - 2.37)	1.50 (1.17 - 1.92)
Pelvic exam or Pap test in past 12 months	64.0	1.24 (1.00 - 1.53)	1.02 (0.81 - 1.27)
Ever injected drugs that were not prescribed	4.6	9.61 (5.38 - 17.16)	6.33 (3.43 - 11.70)

*[*adjusted: demographic vars., # of sexual partners]*

Conclusions: Although WSW have a low risk of HIV transmission from sexual contact with women, elevated risk of sexual violence victimization, injection drug use, and proxies for unprotected sex with men including abortion and use of emergency contraception, suggest risk for STIs including HIV. Healthcare providers should understand that sexual identity does not always predict behavior, or risk, and that women who identify as LGB may still be at risk for HIV. WSW would benefit from trauma-informed medical care as well as culturally sensitive interventions that address HIV risk from injection drug use and unprotected sex with men.

TUPEC0772

Experience of sexual violence and association with HIV risk among adolescent girls and young women engaged in the DREAMS initiative in Kenya

S. Mathur[1], N. Pilgrim[1], J. Okal[2], J. Matheka[2], N. Jani[1], J. Pulerwitz[1]
[1]Population Council, HIV and AIDS Program, Washington, United States, [2]Population Council, HIV and AIDS Program, Nairobi, Kenya
Presenting author email: smathur@popcouncil.org

Background: Research shows sexual violence is associated with HIV acquisition, yet there is insufficient evidence about adolescent girl and young women's (AGYW) experiences of sexual violence and related HIV risk.
We examined the experience of sexual violence by intimate and non-intimate partners (IP vs. non-IP) among 15-24 year old women and its influence on their HIV risk perceptions and STI symptoms.
Methods: We conducted a cross-sectional survey with 914 AGYW enrolled in the DREAMS Initiative in two locations in Kenya between October and December 2016. Survey participants were randomly selected from rosters of DREAMS program beneficiaries. The survey assessed experience of sexual violence with non-IP (i.e. not boyfriend or husband) among all AGYW and sexual violence among partnered AGYW (N=574) in the last 12 months. Participants also reported on perceived risk of HIV (very /somewhat likely versus unlikely/not at all likely) and experiencing any of four STI symptoms (e.g., genital ulcer) in the last 12 months. Multivariable logistic regression analyses examined associations between experience of sexual violence (IP and non-IP) and HIV risk perception and STI symptoms. Informed consent was obtained for each respondent.
Results: Approximately 24% of all AGYW reported experience of sexual violence from non-IP and 19% reported experience of sexual violence from IP in the last 12 months. Among all AGYW, 20.4% perceived that they were at high risk of HIV. Among sexually experienced AGYW, 23.7% had experienced at least one STI symptom in the last 12 months.
Adjusted analyses show that experiencing IP or non-IP sexual violence was significantly associated with high HIV risk perception (OR_{adj}: 2.44 [1.54-3.84] and 2.68 [1.87-3.85], respectively), after controlling for age and other sociodemographic factors. Similarly, AGYW who experienced IP or non-IP sexual violence had increased odds of experiencing an STI symptom in the last 12 months (OR_{adj}: 2.23 [1.34-3.69] and 1.74 [1.13-2.66], respectively).
Conclusions: AGYW experience sexual violence from both intimate and non-intimate partners, and both experiences are associated with STI symptoms. Primary prevention programs for sexual violence are urgently needed. Further, screening for sexual violence history and provision of post-violence care is critical within HIV prevention programs for young women.

HIV risk, risk perception and uptake of HIV testing and counseling among youth men who have sex with men attending a gay sauna

T. Khawcharoenporn[1], S. Mongkolkaewsub[2], C. Naijitra[2], W. Khonphiern[2], A. Apisarnthanarak[1], N. Phanuphak[3]
[1]*Thammasat University, Infectious Diseases/Internal Medicine, Bangkok, Thailand,* [2]*Thammasat University Hospital, Pathumthani, Thailand,* [3]*The Thai Red Cross AIDS and Research Center, Bangkok, Thailand*
Presenting author email: thanak30@yahoo.com

Background: Men who have sex with men (MSM) are amongst populations at-risk for HIV acquisition in Thailand. In youth MSM (aged 13-24 years), the incidence of HIV infection has substantially increased. However, data on HIV risk, risk perception and HIV testing and counseling (HTC) uptake among youth MSM in hotspots are limited.
Methods: A 3-year prospective study was conducted among MSM attending a gay sauna in Pathumthani, Thailand during 2013-2016. HIV risk and risk perception were assessed by an anonymous survey. HTC was provided on-site with result notification within 1 hour. HIV care establishment appointment was arranged by the counselors for HIV-infected participants. Care engagement within 1 year of diagnosis was subsequently assessed.
Results: There were 358 MSM participants; 87 (24%) were youth MSM. Of these 87 youth MSM, 48% were college or university students. Comparing to other MSM, youth MSM had significantly higher median number of different sexual partner (2 vs. 1; P <0.001), were more-likely to exchange sex for money (44% vs. 9%; P <0.001) and have sexual partner who exchanged sex for money (8% vs. 1%; P <0.001). Rates of consistent condom use for anal, oral and vaginal sexes were low and not significantly different between youth and other MSM (51% vs. 61%, 26% vs. 35% and 72% vs. 61%, respectively). By using the study risk categorization tool, there were 68 youth MSM with moderate or high-risk for HIV acquisition, of which 43 (63%) had false perception of low HIV risk. Youth MSM were more-likely than other MSM to accept HTC (68% vs. 33%) and to be first-time testers (42% vs. 28%). By HTC, the rates of HIV infection were higher among youth MSM comparing to other MSM [14/59 (24%) vs. 11/89 (12%); P=0.07]. Among the 14 youth MSM newly-diagnosed with HIV infection, only 6 (43%) showed-up for continuity care.
Conclusions: Youth MSM had substantial high HIV risk, false perception of low HIV risk and low rate of care engagement but demonstrated considerable rate of HTC uptake. Strategies to improve access to HTC, risk perception and linkage to care are needed for HIV prevention and management among the youth MSM.

TUPEC0774

Epidemiology of HIV and cascade of care in 2016 in injecting drug users from 1983 to 2016 in Luxembourg

A. Fischer[1], V. Etienne[2], L. Guillorit[3], G. Biwersi[4], A. Origer[5], C. Devaux[3], T. Staub[6], V. Arendt[6]
[1]*Luxembourg Institute of Health, Clinical and Epidemiological Investigation Center, Strassen, Luxembourg,* [2]*Luxembourg Institute of Health, CIEC, Strassen, Luxembourg,* [3]*Luxembourg Institute of Health, Esch sur Alzette, Luxembourg,* [4]*Fondation Jugend-an Drogenhëllef, Luxembourg, Luxembourg,* [5]*Ministry of Health, Luxembourg, Luxembourg,* [6]*Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg*
Presenting author email: aurelie.fischer@lih.lu

Background: HIV prevention, treatment and care for injecting drug users (IDUs), as a key population, is a priority for WHO. The National Service of Infectious Diseases (NSID) follows a cohort of all HIV infected persons in Luxembourg. In this context the epidemiology of all IDUs infected by HIV from the beginning of the epidemic could be analyzed.
Methods: Our retrospective cohort study included all HIV infected injecting drug users from 1983 to 2016. Detailed informations were reviewed from patient files to characterize the IVDU cohort, the proportion of IDUs among newly HIV infected persons, and the cascade of care in this population.
Results: Since 1983, 202/1184 (17%) new HIV infections were due to injecting drugs. 152/202 (75.2%) were coinfected with HCV, 13/202 (6.4%) with HBV and 11/202 (5.5%) with HCV/HBV. 147 (72.9%) are still alive and 49 (24.5%) died. IDUs prevalence rate was estimated in 2009 at 3.9 per 1000 persons (95% CI : 3.7 - 4.0), giving an estimated number of 2224 IDUs in 2016. Based on this estimation the overall HIV prevalence rate in IDUs was 9%. Among the 147 HIV IVDUs alive, 111 (75.5%) were under ARV treatment and 96 (86.5% of the treated persons) had an undetectable viral load.
The proportion of IDUs among new HIV infections decreased from 20% in the 80's-90's to a very low rate around 2% in 2009. However, from 2011 on, this proportion increased regularly to reach 30% in 2016 and phylogenetic analyses showed that this increase was mainly due to an active cluster of 30 IDUs infected by the same virus emerging in 2013.
Conclusions: In Luxembourg 17% of all new HIV infections since 1983 were due to injecting drugs but this rate reached 30% in 2016, showing an alarming recrudescence of HIV in this population. When looking at the cascade of care, improvement could be made in the number of treated IDUs since "only" 75.5% of them were under ARV treatment. A recent and rapid increase in the proportion of IDUs among the new HIV infections was mainly due to an active cluster of IDUs infected by the same virus.

Mixed synthetic drugs and heroin use practices, drug effects, and potential risks for HIV, syphilis, and hepatitis C infections among Chinese drug users

S. Su[1], L. Mao[2], J. Zhao[3], L. Chen[3], F. Cheng[4], J. Jing[4], L. Zhang[1]
[1]*Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia,* [2]*The University of New South Wales, Sydney, Australia,* [3]*Centers for Disease Control and Prevention, Yuxi Prefecture, Yuxi, China,* [4]*Tsinghua University, Beijing, China*
Presenting author email: ssu27@student.monash.edu

Background: Mixed synthetic drugs (SDs) and heroin users have become increasingly prevalent among Chinese drug users in the past decade as the combined effects of polydrug consumption could maximise anticipated satisfaction. This study aims to identify the socio-demographic characteristics, drug-related practices, and blood-borne viruses and sexually transmitted infections among SDs users mixed use with heroin and compare differences to those sole SD and heroin users.
Methods: A total of 1,291 drug users were recruited from the national surveillance settings during 2016 in the Southwest Chinese province, which is near the "Golden Triangle" (the major drug planting and trafficking region in the world). The comparison was conducted in participants according to their drug-use categories by multivariate logistic regression.
Results: Of 1,291 participants, 447 mix-used SDs with heroin, while 526 used SDs only and 318 used heroin only. Mixed users appear to be an older population with worse socioeconomic status, longer drug use history, and consumed drugs more frequently than sole users. Individuals with monthly income below 2000 RMB (≈300 USD) almost doubled the odds of mixed drug-use (ARR=1.86, 95% CI 1.24-3.67) compared with sole-SDs users. People who initiated drug use for pleasure seeking were more likely to mix use than those occasionally use for the recreational purpose (ARR=1.89, 1.09-3.73). Long drug use history and using drug for subsequent sexual excitement were associating factors of mixed drug use (ARR=1.21, 1.12-1.32; 1.59, 1.02-2.47, respectively). Hallucination (37.1%) in sole-SDs users, hyperactivity (32.2%) in sole-heroin users, and sexual arousal (36.8%) in mixed users is the primary concern for the drug effects. Among all the drug users, mixed drug users have highest HIV (7.4%) and syphilis prevalence (2.9%), but highest HCV prevalence (49.7%) was observed in sole-heroin users. Mixed drug use was a risk factor for HIV and syphilis infections (ARR= 2.99, 1.42-8.97; 3.95, 1.43-7.04).
Conclusions: Mixed use of heroin and SDs is more frequent in older drug users and contribute to higher risk of HIV and syphilis infections. Effective interventions and drug-policy for harm and infections reduction are necessary to target an enlarging population of mixed drug users.

TUPEC0776

Potential bridging group for HIV transmission: sexual behaviors and HIV prevalence among motorcycle-taxi drivers in Cameroon (MOVIHCAM study - ANRS 12350)

H. Hidayatou[1], V. Sandres[2], V. Pente[1], G. Beninguisse[3], S. Legac[4], P. Msellati[5], P. De Beaudrap[6]

Presenting author email: hidayahindou10@yahoo.fr

Background: Ending the AIDS epidemic is now discussed, which was unthinkable a few years ago. However, such objective can be achieved only if all affected populations are identified, reached and have access to immediate antiretroviral therapy. While motorcycle-taxi drivers have been identified as a potential bridging group in the late 90s, little is known on their characteristics and sexual behaviors. This work aims to fill this gap by adding to the recently emerging body of information on HIV risk among motorcycle-taxi drivers.
Methods: A cross-sectional survey was conducted with 1411 motorcycle-taxi drivers recruited using a time-location sampling in Yaoundé, Douala, Kribi and Bertoua (Cameroon). Face-to-face interviews were realized with all participants and HIV tests administrated to a subset of them (n = 1003).

Participants characteristics were described using weighted estimators and compared to historical data (DHS and ANRS12302 study conducted respectively in 2011 and 2015). Factors associated with HIV infection were assessed using mixed-effects logistic regression.
Results: Compared to other men, motorcycle-taxi drivers reported a higher number of sexual partners and sexual relationships with commercial and casual partners.

	DHS 2011	ANRS 12302 study	Movihcam
≥2 partners in the past year	38.4% (36.0 - 40.8)	46.4% (40.9 - 51.9)	52.2% (49.2 - 55.2)
Most recent sex partner casual	5.3% (4.1 - 6.6)	2.2% (0.5 - 3.8)	8.9% (7.2 - 10.6)
Commercial sex in the past year	5.9% (4.7 - 7.0)	26.0% (21.2 - 30.7)	35.1% (31.5 - 38.7)

[Table 1.]

During their most recent relationships, 55% of them had multiple partners. Moreover, 32% reported sexual relationships with female clients in exchange of a ride. Consistent condoms use was frequent with casual partners (69.1%) or sex workers (91.9%) but less common with clients (58.9%). HIV prevalence was 2.4% (1.6 - 3.2), slightly higher than the HIV prevalence observed among men in 2015 in the ANRS12302 study (1.5%). The prevalence of HIV infection was significantly higher among participants living with their family (OR 3.8, p=0.01) and among those not owning their motorcycle (OR 3.0, p=0.01). A high proportion of the motorcycle-taxi drivers (82%) get tested for HIV at least once (DHS2011: 65%, ANRS12302: 74%).
Conclusions: Our results show that motorcycle-taxi drivers are often engaged in risky sexual behaviors and suggest they may be at increased risk of HIV infection. As the use of motorcycle-taxi is increasing in many African settings, interventions tailored to this group are urgently needed.

TUPEC0777

Joint effects of alcohol and amphetamine type stimulant (ATS) use disorders on STI acquisition in a cohort of women engaged in sex work in Phnom Penh, Cambodia

J. Evans[1], M.-C. Couture[2], A. Carrico[3], E. Stein[1], M. Sokunny[4], P. Maly[4], L. Aynar[4], S. Ngak[4], C. Sophal[5], Y. Neak[6], L. Maher[7], K. Page[8]
[1]University of California, San Francisco, San Francisco, United States, [2]University of San Francisco, San Francisco, United States, [3]University of Miami, Miami, United States, [4]FHI 360 Cambodia, Phnom Penh, Cambodia, [5]Ministry of Health, Department of Mental Health and Substance Abuse, Phnom Penh, Cambodia, [6]National Authority for Combating Drugs, Phnom Penh, Cambodia, [7]UNSW Australia, Kirby Institute for Infection and Immunity, Syndey, Australia, [8]University of New Mexico, Albuquerque, United States

Background: Female entertainment and sex workers (FESW) have high rates of alcohol consumption and ATS use, which can lead to increased sexual risk, HIV, and other negative health outcomes. We estimated the joint effects of alcohol and ATS use disorders on sexually transmitted infections (STIs) acquisition accounting for time-varying confounding.
Methods: Prospective cohort of 1,198 FESW enrolled in a HIV and stimulant use prevention intervention conducted in 10 provinces in Cambodia. Alcohol and ATS use disorders (AUD and SUD) were assessed using the Alcohol and Substance Use Involvement (ASSIST) scale. STI acquisition was defined as self-reported STI diagnosis by a medical provider in the past 3 months. Marginal structural models were used to estimate the joint effects of AUD and SUD on STI acquisition.
Results: At baseline, 25% scored >27 on the ASSIST for alcohol and 7% for ATS, screening positive for AUD and SUD respectively. Twenty-six percent reported one or more recent STIs during the 18-month follow-up. After accounting for several known confounders including sexual risk behaviors, the adjusted odds ratio (AOR) for STI acquisition associated with screening positive for AUD alone was 3.19 (95% CI: 1.84, 5.54). The AOR ratio for SUD alone was 3.79 (95% CI: 1.40, 10.23). The AOR for the joint effect of AUD and SUD was not significant (AOR = 3.24; 95% CI: 0.95, 11.11; p = 0.22).
Conclusions: Even after accounting for sexual risk taking behavior, AUD and SUD are independently associated with greater odds of STI acquisition among Cambodian FESW. Those who screened positive for SUD alone had the greatest odds of acquiring a STI over follow-up. Further research is needed to understand how AUD and SUD potentiate biological as well as behavioral pathways that influence STI acquisition in FESW. Clinical research is needed to examine if interventions to address AUD and SUD among FESW can boost the effectiveness of existing HIV prevention activities.

TUPEC0778

I am venal out of necessity, but I do not risk my life for money: factors associated with men having sex with other men in exchange for monetary/non-monetary advantages

C.H. Kounta[1], L.S. Teyssier[1,2], G. Maradan[1,2], P.-J. Coulaud[1], A. Coulibaly[3], A.A. Keita[3], B.D. Keita[3], C. Laurent[4], B. Spire[1,2], CohMSM Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Bouches de Rhône, Marseille, France, [2]ORS PACA, Marseille, France, [3]ARCAD-SIDA, Bamako, Mali, [4]Unité TransVIHMI, IRD UMI 233, INSERM U 1175, Université de Montpellier, Montpellier, France
Presenting author email: kountacheick80@yahoo.fr

Background: Men who have sex with men (MSM) are at much greater risk of HIV infection in Sub-Saharan Africa. Little is known about MSM transactional sex in Africa. We aimed to characterize MSM who had sex with other men in exchange for monetary/non-monetary advantages (MSM-SEMA).
Methods: CohMSM is an interventional cohort study of MSM in four West-African countries, including Mali. This analysis focused on Malian MSM enrolled between June 2015 and May 2016 with/without a 6-month follow-up visit. Data on socio-economic dimensions, psychosocial outcomes and sexual behaviours were collected through standardized face-to-face interviews. Three HIV risk-reduction strategy sub-scores were constructed using principal component analysis: avoidance score: avoidance of at-risk situations as a protection strategy; knowledge score: knowledge of ART-related strategies including informal PrEP, treatment as prevention (TasP) and condomless sex only with treated/undetectable viral load HIV-positive men; sero-adaptation score: avoidance of condomless sex with men known to be HIV-positive status or with unknown status. An experienced stigmatization score was also constructed.
Data analysis used a generalized estimating equation model to estimate the population-averaged effects on the probability of being an MSM-SEMA.
Results: Among the 200 participants enrolled in Mali, 149 completed the follow-up visit 6 months later. Of the total 349 visits analysed, 25.5% corresponded to participants reporting to be MSM-SEMA.
Overall, 49.6% were under 24 years old (median[IQR]=24[22-27]), and 79.1% qualified their financial situation as difficult. Declaring oneself to be MSM-SEMA was more frequently associated with younger age (OR[95%CI]: 0.6[0.4-0.9]), alcohol consumption during sex (OR[95%CI]: 6.4[1.5-27.7]), simultaneous multi-partner male sex (OR[95%CI]: 5.7[2.6-12.9]), satisfaction with current sexual life (OR[95%CI]: 4.7[1.5-15.2]), knowledge (OR[95%CI]: 5.6[1.1-29.7]) and sero-adaptation scores (OR[95%CI]: 11.9[1.2-120.3]), and an experienced stigmatization score >2 (OR[95%CI]: 2.3[1.2-4.4]). Having had one's most recent sexual encounter with one's girlfriend (OR[95%CI]: 0.4[0.2-0.9]), having had insertive anal intercourse with one's boyfriend in the previous 6 months (OR[95%CI]: 0.4[0.2-0.8]), and having an avoidance score (OR[95%CI]: 0.1[0.02-0.6]) were all associated with less frequent declaration of being MSM-SEMA.
Conclusions: Malian MSM-SEMA may not be the subpopulation most vulnerable to HIV infection as they seem better informed about risk-reduction strategies, especially informal PrEP, TasP. Tailored HIV prevention health promotion interventions for this group are needed to reduce sexual risks.

TUPEC0779

Does pre-exposure prophylaxis use lead to a higher incidence of sexually transmitted infections? A case-crossover study of men who have sex with men in Los Angeles, California

M. Beymer[1], R. Weiss[2], M. Devost[3], R. Flynn[4], R. Bolan[4], R. Landovitz[1]
[1]University of California, Los Angeles, School of Medicine, Los Angeles, United States, [2]University of California, Los Angeles, Department of Biostatistics, Los Angeles, United States, [3]Los Angeles LGBT Center, Sexual Health and Education Program, Los Angeles, United States, [4]Los Angeles LGBT Center, Research, Los Angeles, United States
Presenting author email: mbeymer@lalgbtcenter.org

Background: Pre-exposure prophylaxis (PrEP) is an effective method for reducing HIV incidence among at-risk populations. However, concerns exist over the potential for an increase in sexually transmitted infections (STIs) following PrEP initiation. This study compares STI incidence before and after PrEP initiation, within subjects among a cohort of men who have sex with men (MSM) in Los Angeles, California.
Methods: This study used data from patients who received PrEP services at the Los Angeles LGBT Center between November 2015 and October 2016 (n = 211). A generalized linear mixed model was used in a case-crossover design to determine if there was a significant difference in STIs within subjects for up to 365 days before PrEP initiation as compared to up to 365 days after. We jointly analyzed syphilis, urethral gonorrhea, rectal gonorrhea, pharyngeal gonorrhea, urethral chlamydia, and rectal chlamydia.

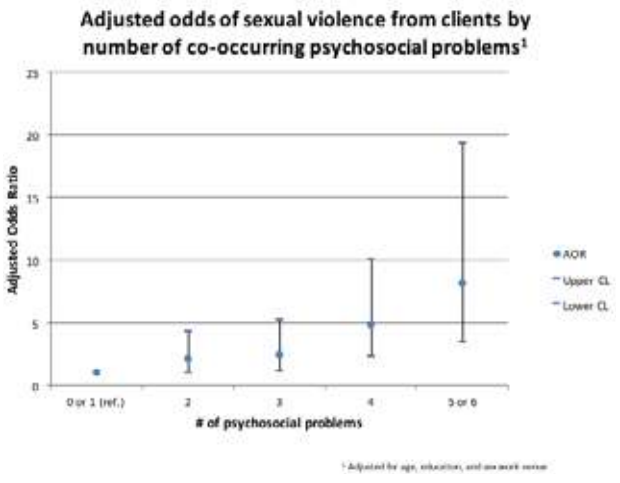
Results: Between the Before PrEP and After PrEP periods, there was a statistically significant within-subject decrease in STIs overall (p = 0.04) that differed by site/disease. Analyzing individual bodily site-STI combinations, there was a statistically significant increase between periods in syphilis (p = 0.01) as well as rectal chlamydia (p = 0.02), but no significant difference between periods in rectal gonorrhea (p = 0.63), pharyngeal gonorrhea (p = 0.48), urethral gonorrhea (p = 0.77), and/or urethral chlamydia (p = 0.62).
Conclusions: There was a statistically significant increase in syphilis and rectal chlamydia, but the remainder of STIs remained unchanged between periods. Future studies should determine whether this increase is an artifact of detection bias or represents a true increase in sexual risk behavior following PrEP uptake for this segment of users.

TUPEC0780

Syndemic psychosocial health problems associated with recent client-perpetrated sexual violence among female entertainment sex workers in Cambodia

M.-C. Couture[1], J.L. Evans[2], S. Muth[3], M. Phou[3], A. Len[3], S. Ngak[3], S. Chhit[4], Y. Neak[5], E.S. Stein[2], A.W. Carrico[6], L. Maher[7], K. Page[8]
[1]University of San Francisco, Population Health Sciences, San Francisco, United States, [2]University of California San Francisco, Department of Epidemiology & Biostatistics, San Francisco, United States, [3]FHI 360, Phnom Penh, Cambodia, [4]Ministry of Health, Department of Mental Health and Substance Abuse, Phnom Penh, Cambodia, [5]National Authority for Combating Drugs, Phnom Penh, Cambodia, [6]University of Miami, Department of Public Health Sciences, School of Medicine, Miami, United States, [7]University of New South Wales, Kirby Institute for Infection and Immunity, Sydney, Australia, [8]University of New Mexico, Division of Epidemiology, Biostatistics and Preventive Medicine, Department of Internal Medicine, Albuquerque, United States
Presenting author email: mccouture1@gmail.com

Background: Female entertainment and sex workers (FESW) are vulnerable to sexual violence, which impedes safe sex behaviors and increases the risk of HIV infection. FESW are also disproportionately affected by multiple co-occurring psychosocial health problems including substance use, depression and economic insecurity, all associated with an increased risk of exposure to violence. We used a syndemic framework to examine the additive effects of co-occurring problems on the risk of recent exposure to sexual violence among FESW in Cambodia.
Methods: Data were obtained from a sample of 1198 FESW participating in an HIV prevention program in 10 provinces in Cambodia. Women were surveyed at baseline regarding recent exposure to client-perpetrated sexual violence (prior 3 months) as well as syndemic psychological health problems (depression, alcohol use, amphetamine-type stimulant (ATS) use, housing insecurity, food insecurity and having a debt). Bivariate and multivariate logistic regression analyses were conducted.
Results: Prevalence of recent exposure to sexual violence from clients was 6.9%. Bivariate analyses showed high correlations between co-occurring psychosocial problems, and all, except ATS use, were associated with exposure to sexual violence. In multivariable models, risk of recent sexual violence increased with the number of psychosocial problems, showing an additive effect (Figure 1). Compared to those with ≤1 problem, FESW with two psychosocial problems had twice the odds (AOR=2.08; 95%CI: 1.00-4.31) and women with 5-6 psychosocial problems had eight-fold higher odds (AOR=8.10; 95%CI: 3.4-19.31) of reporting recent sexual violence from clients.



[Adjusted odds of sexual violence from clients]

Conclusions: Our findings support a syndemic model of co-occurring psychosocial problems among FESW that are associated with increased risk of recent sexual violence from clients. Effective HIV prevention interventions targeting FESW should use a comprehensive approach that takes into consideration the interconnections between these multiple co-occurring psychosocial health problems.

Social epidemiology of HIV acquisition among Afro-Caribbean immigrants post-migration: the MSAFIRI study, Canada

A. Daftary[1,2], L. Calzavara[1], W. Tharao[1,3], A. Burchell[1,4], E. Amoako[1], J. Iveniuk[1], T. Mbulaheni[5], M. Loutfy[6,7], R. Kaul[7], S.T. Ryan[8], L. Leonard[9], MSAFIRI Study Team
[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]McGill University, Epidemiology, Biostatistics & Occupational Health, Montreal, Canada, [3]Women's Health in Women's Hands CHC, Toronto, Canada, [4]Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada, [5]African and Caribbean Council on HIV/AIDS in Ontario (ACCHO), Toronto, Canada, [6]Women's College Hospital, Toronto, Canada, [7]University of Toronto, Department of Medicine, Toronto, Canada, [8]Black Coalition for AIDS Prevention, Toronto, Canada, [9]University of Ottawa, Department of Epidemiology & Community Medicine, Ottawa, Canada
Presenting author email: e.amoako@mail.utoronto.ca

Background: In high-income countries, HIV prevalence is disproportionately high among immigrants originating from HIV-endemic countries. Yet, the extent and drivers of infection after migration are unknown. The MSAFIRI Study uses mixed-methods to characterize the social epidemiology of HIV acquisition among African, Caribbean and Black (ACB) immigrants in Canada.
Methods: Socio-demographic data from a province-wide clinical cohort of 825 ACB adults attending HIV care in Ontario were analyzed to identify those who were born abroad and infected post-arrival. Interviews with a purposive sub-sample were qualitatively analyzed to understand the circumstances of sexually acquired infections post-arrival.
Results: The time of HIV acquisition could be established in 349 ACB adults born abroad (mean age 38y, 57% female); 80% were infected pre-arrival and 20% post-arrival. Persons born abroad and infected post-arrival were significantly more likely to be from the Caribbean (61.4 vs. 16.9%), male (62.9 vs. 38%), identify as gay/bisexual (37.1 vs. 10.4%), and report MSM transmission (32.9 vs. 10.8%), compared to persons infected pre-arrival; age was not a factor. Post-arrival MSM transmission was akin to the general Canadian population, but heterosexual transmission was significantly higher. Interviews with 32 participants (50% female, 34.4% gay/bisexual, 43.8% born in Africa, 56.2% born in the Caribbean) helped to contextualize the determinants of HIV acquisition in Canada: 1) Difficulties assimilating under a racialized, migrant identity post-arrival left most participants detached from traditional social networks. 2) HIV was perceived to affect people of colour in participants' countries of origin but not "white" people. 3) Men's sexual activities were governed by a desire to explore multiple, novel (often, biracial) partnerships, where they felt immune to HIV. 4) Women's sexual encounters were governed by a dependency on their partners, leaving them unable to assert agency. 5) Heterosexual encounters stemmed from long-term monogamous partnerships, whereas MSM encounters were casual.
Conclusions: Risk misperceptions and inequities of race, gender and social capital - emergent in interviews and supported by epidemiological analyses - suggest a reconstructed vulnerability to HIV among Afro-Caribbean immigrants in Canada. Prevention strategies must address the unique, intersecting drivers of HIV acquisition post-migration in persons moving from HIV-endemic countries to countries of perceivably lower risk.

TUPEC0782

High prevalence of HIV and sexually transmitted infections, along with high rate of unprotected sex, among Thai MSM and TG who reported no or low self-perceived risk level for HIV

S. Pengnonyang[1], J. Jantarapakde[1], D. Trachunthong[1], T. Sungsing[1], P. Rodbamrung[1], P. Mingkwanrungruang[1], W. Sirisakyot[1], S. Tongmuang[1], S. Jarupittaya[1], N. Mahachokchai[2], P. Yokchawee[2], S. Samalu[3], M. Uthaikorn[3], P. Potasin[4], W. Champa[5], P. Patpeerapong[6], S. Mills[7], S. Charoenying[7], P. Phanuphak[1], M. Cassell[8], R. Vannakit[8], N. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]The Service Workers In Group Foundation, Bangkok, Thailand, [4]Sisters Foundation, Chonburi, Thailand, [5]Caremat Organisation, Chiang Mai, Thailand, [6]Mplus Foundation, Chiang Mai, Thailand, [7]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [8]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: Self-perceived risk is a significant factor associated with health-seeking behaviors, including the pursuit of HIV testing and counselling. However, discrepancies between self-perceived risk and actual risk can result in less-than optimal coverage of HIV services and allocative inefficiency. We investigated correlations between self-perceived risk and HIV and STI among MSM and TG in Thailand.
Methods: Baseline data was collected from May 2015 to September 2016 using self-administered questionnaires and HIV/STI (syphilis/gonorrhea/chlamydia) testing from MSM and TG enrolled in a cohort study in six community sites in Thailand. Based on their responses, participants were stratified into four categories of perceived HIV risk (no risk, low risk, moderate risk, and high risk). Participant characteristics and prevalence of STI/HIV infection were compared with self-perceived risk levels using Chi-square test. The associations between self-perceived risk and other factors were analyzed by logistic regression.
Results: Of 2468 individuals (70.6% MSM and 29.4% TG) with a mean (±SD) age of 26.8 (7.2) years, 17.9% reported high self-perceived HIV risk, 32.0% moderate, 37.7% low and 11.2% none. Logistic regression identified age >25 years (OR 1.32, 95%CI 1.07-1.64, p=0.009), knowing someone with HIV infection (OR 1.55, 95%CI 1.27-1.89, p< 0.001), having multiple partners in the past six months (OR 2.24, 95%CI 1.76-2.84, p< 0.001), unprotected sex (OR 2.29, 95%CI 1.83-2.87, p< 0.001),
STI (OR 1.80, 95%CI 1.23-2.66, p< 0.001) and group sex (OR 2.22, 95%CI1.68-2.93, p< 0.001) to be associated with increasing level of self-perceived risk.
In high, moderate, low and no risk groups, HIV prevalence was 23.9%, 17.4%, 11.7% and 8.9%
(p< 0.001), while STI prevalence was 39.5%, 35.2%, 30.8% and 26.8% (p=0.001), respectively. Of those who reported no/low risk, their actual risk behaviors were: multiple partners (33.2% and 50.3%), unprotected sex (61.1% and 74.2%), group sex (3.2% and 8.4%), and STI symptoms/diagnosis
(11.4% and 27.4%) in the past six months.
Conclusions: Self-perceived HIV risk positively correlated with the likelihood of having HIV/STI infections. However, self-perceived no/low risk groups exhibited high-risk sexual behaviors. Improved self-assessment skills and more strategic behavior change communication interventions to MSM and TG need to be strengthened to improve uptake of HIV/STI testing in these populations.

TUPEC0783

The portrait of HIV prevalence, risk behavior and HIV prevention response on population men who have sex with men (MSM) in Indonesia 2007-2013

I.F. Lestari Doloksaribu
Country Coordinating Mechanism Indonesia, Jakarta Selatan, Indonesia
Presenting author email: irmadoloksaribu@gmail.com

Background: The prevalence of HIV in Men who have sex with Men (MSM) populations in Indonesia continued to increase, while access to HIV treatment services in this group is low. The HIV burden in most provinces in Indonesia is concentrated in "most at risk" populations and is generalized in Papua and West Papua provinces. Estimates of the prevalence of HIV in 2012 in the general population in Indonesia is 0.4%, while in Papua 2.3%. Men sex with men is one of the key populations at higher risk of contracting HIV than men in the general population. Estimates MSM population in Indonesia by 2012 of 81.338 people.
Methods: The method is a descriptive study using the Integrated Biological and behavioral surveillance (IBBS) by Ministry of Health (MOH) Indonesia (2007,2009,2011,2013), Sero-Surveillance and Behavioral Quick Surveillance by MOH and National AIDS Commission(NAC) (2013), MSM and Transgender Program Studies in Indonesia by MOH and NAC (2013) and Impact Analysis Studies by NAC (2015).
Results: Based on the results of IBBS in 2007-2013 and the Sero Surveillance results of 2013, the prevalence of HIV in the MSM population in Indonesia is increasing. The prevalence on 2007: 5.3%, 2008 : 5.48%, 2009 :7%, 2013:13.6% and 2013:17.3%. For MSM Risk Behavior (the consistency of condom usage) on 2007 :27%, 2011 :33%, 2013 : 31%. Indonesia response for HIV prevention on MSM: Presidential Decree No.75/2006, National Strategy and Action Plan 2010 - 2014 for MSM, MSM community strengthening, Fund for HIV prevention in MSM community is USD17.379.143 in 2011 and USD23.692.860 in 2012.
Conclusions: HIV prevalence in MSM increased between the years 2007-2013 at 5% in 2007 to 17.3% in 2013. On the other survey locations in 2009 by 7% to 12.8% in 2013. Risk behaviors in MSM that may increase the risk of HIV is low proportion of MSM use condoms consistently. Strengthening policies and programs have been conducted, but the effectiveness of the program to achieve the impact of the epidemic is not yet fully meet the expectations where the HIV prevalence among MSM increased by more than 100%. More than 50% of the funding is still sourced from abroad.

Statistical adjustment of network degree in respondent-driven sampling estimator venue attendance as a proxy for personal network size among young MSM

K. Fujimoto[1], M. Cao[1], L. Kuhns[2], D. Li[1], J. Schneider[3]
[1]University of Texas at Houston, Health Promotion and Behavioral Sciences, Houston, United States, [2]Northwestern University Feinberg School of Medicine, Pediatrics - Adolescent Medicine, Chicago, United States, [3]University of Chicago, Department of Medicine, Chicago, United States
Presenting author email: jschnei1@medicine.bsd.uchicago.edu

Background: Respondent-driven sampling (RDS) is widely used to sample hard-to-reach populations, such as men who have sex with men (MSM), and to estimate the prevalence of disease and risk/protective behaviors. Use of RDS among young MSM (YMSM), however, poses challenges that make RDS estimates using the standard degree measure suspect.
The objective of the current study is to introduce a statistical approach to adjust the standard degree measure of self- reported network size, which is then applied to respondent-driven sampling (RDS) estimators.
We propose a new network degree measure based on approximated frequencies of venue attendance.
Methods: We recruited 729 Young men who have sex with men (YMSM) aged 16-29 in 2014-2016 in Chicago, IL, and Houston, TX, and estimated the population seroprevalence of HIV and syphilis, risk behavior, and protective behavior by computing and comparing RDS estimates adjusted by the standard degree measure, a venue-informed degree measure, and the unadjusted sample estimates.
Results: The results indicate that RDS estimates adjusted by a venue-predicted degree tend to be more efficient (smaller variance) than adjustment by the standard self-reported network size for RDS population estimates in both cities sampled.
Conclusions: Venue attendance may provide a more reliable degree measure for RDS estimates of outcomes of interest, which can then be used to better design HIV-prevention interventions that target hard to reach populations such as YMSM.

Characteristic	Percentage (n) or Mean (SD; Min, Max) Chicago (N = 373)	Percentage (n) or Mean (SD; Min, Max) Houston (N = 356)
Age	24.3 (2.8; 17, 30)	24.8 (2.9; 17, 30)

VCT data to estimate HIV incidence among key populations, Ho Chi Minh City, Vietnam

N. Nguyen[1], M. Ackers[2], T. Nguyen[3], P. Le[3]
[1]US CDC Vietnam, DGHT, Ho Chi Minh, Vietnam, [2]US CDC Vietnam, Ho Chi Minh, Vietnam, [3]Ho Chi Minh City AIDS Control Center, Ho Chi Minh, Vietnam

Background: Accurate estimates of HIV incidence are crucial to evaluate program impact. VCT program cohort data can help produce incidence estimates and determine program priorities among key populations (KP) including men who have sex with men (MSM), people who inject drugs (PWID), and female sex workers (FSW).
Methods: We reviewed data from a retrospective cohort of clients at 25 VCT sites in Ho Chi Minh City during 2006-2015. Routine program data were analyzed from clients who reported ≥2 HIV tests ≥3 months apart whose first test result was negative. To calculate person-years of exposure, non-seroconverters contributed the time between the first and last tests; seroconverters contributed the time between the first test and the estimated date of seroconversion (midpoint between the last negative and first positive test). HIV incidence rate (IR) and 95% Confidence Intervals (CI) were calculated.
Results: Among 273,313 tests performed, 33,782 repeat testers with a documented initial HIV negative test contributed 27,509 person-years (py). Median time between tests was 218 days; 13,007 (39%) repeat testers self-identified as KP.
Of 769 seroconverters, 272 (35%) were PWID; 111 (26%), MSM; and 45 (6%), FSW. Overall HIV IR was 2.8 seroconversions per 100 py (95% CI: 2.6 to 3.0) and was highest in 2006 at 9.7 per 100 py, fell annually to 2.5 per 100 py in 2010 and then stabilized.
Among KP subgroups, IR was 5.0 per 100 py (95% CI: 4.2-6.1) among MSM, 4.3 per 100 py (95% CI: 3.8-4.8) in PWID, and 1.7 per 100 py (95% CI: 1.2-2.3) among FSW. IR patterns over time varied among subgroups.

Year	No of tested	No of sero-conversions	Person-years	Incidence rate (95% CI)			
				All clients	PWID	MSM	FSW
2006	795	61	627	9.7 (7.4 - 12.5)	27.6 (17.5 - 41.5)	8.9 (0.2 - 49.7)	2.4 (0.1 - 13.1)
2007	1,585	79	1,199	6.6 (5.2 - 8.2)	25.2 (18.3 - 33.9)	6.3 (1.7 - 16.1)	5.6 (1.5 - 14.3)
2008	2,568	73	2,024	3.6 (2.8 - 4.5)	7.0 (4.5 - 10.4)	0.0 (0.0 - 8.2)	2.2 (0.5 - 6.4)
2009	4,435	133	3,513	3.8 (3.2 - 4.5)	7.8 (5.9 - 10.0)	3.0 (0.6 - 8.8)	1.6 (0.5 - 3.7)
2010	5,354	104	4,211	2.5 (2.0 - 3.0)	5.2 (3.7 - 7.0)	2.2 (0.8 - 4.9)	2.0 (1.0 - 3.7)
2011	4,231	76	3,410	2.2 (1.8 - 2.8)	3.7 (2.4 - 5.6)	4.7 (2.2 - 8.6)	4.5 (2.3 - 7.8)
2012	3,303	43	2,726	1.6 (1.1 - 2.1)	2.6 (1.4 - 4.5)	2.4 (0.9 - 5.1)	0.9 (0.1 - 3.2)
2013	3,972	81	3,422	2.4 (1.9 - 2.9)	1.9 (1.2 - 3.0)	7.2 (4.7 - 10.6)	1.0 (0.2 - 2.8)
2014	3,718	56	3,246	1.7 (1.3 - 2.2)	1.3 (0.7 - 2.3)	4.5 (2.8 - 6.7)	0.6 (0.1 - 2.0)
2015	3,821	63	3,130	2.0 (1.5 - 2.6)	1.1 (0.5 - 1.9)	8.6 (5.9 - 12.1)	0.7 (0.1 - 2.1)
Total	33,782	769	27,509	2.8 (2.6 - 3.0)	4.3 (3.8 - 4.8)	5.0 (4.2 - 6.1)	1.7 (1.2 - 2.3)

[Table: HIV incidence rate among repeat testers by KP group, HCMC, 2006-2015]

Conclusions: From 2006-2015, PWID and FSW demonstrated substantial drops in IR. After initially declining, IR among MSM may be increasing in recent years. Targeted prevention efforts, like PrEP, will be required to reduce incidence further, especially among MSM.

TUPEC0786

Outsider or farmer? Deconstructing the role of migration in the HIV risk of Chinese men who have sex with men

C. Liu[1], R. Fu[1], W. Tang[1,2,3], B. Cao[1], C. Wei[4], J. Tucker[1,2], K. Smith[1]
[1]University of North Carolina at Chapel Hill Project-China, Guangzhou, China, [2]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, [3]Guangdong Center for Skin Diseases and STI Control, Guangzhou, China, [4]University of California, School of Medicine, San Francisco, United States
Presenting author email: chuncheng@seshglobal.org

Background: Migration of men who have sex with men (MSM) from rural to urban areas is common across low- and middle-income countries, and is widely believed to explain elevated HIV risk among migrant MSM. Little consensus exists on whether their risk is due to their transplantation or their being from economically disadvantage rural areas. This study examined HIV risk associated with each of these two migration characteristics - transplantation and being of an economically disadvantaged rural background - to compare the association of each strategy with measures of HIV risk.
Methods: In July 2016, MSM ≥ 16 years old currently residing in one of eight urban cities in China were recruited for an online cross-sectional survey, which collected information on socio-demographics, sexual behaviors, HIV care seeking behaviors, and health services utilization. Based on several questions about residency status, each participant was classified as being either a local or a non-local, and as an urban or a rural person. Multivariable logistic regression was used to examine the associations between risky behaviors and health care utilization and the two migration characteristics.
Results: 2,007 eligible MSM participated, about two thirds (67%, n=1,359) of whom were non-local and half (44%, n=881) of whom were from rural areas. Non-locals differed from locals only in their likelihood of having ever HIV tested (adjusted odds ratio [aOR]=0.72, 95% confidence interval [CI]: 0.55-0.93), rural MSM were less likely to have ever purchased sex (aOR=0.51, 95%CI: 0.34-0.77), to have ever disclosed same-sex behaviors to a healthcare provider (aOR=0.65, 95%CI: 0.51-0.82), to have ever been HIV tested (aOR=0.65, 95%CI: 0.51-0.82), and among those who were HIV positive, to have ever initiated antiretroviral therapy (aOR=0.22, 95%CI: 0.07-0.66), as compared to their urban counterparts.
Conclusions: Migrant status as defined by urban/rural status was a far more salient predictor of HIV associated risk behaviors as compared to transplantation status. Elevated risk of HIV infection in migrants most likely stems more from their lack of social and economic resources rather than from individual behaviors. Health policy efforts to address service gaps faced by these MSM must focus on structural as well as individual level barriers.

TUPEC0787

Studying the most marginalized hijra/transgender population for burden of HIV related risk behavior, HIV prevalence and utilization of related HIV services in India

P. Kumar, B. Sangal, N. Dhingra, M. Zainab
National AIDS Control Organization, Strategic Information Management Unit, New Delhi, India
Presenting author email: drpradeep2014@gmail.com

Background: Hijra/Transgender (H/TG) people are one of the most vulnerable group to HIV epidemic. We aimed to characterize the socio-demographic status, high-risk behaviors, HIV prevalence and the related care continuum among H/TG people in India.
Methods: A cross-sectional probability-based survey enrolled 4,966 self-identified H/TG in 14 districts selected districts from eleven states in India. The H/TG population was reached with the active involvement of Gurus and Nayak. The sociodemographic status, sexual behavior, and utilization of HIV/AIDS related services were assessed using a structured questionnaire. Blood samples were tested for HIV and the prevalence was estimated by the presence of anti-HIV antibodies.
Results: The mean age of respondents was 29 years (IQR 23-32); most were literate and never married (89% and 79% respectively). More than half (55%) were engaged in selling sex and had a variety of sex (penetrative: 91%, oral: 66%, manual: 45%) with clients. Consistent condom use with paying client was 52%. Alcohol consumption during the 12 months preceding the survey was reported by 57% of respondents; 55% of them reported doing so before or during last sex act. 4% reported drug injection for non-medical purposes. Four fifth (81%) of them were at

least once tested for HIV while 40% received comprehensive package of prevention services. Weighted HIV prevalence was 7·5%; correlates of HIV infection included higher age group, being sex worker and exposure to HIV/AIDS programme. Of the 359 H/TG people that were HIV antibody positive, 281 (78%) were ever aware of their status while 255 (71%) were aware of ART. Awareness of HIV positive status was significantly associated with exposure to HIV/AIDS programme.
Conclusions: The high burden of HIV related risk behavior and HIV infection among H/TG people is an area of concern. The programme need to scale up its coverage through the comprehensive package of services in the population. Failure to do so may lead to rising prevalence not only in the population itself but also to general population through the clients as significant proportion of them are also engaged in sex work.

TUPEC0788

Lower HIV prevalence and incidence despite greater demographic and behavioral risks among transgender women when compared to MSM in community-based test and treat cohorts in Thailand

P. Seekaew[1], T. Nakpor[2], S. Pengnonyan[1], J. Jantarapakde[1], S. Keadpudsa[1], R. Reankhomfu[3], D. Lingjongrat[4], S. Janyam[5], T. Sungsing[1], P. Rodbumrung[1], S. Charoenying[6], S. Mills[6], M. Cassell[7], P. Phanuphak[1], R. Vannakit[7], N. Phanuphak[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Sisters Foundation, Chonburi, Thailand, [3]Caremat Organization, Chiang Mai, Thailand, [4]Rainbow Sky Association of Thailand, Bangkok, Thailand, [5]Service Workers In Group Foundation, Bangkok, Thailand, [6]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [7]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand
Presenting author email: jureepornj@trcarc.org

Background: Globally, HIV acquisition risk is 49 times higher in transgender women (TG) and is 24 times higher in men who have sex with men (MSM) than in the general population. More than half of all new HIV infections annually in Thailand occur among MSM and TG women. Better understanding of the gender-specific risks and epidemiologic profiles of Thai MSM and TG is needed to inform programming.
Methods: Baseline data were collected from May 2015 to September 2016 using self-administered questionnaires and HIV/STI (syphilis/gonorrhea/chlamydia) testing from MSM and TG aged ≥18 years enrolled in a cohort study in six community sites in Thailand. HIV testing was performed at least every six months for 18 months. Factors associated with gender-specific HIV prevalence and HIV incidence were determined by logistic regression and Cox proportional hazard analyses, respectively.
Results: Of 1,763 MSM and 734 TG enrolled, mean (SD) ages were 26.4 (7.2) and 25.9 (6.6) years, respectively. TG had lower education (15.7%vs.31.7% with college degree or higher, p<0.001) and lower income (41.7%vs.49.5% >288 USD/month, p<0.001) than MSM.
In the past six months, high proportions of TG and MSM had unprotected sex (66.1%vs.70%, p=0.17) and multiple partners (74.7%vs.72.8%, p=0.71), but more TG practiced anal receptive sex (91.2%vs.61.3%, p<0.001).
HIV prevalence among MSM was 18.15% (95%CI:16.38-20.03) and was associated with: previous HIV testing (OR:0.39; 95%CI:0.28-0.54; p<0.001), self-perceived HIV risks (OR:4.20; 95%CI:1.79-9.85; p<0.001); and having STI (OR:3.09; 95%CI:2.26-4.22; p<0.001).
HIV prevalence among TG was lower at 8.99% (95%CI:7.02-11.30, p<0.001) and associated with: not attending college (OR:3.87; 95%CI:1.14-13.15; p=0.01), previous HIV testing (OR:0.42; 95%CI:0.23-0.75; p<0.01), and having STI (OR:2.71; 95%CI:1.53-4.79; p<0.001).
HIV incidence in MSM was 3.16 per 100 person-years (95%CI:2.00-4.74) and associated with previous STI (HR: 2.86; 95%CI:1.72-4.76; p<0.001). TG had lower HIV incidence (1.13 per 100 person-years, 95%CI:0.31-2.89, p=0.02) than MSM.
Conclusions: TG in Thailand had lower HIV prevalence and incidence than MSM despite having higher demographic and behavioral risks. This finding is contradictory to previous studies, suggesting that sexual networks of MSM and TG in Thailand need to be urgently analyzed to better strategize HIV prevention programs.

Unmet stigma mitigation needs among female sex workers in six countries across sub-Saharan Africa

C. Lyons[1], B. Liestman[2], S. Ketende[1], F. Drame[3,4], D. Diouf[4], I. Njindam[5], G. Turpin[1], K. Coly[2], S. Schwartz[1], A. Rao[1], F. Yang[1], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Dakar, Senegal, [3]Gaston Berger University, Saint-Louis, Senegal, [4]Enda Santé, Dakar, Senegal, [5]Johns Hopkins Bloomberg School of Public Health, Yaounde, Cameroon
Presenting author email: clyons8@jhu.edu

Background: Even in the context of more generalized HIV epidemics across Sub-Saharan Africa (SSA), female sex workers (FSW) bear a disproportionate burden of HIV. While stigma measurement and programming has traditionally focused on HIV-related stigma and stigma affecting gay men and other men who have sex with men, understanding the burden of sex-work-related stigma has direct implications for the implementation of both HIV prevention and treatment programs. Consequently, this study aims to estimate the prevalence of stigma among FSW in 6 countries in SSA, and the association between HIV infection and stigma.
Methods: Biological HIV testing and socio-behavioral questionnaires were conducted with 5253 FSW in Burkina Faso (N=699), Cameroon (N=2272), Cote d'Ivoire (N=466), Senegal (N=758), South Africa (N=410), and Togo (N=648). Participants were recruited via respondent driven sampling between 2013-2016. Consistent stigma metrics were used in each setting measuring social stigma, healthcare-related stigma, and enacted community stigma. Logistic regression was used to assess associations between HIV and stigma.
Results: Pooled HIV prevalence is 22.3% (1174/5253), with prevalence reported by country in Table 1. HIV infection was significantly associated (Table 2) with exclusion from family activities (Odds Ratio [OR]:1.4;95% Confidence Interval [CI]:1.2-1.7; p<0.001); rejection from friends (OR:1.5;95% CI:1.2-1.8 ; p<0.001); healthcare services avoidance (OR: 0.7;95% CI:0.6-0.9; p=0.003); police refusal of protection (OR:1.5;95% CI:1.3-1.8; p<0.001); verbal harassment (OR:1.4;95% CI:1.2-1.6; p<0.001); blackmail (OR:1.2;95% CI:1.1-1.4; p=0.004); physical violence (OR:1.4;95% CI:1.2-1.6; p<0.001); and forced sex (OR:1.2;95% CI:1.0-1.4; p=0.014).
Conclusions: Prevalence of social stigma, healthcare-related stigma, and enacted community stigma is high among FSW in SSA. Given the association between stigma and HIV, upstream determinants of HIV must be identified and targeted through stigma mitigation interventions adapted to the specific needs of FSW to effectively address HIV risk and HIV-related outcomes.

	Burkina Faso (N=699)	Cameroon (N=2272)	Cote d'Ivoire (N=466)	Senegal (N=758)	South Africa (N=410)	Togo (N=648)

TUPEC0790

Trends in HIV infection diagnoses among men who have sex with men, overall and by state, United States, 2008-2014

A.M. Oster, T. Tang, H.I. Hall
Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States
Presenting author email: aoster@cdc.gov

Background: The U.S. National HIV/AIDS Strategy recommends intensification of prevention efforts in communities where HIV is most highly concentrated and establishes targets for reducing diagnoses among key populations, including men who have sex with men (MSM). Although trends in diagnoses among subgroups of MSM have been examined nationally, HIV risk, testing, and prevention behaviors vary geographically, and HIV prevention is typically delivered at a state or local level. We analyzed trends in HIV diagnoses among subgroups of MSM in the United States by state.
Methods: Using National HIV Surveillance System data submitted through June 2016 and adjusted for missing risk information, we determined the annual number of diagnoses among MSM during 2008-2014, overall and by race/ethnicity and age group. To examine trends, we calculated estimated annual percent change (EAPC) for each subgroup, nationally and for each state and the District of Columbia. We present significant increases or decreases ($p < 0.05$), given ≥12 diagnoses per year.
Results: The number of diagnoses among MSM decreased slightly during 2008-2014 (Table). Diagnoses increased among Hispanic/Latino MSM and MSM aged 13-24 y or 25-34 y and decreased among white MSM and MSM aged 35-44 y or 45-54 y. Findings were heterogeneous by state, with 7 states experiencing increases in diagnoses among MSM and 12 experiencing decreases. Notably, diagnoses among Hispanic/Latino MSM increased in 7 states and did not decrease in any states. Diagnoses among MSM aged 13-24 y and 25-34 y increased in 16 and 18 states, respectively.

	2008 diagnoses	2014 diagnoses	EAPC	P-value	No. areas* with increase	No. areas* with decrease	No. areas* with no significant change	No. areas with small cells†
All MSM	27,026	26,637	-0.4	<.01	7	12	26	6
Black MSM	10,018	10,173	-0.1	0.7	8	6	20	17
Hispanic/Latino MSM	6,071	6,907	2.0	<.0001	7	0	24	20
White MSM	9,280	7,950	-2.6	<.0001	1	14	30	6
MSM aged 13–24 y	6,097	7,300	2.6	<.0001	16	3	16	16
MSM aged 25–34 y	7,703	9,182	2.8	<.0001	18	1	20	12
MSM aged 35–44 y	7,138	4,804	-6.9	<.0001	0	23	13	15
MSM aged 45–54 y	4,433	3,690	-3.0	<.0001	0	7	28	16
MSM aged 55–64 y	1,330	1,305	0.3	0.7	0	0	21	30
MSM aged ≥65 y	326	361	2.7	0.3	0	0	4	47

[Table.]

Conclusions: Sub-national trends indicate that achieving national goals to reduce diagnoses will require intervention in a large number of states, with a focus on young, Hispanic/Latino, and black MSM. This analysis also identified states with successes in reducing HIV transmission, which may offer lessons learned.

TUPEC0791

Population size estimates of key populations at risk for HIV infection: men who have sex with men, female sex workers and people who inject drugs in multiple districts of Zambia

R. Keating[1], H.F. Raymond[1,2], M. Musheke[3], N. Pilgrim[4], H. Witola[5], J. Mulwanda[5], L. Banda[3], D. Mulenga[3], L. Phiri[3], S. Geibel[4], W. Tun[4]
[1]University of California, Global Health Sciences, San Francisco, United States, [2]San Francisco Department of Health, San Francisco, United States, [3]Population Council, Lusaka, Zambia, [4]Population Council, HIV and AIDS Program, Washington, United States, [5]National AIDS Council, Lusaka, Zambia
Presenting author email: mmusheke@popcouncil.org

Background: Size estimates of populations at higher risk for HIV infection are needed to help policy makers understand the scope of the epidemic and tailor appropriate interventions. Population size estimates of men who have sex with men (MSM), female sex workers (FSW) and people who inject drugs (PWID) are few or non-existent Zambia.
Methods: In conjunction with a formative assessment of HIV risk factors among key populations, we conducted population size estimation of MSM, FSW and PWID in multiple districts of Zambia using two integrated methods: enumeration and desk review. Enumeration occurred in two steps: first a collection of potential venues where population members are known to congregate and then a direct count of these population members at a number of sites. Desk review consisted of a literature review of previously published data on the prevalence of key populations in regions similar to Zambia, which was applied to recent census figures to obtain age-adjusted estimates. Population size estimates were made for FSW in 9 municipalities, while MSM and PWID estimates were formed for 5 and 3 municipalities, respectively.
Results: For enumeration, a total of 410 FSW, 143 MSM and 73 PWID venues were identified from KIIs; direct counts of these venues yielded an estimated 13,199 FSW, 4,211 MSM and 2,909 PWID. For desk review estimates, we used the lower quartile value of the range of each population occurrence in Africa as described in the literature (2.8% FSW, 1.2% MSM and 0.3% PWID) with national census data to obtain an estimated 23,015 FSW, 8,857 MSM and 1,652 PWID living in the selected sites. Enumeration and desk review estimates form our lower and upper range values respectively, with an overall median estimate of 18,107 FSW, 6,534 MSM and 2,281 PWID in the selected municipalities.
Conclusions: These estimates may be useful to advocate for and to plan, implement and evaluate HIV prevention and care programmes for MSM, FSW and PWID. Given potential biases, these estimates should be triangulated with additional size estimation methods, including multiplier methods, capture-recapture and wisdom of the crowds.

TUPEC0792

HIV prevalence and characteristics of men who have sex with men in the metropolitan region of Chile

V. Stuardo Ávila, M. Fuentes Alburquenque, J. Belmar Prieto
Escuela de Salud Pública, Facultad de Medicina, Universidad de Chile, Santiago de Chile, Chile
Presenting author email: valeria.stuardo@gmail.com

Background: In Chile, the rate of people living with HIV in 2014 reached 9.6 x 100,000 inhabitants, in the Metropolitan Region (MR) is more than 50 x 100,000 inhabitants. Chile currently has an epidemic concentrated in men who have sex with men (MSM). Second-generation HIV surveillance is not established in the country and the preventive social policies are limited. The objective of this study was to determine the prevalence of HIV in MSM in the Metropolitan Region and describe their behavioral, sociodemographic and clinical-epidemiological characteristics.
Methods: Cross-sectional study. The population was MSM living in the MR. The Responding Driven Sampling (RDS) sampling method was used. The HIV prevalence was performed through the ABON ™ HIV 1/2 / O Tri-Line Human Immunodeficiency Virus Rapid Test (Biopharm Hangzhou Co., Ltd.), all positive cases were confirmed with the Enzyme test -Linked ImmunoSorbent Assay (ELISA). A questionnaire adapted and validated for the Chilean population was applied. Data analysis included descriptive analysis, quantitative characteristics will be described using the median and interquartile range (IR), and qualitative characteristics by percentages. All ethical aspects were considered during the study.
Results: 375 men were recruited. The median age was 24 years (minimum 18, maximum 69). There were 52 HIV positive cases, which correspond to a prevalence of 17.6%; between 25-34 years the prevalence was 25.1%. Most cases of low-middle socioeconomic level. 41.7% of the participants did not use the condom with their casual partners in the last 6 months. 28.0% had not had an HIV test in the past 12 months. The majority of subjects (60.0%) had no access to HIV / STI preventive information or received condoms (42.0%) in the last 12 months, which are higher in HIV-positive men.
Conclusions: The prevalence of HIV found in MSM shows a reemergence of HIV in Chile. Cases are concentrated in young men younger than 35 years. Low access to condoms and testing is observed. Sexual education is necessary, including gender and cultural relevance. Prevention programs are insufficient and are not reaching the populations that most need it. Focused preventive interventions such as peer education and access to community testing are required.

TUPEC0793

HIV, serostatus knowledge, and viral load suppression among female sex workers in Kampala, Uganda, 2012: a respondent-driven sampling survey

R.H. Doshi[1,2], E. Sande[3], M. Ogwal[4], H. Kiyingi[3], J. Kusiima[4], A. McIntyre[2], W. Hladik[2]
[1]Centers for Disease Control and Prevention, Epidemic Intelligence Service, Atlanta, United States, [2]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [3]Centers for Disease Control and Prevention, Division of Global HIV and TB, Entebbe, Uganda, [4]Makerere University, School of Public Health, Kampala, Uganda
Presenting author email: reenahdoshi@gmail.com

Background: The Joint United Nations Programme on HIV and AIDS (UNAIDS) set global targets for 2020, aiming for 90% of people living with HIV to know their serostatus and for 73% to have viral load suppression (VLS). We investigated progress towards these targets among female sex workers (FSW) in Kampala, Uganda, who bear a disproportionate burden of HIV.

Methods: Between April and December 2012, FSW, defined as women, 15-49 years, residing in greater Kampala, and selling sex for money in the last 6 months, were recruited using respondent-driven sampling (RDS). Venous blood was collected for HIV testing according to Uganda's national serial rapid test algorithm and for VL testing (VLS defined as <50 copies/mL). We collected data using audio computer-assisted self-interviews. Weighted population estimates were calculated using RDS Analyst software.
Results: Sampling was initiated with 4 respondents; 1,487 FSW were enrolled over 25 recruitment waves; median age was 27 years (interquartile range: 23 to 32). HIV seroprevalence was 31.4% (95% confidence interval [CI]: 28.7-34.0%). Among HIV-positive FSW, serostatus knowledge was 26.5% (95% CI: 21.7-31.4%) and VLS was 21.6% (95% CI: 16.2-27.0%). Assuming that all FSW with VLS know their serostatus yielded a corrected serostatus knowledge estimate of 37.5% (95% CI: 32.4-42.6%).
Conclusions: HIV prevalence among Kampala FSW is high, whereas serostatus knowledge and VLS are far below UNAIDS population-level targets. The high population prevalence of unsuppressed VL suggests substantial risk of transmission to partners and clients. FSW in Kampala are in need of intensified and targeted control efforts, including pre-exposure prophylaxis, frequent HIV screening, and improved linkage to treatment services.

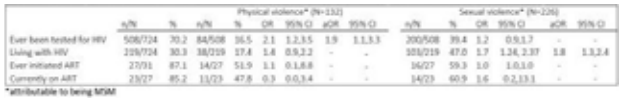
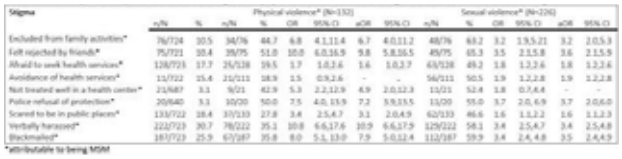
Forced sex and physical violence affecting men who have sex with men in Senegal: associations with HIV and HIV related outcomes and perceived and enacted stigma

C. Lyons[1], F. Drame[2,3], S. Ketende[1], D. Diouf[3], B. Liestman[4], D. Castor[5], N. Leye-Diouf[6], K. Diop[7], G. Turpin[1], K. Coly[4], F. Yang[1], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Gaston Berger University, Saint-Louis, Senegal, [3]Enda Santé, Dakar, Senegal, [4]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Dakar, Senegal, [5]USAID, Office of HIV/AIDS, Bureau for Global Health, Arlington, United States, [6]Institut de Recherche en Santé, de Surveillance Epidemiologique et de Formations, Dakar, Senegal, [7]Division de la lutte contre le Sida et Les IST, Ministry of Health, Dakar, Senegal
Presenting author email: clyons8@jhu.edu

Background: Men who have sex with men(MSM) are disproportionately affected by HIV globally. In Senegal, the estimated HIV prevalence is 23.5% among MSM compared to the 0.5% national prevalence estimate. Social and structural determinants such as limited access to primary HIV prevention, stigma, and violence affecting MSM may further enhance HIV risk. This study aims to measure violence and its intersection with stigma and HIV.
Methods: In 2015, 724 MSM were recruited through respondent driven sampling in Dakar (N=462), Mbour (N=159) and Theis (N=103), Senegal. Participants completed a socio-behavioral questionnaire and biological HIV testing. Bivariate and multivariate logistic regression was used to examine relationships between violence and HIV outcomes, and between violence and stigma.
Results: Overall, 38.0%(275/724) had been forced to have sex, and 14.2%(103/724) have experienced physical violence due to being MSM. Sexual violence was associated with HIV infection (adjusted Odds Ratio [aOR]:1.8;95% Confidence Interval[CI]:1.3-2.4), and physical violence was associated with HIV testing (AOR:1.9;95% CI:1.1-3.3)(Table 1). Sexual violence was associated with stigma from family and friends; fear (AOR:1.8;95% CI:1.2-2.6) and avoidance of seeking healthcare (AOR:1.9;95%CI:1.2-2.8); verbal harassment (AOR:3.4;95%CI:2.5-4.8) and blackmail (AOR:3.5;95%CI:2.4-4.9). Physical violence was associated with fear (AOR:1.6;95%CI:1.0-2.7) and mistreatment in the healthcare setting (AOR:4.9;95%CI:2.0-12.3)(Table 2).



[Table 1. Relationship between HIV treatment cascade with physical and sexual violence among men who have sex with men in Senegal]



[Table 2. Relationship between perceived and enacted stigma with physical and sexual violence among men who have sex with men in Senegal]

Conclusions: Forced sex and physical violence are prevalent among MSM in Senegal, and associated with HIV related outcomes. Family- and social-stigma, stigma related to accessing healthcare, and community enacted stigma was prevalent among this sample. As an antecedent to both HIV and violence, stigma should be targeted through mitigation interventions to effectively reduce these outcomes; and violence reduction interventions should be integrated into HIV programming.

TUPEC0795

Health behaviors and outcomes in a U.S. cohort of transgender women in HIV care

S. Reisner[1], M. Matsuzaki[2], R. Nance[2], C. Grasso[1], J. Delaney[2], E. Fitzsimmons[2], W. Mathews[3], J. Eron[4], G. Chander[5], M. Saag[6], K. Christopoulos[7], E. McCaul[5], M. Kitahata[2], H. Crane[2], K. Mayer[1], R. Fredericksen[2]
[1]Fenway Community Health, Boston, United States, [2]University of Washington, Seattle, United States, [3]University of California at San Diego, San Diego, United States, [4]University of North Carolina, Chapel Hill, United States, [5]Johns Hopkins University, Baltimore, United States, [6]University of Alabama, Birmingham, United States, [7]University of California, San Francisco, United States
Presenting author email: rfrederi@uw.edu

Background: HIV disproportionately affects transgender women (TW), with 28% testing positive for HIV in the U.S., a 34-fold increased odds of infection relative to the general U.S. adult population. We compared the prevalence of mental health symptoms, risk behaviors, and treatment outcomes between TW and cisgender (non-transgender) male patients in HIV care.
Methods: We analyzed cross-sectional data from TW and male patients in HIV care across seven geographically diverse U.S. clinics within the CFAR Network of Integrated Clinical Systems (CNICS) from 2000-2016. We identified TW in the cohort using a combined algorithm that integrated clinical data and identity-based measures. Patient-reported data included antiretroviral medication adherence (VAS), depression (PHQ-9), anxiety (PHQ-5), sexual risk behavior, substance/alcohol/tobacco use (ASSIST, AUDIT-C), and quality of life (EQ-5D). Clinical data included viral load and CD4 count. Analyses compared TW and males for each outcome in log-binomial regression models adjusted for propensity scores based on age, race/ethnicity, year of entry into CNICS cohort, and site of care.
Results: Among 12,235 HIV-infected individuals, 118 TW were identified (mean age=43.9, SD=9.9), of whom 42% were Latino, 29% African-American, 23% White, and 7% other. TW were significantly more likely to report meeting clinical thresholds for moderate-to-severe depression (29.8% vs. 22.2%, p=0.01), anxiety (43.4% vs. 25.8%, p=0.01), and worse quality of life (62.4% vs. 46.7%, p=0.01) compared to males. No statistically significant differences were observed between TW and male patients in terms of viral suppression, CD4 counts, antiretroviral medication adherence, prior and current substance use, binge drinking, or tobacco use. A significantly lower proportion of TW reported hazardous drinking, defined as a score >4 on the AUDIT-C, than in males (21.3% vs 26.7%, p=0.04). The lower rate of condom-less sex in TW relative to male patients only approached statistical significance (42.4% vs 53.1%, p=0.07).
Conclusions: TW living with HIV indicated higher rates of moderate-to-severe depression and anxiety, as well as lower quality of life, when compared to HIV-infected males. These findings suggest a need for improved mental health screening and support for TW in HIV care.

TUPEC0796

Most HIV-positive African MSM screened for HPTN 075 are unaware of their infection

T. Sandfort[1], Y.Q. Chen[2], V. Cummings[3], K. Dominguez[4], X. Guo[2], E.L. Hamilton[5], N. Kayange[6], L. McKinstry[2], A. Ogendo[7], R. Panchia[8], HPTN 075
[1]Columbia University, New York, United States, [2]Statistical Center for HIV/AIDS Research and Prevention (SCHARP), Seattle, United States, [3]Johns Hopkins University School of Medicine, Dept. of Pathology, Baltimore, United States, [4]Desmond Tutu HIV Foundation, Cape Town, South Africa, [5]FHI 360, Durham, United States, [6]Johns Hopkins Project, College of Medicine, Blantyre, Malawi, [7]KEMRI CDC, Kisumu, Kenya, [8]Perinatal HIV Research Unit (PHRU), Soweto, South Africa
Presenting author email: ehamilton@fhi360.org

Background: Scant research has examined HIV testing and diagnosis among men who have sex with men (MSM) in sub-Saharan Africa. Through screening procedures for HPTN 075—a study to evaluate the feasibility of HIV prevention research among this population in four sites in Kenya; Malawi; and South Africa - we
(1) Explored the proportion of MSM who were previously unaware of their positive HIV status, and;
(2) Identified characteristics of these men among those who had ever tested before for HIV.

Methods: A total of 599 MSM (18 to 44 years old) recruited from community locations were screened through HIV testing and a brief questionnaire. Using multivariate logistic regression, we compared MSM who reported to be unaware of their positive HIV status with those who were aware, among men with a prior HIV test.
Results: Of 599 MSM screened, 183 (30.6%) tested HIV positive. One hundred and sixteen of these men (63.4%) reported to be unaware of their infection. Seventeen of these 116 men (14.7%) had never previously tested for HIV, whereas 99 (85.3%) reported prior HIV negative test results. Among men who had tested before, unawareness of one's positive HIV status was not associated with migrant status, behavioral factors, or study site. Multivariate logistic regression, controlling for age and gender identification, showed that not being aware of one's positive HIV status was associated with recency of the last HIV test. Men who tested between 6 to 12 months ago were more likely to be unaware of their positive status than those who had tested in the preceding 6 months (AOR=3.07, 95%CI: 1.24, 7.65); they did not differ significantly from men who had tested over a year ago. There was a marginally significant (p=.09) negative association between number of times ever tested (three or more versus two or less) and not being aware of one's positive status.
Conclusions: Given the UNAIDS 90-90-90 goals, our findings indicate suboptimal awareness of HIV positive status among this population of MSM in sub-Saharan Africa with a high HIV prevalence. Promoting repeat and frequent HIV testing seems an effective first step in addressing the HIV treatment cascade in this population.

TUPEC0797

Incidence and predictors of the initiation of crystal methamphetamine use among gay and bisexual men

M.A. Hammoud[1], F. Jin[1], L. Maher[1], T. Lea[2], S. Vaccher[3], G. Prestage[1]
[1]The Kirby Institute, UNSW Australia, Medicine, Kensington, Australia, [2]Centre for Social Research in Health, UNSW Australia, Kensington, Australia, [3]The Kirby Institute, University of New South Wales, Faculty of Medicine, Kensington, Australia
Presenting author email: svaccher@kirby.unsw.edu.au

Background: Crystal methamphetamine (MA) use among gay and bisexual men (GBM) is higher than in other populations. MA has also been implicated in HIV risk behaviours and transmission among GBM. We identify incident rates and predictive factors at baseline that are associated with the initiation of MA use at follow-up.
Methods: In 2014-2015, 1710 men enrolled in the Flux cohort study of drug use among GBM; by 2016, 1328 men completed at least one follow-up interview. Using multivariate analysis, we identified factors predicting MA initiation at follow-up.
Results: Mean age was 34.9 years. Between baseline and 1-year follow-up: 81.8% had never used MA, 9.6% reported continuous use, 4.0% had ceased use at follow-up, and 4.6% had initiated use at follow-up. At baseline, 34.9% reported having gay friends who used MA.
At baseline, men who reported condomless anal intercourse with casual partners (CLAIC) (HR 1.08; 95%CI 0.62-1.88), had more gay friends who used MA (HR 3.19; 95%CI 1.88-5.43), and scored higher on sexual sensation-seeking (HR 1.08; 95%CI 1.03-1.12) were more likely to subsequently initiate MA at follow-up. In multivariate analysis, compared with men who had never used MA, men who initiated MA scored higher on the sexual sensation seeking scale (HR 1.06; 95%CI 1.02-1.11) and were more socially engaged at baseline with other GBM who used MA (HR 1.32; 95%CI 1.11-1.57).
The most common reasons men cited for using MA among those who initiated were 'fun' (44.3%), for a 'buzz' (39.3%), and 'party-n-play' (chemsex) sessions (37.7%).
Conclusions: Men who had gay friends who used MA and who enjoyed 'risky' sex were more likely to commence MA use themselves. Exposure to, and feeling comfortable around MA use within friendship networks increases the likelihood of MA use. Many men commenced using MA to increase pleasure, specifically during sexual experiences. Their MA use may be viewed as 'functional' for the purposes of enhancing sex and initiation. Initiating MA often appears to occur in the context of CLAIC. Intensive sex partying networks have been previously associated with sexual risk behaviour and HIV transmission, but may also offer opportunities for harm reduction.

TUPEC0798

Incidence and predictors of the initiation of HIV pre-exposure prophylaxis use among gay and bisexual men

M.A. Hammoud[1], F. Jin[1], L. Maher[1], T. Lea[2], S. Vaccher[3], G. Prestage[1]
[1]Kirby Institute, UNSW Australia, Medicine, Kensington, Australia, [2]Centre for Social Research in Health, UNSW Australia, Kensington, Australia, [3]Kirby Institute, University of New South Wales, Faculty of Medicine, Kensington, Australia
Presenting author email: mhammoud@kirby.unsw.edu.au

Background: HIV pre-exposure prophylaxis (PrEP) is becoming increasingly available in Australia. Australian guidelines for access to PrEP for gay and bisexual men (GBM) include condomless anal intercourse with casual partners (CLAIC) and use of crystalline methamphetamine. We estimate incidence and baseline factors associated with initiation of PrEP.
Methods: Between 2014 and 2015, 1133 GBM who reported testing HIV-negative (either at baseline or follow-up) had enrolled in the Flux cohort study of drug use among GBM. They reported their PrEP use at each six-monthly interview. We conducted a multivariate analysis to identify factors independently associated with PrEP initiation at follow-up.
Results: Thirteen men reported PrEP use at baseline. At 12-month follow-up, of 1120 men who were not using PrEP at baseline, 65 men had initiated PrEP. The cumulative12-month incidence for PrEP initiation was 0.6%.
53.6% of those who initiated PrEP at follow-up imported it online, 17.9% were participants in a clinical trial, and 10.7% used prescribed HIV post-exposure prophylaxis (PEP) as PrEP.
Among men who initiated PrEP, 55.4% reported CLAIC at baseline compared to only 26.9% of men who never used PrEP (p< 0.001). One quarter (23.1%) of those who initiated PrEP reported crystal methamphetamine use during the six months before baseline.
In multivariate analysis, factors associated with PrEP initiation included greater social engagment with other gay men (HR 1.25; 95%CI 1.07-1.46) reporting CLAIC (HR 2.29; 95%CI 1.40-3.72), group sex (HR 2.61; 95%CI 1.55-4.39), and recent amyl nitrite use (HR 2.12; 95%CI 1.29-3.50).
Conclusions: Most men who initiated PrEP had engaged in HIV risk behaviours prior to commencing use. This is consistent with the Australian guidelines for access. Men who initiated PrEP tended to be more sexually active and more socially connected to other GBM. Men with stronger connections to gay community may have greater knowledge about PrEP and how to access it.

TUPEC0799

Mapping and size estimation of key populations in Somalia and Somaliland

C. Masika[1], F. Dubow[1], S. Taher[1], A. Yoshino[1], K. Abdullahinur[2], A. Abdulkadir[2], H. Osman[2], A. Abdow[1], S.A. Ali[3], D.S. Tarabi[3], A.I. Omar[4], A.M. Jimale[5], H. Ali[6], M. Fidhin[7], A. Said[8], A. Hirsi[9], C. Pierotti[10], T. Damte[10], C. Ito[1]
[1]International Organization for Migration (IOM), Migration Health Division, Nairobi, Kenya, [2]International Organization for Migration (IOM), Migration Health Division, Mogadishu, Somalia, [3]International Organization for Migration (IOM), Migration Health Division, Garowe, Somalia, [4]International Organization for Migration (IOM), Migration Health Division, Hargeisa, Somalia, [5]Somali National AIDS Commission (SNAC), Mogadishu, Somalia, [6]Somaliland AIDS Commission (SOLNAC), Hargeisa, Somalia, [7]Ministry of Health, Somaliland, Hargeisa, Somalia, [8]Puntland AIDS Commission, Garowe, Somalia, [9]Ministry of Health, Puntland, Garowe, Somalia, [10]United Nations Children's Fund (UNICEF), Nairobi, Kenya

Background: Somalia is characterised by a concentrated HIV epidemic among key populations. Based on two Integrated Biological and Behavioural Surveillance (IBBS) Surveys among sampled female sex workers in Hargeisa, Somaliland HIV prevalence was revealed at 5.2% in 2008 and 4.8% in 2014. Outside Hargeisa, however, the lack of data on where and how key populations exist is limiting the HIV response. Key populations are hidden partially due to cultural norms limiting sexual relations outside marriage and also force those who engage in these behaviours to remain hidden.
This study aimed at establishing the locations and size estimates of key populations to inform HIV policy and programming.
Methods: A cross sectional study was conducted in January 2016 in Mogadishu, Hargeisa and Bossaso using geographical mapping, unique service multiplier, and the Wisdom of Crowds). The study populations comprised female sex workers (FSWs) and their clients including truckers, port workers, fishermen, seafarers, policemen, military personnel, and khat and tea clients. A mobile application was used to collect field data. Descriptive analysis was computed to establish plausible bounds of the key populations.
Results: A total of 2,877 respondents participated in this study. The estimated number of FSWs and their clients were 963 and 2,599 in Mogadishu, 1,126 and 1,827 in Hargeisa and 911 and 3,530 in Bossaso respectively. Over half of the FSWs

57.3%, in Mogadishu and 61.2% in Hargeisa meet their clients at homes whereas 49.1% in Bossaso meet at khat and tea selling joints. In all three locations, commercial sex work mostly occurs on Thursdays and Fridays between 1700 hours and 2000 hours. Only 2.2% of FSWs had received free condoms within the last twelve months prior to this study. The majority of FSWs, 64.1%, are willing to attend a center dedicated to serving FSWs with HIV counselings and testing, and sexually transmitted infections screening and treatment, cervical cancer screening, and condom provision.
Conclusions: This study provided the evidence of the sex work presence and HIV risk in Somalia. Preliminary and critical data from this study showed an alarming HIV vulnerability among sex workers and their clients which need to be timely addressed.

TUPEC0800

Estimating age-specific proportion of new HIV infections among males who have sex with males and transgender women: application of the 2016 Philippine AIDS epidemic model

A. Aquino[1], G.M. Samonte[1], M. Bermejo[1], I. Asuncion[1], W. Peerapatanapokin[2]
[1]Epidemiology Bureau, Department of Health, Manila, Philippines, [2]East West Center, Hawaii, United States
Presenting author email: genesis.samonte@gmail.com

Background: The national bio-behavioral surveillance (IHBSS) revealed an increasing HIV prevalence among 15 to 24 year old males and transgender women who have sex with males (M/TSM) from 2.3% in 2011 to 6.0% in 2015. Existing case registry data do not support this trend; only 30% of newly diagnosed infections among M/TSM were from 15 to 24 years old. Development of the 2016 Philippine AIDS Epidemic Model (AEM) opened a platform to generate age-specific estimates to inform the national HIV program on the age group where the highest number of new infections are occurring.
Methods: To determine incidence by age among M/TSM, change in prevalence was compared in 21 cities of the 2013 and 2015 IHBSS. This was used as input in the age distribution for incidence of the Philippine AEM to produce age-specific proportion of new HIV infections. Supporting factors on sexual debut, age at first condom use, and age at first HIV test were further analysed in the IHBSS.
Results: Estimates from AEM showed that 62% of new infections in 2016 occur among 15 to 24 years old. Majority (89%) of these new infections occur among M/TSM. Average onset of sexual activity is at 16 years old among M/TSM but first condom use starts two years later. Probability of acquiring HIV infection at this age is high due to the gap between first sex and first condom use.
However, laws requiring parental consent for HIV testing delay timely detection of HIV among minors. Among M/TSM, HIV testing uptake is low and generally starts at 22 years old.
Conclusions: Findings raised the need to prioritize young M/TSM in the national HIV plan with the goal of reducing new HIV infections by 2022. Through multisectoral collaboration, bolder strategies are taken to ensure provision of prevention, testing and treatment services to young M/TSM. These include creating partnerships with schools to increase HIV knowledge, making provisions for proxy consent, and revising existing laws so that minors will have access to HIV services.

Presenting author email: bliestm1@jhu.edu

Background: According to syndemic theory, psychosocial factors such as depression, substance abuse, and violence combine with behavioral and biological factors to increase HIV infection and transmission risk. Evidence from high-income countries estimate the prevalence of depression among MSM to be 3-5 times that of other men. However, little data exist on the prevalence and correlates of depression among MSM and transgender women in low- and middle-income countries where existing HIV prevention and treatment programs rarely include mental health components.
Methods: 521 MSM and 184 transgender women were recruited in Dakar, Mbour, and Thies, Senegal using Respondent-Driven Sampling. Participants completed a questionnaire based on the modified socio-ecological model and HIV and viral load testing. Poisson regression with robust variance estimation was used to model prevalence ratios of depression (PHQ-9 score ≥10) and known HIV risk factors.
Results: The estimated prevalence of depression was 19.4%(101/521) among MSM and 23.9%(44/184) among transgender women. 20.4%(106/521) of MSM and 20.1%(37/183) of transgender women reported recent suicidal ideation. Depression was significantly higher among MSM with experiences of exclusion (aPR:2.3, 95%CI:1.6-3.4) and gossip from family (aPR:2.0, 95%CI:1.4-3.0), verbal (aPR:1.8, 95%CI:1.3-2.5) and physical harassment (aPR:2.0, 95%CI:1.3-2.9), rape (aPR:1.6, 95%CI:1.1-2.2), and arrest on charges related to homosexuality (aPR:1.9, 95%CI:1.2-3.1). Among transgender women, depression was significantly higher among those with experiences of exclusion (aPR:2.6, 95%CI:1.6-4.2) or gossip from family (aPR:2.2, 95%CI:1.3-3.6), verbal (aPR:1.8, 95%CI:1.1-3.0) and physical harassment (aPR:2.2, 95%CI:1.3-3.6), rape (aPR:2.6, 95%CI:1.5-4.5), fear of seeking healthcare (aPR:2.0, 95%CI1.2-3.6), and rejection by friends (aPR:3.5, 95%CI2.2-5.5). (Table 1)

[Crude & adjusted PR of depression and risk factors]

Conclusions: In Senegal, the prevalence of depression is high among MSM and transgender women. However, mental health remains largely under-addressed in existing HIV prevention and treatment programs for these high-risk populations. Including mental health as well as stigma mitigation in future programs has the potential to alleviate the burden of depression and contribute to ending the HIV epidemic.

TUPEC0802

More frequent experience of homo/transphobia is associated with higher sexual risk among transgender women compared to men who have sex with men in Lima, Peru

E.M. Reyes Diaz[1], K. Konda[1,2], A. Silva-Santiesteban[3], C. Cáceres[4]
[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]UCLA, Los Angeles, United States, [3]Cayetano Heredia University, Lima, Peru, [4]Cayetano Heredia University, Peru, Peru
Presenting author email: edward.reyes@upch.pe

Background: Transgender women (TW) report exposure to homo/transphobia and sexual risk profiles distinct from those of men who have sex with men (MSM), though these two populations are often grouped. Assessing whether or not exposure to homo/transphobia is associated with differences in sexual risk between TW and MSM will help respond to TW needs.
Methods: We analyzed data from an 18-month clinical trial completed in 2011 that included 166 TW and 404 MSM from 24 low-income neighborhoods of Metropolitan Lima. Surveys collected data on gender identity, experience of homo/transphobia, sexual risk and alcohol abuse. Incidence of any STI (HIV, Syphilis, HSV-2, anal chlamydia and anal gonorrhea) was analyzed based on biological testing at the 9- and 18-month study visits. Experience of homo/transphobia was assessed as a potential mediator by calculating confidence intervals of indirect effect

standardized coefficient (SC) on the pathways between gender identity, sexual risk (number of sex partners, compensated sex and alcohol abuse).
Results: TW had higher scores of homo/transphobic experiences (17.5 vs 14, p <0.001), more sex partners (10 vs 4, p <0.001), more reported compensated sex at least weekly (45% vs 15%, p <0.001) and more alcohol abuse than MSM (68% vs 53%, p <0.001). There was no difference in STI/HIV incidence (39% vs 39%) or unprotected anal sex (60% vs 57%), all p-values >0.05. Experience of homo/transphobia had significant mediation (indirect) effect between gender identity and number of sex partners (IC 0.01 - 0.04), compensated sex (IC 0.01 - 0.06) and alcohol abuse (IC 0.01 - 0.05).
Conclusions: TW report riskier sexual behavior, more alcohol abuse an experiences of homo/transphobia than MSM. Experience of Homo/transphobia appears to contribute to risky sexual behavior and alcohol abuse among TW. The increased experience of homo/transphobia captures the increased stigma and discrimination affecting TW that can also predispose them to negative social and health outcomes. The HIV programmatic response to TW must address the structural underpinnings of social stress to reduce social inequity and subsequent risk behaviors.

Effect	Number of sex partners		Compensated sex		Alcohol Abuse	
	SC	CI	SC	CI	SC	CI

TUPEC0803

Burden of infectious diseases and substance abuse among incarcerated women in Kuala Lumpur, Malaysia

V. Pillai[1], C. Pedersen[2], J. Wickersham[2], F. Altice[2], A. Kamarulzaman[1]
[1]University Malaya, Centre of Excellence for Research in AIDS, Kuala Lumpur, Malaysia, [2]Yale University, Department of Medicine, New Haven, United States
Presenting author email: vnapillai@gmail.com

Background: The prevalence of infectious diseases, including HIV, hepatitis B virus (HBV), hepatitis C virus (HCV), and syphilis, are higher in prisons than in the general population. As a consequence, prisons have become venues where disease transmission is common and often continues after release to the community. While there has been increasing focus on the public health challenges of prisons, limited research has focused on the unique challenges facing incarcerated women. This study reports on the first-ever systematic study of HIV, HBV, HCV, and syphilis burden in incarcerated women in Kuala Lumpur, Malaysia.
Methods: A biobehavioral health assessment was conducted among women incarcerated at Malaysia's largest women's prison. Inclusion criteria were: 18 years of age or older, female sex, able to speak English or Bahasa Malaysia, and have been incarcerated for at least 1 month. After consent, participants underwent a standardized health assessment and serological testing for HIV, HBV, HCV, and syphilis.
Results: A total of 365 female prisoners enrolled in the study. Mean age was 35.9 years (Range 18-60), most were Malaysian nationality (76.8%), and half (49.3) were incarcerated for drug-related offenses. Most (69.8%) participants had at least one prior incarceration. Prevalence of HIV, HBV, HCV, and syphilis were 4.1% (95%CI 2.4-7.1), 2.1% (95%CI 1.0-4.4), 10.7% (95%CI 7.6-14.8), and 3.5% (95%CI 1.9-6.2), respectively. The majority of HCV was previously undiagnosed (71.0%), while only 20.0% of HIV was previously diagnosed. Amphetamine-type substances (36.0%), heroin (19.1%), and alcohol (18.1%) were the most commonly used substances 30 days prior to the current incarceration and 13.1% reported prior injection drug use. Over half (58.8%) met screening criteria for moderate to severe depression.
Conclusions: This study found a high burden of previously undiagnosed HCV among incarcerated women in Kuala Lumpur. Likewise, HIV prevalence in this sample is more than 25 times higher compared to females in the general population in Malaysia. Because there is a high degree of recidivism among this population, treatment prior to release is an important step in preventing onward transmission. Interventions to improve public health in prisons is a necessary step for curbing co-occurring epidemics of HIV, HCV, and injection drug use.

TUPEC0804

Violence and HIV vulnerability among female sex workers recruited by respondent-driven sampling in 10 Brazilian cities: base-line data for future preventive program evaluation

F.S. Da Silva Lima[1], M. Urdaneta[2], E. Merchan-Hamann[2], G. Nogueira Damacena[3], C. Landmann Szwarcwald[3]
[1]Escola Superior de Ciências da Saúde, Brasilia, Brazil, [2]Universidade de Brasília, Saúde Coletiva, Brasilia, Brazil, [3]FIOCRUZ, ICICT, Rio de Janeiro, Brazil
Presenting author email: urdanetamm@gmail.com

Background: Violence and HIV vulnerability among female sex workers (FSW) remains marginalized in most studies on the topic. This study aims to characterize violence against Brazilian FSW and verify possible association with factors of vulnerability to HIV.
Methods: We conducted a cross-sectional study based on data from 2,523 adult FSW in ten cities, recruited by Respondent-Driven Sampling (RDS) in 2009. Weighted prevalence estimates were calculated for different types of violence and perpetrators in the last 12 months. Adjusted Odds Ratios (AOR) were calculated by logistic regression to study the associations between violence (dependent variable) and several social-demographic and behavioral variables, and inconsistent condom use (dependent variable) and violence. Multivariate models took into account the dependency structure of observations.
Results: Prevalence of verbal violence was 59.5%; and of physical violence (PhV), 38.1%. Prevalence of PhV perpetrated by intimate partner was 25.2%, and by clients: 11.7%. Factors associated to PhV were: age < 30 years old (AOR 2.27, 95%CI = 1.56 - 3.29); drug use (AOR 2.02, 95%CI = 1.54-2.65); price of sex work < ~US$ 13.20 (AOR 1.51, 95%CI = 1.07 - 2.13). Factors associated to PhV by an intimate partner were: inconsistent condom use (AOR = 1.99, 95% CI = 1.27-3.11) and age < 30 years old (AOR = 1.92, 95% CI = 1.23 - 2.99). Age under 30 years old was also associated to PhV perpetrated by clients (AOR = 2.24, 95% CI = 1.24-3.75) as well as sex work price less than ~US$ 13.20 (AOR = 2.09, 95% CI 129 - 3.38). Drug consumption was associated significantly with all types of violence and to PhV perpetrated by policemen (AOR = 2.54, 95% CI = 1.61-3.39). Intimate partner- PhV was associated with inconsistent condom use (AOR = 1.98, 95% CI = 1.12-3.51).
Conclusions: Young and underprivileged Brazilian FSW are frequently victimized by violence perpetrated by different social actors. Preventable factors such as substance consumption and inconsistent condom use constitute relevant potential barriers to safe sex practices rendering them more vulnerable to HIV. These results are useful to compare with data from a new RDS study conducted in late 2016.

TUPEC0805

HIV knowledge, perceived HIV risk, and condom use among female sex workers in Kampala, Uganda

D. Kibuuka Musoke[1], C. Oldenburg[2], T. Ngabirano[3], A. Nakitende[1], G. Taasi[4], T. Barnighausen[5], K. Ortblad[6]
[1]International Research Consortium, Kampala, Uganda, [2]Francis I. Proctor Foundation, University of California San Francisco, San Francisco, United States, [3]Uganda Health Marketing Group, Kampala, Uganda, [4]Uganda Ministry of Health, Kampala, Uganda, [5]Heidelberg University, Heidelberg, Germany, [6]Harvard T H Chan School of Public Health, Global Health and Population, Boston, United States
Presenting author email: kibuukamd@sfg-group.com

Background: HIV educational programs are associated with decreased HIV risk-taking behaviors including condomless sex. Female sex workers (FSW) in Kampala, Uganda have been the target of many HIV prevention campaigns. We want to understand if HIV knowledge and perceived risk among members of this high-risk population is associated with decreased HIV risk-taking behaviors, specifically condom use with clients.
Methods: In 2016, 963 HIV uninfected FSW participated in a quantitative questionnaire. HIV knowledge was measured using a 9-item scale that included true/false statements related to HIV transmission (adapted from HIV-KQ-18). The scale had a range of 0-9, points were given for correct responses. Perceived risk of HIV transmission was measured by asking participants how likely (1-10 ladder scale) a HIV negative women was to contract HIV if she had condomless vaginal sex with a HIV positive man once. Inconsistent condom use with clients was identified if the self-reported average number of clients did not match the self-reported average number of clients with whom participants used condoms. Multivariable logistic models, adjusted for sociodemographic variables, were used to measure the association between HIV knowledge, perceived risk, and condom use.
Results: Of the 963 participants, median age was 28 years (IQR: 24-32 years), literacy was 85.7% (N=822), and 55.1% of participants (N=527) reported a monthly income < 250,000 UGX (~USD $70). Median HIV knowledge score was 7 (IQR: 6-8) and median perceived risk of HIV transmission per condomless sex act was 5 (IQR: 5-8), a probability of 0.55 (IQR: 0.55-0.89). Inconsistent condom use among FSW was high (N=388, 40.3%). A higher HIV knowledge score was not

associated with inconsistent condom use with clients (aOR 0.97, 95% CI: 0.88-1.07), nor was a higher perceived risk of HIV per condomless sex act (aOR 0.96, 95% CI: 0.91-1.01).
Conclusions: High HIV knowledge and high perceptions of risk per condomless sex act are not associated with behaviors that decrease HIV transmission, namely condom use, among FSW in Kampala, Uganda. While HIV knowledge remains an important component of HIV prevention campaigns, more research should be done on the drivers of condomless vaginal sex in this FSW community.

TUPEC0806

Factors associated with previously undiagnosed HIV infection in transgender women sex workers in Greater Kuala Lumpur, Malaysia

J.A. Wickersham[1,2], B.A. Gibson[1], R. Rutledge[1], O. Morozova[3], C.J. Pedersen[3], S. Foley[3], V. Pillai[2], N. El-Bassel[4], A. Kamarulzaman[2], F.L. Altice[1,3]
[1]Yale University School of Medicine, Internal Medicine, New Haven, United States, [2]University of Malaya Faculty of Medicine, Centre of Excellence for Research in AIDS, Kuala Lumpur, Malaysia, [3]Yale University School of Public Health, New Haven, United States, [4]Columbia University School of Social Work, New York, United States
Presenting author email: jeffrey.wickersham@yale.edu

Background: Transgender women and transgender women sex workers (TWSW) are among the most at-risk populations for HIV. The estimated worldwide HIV prevalence for transgender women is 19.1% (95% CI 17.4-20.7). For TWSW, the global HIV burden is even higher at 27.3%. Early identification of HIV infection is critical in order to engage individuals in treatment and prevent onward transmission of the virus. This study examined factors associated with previously undiagnosed HIV infection among TWSW in Greater Kuala Lumpur, Malaysia.
Methods: From April to December 2014, respondent-driven sampling was used to recruit 193 TWSW in Greater Kuala Lumpur, Malaysia. Inclusion criteria were: ≥18 years of age, identify as a transgender woman, report involvement in sex work in the last 6 months, and ability to speak Bahasa Malaysia, English, or Tamil. After consent, all participants underwent a comprehensive bio-behavioral survey and serology for HIV, chlamydia, gonorrhea, and syphilis.
Results: HIV prevalence was 12.4% (24/193) for the sample, of which 29.2% (7/24) had been diagnosed with HIV prior to study participation, indicating 70.8% of HIV detected was previously undiagnosed. Multivariate logistic regression was conducted to identify correlates of newly diagnosed HIV (N=186). Results indicated current chlamydia infection (aOR=6.13, p=0.02), current syphilis infection (aOR=2.91, p=0.05), being in a committed interpersonal relationship (aOR=0.21, p=0.01), and any previous incarceration (aOR=3.64, p=0.02) were associated with undiagnosed HIV infection.
Most participants (74.6%) had been HIV tested at least once in their lifetime, however, only 21.2% were tested in the last 12 months. Moreover, the mean time since last HIV test was 2.5 years.
Conclusions: This is the first-ever study to explore factors associated with previously undiagnosed HIV infection among TWSW in Malaysia. Active sexually transmitted infections (STI), including syphilis and chlamydia, were robust correlates of undiagnosed HIV in this sample. Given that primary syphilis facilitates HIV transmission and acquisition, interventions that integrate HIV and STI screening may improve early identification of TWSW at high risk for HIV through early detection and treatment of STIs. Furthermore, the suboptimal frequency of HIV testing suggests a need to develop novel interventions to ensure HIV screening at least once every 12 months.

TUPEC0807

Sub-Saharan African (sSA) migrant women living with HIV lack highly effective contraception: migrant effect or HIV consequence? Results from the ANRS-Parcours study

B. Maraux[1], M. Annequin[1], F. Lert[2], A. Desgrees-du-Lou[1], PARCOURS Study Group
[1]CEPED, UMR 196 Université Paris Descartes-IRD, Paris, France, [2]INSERM, CESP-U 1018, Villejuif, France
Presenting author email: barbara.maraux@gmail.com

Background: Despite consistent evidence that hormonal contraception and IUD are at no risk for women on ART, preliminary study demonstrated that condom remained the predominant contraception among sSA migrant women living with HIV in France. Whether it is due to HIV status or it is related to their migration characteristics is still uncertain.
Objective: Compare prevalence of medical contraception among sSA migrant women in France according to their HIV status.
Methods: PARCOURS is a life-event survey conducted in 2012-2013 in 74 healthcare facilities in the Paris region, among a representative sample of sSA migrants constituted as follows: 926 receiving HIV care and 763 with neither HIV nor hepatitis B (reference group). Women concerned by contraception were in fecund age, sexually active in the past 12 months, not pregnant or seeking to get pregnant, not sterile or menopausal. Contraception was grouped in three categories: condom, medical (oral pill, IUD, implant, sterilization and injection) and no method.
Results: Among women in fecund age (18-49), 441 were HIV positive and 270 were not. Median age at migration was 28 years, 10.2% had once use medical contraception before migration.
Among women concerned by contraception (N=354), 63.3% of HIV positive women use condom, 72.3% use medical contraception in the reference group and one on ten declare no method in both groups. After adjustment on age, children, partnership, level of education, employment, time living in France and access to health insurance, HIV positive women remain less likely to use medical contraception than non HIV infected women (PRR 0.39 (0.29-0.52) p<0.000).
Conclusions: Migration to France provides contraceptive choices for sSA migrants women. However, HIV infection produces a break into access to the highly effective contraception that could not be explained by a single migrant effect. Our finding suggest that message of dual contraception, condom and medical contraception must be strongly promoted, as unintended pregnancies are still frequent.

TUPEC0808

Measures of recent migration predict STI (GC/CT) among adults in East African communities participating in the SEARCH study

C.S. Camlin[1,2], M. Getahun[1], A. Akullian[3], T. Neilands[2], E. Geng[4], C.R. Cohen[1], M. Gandhi[4], T.A. Odeny[5], E.A. Bukusi[5], M.R. Kamya[6,7], E.D. Charlebois[2]
[1]University of California, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [2]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [3]Institute for Disease Modeling, Seattle, United States, [4]University of California, HIV, ID and Global Medicine, San Francisco, United States, [5]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [6]Makerere University College of Health Sciences, Kampala, Uganda, [7]Infectious Diseases Research Collaboration, Kampala, Uganda
Presenting author email: carol.camlin@ucsf.edu

Background: Geographic mobility represents a widespread challenge to HIV prevention and treatment goals: it can break bonds between individuals and care systems, link geographically separate epidemics, and intensify transmission. This study (1R01MH104132), embedded within an ongoing HIV test and treat study (SEARCH, NCT01864603), sought to examine how mobility affects sexual behavior, STI and HIV risk in East African communities.
Methods: Survey data were collected February-November 2016 from 2,750 adults aged 16 and older in 12 communities in Uganda and Kenya, to measure mobility and sexual behavior; STI (Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) were detected using Xpert® assays. Mixed-effects logistic regression models were fitted to test associations of four measures of recent migration with STI infection, controlling for key covariates (gender, age, marital status and household wealth).
Results: 7.3% of adults undertook ≥1 migration in past year; 20.8% in past five years, most of which were internal migrations over county/district boundaries. A greater proportion of men (8.9%) than women migrated in past year (5.9%)(p=.003), and past 5 years (23.7% men vs. 18.1% women)(p=< .001).

	Model 3				Model 4

model constant	--	--	--	--	0.02	0.000	0.01	0.05

[Measures of migration predicting STI]

STI prevalence was 3.14% overall (1.6% CT, 1.5% NG, 0.1 both); 7.1% in past year migrants vs. 2.8% in non-migrants (p= 0.001). In multivariate mixed-effects models, numbers of past year (OR 1.79, 1.23-2.61 [95%CI]) and 5 year migrations (OR 1.36, 1.09-1.70 [95%CI]), and measures of ≥1 migration in past 1 year (OR 2.22, 1.17-4.20 [95%CI]) and 5 years (OR 1.89, 1.17-3.05 [95%CI]) were predictive of STI prevalence, controlling for important covariates.

Conclusions: Greater proportions of men than women participate in migration in Kenya and Uganda. Despite overall low prevalence of STI (GC/CT) among adults in the study in Kenya and Uganda, past year and also past five year migrations were predictive of STI, warranting focused prevention efforts among mobile populations.

TUPEC0809

Prevalence and predictors of human immunodeficiency virus and selected sexually transmitted infections among people who inject drugs in Dar es Salaam, Tanzania: a new focus to get to zero

N.E. Makyao[1], D.E. Mbaga[2], P.K. Moen[3], P.M. Leshabari[4]
[1]Ministry of Health and Social Welfare, National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of, [2]Muhimbili University of Health and Allied Sciencies, Epidemiology, Dar es Salaam, Tanzania, United Republic of, [3]University of Oslo, Department of Community Medicine and Global Health, Institute of Health and Society, Oslo, Norway, [4]Muhimbili University of Health and Allied Sciencies, Dar es Salaam, Tanzania, United Republic of
Presenting author email: neemakirei@gmail.com

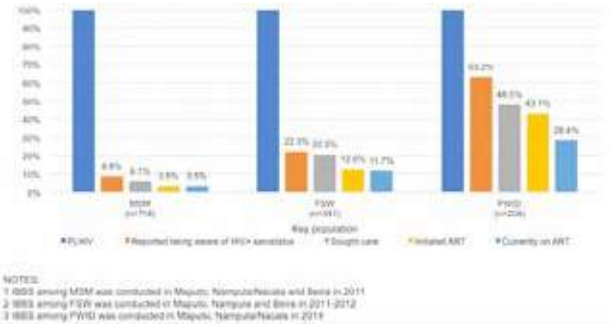
Background: : Previous studies in Tanzania indicated that human immunodeficiency virus (HIV) prevalence among people who inject drugs (PWIDs) could be as high as 40%. We aim to provide data on the prevalence of HIV and sexually transmitted infection among PWIDs to inform national plans to get to zero.
Methods: Respondent-driven sampling was used to collect drug use, and sexual practices data among PWIDs aged 15 years and older. Blood samples were examined for HIV, herpes simplex virus type 2, syphilis, and hepatitis B.
Results: A total of 620 PWIDs with a median age of 32 (interquartile range, 17-52) participated in the study. Their use of drugs had typically started during adolescence. The prevalence of HIV was found to be 15.5%, whereas that of herpes simplex type 2 was 43.3%.
Associated with an increased likelihood of HIV infection was being a female (adjusted odds ratio [aOR], 2.3; 95% confidence interval [CI], 1.0-3.6), sharing of syringes (aOR, 2.4; 95% CI, 1.1-6.1), used syringes hidden in public places (aOR, 5.1; 95% CI, 1.3-10.2), and having had a genital ulcer during the last 12 months before this survey.
On the other hand, being educated, use of non-injectable drugs, access (aOR, 0.5; 95% CI, 0.2-0.8), and use of clean syringes (aOR, 0.3; 95% CI, 0.1-0.6) were associated with decreased likelihood of HIV infection.
Conclusions: The prevalence of HIV infection among PWIDs in Dar es Salaam is 3 times higher than that in the general population. Behavioral and biological risk factors contribute to HIV transmission and needs to be addressed to be able to get to zero.

TUPEC0810

HIV care and treatment cascade among key populations living with HIV in Mozambique: results from the integrated biological and behavioral surveillance (IBBS) surveys 2011-2014

M. Boothe[1,2], I. Sathane[2], C. Semá Baltazar[3], E. Fazito[4], J. Peregoy[5,6], L. Dengo Baloi[7], B. Cummings[8], P. Young[9], R. Horth[10]
[1]University of California, San Francisco (UCSF), Maputo, Mozambique, [2]UCSF Global Programs for Research and Training, Maputo, Mozambique, [3]National Institute of Health, Surveillance, Maputo, Mozambique, [4]The Joint United Nations Program on HIV/AIDS (UNAIDS), Maputo, Mozambique, [5]Association for Schools and Programs of Public Health (ASPPH), Maputo, Mozambique, [6]Centers for Disease Control and Prevention, Maputo, Mozambique, [7]National Institute of Health, San Francisco, Mozambique, [8]Centers for Disease Control and Prevention, Gaborone, Botswana, [9]Centers for Disease Control and Prevention, Nairobi, Kenya, [10]University of California, San Francisco (UCSF), San Francisco, United States
Presenting author email: liliana.dengo.baloi@gmail.com

Background: Although Mozambique has a generalized HIV epidemic, key populations (KP) are disproportionately affected. Our analysis estimates HIV care and treatment cascade indicators among participants in the IBBS surveys among Men Who Have Sex With Men (MSM), Female Sex Workers (FSW), and People Who Inject Drugs (PWID) in three cities in Mozambique to track progression of People Living with HIV (PLHIV) from one service to the next and highlight attrition of coverage.
Methods: We conducted a secondary data analysis of results from respondent-driven sampling surveys conducted in Maputo, Beira and Nampula/Nacala from 2011 to 2014. Results from respondents' HIV testing results and self-reported responses to the survey questionnaire were pooled across survey cities and then used to produce unweighted proxy cascade indicators.
Results: HIV prevalence among survey participants was 8.0% (n=114), 27.5% (n=341), 45.8% (n=204) for MSM, FSW and PWID, respectively, where the number of PLHIV served as the denominators. Figure 1 illustrates the percentage of KPs that progressed through the HIV care cascade. Losses occurred throughout the continuum for the three populations, with the largest breakpoint occurring at knowledge of HIV status, which varied from 8.8% among MSM to 63.2% among PWID. Use of services appears higher among PWID, when compared to the other KPs; however, there is a high dropout rate among PWID who initiated antiretroviral therapy (ART) and those currently on ARTs.



[Figure 1: HIV Care and Treatment Cascade among KPs]

Conclusions: Special attention should be given to interventions that increase service uptake of HIV testing and retention in care among all KPs, but particularly among MSM and FSW. It is possible that some respondents may have been aware of their HIV positive status but refused to disclose, thus representing a bias that may potentially impact results. Future IBBS surveys should include viral load testing to guarantee a more complete picture of the cascade.

Trans identity and HIV risk- findings from a large study of young transwomen

E. Wilson, C. Turner, S. Arayasirikul
San Francisco Department of Public Health, San Francisco, United States
Presenting author email: erincwilson@gmail.com

Background: Globally, transwomen bear a larger burden of HIV than any other population, and research points to discrimination and stigma as a primary cause. Transwomen exposed to more discrimination because they are out as trans at a younger age may experience higher risk for HIV. This analysis uses the first large dataset of young transwomen to examine the impact of realizing trans identity and living as trans on HIV risk.
Methods: Data for this analysis are from 243 participants in the SHINE study- a social epidemiological study of HIV risk and resilience among of young transwomen aged 16-24 years in the San Francisco Bay Area, California, USA. We conducted an exploratory analysis to identify age of transgender identity realization and outness associations with increased sexual risk behavior at baseline. Logistic regression analysis examined increased engagement in condomless anal intercourse (CAI).
Results: The sample consisted of 39.9% white youth, 31.6% Latinas, 12.2% Black/African Americans, and 16.3% youth of other racial/ethnic identities. HIV prevalence was 3% (n=8) at baseline.The mean age at which participants thought they were trans or something other than a man was 8.9 years and 17.5 years for the mean age they began living as trans. Young transwomen had significantly lower odds of engaging in CAI with increasing age at which youth felt they were trans (OR 0.93; 95% CI 0.88-0.98) and began living as trans (OR 0.78; 95% CI 0.70-0.88). African American young transwomen had significantly higher odds of engaging in CAI as age at which they began living as trans increased (OR 1.06; 95% CI 1.00-1.77).
Conclusions: We found overall that the later the age at which young transwomen realized and began living as trans, the lower their odds were for engaging in sexual risk behavior; however, later age of beginning to live as trans may be detrimental to the health of transwomen of color who already face multiple forms of stigma. Though interventions like PrEP and access to HIV testing are important, policy and human rights approaches to reducing stigma and discrimination towards transgender people may have a more sustained impact on reducing HIV and other health risks among transwomen.

TUPEC0812

Prevalence and mapping of hepatitis C infections among men who have sex with men in New York city

H.V. Tieu[1,2], O. Laeyendecker[3,4], V. Nandi[5], R. Rose[6], R. Fernandez[4], B. Lynch[3], D.R. Hoover[7], B.A. Koblin[1], NYC M2M Study Team
[1]New York Blood Center, Laboratory of Infectious Disease Prevention, New York, United States, [2]Columbia University Medical Center, Division of Infectious Diseases, Department of Medicine, New York, United States, [3]National Institute of Allergy and Infectious Diseases, Baltimore, United States, [4]School of Medicine, Johns Hopkins University, Baltimore, United States, [5]New York Blood Center, Laboratory of Data Analytics, New York, United States, [6]BioInfoExperts, LLC, Thibodaux, United States, [7]Rutgers the State University of New Jersey, Department of Statistics, Piscataway, United States
Presenting author email: htieu@nybc.org

Background: Emerging sexually transmitted hepatitis C (HCV) infection epidemics among men who have sex with men (MSM) have been reported worldwide, with higher HCV infection rates among HIV-infected than HIV-negative MSM. This study aims to determine prevalence of recent and chronic HCV infections among community-recruited MSM in New York City (NYC), map HCV infections by home, social, and sexual neighborhoods, and determine clusters of genetically linked HCV variants using phylogenetic analysis.
Methods: The NYC M2M study recruited MSM via modified time-space, venue-based sampling and internet/mobile app-based recruitment during 2011-12. Participants completed a Google Earth map on neighborhoods of where they lived, socialized, and had sex in the last 3 months, an ACASI questionnaire, and a sexual network inventory about their sex partners. The men received HIV testing and provided serum samples.
Testing on stored serum samples included HCV antibody and RNA viral load, HCV antibody avidity assay (avidity index <40% with positive viral load is considered recently infected), and HCV RNA extraction and amplification to generate a 432 base-pair region of Core/E1 for sequencing and phylogenetic analysis. Historic local controls were included in the phylogenetic analysis.
Results: Of 1,028 MSM, 77.2% were HIV-negative and 22.6% HIV-positive. Twenty nine MSM (2.8%) were HCV antibody-positive. MSM who were HCV antibody-positive reported a median of 2 male sex partners in last 3 months, with 6.9% aged 18-24, 17.2% 25-29, 13.8% 30-39, and 62.1% 40 and over. Over half (58.6%) of HIV-positive MSM were HCV antibody-positive vs. 21.5% of HIV-negative men (p<0.001). Of 29 HCV-antibody positive MSM, 12 (41.4%) were HCV RNA-positive (11 subtype 1a and 1 subtype 1b). Two of 12 HCV RNA-positive participants had low antibody avidity values, suggesting recent infection. Mapping of HCV infections differed slightly by home, social, and sexual neighborhoods. Based on phylogenetic analysis from 12 HCV RNA-positive samples, no evidence of a clustered HCV epidemic was found.
Conclusions: Overall HCV seroprevalence was 2.8% among community-recruited MSM in NYC, with higher prevalence among HIV-positive MSM compared to HIV-negative MSM. Only two participants were found to have recent HCV infection, with no evidence of a clustered HCV epidemic based on phylogenetic analysis.

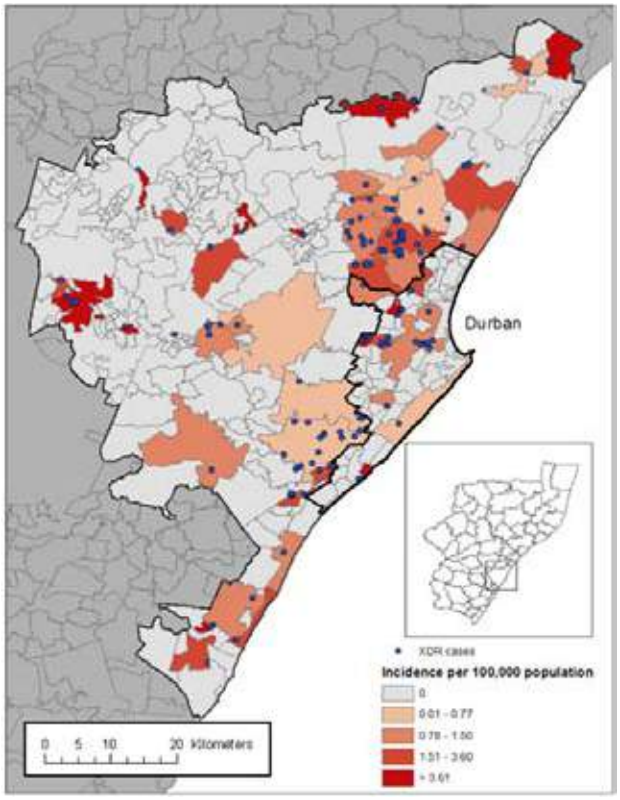
Identification of high-incidence 'hotspots' of HIV-associated extensively drug-resistant (XDR) TB in KwaZulu-Natal, South Africa

K. Nelson[1], S. Auld[1,2], J. Brust[3], B. Mathema[4], T. Cohen[5], P. Moodley[6], A. Campbell[1], S. Allana[1], S. Shah[7], N. Gandhi[1]
[1]Emory University School of Public Health, Atlanta, United States, [2]Emory University School of Medicine, Atlanta, United States, [3]Albert Einstein College of Medicine, Bronx, United States, [4]Columbia University Mailman School of Public Health, New York, United States, [5]Yale University School of Public Health, New Haven, United States, [6]University of KwaZulu-Natal, Durban, South Africa, [7]Centers for Disease Control and Prevention, Atlanta, United States
Presenting author email: knbratt@emory.edu

Background: Drug resistance represents a major threat to global tuberculosis (TB) control, particularly for people with HIV. In KwaZulu-Natal Province, South Africa, we determined that the majority of extensively drug-resistant (XDR) TB is due to transmission of resistant organisms rather than inadequate treatment. We hypothesize that XDR TB cases are concentrated in 'hotspots,' or areas of high incidence, which account for the majority of transmission events. We aimed to characterize the geographic distribution of notified XDR TB cases in a high HIV prevalence setting to identify hotspots for targeted prevention efforts.
Methods: We enrolled newly-diagnosed, culture-confirmed cases of XDR TB from 2011-2014 in KwaZulu-Natal. We collected participants' clinical and demographic information and GPS coordinates of their home residence. We mapped cases by home residence and calculated annual XDR TB incidence by main place (eThekwini) and sub-place (Durban), South African census units. We used Bayesian methods to stabilize rates and defined a hotspot as a unit with annual incidence above 1.5 per 100,000.
Results: We enrolled 404 participants from all 11 districts and 42 of 51 sub-districts in KwaZulu-Natal, 311 (77%) of whom were HIV-positive. eThekwini and Msinga sub-districts had the highest absolute number of cases with 132 (33%) and 42 (10%) cases, respectively. In eThekwini, which includes the provincial population center of Durban, 13 of 168 census units were identified as hotspots and 51% (67/132) of cases in eThekwini were located within a hotspot (Figure, inset shows eThekwini on a map of KwaZulu-Natal province). There was no substantial difference in case distribution by HIV status.



[XDR TB incidence in KwaZulu-Natal, South Africa.]

Conclusions: The urban district of eThekwini has the highest burden of XDR cases in KZN, with distinct hotspots within eThekwini. Bacterial genomics studies focused on these hotspots can clarify local transmission dynamics and inform the design of more effective local interventions.

TUPEC0814

Higher positivity of whole blood Epstein-Barr virus DNA among HIV-infected versus HIV-uninfected men who have sex with men in Shanghai, China

R. Pan[1,2,3], X. Liu[1], S. Zhou[1], Z. Ning[4], H. Zheng[5], M. Gao[1], Y. Ding[1], W. Yao[3], X. Liao[3], Y. Liu[6], N. He[1,2]
[1]School of Public Health, and the Key Laboratory of Public Health Safety of Ministry of Education, Fudan University, Department of Epidemiology, Shanghai, China, [2]Collaborative Innovation Center of Social Risks Governance in Health, Fudan University, Shanghai, China, [3]Hongkou District Center for Disease Control and Prevention, Shanghai, China, [4]Shanghai Center for Disease Control and Prevention, Shanghai, China, [5]Shanghai Piaoxue Cultural Media Limited, Shanghai, China, [6]Putuo District Center for Disease Control and Prevention, Shanghai, China
Presenting author email: petpann@126.com

Background: Approximately 5-10% of men who have sex with men (MSM) in China are infected with HIV. HIV-infected patients are at high risk of developing malignancies including those associated with Epstein-Barr virus (EBV). This study aimed to compare whole blood EBV DNA positivity between HIV-positive and HIV-negative MSM in Shanghai, China.
Methods: HIV-positive MSM and an equal number of age-matched (±5 years) HIV-negative MSM were recruited from an HIV counseling and testing clinic in Shanghai from Nov. 2014 to Nov.2015 and were administered with a cross-sectional questionnaire interview. Whole blood EBV DNA was tested by nested polymerase chain reaction assays on EBNA-1, EBNA-2 and LMP-1 genes.

Results: Among 1008 participants including 504 HIV-positive and 504 HIV-negative MSM, 81.8% aged at 21-40 years, 62.4% were non-local Shanghai residents, 96% were ethnic Han, 66.8% received college or higher education, 76.5% were never married, and 40.5% had depression when measured with CES-D. The two groups were comparable in distributions of residency, ethnicity and marital status, but were significantly different in age and education distributions. Compared with HIV-negative controls, HIV-positive MSM reported significantly higher proportion of lifetime experience of homosexual activities including having ≥5 partners (83.9% vs. 71.2%), unprotected anal sex (76.4% vs. 63.1%), unprotected casual sex (94.6% vs. 77.6%), receptive anal sex (86.9% vs. 76.0%), unprotected sex after drinking (27.4% vs. 21.8%), and unprotected sex after drug use (25.6% vs. 16.9%). The EBV DNA positivity was 56.0% for HIV-positive MSM and 26.0% for HIV-negative controls. Three separate multiple logistic regression analyses were performed and showed that after appropriately adjusted for potential confounding variables, the EBV DNA positivity was significantly associated with HIV infection status (aOR=3.30; 95%CI: 2.53-4.40; P< 0.001) in the whole sample, and with < 200 cells/ul CD4+ cell counts (aOR=1.64; 95%CI: 1.02-2.63; P=0.042) in the HIV-positive group, but with no any factors in the HIV-negative group.
Conclusions: The higher positivity of whole blood EBV DNA and its association with low CD4+ T cell counts among HIV-infected MSM discovered the population at higher risk for active EBV replication and underscore needs of further surveillance and research on EBV-related carcinogenesis in this population.

TUPEC0815

Predictors and incidence of sexually transmitted hepatitis C virus infection in HIV-positive men who have sex with men

N.A. Medland[1], C. Eric P F[1], C.S. Bradshaw[1], T.H.R. Read[1], J.J. Sasadeuz[2], C.K. Fairley[1]
[1]Monash University, Melbourne Sexual Health Centre, Alfred Health, Central Clinical School, Melbourne, Australia, [2]Royal Melbourne Hospital, Victorian Infectious Diseases Service, Melbourne, Australia
Presenting author email: nmedland@mshc.org.au

Background: Sexual transmission of Hepatitis C virus (HCV) in men who have sex with men (MSM) and its interaction with HIV status, sexually transmitted infections and sexual behaviour is poorly understood. We assessed the incidence and predictors of HCV infection in HIV positive MSM.
Methods: The electronic medical record and laboratory results from HIV positive MSM in care at a large urban public specialist HIV clinic embedded in a sexual health centre in Melbourne Australia were collected. Patients with two or more HCV antibody tests between January 2008 and March 2016 and with no record of injecting drug use were included. The HCV exposure intervals were the periods between a negative HCV test and the next HCV test. We compared HCV exposure intervals temporally associated with and without newly acquired syphilis or anorectal chlamydia. HCV exposure intervals were also categorised as being before or after HIV virological suppression and by most recent and nadir CD4 cell count.
Results: 37 new HCV infections were diagnosed in 822 HIV positive MSM with no history of injecting drug use over 3114 person years (PY) of follow-up. Mean age was 43.1 years (±12.5) and mean CD4 cell count nadir was 362 cells/uL (± 186). The incidence of HCV infection in the study population was 1.19/100PY (0.99-1.38). The incidence in exposure periods temporally close to new syphilis infection was 4.72/100PY (3.35-6.08) and to new anorectal chlamydia infection was 1.37/100PY (0.81-1.93). The incidence in men without supressed viral load was 3.19/100PY (1.89-4.49). In the multivariate Cox regression analysis only younger age (aHR 0.67 (0.48-0.92)), exposure periods temporally associated to new syphilis infection (aHR 4.96 (2.46-9.99)) and higher CD4 cell count nadir (aHR 1.26 per 100 cells/uL (1.01-1.58)) were associated with increased risk of HCV infection. During the study period the incidence of syphilis increased dramatically but the incidence of HCV infection remained the same.
Conclusions: Incidence of HCV infection is associated with syphilis but not anorectal chlamydia which suggests a biological rather than behavioural risk modification. Rising syphilis incidence may offset declines in HCV transmission through HCV treatment as prevention.

TUPEC0816

Prevalence and predictors of eye disorders among ART patients in Limpopo, South Africa, 2012-2015

P. Manjengwa-Hungwe[1], L. Kuonza[2], E. Mathatha[3], A. Samie[4]
[1]National Institute of Communicable Diseases, South African Field Epidemiology and Training Programme, Johannesburg, South Africa, [2]National Institute of Communicable Diseases, South African Field Epidemiology Training Progrmme, Johannesburg, South Africa, [3]National Institutes of Communicable Diseases, South African Field Epidemiology Training Progrmme, Johannesburg, South Africa, [4]University of Venda, Microbiology, Limpopo, South Africa
Presenting author email: manjengwa.patience@gmail.com

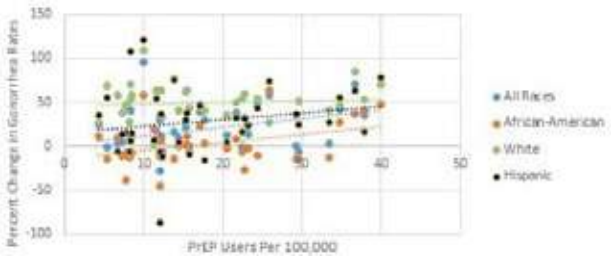
Background: Opportunistic infections are common among HIV positive individuals. Approximately 80% of HIV infected patients will develop HIV associated eye disorders during the course of their illness. Up to 40% of patients with advanced HIV develop cytomegalovirus retinitis which can lead to total blindness. Eye disorders have received minimal attention; hence there is limited data to identify the burden in South Africa (SA).
We determined the prevalence and identified risk factors of eye disorders among HIV positive patients in one South African province.
Methods: A cross sectional study among 535 HIV-infected patients was conducted in Vhembe District, Limpopo province, SA from 2012-2015. Clinical data were collected from the patients using a structured questionnaire and patient files were followed up from 2012-2015. Data were analysed using STATA13. Multivariable logistic regression analysis was used to determine risk factors. Manual backward stepwise procedure was used to select variables and a cut-off p-value of less than 0.05 was used to retain variables in the final multivariate model. We adjusted for confounders of age and gender.
Results: The overall prevalence of eye disorders among HIV positive patients was 33% (177/535, including Scotoma 13% (22/ 177) (95% CI: 8.4 - 18.6); Retinal detachment 13% (22/177) (95% CI: 8.4 - 18.6); Keratoconjunctivitis28% (48/177) (95% CI: 21.4 - 34.7) and Uveitis 54% (93/177) (95% CI: 46.2 - 61.1).
HIV positive patients with diabetes co-morbidity were four times more likely to report eye problems as compared to those without diabetes (OR=4.14, 95%CI=1.22-14.00, p=0.017).
Having a history of TB treatment (OR=1.57, 95%CI=1.04-2.37, p=0.004) and CD4 count less than 200 (OR=2.05, 95%CI=1.92-2.16, p=0.002) were significant predictors of eye disorders among HIV positive patients.
Conclusions: This study demonstrates that eye disorders are common among HIV positive patients in Limpopo. TB diagnosis and treatment, Diabetes and low CD4 count were associated with eye disorders. This highlights that eye disorders are further exacerbated by HIV and having a weakened immune system. Heightened awareness for better management of ocular disorders is recommended among health care personnel and HIV positive people. Policy makers need to integrate ophthalmic examinations in public health facilities when HIV patients receive their treatment.

TUPEC0817

PrEP usage is related to increased STD rates

K. Alaei, C. Paynter, GIHHR
Global Institute for Health and Human Rights, Albany, United States
Presenting author email: kalaei@albany.edu

Background: Truvada has proven to be very effective for use as pre-exposure prophylaxis (PrEP). However, a possible concern is that increased Truvada use will lead to reduced condom usage and increase in STDs that were previously under control.
Methods: We obtained data on rates of Truvada usage for PrEP in the United States. We then ran correlations between Truvada usage and the percent change in STD rates across states between the two-year period from 2011-2012 and the two-year period from 2013-2014. The three STDs examined were gonorrhea, chlamydia, and primary/secondary syphilis. The hypothesis was that a higher rate of PrEP usage would correlate with greater increases in STDs.



[Percent change in gonorrhea among men as a function of PrEP usage across states]

Results: There was a significant positive correlation between PrEP usage and increase in gonorrhea rates (r=0.389, p <0.01) for men across states as well as for women (r=0.438, p <0.005). Correlations were not significant for chlamydia or syphilis. The change in gonorrhea rates were broken down further by racial group and gender. A significant correlation was found for African-American men (r=0.374, p <0.01), but there was no significant correlation for white (p >0.1) or Hispanic (p >0.1) men. For women, a significant correlation was found for whites (r=0.346, p <0.05) and Hispanics (r=0.282, p <0.05) but not African-Americans (r=0.202, p >0.1).
Conclusions: Higher usage of Truvada for PrEP is linked to greater increases in gonorrhea rates among men. Public health officials should ensure that individuals taking PrEP have access to adequate safe sex counseling, particularly if they are either African-American men or white or Hispanic women.

TUPEC0819

Better survival outcomes among HIV-infected women with cervical cancer at a national referral hospital, Kenya

A. Njoroge[1,2], M. Mugo[3], M. Mudenyo[3], L. Muchiri[4], C. Kigondu[4], J. Rajab[4], J. Kinuthia[1,2]
[1]Kenyatta National Hospital, Research & Programs, Nairobi, Kenya, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Kenyatta National Hospital, Health & Information Systems, Nairobi, Kenya, [4]University of Nairobi, Department of Human Pathology, Nairobi, Kenya
Presenting author email: anjoroge@uw.edu

Background: Cervical cancer screening has been integrated into many HIV programs in Sub-Saharan Africa. Most women who screen positive are often referred out for further evaluation with minimal follow-up on their outcomes. We compared survival outcomes among HIV-infected to uninfected women in a cancer registry at a national referral hospital in Kenya.
Methods: Cervical cancer patients whose diagnosis was confirmed by histology/cytology and enrolled for cancer care at Kenyatta National Hospital between April 2014 and July 2015 were included. Patient demographics, HIV testing history, stage of disease at enrolment into cancer care and outcome status (dead or alive) as at Aug 2015 were collected from medical files, laboratory and autopsy records. Logistic regression with recycled predictions was used to obtain the risk ratio of death.
Results: Of 1069 cervical cancer patients, only 435 (41%) had a HIV status indicated. Of these, 211(49%) were HIV-infected. HIV-infected women were younger (median=43 years (IQR 38, 57)) compared to HIV-uninfected women (median=47 years (IQR 40, 54)).Average follow-up duration at the oncology clinic was 9.5 months (8.2, 10.7) and did not vary with HIV status. HIV-infected women had lower stage disease at enrolment compared to HIV-uninfected women (Trend test p=0.042).

Cervical Cancer Stage (FIGO)	HIV-Infected (n)	HIV-Uninfected (n)	Prevalence Ratio	95% CI
I	28	13	1.00	Reference
II	43	48	0.42	0.19, 0.90
III	50	68	0.34	0.16, 0.72
IV	17	19	0.42	0.16, 1.05

[Table 1: Cervical Cancer Stage by HIV status]

Of the 211 HIV-infected women, 17(8.1%) had died while 34(15.2%) of the 224 uninfected women had died. Adjusting for age and stage of disease ,HIV-infected women with cervical cancer were 1.1 times more likely to be alive compared to HIV-uninfected women (risk ratio 1.11 (95%CI: 1.01 - 1.2) p= 0.0174.
Conclusions: HIV-infected women with cervical cancer had lower stage disease at diagnosis and better outcome compared to uninfected women. This could be a result of systematic cervical cancer screening and referral offered in HIV care clinics. This approach could be of benefit if integrated into other programs that routinely offer services to women.

TUPEC0820

Inflammation is an important predictor of diabetes in veterans with HIV infection: a veterans aging cohort study

M. Wellons[1], K. McGinnis[2,3], K. So-Armah[4], J. Blume[1], A. Justice[2,3], M. Freiberg[1], J. Koethe[1]
[1]Vanderbilt University Medical Center, Nashville, United States, [2]VA Connecticut Healthcare System, West Haven, United States, [3]Yale University Schools of Medicine and Public Health, West Haven, United States, [4]Boston University School of Medicine, Boston, United States
Presenting author email: melissa.wellons@vanderbilt.edu

Background: HIV-infected (HIV+) persons on long-term antiretroviral therapy (ART) are at risk of diabetes mellitus (DM), which has been linked to persistent inflammation. Further, an increasing proportion of HIV+ persons are overweight and obese, which is both a risk factor for DM and a pro-inflammatory condition. We used the Veterans Aging Cohort Study biospecimen cohort (VACS-BC) to assess whether the relationship between BMI or inflammatory biomarkers and DM incidence differs by HIV status.
Methods: VACS-BC is a longitudinal cohort study of HIV+ and uninfected (2:1) veterans from 8 Veterans Affairs Healthcare Centers enrolled between 2005 and 2007. DM diagnoses and onset date were determined using an algorithm incorporating glucose, HbA1c, ICD-9 codes, and medications. Cox proportional hazards models were used to model the incidence of DM as a function of baseline interleukin-6 (IL-6), d-dimer, soluble CD14 (sCD14), HIV status and BMI. HIV+ participants were stratified as suppressed (plasma HIV RNA < 500 copies/ml at enrollment) or unsuppressed (≥500 copies/ml). Models were adjusted for age, race, sex, education level, hepatitis C status, smoking status, alcohol use, and interaction terms.
Results: Excluding prevalent cases (n=556), our algorithm identified 231 incident DM cases among 1833 participants. IL-6, HIV status and BMI but not sCD14 or D-dimer were associated with incident DM. After exclusion of underweight (BMI ≤ 18.5) and stratification by HIV status, overweight and obesity as compared with normal weight were significantly associated with risk of DM in uninfected and HIV+ with suppressed virus, but not significantly in unsuppressed HIV+. High serum IL-6 (Q4) was significantly associated with higher DM risk (Q4 versus Q1) in all groups.

	Uninfected Veterans	HIV-infected Veterans	
	Uninfected (n=562)	RNA<500 (n=756)	RNA≥500 (n=454)
Normal weight (BMI 18.5-24.9)	HR 1.00	HR 1.00	HR 1.00
Overweight (BMI 25-29.9)	HR 2.90; 95%CI 1.35-6.22	HR 1.73; 95%CI 1.02-2.96	HR 0.87; 95%CI 0.43-1.77
Obese (BMI ≥30)	HR 4.39; 95%CI 2.10-9.21	HR 2.69; 95%CI 1.38-5.25	HR 1.52; 95%CI 0.67-3.46
Low IL6 (Quartile 1)	HR 1.00	HR 1.00	HR 1.00
High IL6 (Quartile 4)	HR 2.50; 95%CI 1.44-4.33	HR 2.44; 95%CI 1.06-5.63	HR 4.08; 95%CI 1.16-14.43

[Hazard of DM by BMI and IL-6.]

Conclusions: In HIV+ persons with suppressed viremia, being overweight/obese and having elevated IL-6 are independently associated with increased DM risk. BMI has less prognostic value for DM risk in HIV+ persons with unsuppressed viremia.

TUPEC0821

Phylogeographic analysis of HIV-2 ANRS CO5 cohort reveals new trends in HIV-2 epidemic patterns in West Africa

B. Visseaux[1], M. Bertine[1], A. Storto[1], F. Damond[1], F. Collin[2], G. Chêne[2], S. Matheron[3], C. Charpentier[1], S. Huë[4], D. Descamps[1]
[1]Laboratoire Virologie Bichat Claude Bernard - APHP - IAME, UMR 1137, INSERM, Paris, France, [2]Université Bordeaux, ISPED, Centre INSERM U 897, Bordeaux, France, [3]Maladies Infectieuses et Tropicale, Hôpital Bichat, APHP, IAME UMR 1137, Inserm, Université Paris Diderot, Paris, France, [4]Department of Infectious Diseases Epidemiology, Faculty of Epidemiology and Public Health, London School of Hygiene and Tropical Medicine, London, United Kingdom
Presenting author email: benoit.visseaux@aphp.fr

Background: The early spread of HIV-2 in Western Africa is imperfectly described for group B and the recently identified subtype A2. Recent HIV-2 epidemiological data are also scarce outside of Guinea-Bissau. The sequence database of the HIV-2 ANRS CO5-cohort, one of the largest to date, was used to explore the early migration patterns of these strains by phylodynamics means.
Methods: All publicly available (49 and 8 for A and B, respectively) and ANRS CO5-cohort (125 and 68 for A and B, respectively) pol sequences with available time of sampling and patient's country of birth were included. Bayesian phylogeographic reconstructions and effective population size estimations were performed

under the best fitting combination of evolutionary, demographic and molecular clock models using BEAST 1.8. The tree topology was assessed with maximum likelihood trees using RAxML 8.0.0.
Results: The estimated introduction of group A in human was 1945 [95% HPD: 1935-53], as previously reported. Subtype A1, present in Senegal, Gambia, Guinea-Bissau and Guinea, experienced an early diversification around 1946 [1936-54] with two distinct early epidemics in Guinea-Bissau and Senegal. Subtype A2, present in Ivory Coast and Mali, experienced a latter diversification (1956 [1947-63]) in Ivory Coast with two introduction events in Mali (1963 [1957-69] and 1967 [1960-74]). Group B was originally introduced in Ivory Coast in 1962 [1953-13]. Changes in effective population size over time revealed an initial exponential growth followed by a population decline starting in the 2000's for the three HIV-2 strains. The rate of this decline was slower for A2 and B subtypes (Ivory Coast, Mali) than for A1 (Guinea-Bissau, Senegal).
Conclusions: This phylogeographic study is the first to reconstruct the early dispersal of A2 and B HIV-2 clades in Western Africa. Our results suggest that subtype A1 was circulating in Guinea-Bissau and Senegal before the independence war of the former, believed to have contributed to the dispersal of HIV-2. Both A2 and B clades emerged in Ivory Coast and experienced latter diversification and population expansion (starting in 1980 and 1990, respectively) than A1. There is indication of slow decreasing incidence rates of HIV-2 in Ivory Coast or Mali where recent data are scarce.

TUPEC0822

Expansion of HIV BF recombinants among men who have sex with men (MSM) in Buenos Aires, Argentina

M.A. Pando[1], R. Marone[2], I. Balan[3], A. Carballo Dieguez[3], M.M. Avila[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Ciudad Autonoma de Buenos Aires, Argentina, [2]Nexo AC, Ciudad Autónoma de Buenos Aires, Argentina, [3]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, United States
Presenting author email: ac72@cumc.columbia.edu

Background: Several HIV epidemiological studies performed among MSM from Buenos Aires, Argentina revealed high HIV prevalence (11-17%) and incidence (4.5 per 100 persons-year). First studies on molecular epidemiology established that subtype B dominated the epidemic among MSM while BF recombinants were more frequent among heterosexual men and women.
The objective of the study was to describe the subtype diversity of HIV among MSM along 10 years of epidemiological studies in Buenos Aires, Argentina (2000-2009).
Methods: Four different studies were performed from 2000 to 2009 (Study 1, 2, 3 and 4). All the studies included self-reported MSM, including those who have other partners (women and/or transgender) and those who exclusively have male partners. HIV DNA/RNA was isolated from cells/plasma samples using commercial kits and pol gene was amplified from positions 2143 to 3798 (HXB2 numbering) and sequenced in an automatic sequencer. The phylogenetic analysis was performed by Neighbor-joining and bootscanning.
Results: A total of 293 pol gene sequences were obtained and phylogenetic analysis revealed that 221 (75.4%) were subtype B and 72 were BF recombinants (24.6%). Temporal analysis demonstrated that frequency of subtype B significantly decreased over time: 89.6% in Study 1, 83.3% in Study 2, 71.2% in Study 3 and 58.5% in Study 4 (p<0.001). In the last study, the frequency of subtype B was significantly higher among men who exclusively have sex with men as compared with those also having sex with women and/or trans (74.1% vs. 42.3%, p=0.027).
Conclusions: Subtype B continues being predominant among MSM, however, in comparison to previous studies, the frequency of BF recombinants is increasing over time. Our results suggest that even subtype B might have been the subtype that originated the HIV epidemic among MSM, the interconnection with other groups where BF recombinants predominate, has produced a change in the molecular epidemiology of MSM. This fact needs to be considered for any preventive clinical trial to be conducted among MSM, where HIV subtype could be influencing the result.

TUPEC0823

Prevalence of HIV-2 and HIV-1 group O infections among new HIV diagnoses in France, 2003-2015

F. Barin[1,2], F. Cazein[3], J. Pillonel[3], D. Thierry[2], C. Semaille[3], F. Lot[3]
[1]Université F-Rabelais, Virology & Inserm U 966, Tours, France, [2]CHU Bretonneau, Virology Lab & CNR VIH, Tours, France, [3]Santé Publique France, Saint Maurice, France
Presenting author email: francis.barin@univ-tours.fr

Background: Both HIV-2 and HIV-1 group O (HIV-1_O) are considered as restricted geographically, either to west Africa vs Cameroon, respectively. Cases have been described outside Africa, particularly in Europe, but no extensive epidemiological surveys have determined the extent or dynamics of spread of these rare viruses in western countries on a long period.
Methods: The French reporting system for new HIV diagnoses is linked to a virological surveillance using dried serum spots (DSS) on which a serotyping assay that discriminates between HIV-1 group M (HIV-1_M), HIV-1_O and HIV-2 is performed. Clinical and epidemiological variables are collected and entered into the national database, among which: sex, age, country of birth, mode of transmission, clinical stage at HIV diagnosis.
Results: Of 47,097 new HIV diagnoses reported during the 13-year period for which DSS was available, 779 concerned patients infected by HIV-2 (1.65%) and 40 patients infected by HIV-1_O (0.09 %). In addition 46 cases of dual HIV-1/HIV-2 infections and 3 cases of dual HIV-1/HIV-1_O infections were observed. Patients infected by HIV-2 were mostly born in a west African country (83.4%), mainly Ivory Cost, Mali, Senegal, Guinea and Guinea-Bissau. Patients infected by HIV-1_O were mostly born in Cameroon (71.4%). However 34 patients infected by HIV-2 were born in Europe (31 in France and 3 in Portugal) and 6 patients infected by HIV-1_O were born in France. When compared to HIV-1_M, patients infected by HIV-2 or HIV-1_O were older and were more frequently women. Among 12,737 new HIV diagnoses in men who have sex with men, only 5 were infected by HIV-2 and none by HIV-1_O. HIV-2 prevalence decreased since the 2006-08 period: 1.58% (2003-05), 2.24% (2006-08), 1.56% (2009-11) and 1.29% (2012-15) ($p< 10^{-4}$). For HIV-1_O, the decrease was not significant: 0.12%, 0.11%, 0.09% and 0.05% (p=0.054).
Conclusions: The study shows that most of the cases diagnosed during this 13-year period still occurred in patients originating from the endemic areas, west Africa and Cameroon, for HIV-2 and HIV-1_O, respectively. There is no increasing spread of these rare variants in France.

Identification of rapid and emerging transmission clusters from genetic network

T.H. Kwan[1], N.S. Wong[2], K.C.W. Chan[3], O.T.Y. Tsang[4], M.P. Lee[5], D.P.C. Chan[2], W.C. Yam[6], S.S. Lee[2]
[1]Chinese University of Hong Kong, Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, [2]Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Shatin, Hong Kong, [3]Centre for Health Protection, Special Preventive Programme, Department of Health, Hong Kong, Hong Kong, [4]Princess Margaret Hospital, Department of Medicine and Geriatrics, Lai Chi Kok, Hong Kong, [5]Queen Elizabeth Hospital, Department of Medicine, Kowloon, Hong Kong, [6]University of Hong Kong, Department of Microbiology, Pokfulam, Hong Kong
Presenting author email: kwantszho@gmail.com

Background: Transmission network could be inferred from HIV sequences. This study aimed at applying social network analysis to identify clusters with accelerating transmission for informing targeted intervention.
Methods: HIV sequences of gag-pol region with demographics and longitudinal viral load data were collected over a 20-year period from all three HIV clinics in Hong Kong. Individual seroconversion year was estimated by back-calculation. Transmission networks were formed by pairs with TN93 distance ≤1.5%. Network clusters were identified and decomposed by modularity if one contained more than half of the nodes. Clusters were then analysed by the following metrics: density, clustering coefficient, and transmission speed in persons per year (ppy). Emergence of new nodes was evaluated by the average number of nodes added to clusters in the foregone 2 years (2-year cluster incidence).
Results: Between 1994 and 2013, 2352 genetic sequences were available for analysis, accounting for 40% of Hong Kong's reported incident cases. Density of the entire network was 1.65%. Among 131 connected components, 68 were dyads. The largest component consisted of 72% of the connected nodes, from which 20 clusters were decomposed.
A total of 82 clusters were further analysed. Most clusters were of subtype B (62%), while subtypes CRF01_AE and CRF07_BC/CRF08_BC accounted for 22% and 10%, respectively. The largest cluster, with the highest speed (12.31 ppy), was composed of CRF01_AE heterosexuals, men who have sex with men (MSM) and some injection drug users. The second fastest (9.00 ppy) was a subtype B cluster com-

posing of largely MSM. Emerging transmission was identified from MSM clusters of subtype CRF01_AE and CRF07_BC (2-year cluster incidence: 7.00, 6.50). Some 76% of the clusters had not grown further after 2010.
Demographically, clusters with younger individuals had a higher 2-year cluster incidence and clustering coefficient. Percentage of viral suppression in clusters was negatively associated with clustering coefficient.
Conclusions: The new metrics have enabled us to uncover multiple ongoing HIV transmission networks in Hong Kong. Clusters of younger individuals emerged and grew rapidly, which are of public health concern. Viral suppression achieved from antiretroviral therapy had reduced onward viral transmission, resulting in a low clustering coefficient.

TUPEC0825

Near Full-length genomic sequencing and molecular analysis of HIV-infected individuals in a network-based intervention (TRIP) in Athens: phylogenetic clusters correlate with individuals with social links

E.-G. Kostaki[1], D. Paraskevis[1], D. Frampton[2], B. Ferns[3], J. Raffle[2], P. Grant[4], Z. Kozlakidis[5], G. Nikolopoulos[6], A. Hadjikou[7], E. Pavlitina[8], A. Hatzakis[1], L. Williams[9], S.R. Friedman[9], E. Nastouli[3,10], on behalf of the ICONIC Consortium
[1]National and Kapodistrian University of Athens, Medical School, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece, [2]UCL, Department of Infection and Immunity, London, United Kingdom, [3]UCLH/UCL, NIHR Biomedical Research Centre, London, United Kingdom, [4]UCLH, Department of Clinical Virology, London, United Kingdom, [5]UCL and Farr Institute of Health Informatics Research, Faculty of Medical Sciences, Division of Infection and Immunity, London, United Kingdom, [6]University of Cyprus, Medical School, Nicosia, Cyprus, [7]European University Cyprus, Nicosia, Cyprus, [8]Transmission Reduction Intervention Project, Athens, Greece, [9]National Development and Research Institutes, Institute for Infectious Disease Research, New York, United States, [10]UCL GOS Institute of Child Health, Department of Population, Policy and Practice, London, United Kingdom
Presenting author email: ekostakh@med.uoa.gr

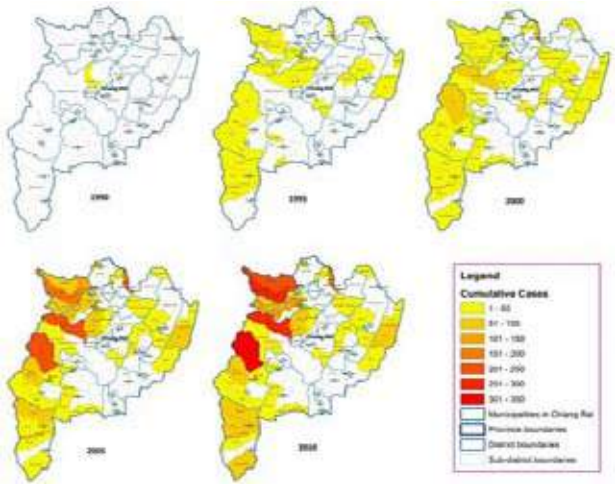
Background: The Transmission Reduction Intervention Project (TRIP) was a social network-based contact tracing study to detect individuals with recent HIV infection within 6 months. Most of the participants were people who inject drugs (PWID). We herein explore factors associated with transmission clustering based on full-length HIV genomic phylogenetic analysis and on well characterized social networks.
Methods: TRIP participants were grouped into clusters following a social network-based contact tracing. HIV whole genomes were generated using methods developed under the Infection Response through Virus Genomics (ICONIC) project. Full-length genomic alignments were performed with MAFFT program available online on HIV sequence database. Phylogenetic trees were inferred by an approximate maximum likelihood method derived from whole genome alignments of samples of 104 HIV+ participants using the FastTree program. Highly supported phylogenetic clusters (subnetworks) were those receiving >0.95 SH-support.
Results: All sequences belonged to previously identified local transmission networks of PWID (CRF14_BG, CRF35_AD, subtypes A and B) (LTNs) in the Athenian outbreak (n=76) and of unique recombinants (n=28). After excluding unique recombinants, phylogenetic analysis of 76 near full-length HIV genomic sequences suggested the existence of 14 subnetworks with 2-4 sequences each and 38 sequences in total (50% of all sequences). Eleven subnetworks (11/14, 78.6%) included sequences of twenty two individuals (22/38, 57.9%) with first degree social links with at least another member of their subnetwork.
Conclusions: Additional HIV whole genome sequencing data helped to better define phylogenetic subnetworks. Interestingly, all sequences falling within phylogenetic clusters (n=7) by Sanger sequencing before did so also by full-length sequence analysis. The percentage of individuals within phylogenetic subnetworks having also social links with other subnetwork members was higher with full-length genome analysis (57.9%) than with Sanger sequencing (43.8%), suggesting that the former describes subnetworks in more detail. Molecular methods can identify infected people with social connections in more than half of the phylogenetic clusters. To our knowledge, this is one of the first studies showing the added value of molecular epidemiology, which uses full-length phylogenetic analysis of HIV sequence data to identify phylogenetic clusters of individuals who also have social ties.

TUPEC0826

The geography of HIV/AIDS among marginalized highland ethnic minorities in Chiang Rai province, Thailand

K.M. Soe[1], P. Saenna[2], T. Apidechkul[3], B. Wilcox[1]
[1]Faculty of Public Health, Mahidol University, Bangkok, Thailand, [2]Faculty of Education, Khon Kaen University, Khon Kaen, Thailand, [3]School of Health Science, Mae Fah Luang University, Chiang Rai, Thailand
Presenting author email: feradodo@gmail.com

Background: Subsequent to Thailand's first HIV/AIDS epidemic wave in its urban center in recent decades, a new epidemic wave emerged among highland ethnic minorities in Northern Thailand. It is a major challenge to combat the burdens imposed by the epidemic on ethnic minorities because of barriers in social cultural-language, political, and health systems.
Methods: The Study describes and determines the spatial and temporal dynamics of the HIV epidemic by HIV cumulative incidences among six highland Hill Tribes in the province of Chiang Rai. Secondary data of 16 hospitals in the province was compiled for ethnic minority HIV reported cases during 1990 to 2011. Quantum GIS Desktop (Version 1.8.0) was used to create maps of HIV incidences of different Hill tribe village locations across districts and sub-districts in Chiang Rai.
Results: A total of 3130 HIV incidences were reported in 294 villages out of 651 with spatial density non-randomly distributed: 1420 (45.4%) female; 2738 (87%) age of 15 - 49, 229 under 15 (7.3 %) and 163 cases (5.2%) 50 or above; 1403 (45%) agriculture workers, 1003 (32%) labor worker and others (23.2%); Sexual transmission 91.6%, Mother to child transmission at 5.7% and injecting drug use <1%. The Akha tribe contributes to the highest no. of cases 1441 (46%) followed by Lahu 617 (19.7%), Yao 298 (9.5%), Lisu 282 (9%) Karen 271 (8.7%) and Hmong 221 (7.1%). The districts with dense population in highlands and those with close proximity to major municipalities are most affected.
Conclusions: Hill tribes living in Chiang Rai are among the most disadvantaged and vulnerable societies who are at risk of HIV infection due to poverty, lack of access to education, increased drug use, increase sex work and social marginalization. Education programs to promote behavioral change and priority focused interventions should be implemented.



[Cumulative HIV Incidence among Hill Tribes]

TUPEC0827

Updated estimates of HIV incidence in France, 2003-2014

C. Sommen[1], F. Cazein[1], Y. Le Strat[1], J. Pillonel[1], F. Lot[1], S. Le Vu[1], F. Barin[2]
[1]Santé Publique France, Saint Maurice, France, [2]National Reference Center for HIV, Tours, France
Presenting author email: francoise.cazein@santepubliquefrance.fr

Background: A surveillance system combining case reporting and biomarker-based identification of recently acquired infection is implemented in France to monitor HIV incidence at the country level. First estimates indicated an overall downward trend in new infections but a stable number in men who have sex with men (MSM), representing half of new cases in 2008 (Le Vu et al, Lancet Inf Dis 2010). Here, we provide revised national estimates for the period 2003 to 2014, accounting for updates in data and methodology.
Methods: We used the stratified extrapolation approach described in Prejean et al. (PloS ONE 2011) that infers yearly number of new infections by weighting reported diagnoses detected as recent infections (EIA-RI assay). The weights reflect

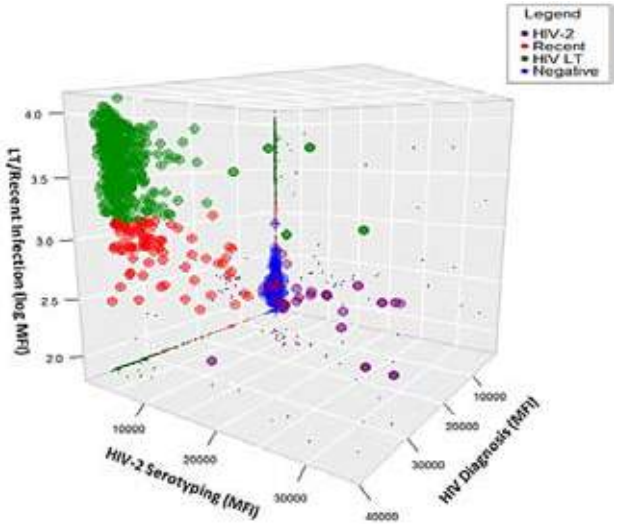
HIV testing behaviors specific to each stratum of transmission category and demographics. Diagnosis data were adjusted for reporting delays and under-reporting. Missing data for key variables was imputed by multiple imputation. Temporal trends in incidence based upon 52 375 diagnoses were compared using variance-weighted least-square regression.
Results: We estimate that 5659 [95%CI: 5129-6189] persons were newly infected with HIV in France in 2014. This led to an overall incidence rate of 13 per 100,000 persons/year (aged from 18 to 69 years). With 2912 (51%) new infections in 2014, MSM still contributed dramatically to the overall number of cases. Among the 2680 (48%) new infections attributed to heterosexual transmission, foreign-born individuals (56%) exceeded French-born (44%). Intravenous drug users accounted for 1% of new infections. The HIV incidence globally decreased from 2003 (with 10 651 [95%CI: 9348-11955] new infections) to 2014. The decrease was significant throughout the whole period in heterosexuals, but only over the 2008-2014 period in MSM.
Conclusions: These updated results confirm the overall decrease of HIV incidence in France since 2003. MSM are still disproportionately contributing to current HIV transmission but after having kept a stable level up to 2008, new infections are now decreasing in this group. An analysis with more intricate breakdown by demographics (world region of birth, age and geographical area) is underway to fully appreciate the progress made in the country to drive down new HIV infections.

TUPEC0828

Development of a multiplex assay for HIV diagnosis, serotyping and detection of recent HIV-1 infection

E. Yufenyuy, B. Parekh
Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States
Presenting author email: bparekh@cdc.gov

Background: Currently LAg-Avidity EIA, developed in our laboratory, is the best tool to detect recent HIV-1 infection. However, efforts to use laboratory-based assays in cross-sectional surveys are often challenged by inaccurate HIV diagnosis and presence of HIV-2 infection, requiring multiple additional steps. We developed a multiplex assay that combines HIV diagnosis, HIV serotyping and detection of recent HIV-1 infection, all in a single test.
Methods: Magpix Luminex technology which uses colored magnetic beads was used for multiplex assay development. HIV diagnosis and HIV-2 serotyping were accomplished by coupling beads with a recombinant HIV-1 p24-gp41 fusion protein and HIV-2 peptide from gp36 immunodominant region, respectively. HIV-1 recent infection detection was accomplished by using limiting amounts of multi-subtype gp41 recombinant protein, rIDR-M.
Assay conditions, including coupling, were optimized using well-characterized specimens in a stepwise manner. Beads were subsequently combined in a multiplex assay to evaluate its performance using a previously characterized world-wide panel of specimens (n=1500) from HIV-1 positive (n=570, recent = 78, long-term= 492), HIV-2 positive (n= 31) and seronegative persons (n=899) from 10 countries, representing subtypes A, B, C, D, and AE.
Reference results were generated using EIA/WB algorithm for HIV status, Multispot assay for HIV-1 and 2 serotyping and LAg-Avidity EIA for recent or long-term classification. Assay cutoffs and algorithms were determined by using 3-parameters comparing it to the results of reference standard.



[Development of a multiplex assay]

Results: The diagnostic component of the assay performed with high sensitivity (99.8%) and specificity (99.7%), while the HIV-2 serotyping sensitivity was 96.7% and specificity was 100%. There was a high level of correlation between the detection of recent infections using the LAg-Avidity EIA and that from the multiplex assay with the possibility of extending the mean duration of recent infection. The assay showed high reproducibility with coefficient of variation of <10%.
Conclusions: The new multiplex assay has the ability to accurately diagnose HIV infection, perform HIV-1 and 2 serotyping and detect and distinguish recent from long-term HIV-1 infections, all in a single test. This novel assay has the potential to simplify HIV surveillance by combining critical biomarkers on a single platform.

TUPEC0829

HIV prevalence in Argentina: a large scale study

N. Haag[1], A. Arce[2], M. Pedrola[3], P. Campos[4], N. Delgadillo[4], M. Laurido[2]
[1]AHF Argentina, HIV Testing and Prevention, Buenos Aires, Argentina, [2]AHF Argentina, Buenos Aires, Argentina, [3]AHF Latin America, Buenos Aires, Argentina, [4]AHF Latin America, Mexico, Mexico
Presenting author email: natalia.haag@aidshealth.org

Background: According to the UNAIDS report of 2015, HIV prevalence in Argentina is 0.4%. This information comes from the estimation of HIV cases of the Ministry of Health in relation to the total country population in 2015. Therefore a study on the HIV prevalence in general population was carried out.
Methods: Between January 2, 2016 and December 30, 2016, HIV antibody determinations were performed in individuals from 10 provinces of Argentina, which together represent more than 60% of the total country population, through a previously validated rapid test (Alere Determine ™ HIV-1/2). Counselling was given to all people and for positive cases established the appropriate referral. The information was collected in an Ad Hoc database. Chi2, Fisher exact or Mid P tests and maximum likelihood odds ratios were used as appropriate.
Results: Determinations were made in 30013 people. Age range: 18 months to over 49 years. Gender distribution: women 53.6%, men 45.4%, transgender 1%. It was the first HIV test for 56%. There were 272 HIV positive results. Prevalence: 0.9% (95%CI: 0.8-1). Although the prevalence was significantly higher in men than in women (1.2% versus 0.5%, $p < 0.001$), the highest level was observed in transgender (4.6%). There was a greater probability of having a positive test in people who had unprotected sex (OR: 1.49 - 95%CI: 1.16-1.91; p = 0.001) and people between 25 and 49 years-old (OR: 1.46 - 95%CI: 1.15-1.86; p = 0.002). No significant differences were found in relation to sexual preferences (p = 0.69) or intravenous drug use (p = 0.40). Consistent condom use was reported in 14.5% of the people with negative results and in 22.3% of those with positive results. 80% of the population tested had at least high school education.
Conclusions: HIV prevalence observed in this population was twice as high as that reported for the general population of Argentina by UNAIDS. Multiple factors such as cultural issues, vulnerability or information on HIV transmission could explain this finding. Large scale testing is necessary to adjust estimates of the total population living with HIV and to establish better strategies for reducing the risk of transmission.

TUPEC0830

Risk factors and HIV care continuum outcomes for diagnosis during recent HIV infection in North Carolina

C. Sellers[1], S. Zhou[2], K. Seaton[3], G. Tomaras[3], S. Zimmerman[4], E. Samoff[4], R. Swanstrom[2], J. Eron[1], M. Cohen[1], A. Dennis[1]
[1]University of North Carolina School of Medicine, Medicine / Infectious Diseases, Chapel Hill, United States, [2]University of North Carolina, Biochemistry and Biophysics, Chapel Hill, United States, [3]Duke University, Duke Human Vaccine Institute, Durham, United States, [4]North Carolina Department of Health and Human Services, Division of Public Health, Communicable Disease Branch, Raleigh, United States
Presenting author email: cjseller@unch.unc.edu

Background: Distinguishing between recent and chronic HIV infection has important implications for HIV transmission dynamics and prevention programs. We examined associations with recent infection among new HIV diagnoses in North Carolina in 2014.
Methods: We used a novel Binding Antibody Multiplex Assay that has performed well compared with existing assays to distinguish recent (< 9 months) from chronic infection among individuals with newly diagnosed, antibody-positive HIV infection using remnant diagnostic specimen at the North Carolina State Laboratory of Public Health. Associations between recent infection and demographics were examined using unadjusted and adjusted logistic regression. HIV care continuum outcomes were measured with surveillance data, examining associations of recent

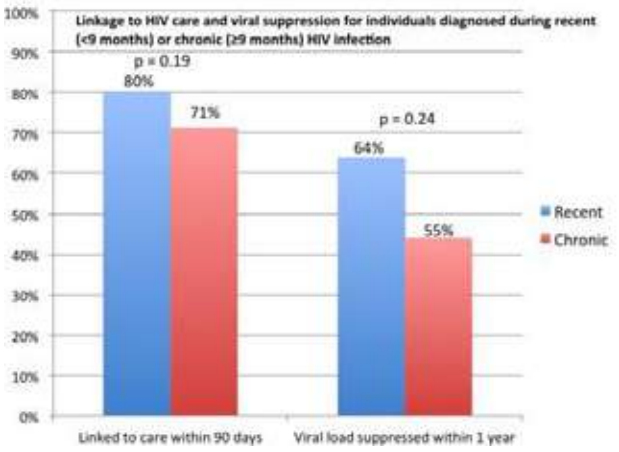
infection with linkage to care (CD4 or viral load [VL] within 90 days of diagnosis) and viral suppression at 1 year (VL < 200 copies/mL).

Results: 32% (61/190) of subjects were classified as recently infected. Median baseline CD4 and VL were 473 (quartiles: 351, 618) and 54,000 (11,560, 143,040) copies/ml for recent versus 350 (212, 609) and 28,893 (7620, 66,665) copies/ml for chronic. Younger age and traditional high-risk groups had significant associations with recent infection. More individuals with recent infection were linked and had viral suppression.

	N	% Recent	Unadjusted prevalence ratio (PR) for recent vs. chronic (95% CI)	Adjusted PR (95% CI), if retained in final model
Male (vs female)	148 (vs 42)	34% (vs 26%)	1.12 (0.51, 2.43)	-
<30 years old vs >30	106 (vs 84)	40% (vs 23%)	1.58 (1.01, 2.49)	1.65 (1.04, 2.61)
African-American (vs Hispanic)	134 (vs 18)	33% (vs 17%)	1.72 (0.61, 4.12)	-
White (vs Hispanic)	35 (vs 18)	40% (vs 17%)	2.06 (0.70, 6.09)	-
MSM (vs denied high risk transmission exposure)	112 (vs 32)	38% (vs 3%)	9.90 (1.36, 72.14)	11.61 (1.66, 81.34)
IDU (vs denied high risk transmission exposure)	10 (vs 32)	40% (vs 3%)	14.67 (1.90, 113.31)	15.09 (1.92, 118.76)
High-risk non-MSM sex* (vs denied high risk transmission exposure)	34 (vs 32)	38% (vs 3%)	11.93 (1.64, 86.70)	13.12 (1.82, 94.34)
Tested by county health department (HD) (vs non-HD testing site)	150 (vs 40)	35% (vs 20%)	1.15 (0.62, 2.13)	-

High-risk non-MSM sex defined as: not MSM and 1 or more of: female partner of MSM, sexual partner of IDU, transactional sex, sex while intoxicated, multiple sexual partners in past year

[Associations with recent HIV at time of diagnosis]



[Figure. Linkage to HIV care and viral suppression]

Conclusions: There was a strong association between diagnosis during recent infection and history of MSM, IDU and high-risk non-MSM sex, possibly reflecting high ongoing local HIV transmission in these groups and poor uptake of HIV testing in those without these risk factors. Our results also suggest that diagnosis during recent infection is not a barrier to linkage or viral suppression.

TUPEC0831

Leveraging individual and ego-network predictors of HIV incidence among Nigerian Men who have sex with men to guide network-level interventions

R. Nowak[1], A. Mitchell[1], T. Crowell[2,3], H. Ramadhani[1], N. Ndembi[4], I. Orazulike[5], S. Baral[6], J. Ake[2], H. Liu[7], M. Charurat[1], TRUST/RV368 Study Group

[1]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [2]US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [3]Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [4]Institute of Human Virology Nigeria, Abuja, Nigeria, [5]International Center on Advocacy and Rights to Health, Abuja, Nigeria, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [7]University of Maryland School of Public Health, College Park, United States

Presenting author email: rnowak@ihv.umaryland.edu

Background: In Nigeria, the rate of new HIV infections in the population are declining but appears to be increasing among men who have sex with men (MSM). To guide the development of comprehensive HIV prevention and treatment interventions needed to reverse these trends, this study characterizes the individual and network-level determinants of new HIV infections among MSM in Nigeria.

Methods: TRUST/RV368 recruited MSM into HIV care and treatment in Abuja and Lagos, Nigeria. At baseline and every quarterly visit, participants (ego) completed a structured instrument studying characteristics of the individual and five most recent sexual partners (alters) along with biological specimens for HIV and sexually transmitted infections (STIs). From March/2013-Oct/2016, 365 MSM who tested negative for HIV at baseline and returned for at least one additional HIV test were included in the analysis. Crude hazard ratios (HR) were estimated for predictors of HIV incidence using Cox proportional hazard models.

Results: Fifty-one individuals seroconverted during follow-up and the overall incidence was 18.8 infections per 100 person-years [PY] (95% confidence interval [CI], 14.1-24.5/100 PY. Those who were younger, unemployed, engaged in receptive intercourse, engaged in recent condomless sex, diagnosed with rectal gonorrhea at the preceding visit were significantly correlated with incident HIV infections. Significant network-level level determinants of incident HIV infections included having older sexual partners by five years, more educated partners, and partners with a higher socio-economic status. (Table 1).

Conclusions: The high HIV incidence rate observed in our study confirms that evidence-based and appropriately scaled HIV prevention and treatment interventions are a public health priority for MSM in Nigeria. While the focus of most of these interventions to date has been addressing individual-level risks, these data reinforce the importance of addressing network-level risks when considering the implementation of interventions especially for young MSM in Nigeria.

Predictor	Category vs. Reference	Unadjusted HR (95% CI)
Age (years)	16-23 vs. 24+	3.5 (1.8-6.7)
Employment status	Unemployed vs. Employed	3.4 (1.9-6.4)
Sexual Positioning	Receptive vs. Insertive	16.0 (4.7-54.5)
Condomless sex at last anal sex	Yes vs. No	1.8 (1.0-3.3)
Rectal gonorrhea preceding visit	Pos vs. Neg	4.2 (2.3-7.4)
Any % of alters 5+ years older than ego	>1% vs. 0%	6.9 (2.8-17.5)
Any % of alters with higher education	>1% vs. 0%	2.5 (1.4-4.6)
Percent of alters with higher socio-economic status	68-100% vs. 0-33%	4.4 (2.2-8.9)
Abbreviations: vs., versus; HR, hazard ratio; CI, confidence intervals

Presenting author email: egonese@cdc.gov

Background: Zimbabwe estimated a decline in HIV incidence from 4.6% (1993) to 0.88% (2015) using Spectrum model. The country has made significant investments in HIV prevention, care and treatment in the last decade. Zimbabwe conducted a Population-Based HIV Impact Assessment (PHIA) that measured HIV incidence in 2015/16.
Methods: A total 22,496 adults (15-645 years) consented to both a face-face questionnaire and biomarker testing in the nationally-representative household survey which had 83.9% response. Home-based HIV testing was performed using the national serial rapid test algorithm of Determineä, First Responseä and Stat-Pak (tie-breaker). HIV positives were confirmed in a satellite laboratory using Geenius HIV-1/2ä, viral load using Roche Taqman and Biomerieux nuclisens and recency using Limiting Antigen Avidityä (LAg). Recent was confirmed by an algorithm of LAg normalized optical density < 1.5 + viral load >1000 copies. We calculated weighted annual HIV incidence.
Results: Overall, 36 of 3,503-(1.03%) HIV positive cases were confirmed as recent infection. Among these, 11 were male and 25 female. The weighted annual incidence was 0.45% (95% CI 0.28 -0.62) and 0.48% (0.29-0.66) for adults 15-64years and 15-49years respectively. The observed incidence (0.48%) is nearly half that reported by Spectrum (0.88%) The point-estimate for incidence was more than twice as high among women (0.67% [0.37-0.97]) compared to men (0.28% [0.06-0.50]) in the 15-49 year age-group. Young men (15-24 years) had lowest incidence, 0.13% (0.00-0.34), while it was three-times high (0.54% [0.14 - 0.94]) in women of similar age-group. By residence, overall incidence for adults (15-49 years) was higher in urban, 0.63% (0.25-1.01) compared to 0.38% (0.18-0.59) in rural setting. The majority of respondents (15-49 years) with incident infections (26/31, 83.9%) had previously been tested. The point-estimate among those ever tested was 0.56% (0.32 -0.80) compared to 0.25% (0.00 -0.52) for participants without prior HIV testing.
Conclusions: HIV incidence remains high among women especially in young women. The high incidence in urban setting may be a signal for increase in high risk behaviours and emergence of sub-epidemics. High incidence among previously tested cases suggest the need to strengthen prevention messaging. Additional exploration, focused interventions should be prioritized.

TUPEC0833

Estimated cumulative HIV incidence rate among men who have sex with men (MSM) in Georgia: study results from repeated bio-behavioral surveys between 2010-2015

N. Shengelia[1], A. Noori[2], I. Chikovani[1], A. Mirzazadeh[2]
[1]Curatio International Foundation, Research Unit, Tbilisi, Georgia, [2]Kerman University of Medical Sciences, The Regional Knowledge Hub and WHO Collaborating Centre for HIV Surveillance, Kerman, Iran, Islamic Republic of
Presenting author email: n.shengelia@curatio.com

Background: Georgia is among the countries with rapidly increasing HIV epidemics among men who have sex with men (MSM). While preventive interventions for this key population are in place, HIV transmission from homosexual contacts is increasing among all new cases and HIV prevalence among MSM reached 25.1% in 2015. This study evaluates incidence trend among MSM in Tbilisi, Georgia.
Methods: To estimate the cumulative incidence rate we used the three rounds of Bio-behavioural surveillance surveys (BBSS) data with respondent driven sampling, conducted in 2010 (N=278), 2012 (N=218) and 2015 (N=300) among MSM in Tbilisi, Georgia. Estimates of annual cumulative incidence rate were derived as follows: the prevalence of HIV infection/person-year at risk for HIV (summing the number of days since the first anal intercourse (as the proxy of HIV negativity and start of exposure risk) and the first HIV test result). The earliest age of anal intercourse was assumed 15 years old. HIV cumulative incidence rates (per 100 persons) along with their 95% confidence intervals (CI) were calculated using Kaplan Meier method and compared among the three respective BBSS rounds by log-rank test.
Results: Cumulative incidence rate per 100 persons increased significantly from 0.59 (0.38-0.93) to 1.26 (0.87-1.83), and 2.06 (1.67-2.55) in 2010, 2012 and 2015, respectively. As for the incidence rate ratio (IRR), analyses showed that the cumulative incidence rate was 2.12 (1.18-3.79) times higher in 2012 and 3.46 (2.10-5.69) times higher in 2015 compared to 2010.

	Estimated incidence rate per 100 persons	95% CI for IR	Estimated Incidence rate ratio	95% CI for IRR	P-value for comparing the IRR
Survey 2010	0.59	0.38-0.93	1	-	-
Survey 2012	1.26	0.87-1.83	2.12	1.18-3.79	0.011
Survey 20105	2.06	1.67-2.55	3.46	2.10-5.69	<0.001
Overall	-	-	1.25	1.16-1.36	<0.001

[Incidence rates and rate ratios of HIV among MSM]

Conclusions: Given rapidly increasing HIV infection among MSM, having estimated HIV incidence along with HIV prevalence data is more useful as it reveals latest and more specific picture of HIV epidemics for effective planning of preventive interventions.

Presenting author email: johnsonc@who.int

Background: Interest in HIV self-testing (HIVST) is increasing as countries pursue the UN "90-90-90" targets and consider adopting WHO's recommendation to offer HIVST. While many self-testers can achieve results similar to trained testers, performance can vary based on context and approach. Among other important considerations is the minimum performance by self-testers at which public health benefit is achieved; defined here as "clinical utility".
Methods: To assess HIVST's clinical utility and weigh performance-related risks and benefits: sensitivity (65-99.8%), specificity (65-100%), HIV prevalence (0.01-15%), linkage to care (50-85%) and linkage to prevention (0-35%) were considered. Different scenarios characterized by varying levels of the factors listed above were simulated. A net benefit score was derived from Total Benefit (true reactive linked to care; true nonreactive linked to prevention) minus Total Risk (false reactive; false nonreactive). False nonreactives and true reactives linked to care were weighted based on expert consultation. The proportion of scenarios with positive net benefit was calculated. Sub-analysis of high (5-10%) and low (0.1-1%) prevalence scenarios, high (20-30%) and low (0-10%) linkage to prevention; and high (70-80%) and low (50-60%) linkage to care was conducted.
Results: 61% of scenarios with ≥70% sensitivity and ≥90% specificity yielded greater benefit than risk. In high prevalence scenarios, positive net benefit was observed at ≥80% specificity and ≥70% sensitivity. For low prevalence scenarios, net benefit marginally increased when sensitivity increased from 70% to 90%. Linkage to prevention drove net benefit; when high, benefit was achieved at ≥80% specificity but when low ≥90% specificity was needed. Linkage to care had modest impact except in very high prevalence settings, e.g. net benefit in all scenarios was not observed among female sex workers in Johannesburg until linkage to care was ≥50%.
Conclusions: In all scenarios, there were some false non-reactive and false reactive results; but in most, risks were exceeded by the benefits of diagnosis and linkage to prevention and treatment. While HIVST's clinical utility is greatest when performance is greatest, this analysis suggests ≥90% specificity and ≥70% sensitivity is needed to achieve a net benefit. For very high prevalence settings with very low linkage, ≥90% sensitivity and specificity would be needed.

Presenting author email: judith.leblanc@aphp.fr

Background: In the ANRS DICI-VIH trial, nurse-driven targeted HIV screening combined with physician-directed diagnostic testing (NTS strategy) substantially increased new HIV diagnoses compared to diagnostic testing alone (DT strategy) in Emergency Departments (ED) of metropolitan Paris, one of the most affected regions in France. A cost-effectiveness evaluation of the NTS strategy was conducted and is reported here.
Methods: A prospective economic evaluation, adopting the hospital perspective, estimated the additional costs of the NTS strategy per additional HIV diagnosis among participants (18-64 year old patients presenting to the ED for reasons other than HIV exposure) compared to the DT strategy. The costs of nurse-driven targeted screening by rapid test (RT) were estimated using a bottom-up micro-costing approach and included testing equipment, procedure duration and staff involved. The total costs of both strategies were estimated for all participants. The cost difference was directly calculated. A scenario analysis explored the impact of various costs, including RT price and staff time required for positive RT result disclosure (physician vs. nurse).
Results: During the DICI-VIH trial, a total of 74,161 (NTS strategy) and 74,166 participants (DT strategy) were included in 8 EDs of metropolitan Paris. The proportion of new HIV diagnoses was higher in the NTS strategy than in the DT strategy (3.0 per 10,000 vs. 0.8 per 10,000, relative risk 3.7, 95%CI 1.4-9.8). The total costs were estimated as 23,011€ with the NTS strategy vs. 1,954€ with the DT strategy, corresponding to €0.31 and €0.03 per participant, respectively. The nurse time costs represented 60% of the costs in the NTS strategy. The Incremental Cost-Effectiveness Ratio (ICER) for the NTS strategy was €1,298 per additional new HIV diagnosis.
The scenario analysis yielded an ICER ranging from €1,251 to €1,947, which compares favorably to the 20,400€ average cost per new diagnosis estimated in 2015 in voluntary testing centers in the region.
Conclusions: Our results support the cost-effectiveness of a targeted screening strategy for HIV in areas with concentrated epidemics.

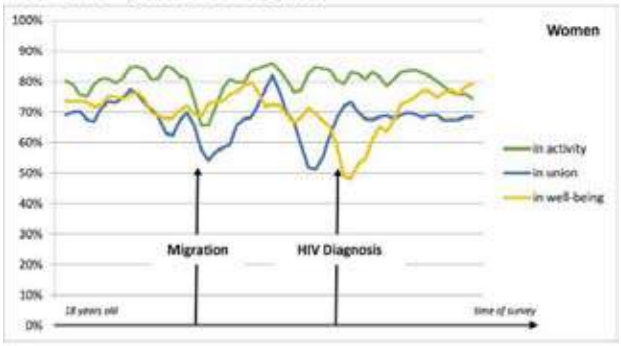
TUPEC0836

Migration and HIV: a double penalty? Assessing the respective impacts of migration and HIV diagnosis on sub-Saharan immigrants' lives in Paris greater area. Results from the ANRS parcours survey

A. Gosselin[1], E. Lelièvre[2], A. Ravalihasy[1,3], F. Lert[1], N. Lydié[4], A. Desgrées du Loû[1,3], Parcours Study Group
[1]CEPED (Paris Descartes University-IRD), Paris, France, [2]Institut National d'Etudes Démographiques (INED), Paris, France, [3]Institut de Recherche pour le Developpement (IRD), Marseille, France, [4]Santé Publique France, National Agency for Public Health, Saint-Maurice, France
Presenting author email: anne.gosselin@ceped.org

Background: Immigrants account for 35% of HIV diagnoses in the European Union (ECDC 2014). Yet little is known about the impact of such a lifelong infection diagnosis on live-courses that are already marked by migration. In this study, we assess the respective impact of migration and HIV diagnosis on the loss of activity, conjugal break up, degradation of perceived well-being among Sub-Saharan migrants living in Ile-de-France.
Methods: We use the ANRS PARCOURS retrospective life-event survey (2012-2013) which collected 926 life histories of randomly-sampled Sub-Saharan immigrants living with HIV in 24 health structures in in Ile-de-France. We use relative-time graphs to describe the levels of activity, union and perceived well-being across time. We model year by year since 18 years of age until data collection the probabilities to lose one's activity, to experience a conjugal break up and the probability of degradation of perceived well-being. We estimate the impact of migration and of HIV diagnosis on these probabilities, thanks to discrete-time logistic regressions.
Results: Our results show that the probability to lose one's activity is higher at the moment of migration than before (aOR= 8.0 [3.6-18.1] for men and 8.7 [5.1-15.0] for women), as well as the probability to experience a conjugal break up (aOR=3.7 [1.8-7.5] for men and 3.0 [1.7-5.4] for women). These probabilities do not vary at time of HIV diagnosis. However, the probability of experiencing a degradation of perceived well-being increases both at time of migration and at time of HIV diagnosis (aOR=11.3 [4.6-27.6] for men and 5.8 [2.8-11.9] for women).

Proportion of Sub-Saharan women in activity, union and perceived well-being in relation to migration and HIV diagnosis



Note: The time spent in each period (between 18 years old and migration, migration to diagnosis and diagnosis until time of survey) was scaled up for all individuals.

[Graph 1]

Conclusions: When HIV diagnosis occurs, it reinforces the negative impact of migration. Migrants living with HIV in France then face a double penalty. These results plead for better social support for recently diagnosed Sub-Saharan immigrants in France.

Advanced HIV disease and severe immunosuppression at diagnosis as Mozambique and Swaziland prepare for test and start

S. Kujawski[1], M.R. Lamb[1,2], M. Lahuerta[1,2], M. McNairy[2], L. Ahoua[3], F. Abacassamo[4], H. Nuwagaba-Biribonwoha[1,5], A. Gachuhi[2], W. El-Sadr[1,2], B. Elul[1]
[1]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States, [2]ICAP-Columbia University Mailman School of Public Health, New York, United States, [3]ICAP-Columbia University Mailman School of Public Health, Maputo, Mozambique, [4]Centro de Colaboração em Saude, Maputo, Mozambique, [5]ICAP-Columbia University Mailman School of Public Health, Mbabane, Swaziland
Presenting author email: be2124@columbia.edu

Background: Early diagnosis of HIV is critical to preventing disease progression and reducing onward transmission of HIV.
Methods: We used data from two implementation science studies conducted in Mozambique and Swaziland to examine the magnitude and predictors of advanced HIV disease and severe immunosuppression at HIV diagnosis. Adults ≥18 years of age were enrolled following diagnosis in HIV testing and counseling clinics at 10 health facilities from 4/2013-6/2015 in Mozambique and 8/2013-11/2014 in Swaziland, and received same day point-of-care CD4 testing. Advanced disease was defined as CD4 count ≤350 cells/µl. Severe immunosuppression was defined as CD4 count ≤100 cells/µl. We estimated the relative risk (RR) of advanced HIV disease and severe immunosuppression in adjusted multilevel regression models.
Results: 2335 adults newly diagnosed with HIV (62.7% female) were included in the analysis. The median CD4 count at diagnosis was 314 cells/µl (IQR: 165-485) with significant differences by sex but not country (Table 1). More than half (56.4%) of the participants had CD4 ≤350 cells/µl, and 13.9% had CD4 ≤100 cells/µl, with differences observed by sex but not country. The adjusted risk of both outcomes was higher in men compared to women (advanced disease aRR=1.31, 95% CI: 1.10-1.56; severe immunosuppression aRR=1.53, 95% CI: 1.16-2.0), and those HIV tested because they felt ill (advanced disease aRR=1.31, 95% CI: 1.10-1.56; severe immunosuppression aRR=2.11, 95% CI: 1.36-2.29). Age 18-24 (vs. age 24-39) was associated with a significantly lower risk of both outcomes (advanced disease

aRR=0.71, 95% CI: 0.59-0.84; severe immunosuppression aRR=0.62, 95% CI: 0.40-0.95). No significant differences emerged when the analysis was stratified by country or sex.

Conclusions: More than 10 years into the global scale-up of HIV services, the majority of adults diagnosed with HIV in two high prevalence countries have advanced disease. Innovative strategies to identify people living with HIV earlier are urgently needed for individual and societal benefits.

Performance of 9 rapid diagnostic HIV tests on a wide panel of whole blood samples

T. Mourez[1], V. Lemée[1], V. Delbos[2], C. Delaugerre[3], M. Etienne[2,4], E. Alessandri-Gradt[1], F. Simon[3], M.-L. Chaix[3], J.-C. Plantier[1]

Presenting author email: thomas.mourez@chu-rouen.fr

Background: Rapid diagnostic HIV tests (RDTs) are now used in and outside laboratories or as self-tests, to improve HIV diagnosis coverage. RDTs performances are classically tested on serum, and more rarely on whole blood, limiting interpretation on a "real life" use. Moreover, most of the RDTs tested only detect antibodies (3rd generation). We tested the performance of 9 RDTs, including two detecting p24 and antibodies (4th generation) on a large panel of fresh and reconstituted whole blood samples, corresponding to diverse clinical status and representative of the wide genetic diversity of HIV.

Methods: Seven 3rd generation RDTs - STAT-VIEW HIV 1/2 (Chembio diagnostic systems), EXACTO PRO TEST HIV (Biosynex), EZ-TRUST HIV 1 & 2 Rapid Screen Test (CS Innovation Ltd), Genie Fast HIV1/2 (Bio-Rad), HIVTOP (Biosynex), INSTI (bioLytical), VIKIA HIV 1/2 (bioMérieux) - and two 4th generation RDTs - BioTechMed HIV1/2 Rapid-4 (BioTechMed) and HIV Combo (Alere) - were tested. The specificity and sensitivity were evaluated on 200 negative and 300 positive samples. Among these latter, 100 corresponded to ART-naïve patients; 150 were representative of HIV diversity, including HIV-1/O and HIV-2; and 50 were collected during the primary HIV infection phase.

Results: HIV-1/M and HIV-2 samples were positive with all the RDTs, except for 6/13 HIV-2 samples not detected with BioTechMed assay. Only the HIV Combo and VIKIA HIV 1/2 detected all HIV-1/O samples. Among the 50 PHI samples, 27 to 37 were found positive using the 3rd generation tests; the two 4th generation tests, HIV BioTechMed HIV1/2 Rapid-4 and HIV Combo, detected 30 and 43 of the 50 samples, respectively. The specificity ranged from 98 to 100%.

Conclusions: Our method of reconstituted whole blood allowed us to evaluate RDTs close to real-life conditions, on a large panel of samples in terms of genetic diversity and clinical status. No difference was observed for diagnosis of HIV-1/M infections; nonetheless, divergent HIV-1/O samples remains of concern, with only 2 tests detecting them all. Use of 4th generation RDT can significantly increase the diagnosis of primary infection, but results are largely depending on the test used, the HIV BioTechMed Rapid-4 being worse than some 3rd generation RDTs.

TUPEC0839

Characteristics associated with HIV self-testing reported by internet-recruited MSM in the United States, eSTAMP baseline data, 2015

P.R. Chavez[1], R.J. MacGowan[1], C.B. Borkowf[1], W.D. Johnson[1], L. Wesolowski[1], A.D. McNaghten[1], P. Sullivan[2]
[1]*Centers for Disease Control and Prevention, NCHHSTP/Division of HIV/AIDS Prevention, Atlanta, United States,* [2]*Emory University, Atlanta, United States*
Presenting author email: pssulli@emory.edu

Background: The introduction of OraQuick® In-home HIV Test (OQ) into the US market in 2012 renewed questions about the use, reach, and public health implications of HIV self-testing (HIVST) for men who have sex with men (MSM). Using baseline data from the Evaluation of HIV Self-testing among MSM Project (eSTAMP), we report on HIV home test (HHT) use and associated factors among MSM.

Methods: Between March 25 and August 4, 2015, MSM reporting HIV-negative or HIV-unknown status were recruited online into a 12-month randomized controlled trial of HIVST. Before randomization all participants completed an online survey. Using these data, we examined participant characteristics and calculated frequency and associations of past 12 months HIVST with selected sociodemographic characteristics. We present unadjusted relative risks (RR) and 95% confidence intervals (95% CI).

Results: Among 2,665 participants [32% 18-24 years; 58% white; 43% ≥college degree; 84% employed; 23% < $20K household income; 63% had anal sex with ≥2 male partners, past 3 months; 6% had condomless anal sex (CAS) with an HIV infected male partner, past 3 months] 59% tested for HIV in the past year, 17% tested ≥3 times in the past year, and 70% had heard of HHTs. Among 10% (259) who reported HIVST in the past year, 92% used OQ and 61% acquired HHTs from a pharmacy. Convenience and privacy were the most common reasons for HIVST, 61% and 52%, respectively. Significant associations with HIVST shown below.

Characteristics (referent is on the right side)	Proportion	RR (95% CI)	p-value
Age (years): 25-39 vs 18-24	0.10 vs 0.08	1.34 (1.01-1.78)	<0.05
Age (years): 40+ vs 18-24	0.12 vs 0.08	1.63 (1.16-2.28)	<0.01
Race/Ethnicity: Hispanic vs Non-Hispanic White	0.06 vs 0.11	0.58 (0.41-0.81)	<0.01
Education (College Graduate): Yes vs No	0.13 vs 0.07	1.79 (1.41-2.26)	<0.001
Employment: Employed vs Unemployed	0.11 vs 0.05	2.09 (1.34-3.27)	<0.01
Household income (US $): 40,000 - 74,999 vs <20,000	0.13 vs 0.06	2.21 (1.51-3.25)	<0.001
Household income (US $): ≥75,000 vs <20,000	0.16 vs 0.06	2.79 (1.90-4.11)	<0.001
Anal sex with ≥2 male sex partners, past 3 months: Yes vs No	0.11 vs 0.08	1.40 (1.09-1.81)	<0.01
CAS with HIV infected male partner, past 3 months: Yes vs No	0.15 vs 0.09	1.53 (1.02-2.30)	<0.05

[Table 1]

Conclusions: Awareness of HHTs was high, but few MSM reported HIVST in the past year. MSM who engage in HIV sexual risk behaviors may have been earlier HIVST adopters. HIVST was positively associated with higher socioeconomic status possibly due to test cost in the US (approximately $40). Providing free or subsidized tests may be necessary to increase HIVST among MSM in the US, especially among lower income populations.

TUPEC0840

Factors associated with late HIV diagnosis, based on data from 7 years of national surveillance

F. Cazein, Y. Le Strat, J. Pillonel, F. Lot
Santé Publique France, Saint Maurice, France
Presenting author email: francoise.cazein@santepubliquefrance.fr

Background: Late HIV diagnosis is a major concern, as it compromises both early treatment of infected persons and prevention of HIV transmission. The aim of this analysis was to identify factors associated with late diagnosis among all HIV infections diagnosed in France between 2009 and 2015.

Methods: We used data from the mandatory HIV surveillance system in France, adjusted for under-reporting, reporting delays and missing values. Late HIV diagnoses were defined as diagnoses with a CD4 count below 350 cells/mm^3 excluding HIV acute illness, or with an AIDS defining disease regardless of the CD4 count. Correlates of late diagnosis were assessed through Poisson regression.

Results: Among 43,416 new HIV diagnoses in France from 2009 to 2015, 45.2% were lately diagnosed. This proportion seemed to decrease from 46.6% in 2009, to 42.5% in 2015.

In multivariate analysis, year of diagnosis was not associated to late diagnosis. Male gender, age, transmission through heterosexual sex or through sharing of drug injection equipment, residence outside the Paris area or in the French overseas, being born abroad, occupational category as business owners or merchants, circumstances of HIV test (tested because of HIV related signs, on the occasion of another illness or because of belonging to an exposed group, test performed at physician's request), and having never been tested for HIV before the diagnosis, were positively and significantly associated to late diagnosis.
Conclusions: Late HIV diagnosis was related both to the circumstances of the test and to some epidemiological characteristics, and has not decreased between 2009 and 2015 once those factors are taken into account.
These results highlight the importance of encouraging people to ask for a test rapidly after having been exposed to HIV, and health professionals to offer a test to people exposed or never tested, especially in groups identified as more likely to be lately diagnosed.

TUPEC0841

Undiagnosed HIV is higher among urban residents, young adults and men: first findings from Malawi Population-based HIV Impact Assessment (MPHIA)

E. Radin[1], G. Chipungu[2], S. Saito[1], J. Kadzandira[3], J. Burnett[4], K. Brown[4], Y. Duong[1], N. Wadonda-Kabondo[5], S. Jonnalagadda[4], B. Parekh[4], S. Nkoka[2], T. Kalua[6], The MPHIA Study Team
[1]ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University, Lilongwe, Malawi, [3]Centre for Social Research, Chancellor College, University of Malawi, Zomba, Malawi, [4]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [5]U.S. Centers for Disease Control and Prevention, Lilongwe, Malawi, [6]Ministry of Health, Government of Malawi, Lilongwe, Malawi
Presenting author email: er2743@columbia.edu

Background: Malawi has made substantial progress towards the 90/90/90 goals. However, further progress in diagnosing people living with HIV (PLHIV), the first 90, is needed to control the HIV epidemic. Providing testing to undiagnosed PLHIV, particularly in areas with high HIV prevalence, will be critical. Here we identify which PLHIV are at greatest risk of being undiagnosed.
Methods: From November 2015-August 2016, MPHIA recruited a nationally representative sample of 17,127 adults age 15-64. Participants completed an interview and received home-based HIV testing and counseling per national guidelines. We defined participants that tested HIV positive as previously undiagnosed if they reported 1) never previously having an HIV test; or 2) testing negative on their most recent test. We estimated the relative risk of previously undiagnosed HIV by area of residence, age and sex using a multivariate log-binomial regression. All analyses accounted for complex survey design.
Results: MPHIA identified 2,214 HIV-positive adults among whom 578 (26%) were undiagnosed, 1,054 (48%) live in urban areas, 709 (32%) were male, and median age was 37 [Interquartile Range: 30-45]. HIV prevalence was significantly higher in urban areas (14.3%, 95% CI: 13.2-15.4%) vs rural areas (9.7%, 95% CI: 8.9-10.4%).
Previously undiagnosed HIV was higher in urban (30.6%, 95% CI: 27.6-33.6%) vs rural areas (25.9%, 95% CI: 22.9%-28.9%), and significantly higher in men (33.3%, 95% CI: 28.8-37.7%) vs women (23.6%, 95% CI: 21.2-25.9%) and younger (15-24 years: 46.7%, 95% CI: 38.0-55.3%) (25-34 years: 32.1, 95% CI: 27.4-36.9%) vs older age groups (35-64: 21.7, 95% CI: 18.9-24.6%). In multivariate analysis, living in an urban area (RR_{urban}=1.18, 95% CI: 1.01-1.37), being male (RR_{male}=1.56, 95% CI: 1.34-1.82) and being 15-24 or 25-34 vs 35-64 years old (RR_{15-24}=2.30, 95% CI: 1.86-2.85; RR_{25-34} =1.58, 95% CI: 1.29-1.94, respectively) were all associated with having previously undiagnosed HIV.
Conclusions: Young, male and urban PLHIV were at increased risk of having undiagnosed HIV in Malawi. These disparities threaten HIV epidemic control as urban areas have higher HIV prevalence and increasing population due to urbanization. To achieve epidemic control, Malawi's HIV programs should focus on diagnosing HIV in urban areas, particularly among young adults and men.

TUPEC0842

Is OraQuick® HIV-self-testing valid among intended users? Analysis from a clinical performance study in Lusaka, Zambia

K.N. Kapaku[1], M. Neuman[2], K. Maluzi[1], L. Sigande[1], M. Nalubamba[3], M. Taegtmeyer[4], E. Corbett[2], C. Johnson[5], K. Hatzold[6], B. Kosloff[1,2], A. Schaap[1,2], A. Mwinga[1], H. Ayles[1,2]
[1]Zambart Project, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Society for Family Health, Lusaka, Zambia, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]World Health Organisation, Geneva, Switzerland, [6]Population Services International, Harare, Zimbabwe
Presenting author email: knjamba@yahoo.co.uk

Background: HIVST has been proposed to increase the uptake of HIV testing and enable more linkage to treatment and prevention services thereby preventing HIV transmission. The aim of this study was to assess the clinical performance of OraQuick® self-testing (OFT-ST) among intended users in Zambia.
Methods: Consenting participants ≥16 years were randomly selected from urban and rural communities in Lusaka, Zambia. Consecutive attendees for HIV counselling and testing in the urban health facility were invited to participate. Researchers demonstrated use of OFT and provided manufacturer's instructions for use. Participants conducted the test and recorded their results by themselves. Researchers repeated the OFT and re-read the participant's test strip. Following the Zambian national algorithm a nurse blinded to OFT results performed a series of rapid HIV diagnostic tests (RDTs). A blood sample was tested for HIV following a reference standard algorithm consisting of fourth generation EIA tests. Demographic data and information of prior HIV testing was collected. The study is ongoing and we report data from 22/06/16-10/11/16.
Results: A total of 1,104 participants were recruited (Table 1).

	Rural Community	Urban Community	Urban Health Facility	Total
Overall total	460	291	353	1104
Female	216 (47%)	222 (76.3%)	189 (53.5%)	627 (56.8%)
Median Age (IQR)	31 (22,43)	26 (21,33)	25 (22,32)	27 (22,37)
Previously tested for HIV	369 (80.2%)	243 (83.5%)	316 (89.5%)	928 (84.1%)
Self-reported HIV+ (% of previously tested)	10 (2.8%)	4 (1.7%)	9 (2.5%)	22 (2.4%)

[Table 1. Participant sociodemographic characterist]

There was good agreement (kappa=0.96) between participant and researcher conducted OFT. The sensitivity of OFT-ST was 95.5% (95%CI 89.7, 98.5) when compared to RDT, and fell to 87.5% (95%CI 80.2, 92.8) when compared to laboratory testing. Specificity was 99.3% (95%CI 98.5, 99.7) compared with laboratory reference. Self-testers from the rural community achieved a lower sensitivity (74.3%, 95%CI 56.7, 87.5) compared to the urban community (92.3%, 95%CI 74.9, 99.1).
Conclusions: OFT-ST with prior demonstration provides reasonable specificity and sensitivity when compared to the Zambian rapid test algorithm. When compared to the laboratory reference standard the sensitivity decreases, though the specificity remains constant. Although HIVST is a screening test, its ability to increase HIV testing must be weighed against the lower sensitivity of test results.

TUPEC0843

Reducing the HIV undiagnosed fraction: systematic review on testing for HIV in prison settings

H. Vroling[1], A. Oordt[1], G. Madeddu[2], S. Babudieri[2], R. Monarca[3], M. Vonk Noordegraaf-Schouten[1], L. Tavoschi[4]
[1]Pallas Health Research and Consultancy, Rotterdam, Netherlands, [2]University of Sassari, Department of Clinical and Experimental Medicine, Unit of Infectious Diseases, Sassari, Italy, [3]Health Without Barriers - European Federation for Prison Health, Viterbo, Italy, [4]European Centre for Disease Prevention and Control, Surveillance and Response Unit, Stockholm, Sweden
Presenting author email: lara.tavoschi@gmail.com

Background: UNAIDS and the WHO have set the ambitious target of 90% of people living with HIV diagnosed. This depends primarily on effectiveness of HIV-testing interventions in targeting high-risk groups and boosting early diagnosis. Across the EU/EEA HIV prevalence in prison populations is much higher than in the community, therefore prison settings offer a key opportunity for active case finding (ACF). The objective was to systematically review data on HIV-ACF in EU/EEA correctional facilities.
Methods: A systematic review of literature on Pubmed and Embase (from 1990 onwards) and Cochrane Library (from 1980 onwards) was performed. This search was complemented with conference abstracts and unpublished research reports, and discussed during expert meetings.

Results: Sixteen primary studies and one systematic review (including eleven relevant studies) were included in the review. Three primary studies were from the EU/EEA and the others from the USA. Within-study comparisons were hardly performed. When comparing results across studies, no trends were seen regarding uptake, positivity rates, effectiveness or treatment initiation. Overall, opt-in testing at entry was most frequently investigated in the peer-reviewed literature, resulting in an uptake rate ranging from 6%-97%, HIV positivity rate of 0%-5.4%, and identification of 0%-1.8% new HIV cases.
For opt-out testing at entry these ranges were 22%-98%, 0%-2% and 0.1%-0.8%, respectively. However, due to heterogeneity of the studies regarding timing, offer, promoting and testing methods,
no conclusions can be drawn based on comparisons across studies. In conference abstracts, using different ACF methods, the uptake and positivity rates were 56.3-91.5% and 1.0-26.6%, respectively, and 35.2%-78.0% initiated treatment after diagnosis.
Conclusions: The evidence on HIV-testing in correctional facilities is limited and variable. Positivity rates among tested inmates indicate cases are continuously being identified. ACF for HIV in prison settings could contribute to prevent onward transmission and lower the undiagnosed fraction in the EU/EEA. Our study suggests to actively offer provider-initiated HIV-testing at entrance to all people in prison. Furthermore, it is advisable to consider offering provider-initiated HIV-testing at regular intervals during prison stay for high-risk subgroups and in case of an exposure incident and to promote client-initiated HIV-testing throughout prison stay.

TUPEC0844

How acceptable and feasible is HIV self-testing among key populations in Vietnam? Preliminary results from an intervention evaluation study

K. Green[1], B. Vu Ngoc[1], H. Phan Thi Thu[2], M. Tran Hung[3], S. Vo Hai[2], H. Ngo Van[1], H.A. Doan[1], L. Dang Hong[4]
[1]PATH, Hanoi, Vietnam, [2]MoH/VAAC, Hanoi, Vietnam, [3]Center for Creative Initiatives in Health and Population (CCIHP), Hanoi, Vietnam, [4]CCIHP, Hanoi, Vietnam
Presenting author email: bvu@path.org

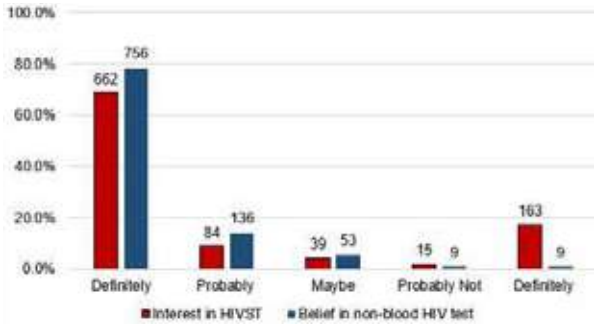
Background: Annual HIV testing uptake among key populations is low (~30%) in Vietnam. Barriers include concerns regarding confidentiality of test result, wait time, and travel/opportunity costs. MoH leaders recognized the potential of HIV self-testing (HIVST) to accelerate 90-90-90 case detection goals, and endorsed a pilot to assess HIVST acceptability, feasibility and service linkages to inform HIV testing guidelines and scale-up.
Methods: Fourteen KP-led community-based organizations (CBOs) in Saigon and Hanoi that serve men who have sex with men (MSM), transgender women (TGW), people who inject drugs (PWID), their sex partners (PWID-SP), and/or female sex workers (FSW) were trained to offer assisted and unassisted HIVST. Clients were offered a choice of a blood-based (Determine_HIV-1/2_Antibody) or oral fluid (OraQuick_ADVANCE_Rapid_**HIV**-1/2_Antibody) assay. Vietnamese language test inserts, pamphlets and tutorial videos were provided to clients. A post-test intervention evaluation included 552 individuals out of 1,994 that HIV self-tested from June-December, 2016. Participants were recruited at randomly chosen service days and completed a computer-assisted/self-administered survey.
Results: MSM represented the majority of HIV self-testers (76.6%), then PWID (12.3%), PWID-SP (8.2%) and FSW (2.9%). The most common reasons for selecting HIVST were: being the first person to know result (59.1%), confidentiality (55.4%), and rapid result (54.2%). 41.5% of HIV self-testers had tested for HIV before. MSM were more likely to have tested previously (46.8%), compared to PWID (25%), PWID-SP (22.7%) and FSW (12.5%), representing a statistically significant difference ($p < 0.05$). 92.8% of those using Determine (n=296), and 85.4% using OraQuick (n=199) shared their test results with the CBO provider. HIV test result concordance between an observer and self-tester were high (99%) for both tests. However, 63.6% reported difficulty using Determine and 8.1% OraQuick. 8.1% of those that revealed their test results tested reactive (compared to 0.9% in public testing sites), 91% received confirmation testing, and 97.7% of those confirmed were enrolled in ART.
Conclusions: HIVST reached a majority of new HIV testers, with a high HIV yield compared to conventional HIV testing sites (0.9%), and a strong HIV-testing-to-ART-enrollment cascade. HIV self-testers generated accurate results despite challenges. Recommend integrating HIVST into national HIV testing guidelines, and increasing targeted access to HIVST.

TUPEC0845

Perceptions of HIV self-testing among a population of self-testing naïve female sex workers in Kampala, Uganda

T. Ngabirano[1], C. Oldenburg[2], D. Kibuuka Musoke[3], A. Nakitende[3], G. Taasi[4], T. Barnighausen[5], K. Ortblad[6]
[1]Uganda Health Marketing Group, Kampala, Uganda, [2]Francis I. Proctor Foundation, University of California San Francisco, San Francisco, United States, [3]International Research Consortium, Kampala, Uganda, [4]Uganda Ministry of Health, Kampala, Uganda, [5]Heidelberg University, Heidelberg, Germany, [6]Harvard T H Chan School of Public Health, Global Health and Population, Boston, United States
Presenting author email: taasi.taasi@gmail.com

Background: Oral HIV self-testing (HIVST) has the potential to complement traditional HIV testing and counseling programs and reach individuals who are not currently accessing health services. Female sex workers (FSW) often have difficulty accessing health services as a result of stigma and working hours. Majority of sub-Saharan African countries have no policies related to HIVST; a few even have policies specifying it as illegal (i.e. Uganda). Here we measure interest in oral HIVST and belief in non-blood based testing among FSW in Kampala, Uganda.
Methods: In 2016, 963 FSW participated in a quantitative questionnaire. Eligible participants were 18 years or older, reported the exchange of sex for money or goods in the past month, and were perceived to be HIV uninfected. All participants were asked if they had ever heard of HIVST, if they would ever consider using a self-test kit to test for HIV, and if they would believe the results of a self-test kits that was not blood based. The percentage of participants that reported the various response categories was calculated and reported.
Results: Among 963 study participants, median age was 28 years (IQR: 24-32 years) and literacy was 85.7% (N=882). Only 15.4% of all participants (N=148) had ever heard of HIVST and reported interest in HIVST was high; 662 participants (68.7%) reported a definite interest, while only 163 participants (16.9%) reported that they would definitely not be interested. Majority of study participants (N=756, 78.5%) said they would definitely believe the results of a HIV test kit that did not draw blood, only 9 participants (0.9%) said they definitely would not, Figure 1.



[Figure 1. Reported interest in HIV self-testing (red) and belief in a non-blood based HIV test (blue) among 963 FSW study participants]

Conclusions: Interest in HIVST among a self-testing naïve population was high, as was reported belief in a non-blood based self-testing kit. This indicates a potential demand for self-testing and need for government HIVST policies.

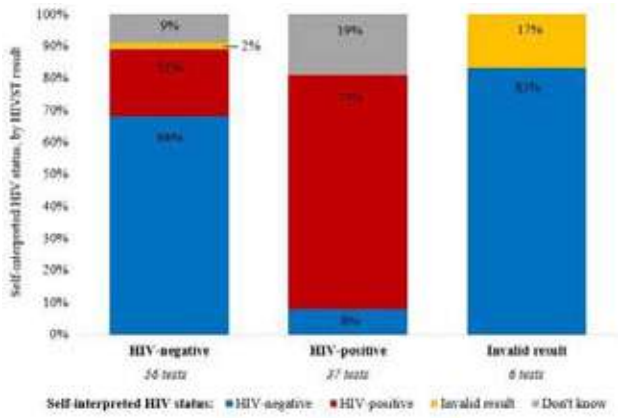
TUPEC0846

An assessment of oral HIV self-testing process accuracy and results interpretation among female sex worker peer educators in Kampala, Uganda

K. Ortblad[1], D. Kibuuka Musoke[2], T. Ngabirano[3], A. Nakitende[2], G. Taasi[4], T. Barnighausen[5], C. Oldenburg[6]
[1]Harvard T H Chan School of Public Health, Global Health and Population, Boston, United States, [2]International Research Consortium, Kampala, Uganda, [3]Uganda Health Marketing Group, Kampala, Uganda, [4]Uganda Ministry of Health, Kampala, Uganda, [5]Heidelberg University, Heidelberg, Germany, [6]Francis I. Proctor Foundation, University of California San Francisco, San Francisco, United States
Presenting author email: katrina.ortblad@mail.harvard.edu

Background: Oral HIV self-testing (HIVST) may be an attractive alternative to clinic-based testing, particularly for stigmatized and inaccessible populations. Available oral HIV self-test kits (OraQuick ADVANCE Rapid HIV-1/2 Antibody Test) have high sensitivity and specificity when used precisely as intended (93.6% and 99.9% respectively), but test performance may be worse if the sequence of testing steps are not correctly executed or results are misinterpreted. We evaluate whether female sex workers (FSW) in Kampala, Uganda can correctly use HIVST

kits and interpret test results under potential real-world conditions where no pre-test training is available.
Methods: 104 FSW performed an oral HIVST without supervision under observation by a trained research assistant. Participants were given no pre-test training on kit use and had only the kit's standard pictorial and written instructions to guide them. Study participants were asked to interpret a randomly drawn, anonymous, used oral HIV self-test kit. Self-read sensitivity and specificity were calculated in reference to the trained research assistants' interpretation of the randomly drawn tests and adjusted for the kit's sensitivity and specificity when used and interpreted as intended.
Results: The majority of participants (61%) completed the necessary steps for an interpretable test result, but most (96%) struggled with the testing process in some way. Incorrect interpretation of test results was common: 23% of HIV-negative tests were interpreted as HIV-positive while 8% of HIV-positive tests were interpreted as HIV-negative, Figure 1. The self-interpreted real-world sensitivity and specificity were 67.9% (95% CI: 54.5-81.4%) and 67.7% (95% CI: 56.1-79.6%) respectively.



[Figure 1. Self-interpretation of the oral HIV self-test kit results by "true" result, determined from pictorial research assistant drawings of the used oral HIV self-test kits]

Conclusions: In the absence of pre-test training, participants struggle with the oral HIV self-testing process and self-interpreted sensitivity and specificity is lower than expected. Training on HIVST kit use or improved self-test kit instructions may be necessary to avoid false positive and false negative test results.

TUPEC0847

Closing the HIV testing gap: facility-based integration of HIV self-testing, a way to improve testing coverage, yield and efficiency of client-initiated HIV testing services in Zimbabwe

K. Hatzold[1], M. Mutseta[2], E. Sibanda[3], S. Gudukeya[2], M. Tumushime[3], C. Lopez[1], P. Stankard[1], M. Taegtmeyer[4], C. Johnson[5], E. Corbett[6], F. Cowan[3,4]
[1]Population Services International, Washington, United States, [2]Population Services International, Harare, Zimbabwe, [3]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]World Health Organization, Geneva, Switzerland, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom
Presenting author email: khatzold@psi.org

Background: HIV self-testing (HIVST) is a new approach to HIV testing that could help identify HIV-positive individuals reluctant to test with a provider. HIVST used as a triage test with provider initiated (PITC) and client initiated HIV testing services (CITC) could relieve human resource challenges with HIV testing services, increase efficiency, reduce costs and increase HIV testing coverage.
Methods: HIVST was introduced at 4 CITC centres in 4 urban areas in Zimbabwe as an alternative option to provider delivered testing (PDT). Participants opting for HIVST were shown a short instructional video and provided the option to conduct the self-test in a private space or to conduct the self-test off site. One counselor was available to assist and facilitate linkage for self-testers needing on-site confirmative testing and anti-retroviral-therapy (ART). Demographics were captured electronically. Self-testers were asked to return used kits to locked drop-boxes and complete a short questionnaire on testing history and interpretation of HIVST results. Used kits were read by a professional and reactive results were used to estimate positivity rates. Costing, cost-effectiveness, and qualitative research to assess provider/client perceptions are underway.
Results: Between September-December 2016 a total of 6636 HIVST kits were distributed in 4 CITC clinics. HIVST was chosen over parallel PDT services by 31.2% of clients presenting at the site (6636/21260, 27.1% of females, 31.4% of men). 98.4% of self-test accepters opted to test on-site; all of whom returned their used test. 4.3% of self-testers had reactive tests (5.8% of women, 3.1% of men) as compared to 12.8% (14.2% of women, 7.2% of men) with PDT. 23% were first-time-testers. Among those who had tested before, 3% tested positive previously, none reported being on ART. All self-testers with reactive result linked to confirmative testing, 95.5% tested HIV-positive and initiated ART.
Conclusions: Uptake of HIVST as alternative testing option to PDT is high at CITC clinics. Used as triage test, HIVST might increase efficiency, freeing counsellor time previously spent on testing HIV-negative individuals to focus on those with reactive results in need of further testing and ART. HIVST will be expanded to improve PITC at public sector health facilities.

TUPEC0848

Prevalence and correlates of HIV diagnosis in domiciliary testing of transgender women in Argentina

C. Frola[1,2], V. Zalazar[1], N. Cardozo[1,3,4], Y. Gómez[1,3], E. Fojo[1], I. Aristegui[1,5], M. Lucas[6], M. Romero[3,4], A. Gun[1], P. Cahn[1], O. Sued[1]
[1]Fundacion Huesped, Clinical Research, Buenos Aires, Argentina, [2]Hospital Juan A. Fernandez, Infectious Diseases Unit, Buenos Aires, Argentina, [3]Asociación de Travestis, Transexuales y Transgéneros de Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [4]REDLACTRANS, Buenos Aires, Argentina, [5]Universidad de Palermo, Buenos Aires, Argentina, [6]Fundacion Huesped, Buenos Aires, Argentina
Presenting author email: mar.lucas@huesped.org.ar

Background: Transgender women (TGW) are at the highest risk of HIV and often suffer discrimination in healthcare settings. The objective of this study was to explore if a proactive provider-initiated testing strategy, visiting TGW at home and other sites could improve testing rates in this population. Correlation between two different rapid tests (HIV Determine™ and HIV combo Determine™) and 4th generation ELISA (HIV DUO, BioMérieux) was also explored.
Methods: From November 2015 to December 2016, a team of infectious diseases physicians, psychologists, peer counselors and laboratory technicians performed testing in rooming-houses and other venues were TGW congregate in 4 cities in Argentina. Self-identified TGW, ≥14 years old, with unknown HIV status or previous negative test (>3 months), were included. After obtaining informed consent, participants completed social and behavioral questionnaires. Two rapid tests were used and compared with 4th generation ELISA. Using bivariable and multivariate logistic regression, we assessed factors associated with positive results.
Results: A total of 180 TGW were tested with a median age of 29 (IQR: 24-38). HIV prevalence was 24%. Most of them had a history of sex-work (86.2%) and 10.2% were foreign born. No acute infections were detected and both rapid tests and ELISA showed a correlation of 100%. A bivariable logistic regression showed that factors associated with HIV positive results were: being foreign born (OR=0.99, 95% CI:0.96-1.03), current sex-work (OR=2.16, 95% CI:1.05-4.45), previous STIs (OR=2.16, 95% CI:1.05-4.41) and not being tested before (OR=4.58, 95% CI:1.98-10.55). In multivariate analysis (Table), all factors remain with a positive correlate except foreign born. Among positive cases median CD4 was 432 (IQR:222-662).

Multivariable logistic regression of factors associated with HIV positive result in TGW

Variable	Adjusted Odds Ratio (AOR)	95% Confidence Interval (CI)	p - value
Foreign born (yes vs. no)	2.41	(0.62- 9.37)	0.202
Current sex-work (yes vs. no)	3.02	(1.16- 7.89)	0.024
Not tested before (yes vs. no)	4.79	(1.77- 12.94)	0.002
Previous STIs (yes vs. no)	3.71	(1.43- 9.59)	0.007

[Table]

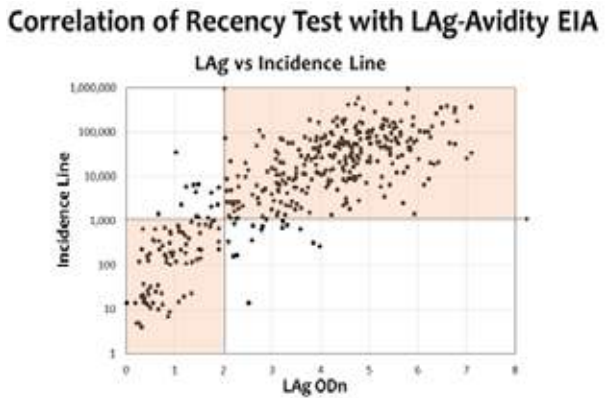
Conclusions: TGW had a high prevalence of HIV. Current sex-work, previous STIs and lacking previous HIV test correlated with positive results, indicating efforts should focused on TGW sex workers. Domiciliary testing is a successful approach for this hard-to reach population and, as the quite low CD4 counts shows, a timely linkage to healthcare.

TUPEC0849

Performance evaluation of Asante™ Rapid Recency Assay for HIV diagnosis and detection of recent infection: potential for surveillance and prevention

B. Parekh, M. Detorio, V. Shanmugam, E. Yufenyuy, T. Dobbs, A. Kim, J. Nkengasong
Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States
Presenting author email: bparekh@cdc.gov

Background: Detection of recent infection is critical for incidence estimates from surveys and can also help in targeted prevention. We previously described development of a rapid test that can diagnose HIV infection and detect recency of infection in one device. This technology was successfully transferred to a commercial partner as Asante™ Rapid Recency Assay developed by Sedia BioSciences (Portland, OR). We evaluated performance of this assay in laboratory using a well-characterized panel of specimens.
Methods: Specimen panel consisted of 1500 sera or plasma from 580 HIV positive (570 HIV-1, 10 HIV-2), and 920 seronegative individuals representing subtypes A, B, C, D, and AE from multiple geographic areas. Reference data were generated using Bio-Rad HIV-1-2-O EIA + Western blot algorithm with further serotyping done using Multispot HIV-1/2 assay. LAg-Avidity EIA was used to generate recency information. Asante™ assay was performed as recommended by the manufacturer and line intensities for diagnostic and incidence lines were read using a hand-held reader. Ability to diagnose HIV and detect recent infections were determined using a recommended reader cut-off values of 1000 for each and results were compared to reference results. Reproducibility of the assay was measured with multiple measurements.
Results: Asante™ rapid recency assay detected 575/580 HIV positive specimens correctly resulting in a sensitivity of 99.1% (95% CI 98.0-99.6) while specificity of Asante assay was 98.7% (908/920) (95% CI 97.7-99.3). There was high correlation (Spearman rank correlation r=0.785) between ODn of LAg-Avidity EIA and incidence line intensity of the Asante test for 570 HIV-1 specimens with cutoff of 1000 matching with LAg ODn of 2.0 (See Figure) corresponding to mean duration of recent infection of about 180 days. Recency assay classified 98 specimens as recent infections compared to 103 by LAg-Avidity EIA. The assay had high reproducibility with %CV of < 10% in the dynamic range.



[Performance evaluation of Asante]

Conclusions: Asante™ assay meets requirements of a diagnostic assay with sensitivity and specificity close to 99%, while identifying recent infections with a mean window period of about 6 months post-seroconversion. This point-of-care assay has implications for enhancing surveillance and targeted prevention in high incidence population.

Leveraging HIV-1 resistance patterns to guide the implementation of treatment programs for MSM living with HIV in Senegal: the HIV prevention 2.0 project

Presenting author email: nafissatouleye@yahoo.fr

Background: Senegal represents a country with significant successes in HIV response given early implementation of routine HIV testing and access to antiretroviral therapy(ART) for those living with HIV. However, HIV prevalence among men who have sex with men(MSM) remains elevated with estimates consistently over 20%. While universal access to ART is a core component of an effective HIV response for MSM, increasing drug resistance may compromise ART effectiveness. Here we describe the prevalence of primary HIV drug resistance among MSM living with HIV in Senegal.
Methods: MSM were enrolled in 3 sites using respondent-driven-sampling including a structured survey instrument and viral load(VL) testing with an Abbott m2000 or NucliSens EasyQ. Drug resistance was evaluated for all with HIV-1 VL≥1000 copies/ml and phylogenetic analyses were completed with Seaview 4.0 and recombination by Simplot version 3.5. Interpretation of drug resistance mutations (DRMs) was performed using HIVDB algorithms with statistical analyses performed using STATA 13.
Results: Of 730 MSMs included in this analysis, HIV prevalence was 30.4%(N=222/730), with a median age of 24 years(n=217). Among the 151 MSM living with HIV who had never taken ART, 107 had VL≥1000 copies/ml. Among them, 46 sequences were obtained on RT+PROT gene, 18 on RT, 11 on PROT only. The 64 RT sequences showed that 10/64 had at least 1 DRMs, with 12.5%(8/64) no-nuc and 4.7%(3/64) nuc. No DRMs were found on the 57 proteases sequences. DRMs were T215Y/A(n=2) and M184V(n=1) for NRTI and K103N(n=4), V108I(n=3), V106M(n=3) for NNRTI. Phylogenetic analyses on the 75 RT and or PROT sequences showed 50.7%(n=38) of subtype C, 44%(n=33) of CRF02_AG, 2.7%(n=2) of B and 1.3%(n=1) of each of CRF06_cpx and URFs.
Conclusions: The data highlight that one in eight MSM living with HIV show evidence of non-nucleoside drug resistance in Senegal, which is particularly challenging given the current first line treatment regimens in Senegal. These data reinforce the importance of ART retention programs, the implementation of HIV drug surveillance as recommended by WHO including the pre-treatment HIV drug resistance and leveraging all data such as this to guide the implementation of ART choice including the potential integration of integrase inhibitors in Senegal.

Background: As recommended by French ANRS program for HIV-1 resistance surveillance, we estimated prevalence of transmitted drug resistance associated mutations (TDRAMs) in antiretroviral-naive chronically HIV-1-infected patients.
Methods: TDRAMs were sought in samples from 674 newly diagnosed HIV-1-infected patients in 2015/16 in 33 HIV clinical cares. Protease and reverse-transcriptase TDRAMs were identified from the 2009 Stanford Resistance Surveillance list. Etravirine, rilpivirine and integrase (IN) mutations were identified from IAS and ANRS lists. Weighted analyses, taking into account the number of patients followed in each center, were used to derive representative estimates of the percentage of patients with TDRAMs.
Results: At inclusion, median CD4 cell counts and plasma HIV-1 RNA were 357/mm^3 (IQR: 186-524) and 4.6 $\log_{10}$ cps/ml (IQR: 4.0-5.1), respectively. Median duration of known seropositivity was 0.39 months (IQR: 0.07-2.83) and below 6 months in 81.5 % of patients. Non-B subtypes were observed in 58.8% of patients. Using Stanford list, prevalence of virus with PR or RT RAMs was 10.2% (CI95%: 7.9-12.5). Prevalence of PIs, NRTIs, NNRTIs and INI RAMs was not different according to duration of HIV diagnosis and was 3.1% (CI95%: 1.8-4.5), 5.8% (4.0-7.6), 5.4% (3.7-7.1) (15.7% (12.9-18.4) including etravirine and rilpivirine RAMs) and 8.7% (6.4-11), respectively. IN RAMs observed were: L74M n=13, T97A n=11, E138K n=1, G140A n=1, Q148K/R n=2, E157Q n=30, R263K n=6. The double mutant G140A+Q148R was observed in 1 patient. Resistance to 1, 2, 3 and 4 classes of ARV was evidenced in 14.2%, 2.2%, 1.1% and 0.2% of patients, respectively. Baseline characteristics such as gender, age, transmission routes, country of transmission, CD4, viral load and subtypes were not associated with prevalence of TDRAMs, except CRF_02 strains which exhibited lower frequency of TDRAMs compared with B subtype (6.6% versus 12.4%, P=0.04, respectively). When comparing 2010/11 survey, prevalence of non-B subtype viruses increased from 43.5% to 58.8% (p< 0.001).
Conclusions: In France in 2015/2016, overall prevalence of TDRAMs was 10.2% and stable compared to 2010/2011 previous survey as well as for PI and NRTI whereas NNRTI RAMs increased. High prevalence of INI RAMs was observed. Non-B subtypes dramatically increased since 2010.

Garrahan', Servicio de Infectología, Buenos Aires, Argentina
Presenting author email: pauauli@gmail.com

Background: Transmitted HIV drug resistance (TDR) is on the rise in Argentina, mostly associated to Non-nucleoside reverse transcriptase inhibitors (NNRTIs). Of concern, antiretroviral (ARV)-naive pregnant women already show high levels of TDR (20%), which may jeopardize the efficacy of NNRTI-based regimens used for prevention of mother-to-child transmission (pMTCT). However, TDR rate in newborns is unknown in our country. We sought to investigate HIV drug resistance (HIVDR) in ARV-naive and pMTCT-exposed newborns before starting 1st line antiretroviral therapy.
Methods: HIV-1 genotypic resistance test was performed in 115 newborns born between 2007 and 2014. Median age was 2.3 months (IQR 1.5-5.5). Characteristics and ARV exposure for pMTCT were collected in all mother-child pairs. Surveillance drug resistance mutations (SDRMs) were considered to determine TDR rates in ARV-naive infants, and acquired drug resistance mutations (DRMs) listed by IAS were identified among pMTCT-exposed infants.
Results: According to ARV exposure of the mother-child pairs, 50 of 115 infants were considered ARV-naive (no maternal cART during pregnancy and no pMTCT or AZT alone according to PACTG 076 at birth). At least one SDRM was found in 12 cases (TDR= 24%, 16% to NNRTIs, 8% to NRTIs and 8% to protease inhibitors (PIs)). In 9 of them, the mother was also ARV naïve and unaware of her HIV-1 positive status. Among 65 pMTCT-exposed infants, DRMs were found in: 75% of 28 cases exposed to a maternal NNRTI-based cART (67% to NNRTIs, 42% to NRTIs, 0% to PIs), 18% of 12 cases exposed to a maternal PI-based cART (14% to NNRTIs, 7% to NRTIs, 0% to PIs), and 40% of 25 cases who received a nevirapine-based extended prophylaxis at birth with 2 doses of nevirapine at first and third day of life according to NICHD HPTN 040/PACTG 1043 (36% to NNRTIs, 8% to NRTIs, 0% to PIs).
Conclusions: High TDR levels were found in newborns from Argentina (24%), mostly fueled by onward transmission from ARV-naive mothers. Repeated HIV-1 testing during pregnancy and rational use of NNRTI-based prophylaxis based on maternal HIV-1 drug susceptibility profiles should be implemented not only to reduce the rates of mother-to-child transmission but also prevent HIVDR from spreading.

TUPEC0853

HIV pre-treatment drug resistance in West Africa and South-East Asia

N. Ngo-Giang-Huong[1], T. Hoang Khanh[2], A. Dagnra[3], T. D'Aquin[4], A.I. Maiga[5], S. Eymard-Duvernay[6], M. Peeters[6], C. Soulie[7], A. Aghokeng Fobang[6,8]

Background: The ongoing scale-up of antiretroviral treatment (ART) in the developing world has now moved to a new era with the recent WHO recommendations to test and immediately treat HIV-positive individuals. High frequency of Pre-treatment drug resistance (PDR) can compromise ART efficacy and the 90-90-90 objectives. Our study presents updated estimates of PDR in six countries from West Africa (Cameroon-CM, Cote d'Ivoire-CI, Mali-ML, Togo-TG) and South-east Asia (Thailand-TH, Vietnam-VN).
Methods: The study was a pilot approach based on the 2014 WHO PDR protocol (www.who.int/hiv/pub/drugresistance/pretreatment_drugresistance). Eligible participants were HIV-1 positive adults, initiating the first-line ART as per national recommendations. Recruitments were conducted from December 2015 to November

2016 and enrolment sites included 1 to 5 major ART clinics in each country. HIV drug resistance (HIVDR) testings were conducted for all specimens and interpretation was done using the Stanford algorithm.
Results: Overall, 1,093 participants were recruited from the six countries, CM (n=202), CI (n=203), ML (n=175), TG (n=158), TH (n=180), and VN (n=175). Genotyping assays were successful for 944 samples. Overall, 880 pol sequences were successfully analyzed and interpreted. PDR frequency among all initiators was 10.1% (95% CI: 8.1-12.1%) overall, ranging from 4.5% and 5% in TH and ML respectively; 12% in CM, CI, and VN; to 16.8% in TG.
Among all participants with available sequences, the frequency of NNRTI resistance mutations was 7.5%, the frequency of NRTI resistance mutations was 4.2%, and PI resistance mutations represented 1.9%. Both NRTI and NNRTI mutations were observed in 2.5% of participants. K103N and M184V mutations predominated, at frequency of 50.6% and 21.3% respectively, but complex resistance profiles including TAMs profiles were found also.
Conclusions: Access to ART in the developing world relies on the used of standard first-line regimens. A low frequency of PDR is important to maintain the success of this public health approach. Our study indicates that PDR is increasing critically in many countries, exceeding 15% in some sites. Nationally representative studies are needed in countries to confirm our findings, but actions to prevent drug resistance should be implemented or improved.

Presenting author email: jchapi2@emory.edu

Background: An increase in HIV diagnoses in men who have sex with men (MSM) in high-income countries was identified from 2000-2005. We sought to investigate recent trends through 2014 to better inform treatment and prevention strategies.
Methods: Data on annual rates of HIV diagnoses among MSM ages 15-65 from 2000-2014 were collected from 13 high-income countries. Joinpoint regression software was used to empirically determine country-specific trend periods. Trends in the annual HIV diagnoses rates and in the proportion of diagnoses occurring in young MSM ages 15-24 were analyzed using Poisson regression and log-binomial regression respectively.
Results: Four trend typologies were identified. Six countries experienced an increasing trend from 2000 to 2007-08 followed by either a stable or declining trend through 2014. Five countries had recently increasing trends and two countries had one stable trend from 2000-2014. Trends in unprotected anal intercourse and syphilis rates increased in most countries.
All 13 countries experienced increasing trends in the proportion of HIV diagnoses in young MSM during this period.
Conclusions: High-income countries differed in HIV trend typologies. Half of the countries experienced a stable or decreasing trend in recent years despite increasing UAI and STIs, suggesting that recent treatment advances and improved ART coverage and adherence may be contributing to declines in HIV rates among MSM. Still, young MSM do not appear to be benefitting equally from such treatment-as-prevention initiatives.
Global efforts to support early sexual health promotion, reduce barriers to PrEP, and improve care engagement for YMSM are critical to addressing current international HIV trends.

Presenting author email: santiago.avila@cieni.org.mx

Background: Guatemala has the largest cohort of adults on antiretroviral treatment (ART) in Central America. HIV drug resistance (HIVDR) emergence might compromise Guatemalan efforts to achieve 90-90-90 targets by 2020. In 2016, we conducted the first nationally representative survey to estimate the prevalence of pretreatment drug resistance (PDR) and acquired drug resistance among persons living with HIV (PLHIV) on ART for 12±3 months (ADR12) and ≥48 months (ADR48) following World Health Organization (WHO) guidelines.
Methods: We included 10 out of 14 ART clinics in the survey (excluding clinics that represented < 10% of the national cohort of PLHIV on ART). Clinic sample size was estimated using the WHO standardized calculator. Eligible participants (according to WHO survey guidelines criteria) were recruited consecutively for 6 months. All patients provided written informed consent to participate in the study. HIV Viral Load (VL) was measured using a RT-qPCR assay. HIVDR was assessed using Sanger sequencing and the Stanford HIVdb algorithm at a WHO designated regional genotyping laboratory. All analysis accounted for the survey design.
Results: We enrolled 869 participants: 269 for PDR, 222 for ADR12, and 378 for ADR48. Overall PDR prevalence was 13.6% (95%CI 9.6-18.5%), mostly related to non-nucleoside reverse transcriptase inhibitors (NNRTI) resistance (11.6%), followed by nucleoside reverse transcriptase inhibitors (NRTI, 3.6%) and protease

inhibitors (PI, 0.8%). Approximately 13% of ART initiators had prior exposure to antiretrovirals; however, PDR prevalence in this group did not differ from individuals with no previous exposure to ART. Viral suppression rate was 88.7% (95%CI 83.8-92.6%) and 86.8% (95%CI 83.0-89.8%) among PLHIV on ART for 12±3 and ≥48 months, respectively. ADR12 prevalence among patients with VL≥1000 copies/ml was 78.9% (95%CI 54.4-93.9%) with 73.7% and 57.9% NNRTI and NRTI resistance, respectively. ADR48 prevalence among patients with VL≥1000 copies/ml, was 75.6% (95%CI 59.7-87.6%), with 73.2%, 63.4%, and 2.4% of NNRTI, NRTI and PI resistance, respectively.
Conclusions: Guatemala reached a moderate PDR level (5-15%). Viral suppression rates were >85% and ADR levels >75% in those with a VL>1000 copies/ml. Our findings underscore the importance of targeted efforts to improve ART adherence strategies and review current programmatic actions to prevent HIVDR transmission to uninfected individuals.

Presenting author email: aflaviapires@gmail.com

Background: In Brazil, more than 487,450 individuals are currently undergoing antiretroviral treatment. In order to monitor the transmission of drug-resistant strains and HIV subtype distribution in Brazil, the present work aimed to estimate the prevalence and to characterize the nationwide pre-treatment drug resistance in individuals recently diagnosed with HIV
Methods: The HIV Threshold Survey methodology (HIV-THS, WHO) targeting antiretroviral-naïve individuals with recent HIV diagnosis was utilized, and subjects were selected from 51 highly populated cities present in all five Brazilian macro-regions. HIV pol genotypic test was performed by genomic sequencing.TDR analyses based on the CPR algorithm were conducted for each geographic region separately
Results: We analyzed samples from 1,568 antiretroviral naïve individuals with recent HIV infection, and the overall transmitted drug resistance (TDR) prevalence 9·5% (150 sequences). The mean viral load was 54,827 copies/mL. The regional prevalence of resistance was 9·4% in the Northeast, 11·2% in the Southeast, 6·8% in the Central region, 10·2% in the North, and 8·8% in the South. The inhibitor-specific TDR prevalence was 3·6% for nucleoside reverse transcriptase inhibitors (NRTIs), 5·8% for non-nucleoside reverse transcriptase inhibitors (NNRTIs), and 1·6% for protease inhibitors (PIs); 1·0% of individuals presented resistance to more than one class of inhibitors. Overall, subtype B was more prevalent in all regions besides the South region where C prevails. prevalence of the NNRTI mutation K103N in recently diagnosed individuals in all Brazilian regions, ranging from 3·4 to 5·5%, which reconciles with the world trends for
Conclusions: In conclusion, we believe that the sampling technique used herein provides for the first time results on TDR that are truly representative of Brazil, revealing a moderate rate of primary prevalence of TDR in the five Brazilian macro regions, although some cities such as the city of Sao Paulo in the Southeast region and the city of Salvador in the Northeast region presents higher prevalence. These results further illustrate the important contribution of studies of surveillance in designing future strategies to mitigate TDR or initial treatment related strategies, as well as help in predicting future trends in other regions of the Globe where massive ARV treatment was implemented

Correlates of recent HIV testing among female sex workers in South Sudan

K. Weiss[1], V. Achut[2], A. Bolo[3], A. Okiria[4], J. Wesson[5], J. Katoro[3], G. Caesar[2], A. Taban[4], A. Hakim[6]
[1]Emory University - Rollins School of Public Health, Epidemiology, Atlanta, United States, [2]South Sudan Ministry of Health, Juba, South Sudan, [3]CDC South Sudan, Juba, South Sudan, [4]IntraHealth International, Juba, South Sudan, [5]IntraHealth International, Chapel Hill, United States, [6]CDC, Atlanta, United States
Presenting author email: hxv8@cdc.gov

Background: Behavioral and HIV prevalence data have not yet been described for female sex workers (FSW) in South Sudan, a key population in the HIV epidemic. Using a biobehavioral survey, we aimed to describe demographic, biological, and behavioral characteristics of FSW in South Sudan, and identify correlates of recent HIV testing to detect and target women not testing every six months.
Methods: Respondent-driven sampling (RDS) was used to recruit 846 FSW in Juba, South Sudan from November 2015-March 2016. Participants completed a risk behavior questionnaire, pre- and post-test counseling, and rapid HIV testing. We collected geospatial data on participant activity, HIV clinics, and outreach testing sites in Juba, and conducted bivariate and multivariate analyses of factors associated with HIV testing in the past 6 months. Data were analyzed in SAS, ArcGIS, and RDS-A, with RDS-adjusted results presented.
Results: Among FSW who reported being HIV-negative at last test, 27.8% had been tested in the last 6 months and 14.6% were currently infected with HIV. Nearly two-thirds (63.3%) had last tested at a clinic, and 30.2% had ever had a peer educator or outreach worker talk to them about HIV. Over half (57.1%) of FSW were from outside South Sudan, and 56.8% had been in Juba for 1-4 years. 76.7% felt FSW peers supported them in condom use, and, respectively, 35.8% and 80.3% of FSW sold sex within half a kilometer and one kilometer of a clinic or outreach testing site. Based on multivariate logistic regression, non-South Sudanese nationals (Odds Ratio (OR) = 3.38, 95% CI: 1.69-6.77) and those who had a counselor or outreach worker talk to them about HIV (OR=2.22, 95% CI: 1.29-3.83) had significantly increased odds of testing in the past 6 months, while residency longer than 1-4 years was significantly associated with decreased odds (5-9 years OR=0.34, 95% CI: 0.19-0.63, 10+ years OR=0.25, 95% CI: 0.09-0.70).
Conclusions: HIV testing in the past six months among FSW in Juba is low despite proximity to clinics or outreach sites. Greater outreach, specifically targeting South Sudanese FSW and including discussion of HIV, is needed to increase testing among FSW in Juba every six months.

Early warning indicators of HIV drug resistance among antiretroviral therapy sites in Namibia: a geospatial approach to population-based surveillance

F. Kimelman[1], T. Stopka[1], N. Mutenda[2], T. Nakanyala[2], N. Hamunime[2], G. Mazibuko[3], S. Mwinga[3], D. Mabirizi[3], E. Sagawa[3], R. Indongo[4], A. Kerrigan[1], M. Jordan[1,5], S. Hong[1,5]
[1]Tufts University School of Medicine, Department of Public Health and Community Medicine, Boston, United States, [2]Republic of Namibia Ministry of Health and Social Services, Directorate of Special Programmes, Windhoek, Namibia, [3]Management Sciences for Health, Systems for Improved Access to Pharmaceuticals and Services Program, Windhoek, Namibia, [4]United States Agency for International Development, Windhoek, Namibia, [5]Tufts Medical Center, Division of Geographic Medicine and Infectious Diseases, Boston, United States
Presenting author email: francescaariel@gmail.com

Background: HIV drug resistance (HIVDR) poses a significant threat to successful antiretroviral therapy (ART). The World Health Organization's Early Warning Indicators (EWIs) of HIVDR monitor site-level performance of factors associated with the emergence of HIVDR. Geographic information systems (GIS) offer a unique opportunity for Namibia and other resource-limited countries to better understand the geospatial distribution of the HIV epidemic and EWI measures to inform appropriate public health interventions.
Methods: We conducted geospatial analysis of the following EWIs at ART site level: 1. On-Time Pill Pick-Up, 2. Retention on ART at 12 months, 3. Pharmacy Stock-Outs, 4. Antiretroviral Dispensing Practices, 5. Viral Load Suppression at 12 months, and 5a. Viral Load Completion at 12 months. We assessed the geolocation and EWI indicators among 249 adult and 216 pediatric ART sites with 2015 and 2016 data. We developed thematic maps to assess geospatial patterns for HIV prevalence, EWI status, and ART delivery performance throughout Namibia.
Results: We identified regions with high HIV prevalence (>25%) and inconsistent EWI performance along Namibia's northern border with Angola. While on-time pill pick up was excellent in the northeastern region (>90%) in 2015, it was fair (80-90%) to poor (< 80%) in most other regions of the country. Retention in care was inconsistent across all regions during 2015 and 2016. Pharmacy stock-outs were widespread across all regions, with the exception of a few sites in the northern border in 2015 and one district in the northeast in 2016. ARV dispensing practices were excellent (0% mono-dual therapy) through all regions in both years. Viral load completion was poor (< 70%) across all regions in both years. Viral load suppression was unavailable in any regions in 2015, but in 2016 in regions with data available viral load suppression rates were excellent (≥90%).
Conclusions: We provided the first geospatial assessment of EWIs for HIVDR, and identified regions with EWI successes and challenges in Namibia. Integration of GIS into routine EWI analysis offers valuable insight for evidence-based decision-making at site-specific and programmatic levels and can inform targeted interventions to minimize the emergence of HIVDR and optimize patient care.

Population HIV viral load metrics: findings from household surveys in KwaZulu-Natal, South Africa

A.B. Kharsany[1], C. Cawood[2], D. Khanyile[2], A. Grobler[1], L. Lewis[1], A. Puren[3]
[1]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [2]Epicentre AIDS Risk Management (Pty) Limited, Durban, South Africa, [3]National Health Laboratory Services, Centre for HIV and STIs, National Institute for Communicable Diseases, Johannesburg, South Africa
Presenting author email: ayesha.kharsany@caprisa.org

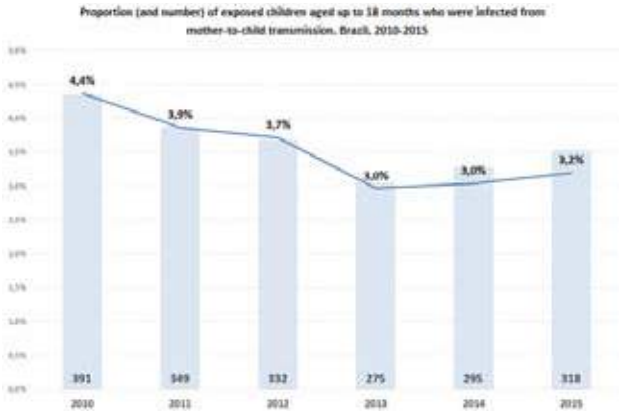
Background: To assess the impact of combination HIV prevention strategies on achieving epidemic control, quantifiable population HIV viral load (VL) metrics are important and useful. We report on the VL metrics in HIV positive individuals irrespective of ART use.
Methods: Two sequential cross-sectional household surveys were undertaken across two sub-districts of uMgungundlovu, KwaZulu-Natal. Surveys one and two were undertaken one year apart from June 2014 to June 2015 and from July 2015 to June 2016 respectively. A randomly selected individual
(15-49 years) per household was enrolled and provided clinical samples for laboratory measurements and had a questionnaire administered.
Results: In survey one 3969/9812 tested antibody positive for HIV (weighted prevalence 36.3%, 95% CI 34.8-37.8) with 42.3% of HIV positive participants reported being on ART (36.7% males and 45.6% females). The population mean and median VL were 45913 (range 0-5400000) and 402 (IQR 0-23656) copies/ml respectively. Whilst 50% of individuals had VL < 400 copies/ml, 15.4%, 18.7% and 15.9% had VL of 400-10000, 10001-50000 and >50000 copies/ml respectively. In survey two 3870/10236 tested antibody positive for HIV (weighted prevalence 35.2%, 95% CI 33.9-36.4), despite 55.3% of HIV positive participants reporting to be on ART (48.6% males and 58.8% females). The population mean and median VL were 91896 (range 0-18000000) and 6.9 (IQR 0-14440) copies /ml respectively. The proportion of individuals with VL <400 copies/ml increased to 58.0%, however, 14.5%, 11.3% and 16.2% had VL of 400-10000, 10001-50000 and >50000 copies/ml respectively. Across both surveys men were more likely to have VL >50000 copies/ml (p<0.001). After controlling for gender, individuals <30 years of age (p<0.001), never having had an HIV test (p< 0.001) and not knowing their HIV status (p<0.0001) were more likely to have VL >50000 copies/ml.
Conclusions: Our findings show that the proportion of potential transmitters with VL >50000 copies/ml remains high. To achieve epidemic control, HIV combination prevention efforts including universal test and treat programmes must identify potential transmitters with VL >50000 copies/ml, specifically men, those <30 years of age, those not having had an HIV test and unaware of HIV status.

TUPEC0860

Estimation of mother to child transmission of HIV in the Brazilian public health system based on programmatic data on viral load, 2009-2015

M. Veloso Meireles[1,2], A.R. Pati Pascom[1], M. Jorge de Queiroz[1], M. Araújo de Freitas[3], J.P. Toledo[1], A. Schwartz Benzaken[1]
[1]Ministry of Health of Brazil, Department of STI, HIV/AIDS and Viral Hepatitis, Brasília, Brazil, [2]Universidade de Brasília, Núcleo de Medicina Tropical, Brasília, Brazil, [3]Columbia University, Maputo, Mozambique
Presenting author email: adele.benzaken@aids.gov.br

Background: The elimination of mother-to-child transmission (MTCT) is a worldwide priority for HIV programmes. For HIV MTCT elimination, transmission rates must be below 2%. This study estimates MTCT of HIV among newborns from HIV-infected mothers followed in the public health system in Brazil from 2010 to 2015 and its trends.
Methods:)We used individual-level programmatic information on HIV viral load (VL) results performed in the Brazilian public health system. We analyzed data for 55,822 children aged up to 18 months exposed to HIV from 2010 to 2015. All treatment-naïve exposed children were classified into three categories: infected (those who presented at least two VL≥5,000 copies/mL); not infected (those with at least two VL< 5,000); and undefined (those who performed only one VL in the first 18mo of life or present two discordant VL, below and above 5,000). The MTCT rate was calculated as the percentage of infected over the total analyzed.
Results: In the period of 2010-2015, the number of infected children was 1,960 and the overall MTCT rate 3.5%. Trend analysis showed a decrease in the rates from 4.4% to 3.2% (p-value< 0.001) and in the numbers of infected children from 391 to 318 (p-value< 0.001) in the period. Nevertheless, we observed an increase in both number and rate in the last three years of observation (p-value=0.030).
Conclusions: Despite the decrease trends from 2010 to 2015, the increase in the last 3 years has drawn the Ministry of Health´s (MoH) attention, who has intensified actions to prevent MTCT. This national increase conceals regional disparities, and several municipalities that have already implemented successful MTCT programs have shown relevant declines or even elimination. Among the MoH's initiatives is the certification process of municipalities that eliminated MTCT. These municipalities may serve as models for others to implement similar programs and contribute to MTCT elimination in Brazil.



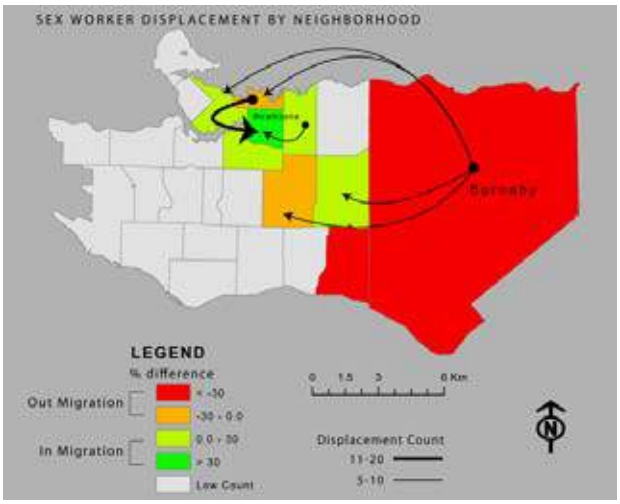
[Figure 1]

TUPEC0861

Patterns and correlates of displacement of sex workers and implications for HIV programmes: findings of a community-based project in Vancouver, Canada

O. Amram, K. Shannon, M. Braschel, S. Machat, S. Moreheart, J. Montaner, S. Goldenberg
B.C. Centre for Excellence in HIV/AIDS, Vancouver, Canada
Presenting author email: oamram@cfenet.ubc.ca

Background: Urban gentrification, criminalization and policing have increasingly displaced sex workers outside of neighbourhoods or workspaces. This displacement has been associated with increased HIV risk and reduced access to HIV services. Drawing on a community-based cohort, community mapping and spatial epidemiological analyses were used to identify:
1. spatial patterns of workplace displacement and;
2. contextual (policing, violence, and safety) and individual correlates of displacement (defined as changing the primary working neighbourhood) among sex workers in an urban Canadian setting, over time.
Methods: This analysis utilized data from a longitudinal community-based cohort of women sex workers in Metro Vancouver (AESHA, 2010-2016), including interviewer-administered questionnaires and voluntary HIV/STI/HCV testing by experiential/community interviewers. Multivariable logistic regression with generalized estimating equations was used to examine correlates of displacement. Mapping was used to examine patterns of displacement by neighbourhood (Figure1).
Results: Analyses were restricted to 543 sex workers who reported their neighbourhood of solicitation and/or service in at least two separate study visits (2010-2016).Displacement was associated with being of a younger age (adjusted odds ratio (AOR) 0.99, 95 % confidence interval (CI) 0.97- 1.00), whereas homelessness (AOR 1.41, 95 % CI 1.11-1.79), identifying as a gender/sexual minority (AOR 1.31, 95 % CI 1.02-1.67), being harassed by police(AOR 1.19, 95 % CI 0.96-1.48), changing work environments due to safety (AOR 1.37, 95 % CI 0.94-2.00) and servicing outdoors (AOR 1.48, 95 % CI 1.21-1.81) were correlated with increased odds of displacement.



[Figure 1]

Conclusions: This study indicates that the marginalized populations of sex workers (e.g., youth, sexual/gender minorities, street-based) were most likely to experience displacement. In light of prior research suggesting that displacement may exacerbate HIV risks and reduce access to critical HIV and sexual health services, structural interventions to reduce criminalization and displacement and support sex workers' access to safer work and housing environments and HIV services remain critically needed.

TUPEC0862

Trends of racial and ethnic disparities in virologic suppression among women in the HIV Outpatient Study, 2010-2015

A. Geter[1], M. Sutton[1], C. Armon[2], M. Durham[1], F. Palella, Jr.[3], E. Tedaldi[4], R. Hart[2], K. Buchacz[1]
[1]Centers for Disease Control and Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Atlanta, United States, [2]Cerner Corporation, Kansas City, United States, [3]Northwestern University, Chicago, United States, [4]Temple University, Philadelphia, United States
Presenting author email: hyt7@cdc.gov

Background: In the United States (US), women accounted for 19% of HIV diagnoses in 2015. Black/African American (black) and Hispanic women/Latinas (Latinas) were disproportionately affected; they comprised 76.7% of all women diagnosed with HIV infection. Antiretroviral therapy (ART)-induced viral suppression (VS) results in decreased morbidity and mortality; a goal of the National HIV/AIDS Strategy (NHAS) is to have 80% of HIV-infected persons reach VS by 2020. However, factors influencing VS have been understudied among women. We sought to examine VS among women to inform gender-specific HIV management interventions.
Methods: We used medical records data from the HIV Outpatient Study (HOPS), a cohort study of HIV-infected adults receiving care at several US clinical sites. We limited analyses to women aged ≥ 18 years with ≥ 1 HOPS visit, on ART, and at least one viral load (VL) test performed between 2010 and 2015. We defined VS as VL < 50 copies/mL and calculated prevalence ratios (PR) with 95% confidence intervals (CI) for VS among women by race/ethnicity and by year of measure. Generalized estimating equations were used for multivariable analyses to assess factors associated with VS among women.
Results: Among 809 women (entering observation at median age = 44 years), 482 (59.6%) were black, 177 (21.9%) were white, 150 (18.5%) were Latina. VS was less prevalent among black women (73.0%) compared with Latinas (82.7%) and whites (90.7%) even when limited to women for whom ART was prescribed. In multivariable analyses, adjusting for age and time-updated ART use, VS was less likely among women who were black (aPR=0.45; CI=0.33-0.63) or Latina (aPR=0.61; CI=0.41-0.92) compared with white women, and who attended a public clinic (aPR=0.71; CI=0.54-0.93) compared with a private one. Among all women, VS increased from 62.5% to 77.4% between 2010 and 2015, but racial/ethnic disparities persisted in each year.
Conclusions: Despite improvements in VS over time toward the NHAS goal of 80%, racial/ethnic disparities persist among HIV-infected women, with black women and Latinas achieving significantly lower rates of VS than white women. Interventions targeting VS improvement among black women and Latinas, especially those who attend public clinics, are warranted.

TUPEC0863

Clinical, health and social outcomes associated with food and housing insecurity among a national cohort of women living with HIV in Canada

C.H. Logie[1], Y. Wang[1], N. O'Brien[2], A. Kaida[3], V. Nicholson[3], K. Webster[3], A. de Pokomandy[2], T. Conway[4], M.R. Loutfy[4]
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]McGill University, Montreal, Canada, [3]Simon Frasier University, Vancouver, Canada, [4]Women's College Research Institute, Toronto, Canada
Presenting author email: yings.wang@mail.utoronto.ca

Background: Women living with HIV (WLWH) in Canada experience disproportionate rates of food and housing insecurity. The study objective was to examine factors associated with experiencing food and housing insecurity among a Canadian cohort of WLWH.
Methods: We analyzed baseline survey data for WLWH (≥16 years) enrolled in a community-based cohort study in British Columbia, Ontario, and Québec. We assessed self-reported housing insecurity (unstable housing [transitional/shelter, living outdoors, couch surfing], difficulty paying rent) and food insecurity (concerns and/or experiences with running out of food) in the past 12 months. Multinomial logistic regression analyses were conducted to identify socio-demographic, social, health and clinical factors associated with experiencing: food insecurity, housing insecurity, or both food and housing insecurity.
Results: Of 1425 participants, the median age was 43 (IQR=36-51) years. Of 1404 participants included in analyses: one-fifth (n=300; 21%) reported no food/housing insecurity, 27% (n=381) reported food insecurity alone, 14% (n=200) housing insecurity alone, and 37% (n=523) both food and housing insecurity. In unadjusted analyses, socio-demographic factors associated with food and housing insecurity included: <high school education, <$20,000 annual income, and Indigenous or African Caribbean Black vs. Caucasian ethno-racial identity. In adjusted multinomial analyses controlling for socio-demographics, food insecurity alone was

associated with health outcomes (depression, lower health-related quality of life [HrQOL], reduced resilience, lower odds of ever received a Pap test), clinical outcomes (detectable viral load, HIV medical care barriers), and social factors (HIV-related stigma, racial discrimination, gender discrimination). In multivariable analyses housing insecurity alone was associated with social (lower social support) and clinical (CD4 count of <200 cells/mm3 vs. >500 cells/mm3) outcomes. Experiencing food and housing insecurity concurrently was associated with: health (current injection drug use, depression symptoms, lower HrQOL, lower resilience), social (lower social support, HIV-related stigma, racial discrimination, gender discrimination) and clinical (CD4 count of < 200 cells/mm3 vs. >500 cells/mm3, <80% antiretroviral adherence vs. 100% adherence) outcomes.
Conclusions: Food and housing insecurity are widespread among WLWH and associated with poorer social, health and clinical outcomes, including lower adherence and CD4 count. Findings highlight an urgent need to address housing and food insecurity to promote WLWH's health and wellbeing.

TUPEC0864

Gender and age disparities in achieving each of the 90-90-90 UNAIDS goals in three sub-Saharan countries

H. Huerga[1], J. Ben Farhat[1], S. Wanjala[2], L. Salumu[3], G. Van Cutsem[4], T. Ellman[4], D. Maman[5], J.F. Etard[5,6]
[1]Epicentre, Clinical Research, Paris, France, [2]Medecins Sans Frontieres, Nairobi, Kenya, [3]Medecins Sans Frontieres, Paris, France, [4]Medecins Sans Frontieres, Cape Town, South Africa, [5]Epicentre, Paris, France, [6]Institut de Recherche pour le Développement, UMI 233, Montpellier, France
Presenting author email: helena.huerga@epicentre.msf.org

Background: Understanding gender and age disparities in the HIV cascade of care can help to focus HIV strategies to achieve the 90-90-90 UNAIDS goals. We aimed to assess the effect of gender and age at each step of the HIV cascade of care in 3 sub-Saharan African countries.
Methods: Three population-based cross-sectional surveys were conducted in Ndhiwa (Kenya), KwaZulu-Natal (South Africa) and Chiradzulu (Malawi) between September 2012 and November 2013. Persons aged 15-59 years were eligible. Individuals were interviewed and tested for HIV at home. Those positive had a viral load (VL). Multivariable logistic regression models were used to assess factors associated with being diagnosed among all HIV-positive, untreated among those diagnosed, and virally unsuppressed (VL≥1000cp/mL) among those on ART.
Results: In total 9,802 houses were visited, 21,782 individuals were eligible and 19,006 (87.5%) included. In total, 1457 (24.1%) individuals were HIV positive in Kenya, 1423 (25.2%) in South Africa and 1234 (17.0%) in Malawi. Overall 90-90-90 UNAIDS goals were achieved at 59.6%-68.2%-82.5% in Kenya, 75.2%-66.9%-89.8% in South Africa, and 76.8%-82.9%-90.8% in Malawi with viral suppression among HIV-positive being 39.9%, 57.1% and 61.7% respectively. HIV diagnosis was lower in men (62.2%, 95%CI: 59.0-65.2) than in women (73.4%, 95%CI: 71.5-75.2). This difference persisted in the multivariable model (aOR: 2.1, 95%CI: 1.8-2.5). Viral suppression among HIV-positive was lower in men (46.9%, 95%CI: 43.6-50.2) than in women (54.8%, 95%CI: 52.9-56.6). However, diagnosed men did not have a higher risk of being untreated or, when on ART, being virally unsuppressed. Individuals aged 15-24 years had a 4 to 7 times increased risk of attrition all along the cascade compared to those aged 45-59 years (diagnosed aOR: 4.9, 95%CI:3.7-6.4; untreated aOR: 5.1, 95%CI:3.7-7.3; unsuppressed aOR: 6.9, 95%CI:3.9-12.0).
Conclusions: In these 3 settings, men had higher viral loads compared to women due to their lower HIV diagnosis. However, men did not have a higher risk of being untreated once they were diagnosed or of being virally unsuppressed once on ART. The effect of age persisted along the HIV cascade of care. Individuals aged 15-24 years had a higher risk of not achieving the UNAIDS 90-90-90 goals.

Background: High HIV-1 RNA load is associated with higher risk of virus transmission, and it is believed that virologically suppressed individuals do not transmit the virus. Identification of subpopulations with elevated levels of HIV-1 RNA is relevant to public health strategies aimed to reduce HIV transmission and control the HIV epidemic.
Methods: HIV-infected individuals (n=3,596) were identified during a household survey performed in 30 communities across Botswana. We focused on the most likely subpopulation of HIV-infected individuals able to transmit virus - ART-naïve HIV-infected people with HIV-1 RNA above 400 copies/mL (considered as a threshold of virus transmission). Within this group, we compared levels of HIV-1 RNA between newly diagnosed people and individuals who knew that they were infected at the time of household visit. We analyzed levels of HIV-1 RNA among newly and previously diagnosed people, overall and by age and gender. Individuals with recent HIV-1C infection were identified by using combined Limiting-Antigen Avidity Assay data, ART status and HIV-1 RNA load, as described in Rehle et al. (PLoS One 2015; 10(7):e0133255).
Results: Among 815 HIV-infected ART-naïve persons with detectable virus (HIV-1 RNA >400 copies/mL), newly diagnosed individuals had higher levels of HIV-1 RNA (n=490, median HIV-1 RNA 4.35, IQR 3.79-4.91 $\log_{10}$ copies/mL) than those aware of their HIV-positive status at the time of household visit (n=325, median HIV-1 RNA 4.10, IQR 3.55-4.68 $\log_{10}$ copies/mL; p-value <0.001, but p-value =0.011 after adjusting for age and gender). A non-significant trend for higher HIV-1 RNA was evident among newly diagnosed men aged 30 years or older (median HIV-1 RNA 4.58, IQR 4.07-5.02 $\log_{10}$ copies/mL vs. 4.17, 3.61-4.71 $\log_{10}$ copies/mL). Only 5% (95% CI 3-7%) of newly diagnosed people were tested as recently infected.
Conclusions: Among HIV-infected individuals with detectable viral load, newly diagnosed individuals had elevated levels of HIV-1 RNA, as compared with people who were previously aware of their HIV-positive status. Interventions targeting undiagnosed middle-aged men could enhance the value of Treatment-as-Prevention and Universal Treatment campaigns.

TUPEC0866

HIV testing preferences among men who have sex with men in China: a discrete choice experiment from a nationwide sample

S.W. Pan[1,2], M. Durvasula[3], C. Liu[1,2], H. Fu[4], J. Ong[1,5], C. Wei[6], W. Tang[1,2], J. Tucker[1,2]
[1]Social Entrepreneurship for Sexual Health, Guangzhou, China, [2]University of North Carolina at Chapel Hill, UNC - Project China, Guangzhou, China, [3]Duke University, Durham, United States, [4]Eastern Virginia Medical School, Norfolk, United States, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States
Presenting author email: stephen.w.pan@gmail.com

Background: Discrete choice experiments (DCE) present study participants with hypothetical choice scenarios in order to quantitatively determine the relative influence of specific factors underpinning individual choice decisions. We used DCEs to identify the most important considerations and preferences driving MSM HIV testing decisions, stratified by income and sexual orientation.
Methods: In January 2017, men over 16 years old and reported ever having sex with another man were recruited via social media throughout China to complete an online DCE. Participants were given six choice sets, each asking the participant to choose from two hypothetical HIV testing scenarios or a "do not test" selection. Each testing scenario had a combination of attributes including: test location, venipuncture or finger prick test type, whether true names were collected, whether test administrator was a health professional or person with on-the-job training, whether disclosure of MSM status was required, and cost/incentive ($7.25 USD incentive; free; pay $7.25 USD; pay $14.50 USD). Design of the DCE attributes and levels

were based on results from five focus groups and a pilot study with 95 participants. Parameter estimates and attribute influence were calculated using mixed multinomial logit modeling.
Results: 717 individuals completed 3663 choice tasks. Median age was 24 years, 51% had monthly income below $435 USD, and 20% did not identify as gay.
Overall, cost/incentive was the most important consideration for HIV testing decisions, influencing 39% of testing choices. Free HIV testing was the most preferred option, followed by $7.25 USD testing incentives and fee-based testing. Test administrator considerations influenced 20% of testing choices, with health professionals being preferred over individuals with on-the-job training. Considerations about disclosure of identifying information influenced 17% of testing choices, with anonymous testing being preferred over disclosure of true names.
Test administrator was a more important consideration for gay-identifying participants than non-gay identifying participants, influencing 21.8% and 11.7% of testing choices, respectively. Compared to higher income participants, those with lower income were more averse to any fee-based testing.
Conclusions: Increasing anonymous and free HIV-testing services administered by health professionals may increase HIV test uptake among MSM, especially for those with lower monthly income.

90-90-90 and the HIV continuum of care: how well is Papua New Guinea doing amongst key populations?

A. Kelly-Hanku[1,2], S. Badman[2], B. Willie[1], R. Narakobi[1], A. Amos-Kuma[1], S. Pekon[3], M. Kupul[1], H. Aeno[1], R. Boli Neo[1], S. Ase[1], J. Nembari[1], P. Hou[1], N. Dala[3], D. Weikum[4], A. Vallely[1,2], A. Hakim[4], Kauntim mi tu Study Group
[1]PNG Institute of Medical Research, Goroka, Papua New Guinea, [2]UNSW Australia, Kirby Institute, Sydney, Australia, [3]PNG National Department of Health, Port Moresby, Papua New Guinea, [4]US Centres for Disease Control and Prevention, Atlanta, United States
Presenting author email: a.kelly@unsw.edu.au

Background: With the largest HIV epidemic in the Pacific, and limited availability of HIV Viral load testing, describing Papua New Guinea's (PNG) HIV cascade has been impossible until now. We conducted an integrated bio-behavioral survey (IBBS) of female sex workers (FSW) and men who have sex with men (MSM) and transgender women (TG) in Port Moresby, PNG to obtain these important data and inform the National HIV Strategy.
Methods: Using Respondent-Driven Sampling (RDS) we conducted a cross-sectional IBBS from June to October 2016 for FSW and MSM/TG. Eligibility criteria for FSW were: born female, ≥12 years or older, could speak English or Tok Pisin (Melanesian Pidgin) and had sold or exchanged sex with a man in the past 6 months. The Eligibility for MSM/TG were: born male, ≥12 years or older, could speak English or Tok Pisin and had oral or anal sex with another person born male in the past 6 months. Consenting eligible participants (FSW N=676; MSM/TG=400) were interviewed face-to-face and offered an HIV test, and HIV viral load, as appropriate. All tests were provided at point-of-care and results provided the same day to participants. Weighted data analysis was conducted using RDS-Analyst, except where the sample counts were too small.
Results: HIV prevalence was 14.9% among FSW and 8.5% among MSM/TG. Among FSW, only 39.3% were aware they had HIV. Of those with known HIV, 84.4% self-reported being on treatment, among whom, 54.6% had suppressed viral load (HIV RNA < 1000 copies per millilitre). Awareness of HIV status was lower among MSM/TG, (24.4%; n=6). Among this group, only three participants self-reported being on treatment, of whom, two were virally suppressed.
Conclusions: While PNG appears to be achieving high treatment access and HIV viral suppression among those who are aware of their HIV positive status, urgent intervention is needed to increase HIV testing uptake among key population groups in order to reach the first continuum of care coverage target.

TUPEC0868

Rising HIV prevalence among men who have sex with men in Nigeria: a trend analysis (2007 - 2014)

G.I. Eluwa, J. Njab, S. Adebajo
Population Council, Abuja, Nigeria

Background: Men who have sex with men (MSM) constitute less than 1% of the Nigerian population yet nationally account for about 20% of new HIV infection. We estimated the trend in HIV prevalence and determined correlates of HIV transmission among MSM.
Methods: Data from three rounds of integrated biological and behavioral surveillance survey (2007, 2010 and 2014) were evaluated in a cross-sectional analysis. Each round used similar methodology and thus allows for comparison. Behavioral data were obtained using a structured pre-coded questionnaire. Differences in categorical variables were assessed with Chi Square. Logistic regression was used to identify factors associated with risk behaviors.
Results: A total of 879, 1,545 and 3,611 MSM were recruited in 2007, 2010 and 2014 respectively. Median age was 22 years for 2007 and 2014 while it was 24 years in 2010. Majority of the respondents had achieved secondary level education in 2007 (68%), 2010 (50%) and 2014 (55%). Over one-third of MSM in 2007 and 2014 and about two-fifths in 2010 had engaged in transactional sex. HIV prevalence increased from 14% in 2007 to 17% in 2010 to 23% in 2014 (p<0.0001). HIV prevalence was higher among those aged >= 25 years in 2007 (25% vs. 11%; p< 0.0001), 2010 (20% vs. 16%; p=0.031) and 2014 (34% vs. 19%; p< 0.0001). HIV prevalence was higher among those who engaged in receptive anal sex in 2007 (14% vs. 8%; p=0.025), 2010 (19% vs. 14%; p=0.016) and 2014 (25%vs.18%; p< 0.0001). When controlled for age [(reference) < 25 years vs. >= 25 years], educational status, engaging in transactional sex, consistent use of condom during transactional age and receptive sex [(reference) yes vs. no], only age [AOR:1.78; 95% CI:1.32-2.39, p<0.00001] and engaging in receptive sex [AOR:1.61; 95% CI:1.14 - 2.27, p=0.006] were associated with HIV.
Conclusions: There's been a consistent and significant increase in HIV prevalence among MSM with a 64% increase over seven years. Older MSM were more likely to be HIV positive and this may reflect their prolonged exposure to high risk sexual activities. Evidence based interventions are urgently needed to mitigate a vicious intra-group HIV transmission.

TUPEC0869

Religious affiliation and uptake of HIV testing, treatment and viral suppression in Botswana

M.O. Mmalane[1], J. Leidner[2], N. Khan[3], M. Pretorius Holme[3], B.W. Sento[4], M.G. Alwano[5], J.M. Makhema[1], T. Phindela[6], K. Bennett[7], K.E. Wirth[3,8]
[1]Botswana-Harvard Partnership, Admin, Gaborone, Botswana, [2]Goodtables Consulting, Oklahoma, United States, [3]Harvard T H Chan School of Public Health, Immunology and Infectious Diseases, Boston, United States, [4]Tebelopele, Gaborone, Botswana, [5]Centers for Disease Control and Prevention, Gaborone, Botswana, [6]Ministry of Health Botswana, Gaborone, Botswana, [7]Ben, Ballton Lake, United States, [8]Harvard T H Chan School of Public Health, Immunology and Infectious Diseases, Epidemiology, Boston, United States
Presenting author email: mmmalane@bhp.org.bw

Background: Religious beliefs and practices can influence HIV-related health-seeking behaviours including HIV testing, treatment initiation and adherence. Using data from a large ongoing community-based randomized trial in Botswana, we examined the relationship between religious affiliation, HIV prevalence and uptake of HIV testing and treatment as defined by the UNAIDS 90-90-90 targets for 2020.
Methods: As part of the Botswana Combination Prevention Project, baseline household surveys were administered to 30 communities from Oct 2013 to Nov 2015. The survey was administered to all consenting Botswana citizens or spouses of citizens aged 16-64 years, in 20% of households per community, and obtained information on religious affiliation and HIV status; among HIV-infected subjects, documentation of prior diagnosis and treatment status was collected. Blood was taken for HIV testing (in the absence of prior documentation of a positive HIV status) and viral load measurement. Achievement of the combined UNAIDS 90-90-90 targets was defined as the proportion of HIV-infected participants diagnosed, on treatment and virally suppressed. Modified Poisson generalized estimating equations were used to obtain univariable and multivariable-adjusted prevalence ratios (PR) and 95% confidence intervals (CI) for the associations between religious affiliation and
(a) HIV status and;
(b) binary outcome indicating achievement of the combined UNAIDS 90-90-90 target.
Results: Among the 12,601 participants with religious affiliation data, 3,968 (32%) reported no affiliation; these participants were significantly more likely to be male and younger compared to affiliated subjects. After adjustment for age and gender, HIV prevalence was significantly lower (PR: 0.88; 95%CI: 0.83-0.95) among affiliated participants compared to unaffiliated. In univariable analyses, any religious affiliation was positively associated with achievement of the combined UNAIDS 90-90-90 target (P=0.001); the association remained significant after adjustment for age and gender (PR: 1.08; 95%CI: 1.02-1.14). Similarly, in adjusted analyses, self-reported affiliation with Apostolic, Pentecostal and Zion Christian Church religious groups (as compared to no affiliation) was significantly associated with a 7%, 9% and 13% higher probability of meeting the combined UNAIDS 90-90-90 target, respectively (P=0.02).
Conclusions: Religious affiliation was significantly associated with increased uptake of HIV testing, treatment and viral suppression in Botswana.

HIV infection among men who have sex with men attending gay venues in France: results from a time-location sampling bio-behavioural survey conducted in 5 cities PREVAGAY2015 survey

A. Velter[1], F. Barin[2], G. Peytavin[3], L. Saboni[1], C. Sauvage[1], A. Alexandre[4], N. Lydié[1], C. Sommen[1], F. Lot[1]
[1]Santé Publique France, Saint Maurice, France, [2]CHU Bretonneau, Laboratoire de Virologie, Tours, France, [3]IAME, Inserm UMR 1137, Université Paris 7, UF 301 Laboratoire de Pharmaco-Toxicologie, Paris, France, [4]ENIPSE, Paris, France
Presenting author email: annie.velter@santepubliquefrance.fr

Background: In France, Men who have Sex with Men (MSM) remain the only population for whom new HIV diagnoses have not decreased overtime. In 2015, to update data, a survey was set up to estimate the prevalence of HIV infections among MSM, including the prevalence of both undiagnosed and recent infections.
Methods: An anonymous cross-sectional survey, using a time-location sampling method and the generalized method of sampling weights, was conducted among MSM attending gay venues in five cities. Behavioral questionnaires and finger-prick blood samples on blotting paper (DBS) were collected. Samples were screened using the Genscreen ultra HIV Ag-Ab® (Biorad) assay and confirmed by western Blot and serotyping. Positive specimens were tested using an enzyme immunoassay for recent HIV-1 infection (EIA-RI). Antiretrovirals (ART) among positive specimens were detected on DBS using UPLC-MS/MS and taken into account to determine recency of infection. Viral load (VL) was estimated using the Abbott Realtime HIV-1-RNA assay for DBS (high VL ≥ $3.5\log_{10}$ copies/mL). Inclusion probabilities, frequency of venue attendance and multi-stage survey design were taken into account for all statistical analyses.
Results: Of 2,646 participants tested and analyzed, 433 were HIV-positive. The HIV weighted prevalence was estimated to 14.3% [95% CI: 12.0-16.9], ranging from 7.6% [5.1-11.1] to 17.1% [11.8-24.1] according to cities.
Among HIV-positive MSM, 90.5% [95%CI: 84.5- 94.4] were diagnosed for their HIV-infection, 94.9% [95%CI: 91.9-96.8] were on ART and among them 1.5% [95% CI: 0.6- 3.9] had high VL.
Undiagnosed HIV-positive MSM were estimated to 9.4% [95% CI: 5.6- 15.5%]. Among them, 24.7% [95% CI: 10.1-48.9] had recent infection and 33.4% [95% CI: 13.9-61.1] had a high VL.
Conclusions: The implementation of innovative statistical methodologies and biological analyses enabled us to evaluate, the current burden of HIV among MSM attending gay venues in France. Despite a high HIV prevalence, diagnosed HIV-positive MSM were mostly treated with succeed reducing VL and sexual HIV transmission risk. The proportion of undiagnosed HIV-positive MSM was low, but in regards to their high VL, they may contribute disproportionately to new HIV infections.

TUPEC0871

Only 36% of adults living with HIV aware of their HIV+ status but progress in ART coverage and viral suppression in a subnational survey in Uganda: progress towards UNAIDS 90-90-90

S.M. Kiene[1], R. Naigino[2], K.M. Sileo[1], S.C. Kalichman[3], N. Menzies[4], H. Lule[5], M.H. Bategenya[6], C.D. Lin[7], B. Nogueira[1], T. Snyder[1], R.K. Wanyenze[2], PATH/Ekkubo Study Team
[1]San Diego State University Graduate School of Public Health, Division of Epidemiology and Biostatistics, San Diego, United States, [2]Makerere University School of Public Health, Department of Disease Control and Environmental Health, Kampala, Uganda, [3]University of Connecticut, Storrs, United States, [4]Harvard School of Public Health, Department of Global Health and Population, Boston, United States, [5]Gombe Hospital, Gombe, Uganda, [6]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [7]San Diego State University, Department of Mathematics and Statistics, San Diego, United States
Presenting author email: skiene@mail.sdsu.edu

Background: Recent data suggests that Uganda is making gains towards meeting the second and third UNAIDS 90-90-90 targets, however, less is known about progress on the first—90% of those living with HIV being aware of their status as well as the target of 73% population-level viral suppression.
Methods: As part of a randomized trial (NCT02545673) evaluating the effectiveness of a linkage to care intervention at achieving HIV viral suppression we conducted a population-based survey of individuals aged 15-59 residing in two rural districts in Uganda between December 2015 and December 2016. Teams visited households and offered individuals participation in a survey and HIV testing. The questionnaire captured previous HIV testing, and linkage to HIV care and treatment for those aware they were positive. Venous blood was collected for HIV viral load testing.
Results: There were 5,401 individuals eligible for participation (aged 15-59, residing in household); 201 (3.7%) declined participation. We tested 5,200 individuals (56% female) for HIV, of which 242 (4.7%) tested HIV positive. 35.5% of those who tested HIV positive knew they were positive, 86.0% of those who knew they were positive were taking ARVs, 88.9% of those taking ARVs were virally suppressed (VL < 500) and 62.8% had an undetectable viral load (VL < 20). Population-level viral suppression (VL< 500) was 46.6%. Of those unaware of their HIV positive status: 21.8% had never tested, 17.3% tested more than 2 years ago, 16.7% tested 1-2 years ago, 18.6% tested 6 months-1 year ago, 12.2% tested 3-6 months ago, and 13.5% had tested within the prior 3 months.
Conclusions: These data from rural Uganda suggest that challenges remain in reaching the first of the UNAIDS 90-90-90 targets—90% of people living with HIV aware of their status. Consequently, achieving population-level viral suppression was well below the target of 73%. These gaps may reflect disparities in access/uptake of testing. Performance was better for the second and third 90-90-90 targets (90% ART coverage for individuals with known HIV positive status, and 90% viral suppression for individuals on ART). In rural areas of Uganda, increased efforts to reach HIV positive individuals unaware of their HIV status are needed.

TUPEC0872

Fishermen and Fishing communities in East Africa: most-at-risk population of acquiring HIV infection. Results from a population-based survey

J. Burgos-Soto[1], I. Alley[1], P. Ojuka[2], E. Mulogo[3], T. Bamulekise[4], M. Bouhenia[1], L. Salumu[5], P. Mendiharat[5], R. Mathela[6], C. Langendorf[1], S. Cohuet[1], H. Huerga[1]
[1]Epicentre, Paris, France, [2]Epicentre, Mbarara, Mbarara, Uganda, [3]Mbarara University of Science and Technology, Mbarara, Uganda, [4]Ministry of Health of Uganda, Mbarara, Uganda, [5]Medecins Sans Frontieres, Paris, France, [6]Medecins Sans Frontieres, Kampala, Uganda
Presenting author email: juanburgosmd@gmail.com

Background: In East-Africa, fishermen and fishing communities are considered most-at-risk population of acquiring HIV but knowledge about the epidemic in these contexts is scarce.
Objective: To estimate the HIV-prevalence rate among adults and children in 12 fishing communities surrounding Lake George and Edward, Uganda and; to assess the HIV cascade of care in these settings.
Methods: We conducted a cross-sectional household-based survey. Following an exhaustive household enumeration using GPS, trained-nurses visited 890 randomly-selected households during two months, interviewing 15-69 years' old men and women. All HIV-positive individuals were asked to provide a blood sample for viral load measures. Children < 15 years old were eligible for testing only if their parents were HIV-positive. Logistic regression models, adjusted on sociodemographic-behavioral variables were used to identify factors associated with HIV testing and being HIV-positive and, factors associated with HIV-status unawareness and viral suppression among HIV-positive adults.
Results: Overall, 1738 adults and 148 children were included. The HIV-prevalence rate among adults was of 17.5%(95%CI:15.8-19.4) and among HIV-exposed children 6.1%(95%CI:3.1-11.4). HIV-Prevalence rate was higher among women (20.9%;95%CI:18.4-23.5) than among men (13.5%;95%CI:11.3-16.1). According to occupation and sex, farmers had the highest HIV-prevalence rate among women (27.6%) and fishermen among men (18.7%). After adjustment, only fishermen remained with a 4-times higher risk of being HIV-positive (aOR: 3.9; 95%CI [1.6-9.4]), compared to men of other occupations. Among HIV-negatives, 81.0% declared had a test < =12 months ago. Among HIV-positives, 86.0% declared HIV-status awareness, 78.0% on ART and 56.0% had a viral load < 20cp/ml (On ART: 67.6%) (Figure1). Men had a higher risk of being untested (aOR: 2.2;95%CI:1.4-3.7) and virally detectable (aOR:6.6; 95%CI:1.9-22.0) than women. Fishermen did not have a higher risk of being untested or virally unsuppressed.
Conclusions: In Uganda, HIV-prevalence rate in fishing communities is high, particularly among women and fishermen. Although HIV testing and ART initiation rates are high, viral suppression rate remains poor, especially among men. Nevertheless, fishermen do not seem to have a lower access to care than other men. More HIV preventive interventions are needed in these settings, particularly targeting women and fishermen. Strengthen ART-retention, particularly among men, should be a priority in these settings.

Chan School of Public Health, Department of Global Health and Population, Boston, United States, [5]International Clinical Research Center, Department of Global Health, University of Washington, Seattle, United States, [6]University College London, Research Department of Infection and Population Health, London, United Kingdom, [7]Division of Infection and Immunity, University College London, London, United Kingdom, [8]Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Durban, South Africa
Presenting author email: avandormael@africacentre.ac.za

Background: HIV population viral load (PVL) has been widely advocated as a sensitive biological index of the transmission potential and the treatment program effectiveness of a particular geography. In this study, we aimed to quantify the change in the PVL over time for a South African community with a high HIV burden and a well-established ART program.
Methods: The data comes from a large population-based surveillance program, situated in the northern KwaZulu-Natal province, that has tested approximately 60% (~40,000) of all adults for HIV since 2004. We performed viral load measurements on 6959 dried blood spot samples with a HIV-positive test result in 2011 (n=2420), 2013 (n=2203), and 2014 (n=2336). For the HIV-positive population, we calculated the $\log_{10}$ viral load level and the proportion with virologic suppression, as indicated by a detection limit of <1550 copies/mL.
Results: Overall, the $\log_{10}$ viral load decreased from 3.91 copies/mL in 2011 to 3.64 copies/mL and 3.55 copies/mL in 2013 and 2014 respectively (p-value <0.001). The percentage of HIV-positive participants with viral suppression increased from 30% in 2011 to 39.1% and then 45.2% in 2013 and 2014 (p-value <0.001). Men and participants <30 years had higher $\log_{10}$ viral loads and lower rates of viral suppression (p-value <0.001).
Conclusions: Our study has evaluated the change in HIV viral load patterns in a full population (irrespective of knowledge of HIV status or linkage to care) over time in a sub-Saharan African setting. We have observed a substantial increase in the rate of viral suppression, by approximately 50%, during a four year period. Although this result is encouraging, we acknowledge that only 45% of our sample had a suppressed viral load in 2014. This result is currently well below the UNAIDS benchmark to ensure 73% of all HIV infected patients have virologic suppression by 2020.

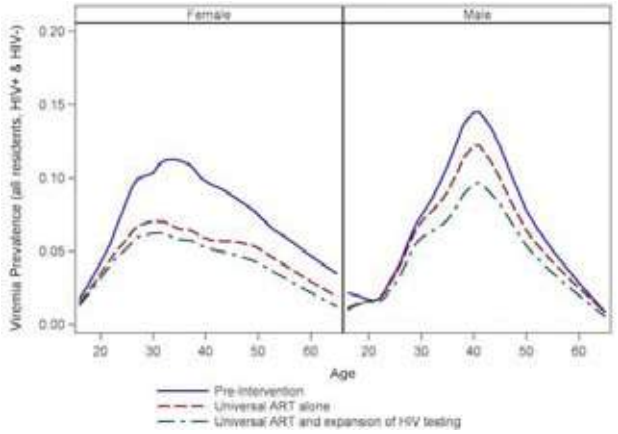
Presenting author email: scott_peterson@post.harvard.edu

Background: Prior to universal ART, Botswana had nearly achieved the UNAIDS 90-90-90 target (83%, 87%, and 97%, respectively) in 30 surveyed communities, but annual HIV incidence remained >1%. We sought to describe residual populations at risk for transmitting HIV to guide prevention efforts.
Methods: During a baseline survey for an HIV prevention trial, we performed HIV testing (CD4 and HIV viral load, if positive) among residents (age 16-64) in a 20% random household sample in 30 small Botswana communities. Among persons with HIV viremia (>400 copies/mL), we describe knowledge of HIV status, ART history, and CD4 cell count (eligibility for ART ≤350 cells/μL at time). We modeled the effects of expanded HIV testing and/or universal ART on community viremia prevalence by age.
Results: A total of 12,610 residents participated, including 3,596 (29%) with HIV infection, 932 (26%) of whom had HIV viremia. Community prevalence of HIV viremia (including all residents, both HIV+ and HIV-) was 7.4% (women 7.9%, men 6.5%, Figure 1). Lack of knowledge of HIV+ status was the leading contributor to viremia (Table 1). Modeling projected that transition to universal ART alone would reduce viremia prevalence to 5.2% (-2.7%) in women and 5.6% (-0.9%) in men. Concurrent expansion of HIV testing (reduction in unknown HIV+ status by 50%) with universal ART lead to projected viremia prevalence of 4.5% in women (-3.4%) and 4.6% men (-1.9%).



[Figure 1. Measured community prevalence of viremia (all residents, including HIV+ and HIV-) prior to intervention and projected prevalence with universal ART with/without expansion of HIV testing]

Cause		Female	Male	Total
Unaware HIV+		233 (37%)	167 (56%)	400 (44%)
Aware HIV+, ART-naive				
	CD4 Eligible but not yet on ART	110 (17%)	45 (15%)	155 (17%)
	CD4 Ineligible and not on ART	219 (34%)	43 (15%)	262 (28%)
Aware HIV+, history of ART				
	Default from ART	12 (2%)	11 (4%)	23 (2%)
	Virologic failure	62 (10%)	30 (10%)	92 (10%)

[Table 1: Leading contributing cause for viremia]

Conclusions: Nearing the UNAIDS 90-90-90 targets, community prevalence of HIV viremia is high in Botswana. Women previously ineligible for ART by CD4 count and men unaware of their HIV status account for a disproportionate burden of viremia.

TUPEC0875

Closing the 90-90-90 Gap: ZAMPHIA, 2016

D.T. Barradas[1], C. Moyo[2], S. Gupta[1], D.B. Williams[3], W. Kaonga[2], K. Sachathep[4], D. Hoos[4], K. Dzekedzeke[5], N. Nkombo[6], W. Kasongo[7], B. Parekh[3], H. Patel[3], S. Kamocha[1], C.B. Ndongmo[1], K. Hageman[1], M.A. Riggs[1], ZAMPHIA Study Team
[1]Centers for Disease Control and Prevention, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia, [3]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [4]ICAP, Mailman School of Public Health, Columbia University, New York, United States, [5]ICAP, Lusaka, Zambia, [6]Central Statistics Office, Lusaka, Zambia, [7]Tropical Disease Research Centre, Ndola, Zambia

Background: Findings from the 2016 Zambia Population-based HIV Impact Assessment (ZAMPHIA) indicate that Zambia has achieved significant progress towards meeting UNAIDS 90-90-90 goals. To better target expansion of HIV treatment services, ZAMPHIA data can be used to identify gaps in uptake of HIV testing counseling, initiation of antiretroviral therapy (ART), and adherence leading to viral load suppression (VLS).
Methods: A nationally representative, household-based sample of adults and children was recruited in all 10 Zambian provinces. Consenting participants provided demographic and clinical information and blood samples for household HIV testing per national guidelines. HIV-seropositive results were confirmed via a supplemental assay; viral load and limiting antigen (LAg) avidity testing were performed on all HIV-seropositive samples. VLS was defined as HIV RNA < 1000 c/ml.
Results: In 2016, 19,029 adults (15-59 y) from 10,959 selected households provided interviews and blood samples. One-third (32.7% [95% CI 30.2-35.3]) of persons living with HIV (PLHIV) reported being unaware of their HIV status; this was highest among adults ages 15-24 y (58.2% [52.0-64.3]).
HIV-seropositive males ages 25-34 y (58.2% [49.5-66.9]) and 35-44 y (32.2% [25.9-38.4]) had higher prevalence of unknown HIV status relative to females of the same age (25-34 y: 29.0% [24.5-33.4]; 35-44 y: 20.8%[16.9-24.7]).
Among PLHIV who reported being aware of their status, 14.6% (95% 12.5-16.7) reported they were not receiving ART; this was highest among adults ages 15-24 y (21.5% [13.2-29.7]) and 25-34 y (22.1% [17.2-27.0]).
VLS among PLHIV who reported receiving ART was 89.2% [87.4-91.0].
VLS was lowest among 15-24 y males; 48.5% (23.0-73.9) were not virally suppressed. Gender differences did not reach statistical significance for reported receipt of ART and VLS.
Conclusions: Young adults (15-34 y) living with HIV in Zambia had the lowest prevalence for each of the 90's: awareness of their HIV status, receipt of ART, and VLS. Results from ZAMPHIA confirm the need to increase HIV testing, treatment, retention and adherence for both young men and young women, in an effort to make further progress in controlling Zambia's HIV epidemic.

Unmet 90-90-90 targets among adolescent girls and young women living with HIV in Malawi

D. Payne[1], C. West[1], T. Kalua[2], A. Low[3], C. Chung[4], A. Auld[1], F.M. Ogollah[4], M. Tsoka[5], K. Brown[6], J. Burnett[6], E. Kim[1], M. Cates[6], S. Birhanu[6], S. Jonnalagadda[6], for the MPHIA Study Team
[1]U.S. Centers for Disease Control and Prevention, Lilongwe, Malawi, [2]Malawi Ministry of Health, Lilongwe, Malawi, [3]ICAP at Columbia University, New York, United States, [4]ICAP at Columbia University, Lilongwe, Malawi, [5]Centre for Social Research, Chancellor College, University of Malawi, Zomba, Malawi, [6]U.S. Centers for Disease Control and Prevention, Atlanta, United States
Presenting author email: wau4@cdc.gov

Background: In 2015, adolescent girls and young women (AGYW), aged 15-24 years in Sub-Saharan Africa, accounted for 25% of new HIV infections among adults despite being 17% of the adult population. Nationally representative data on HIV for AGYW in Malawi are limited in scope. This analysis describes the burden of HIV among AGYW in Malawi and their progress towards achieving the UNAIDS 90-90-90 targets.
Methods: The Malawi Population-based HIV Impact Assessment (MPHIA), a national household survey, was conducted from November 2015 to August 2016 to measure national HIV incidence and sub-national viral load suppression (VLS). Participants answered questionnaires and provided blood for home-based HIV testing using the national rapid HIV testing algorithm, followed by laboratory-based confirmation using Geenius HIV 1/2 Confirmatory Assay (Bio-Rad). Viral load measurements <1,000 copies/mL were considered suppressed. Weighted point estimates and survey-adjusted 95% confidence intervals (CIs), calculated using the Jackknife replication method, are presented for the number of young women living with HIV (using population projections from the Malawi National Statistical Office), prevalence, awareness of HIV status, self-reported antiretroviral therapy (ART) status and VLS.
Results: Of 4,592 eligible women, 3,571 (78%) responded to the questionnaire and provided blood. Of those tested, 169 were HIV positive, resulting in a 3.7% prevalence (95% CI: 2.9-4.5); 1.9% (95% CI: 1.2-2.8) in 15-19 year olds (n=38) and 5.2% (95% CI: 3.9-6.6) in 20-24 year olds (n=131). HIV prevalence was significantly greater in urban (6.3%; 95% CI: 4.4-8.2) compared to rural areas (3.0%; 95% CI: 2.1-3.9). Of the 61,855 (95% CI: 48,119-75,593) AGYW estimated to be HIV infected, 58.6% (95% CI: 49.2-68.3) were aware of their HIV positive status; 76.9% (95% CI: 57.6-96.1) of those aware of their status were on ART, and 79.3% (95% CI: 67.6-91.1) of those on ART were virally suppressed. Overall VLS among all HIV positive AGYW was 52.0% (95% CI: 41.0-62.8%).
Conclusions: These results indicate a gap among AGYW in awareness of their HIV positive status, receiving ART and achieving viral suppression compared to the UNAIDS 90-90-90 targets. Concerted efforts are needed to improve prevention, diagnosis, treatment initiation and adherence among AGYW.

TUPEC0877

Geographical distribution of HIV burden in Malawi: where is the gap in achieving the 3rd 90?

G. Bello[1], G. Chipungu[2], B. Janet[3], B. Parekh[4], T. Dobbs[4], D. Hoos[5], A. Munthali[6], M. Nzima[7], B. Matatiyo[8], S. Dadabhai[9], C. West[10], N. Wadonda-Kabondo[10], MPHIA Study Team
[1]I-TECH, Lilongwe, Malawi, [2]ICAP at Columbia University, Lilongwe, Malawi, [3]CDC, Atlanta, United States, [4]CDC, Atlanta, United States, [5]ICAP at Columbia University, New York, United States, [6]Centre for Social Research, Chancellor College, University of Malawi, Zomba, Malawi, [7]UNAIDS, Lilongwe, Malawi, [8]Malawi National AIDS Commission, Lilongwe, Malawi, [9]Johns Hopkins Project, College of Medicine, Blantyre, Malawi, [10]CDC, Lilongwe, Malawi
Presenting author email: gbello@itech-malawi.org

Background: Although Malawi has a generalized epidemic, previous studies have shown that the prevalence varies widely by geography, gender and other socio-economic indicators. We recently conducted a survey to measure national and sub-national prevalence and viral load suppression in Malawi to understand the progress in controlling the epidemic.
Methods: Malawi conducted a Population-based HIV Impact Assessment survey between November 2015 and August 2016, stratified by seven geographical zones (Central East, Central West, and Lilongwe City in the Centre, Blantyre City, South East, and South West in the South and North). This household level survey assessed HIV prevalence in 0-64 year olds and viral load suppression in 15-64 year olds. The estimates and confidence intervals accounted for the survey design. Home-based HIV rapid testing using the national algorithm and Geenius supplemental test for confirmation at satellite labs were conducted. HIV positive samples were centrally tested for viral load suppression and recency of infection using LAg-Avidity EIA. Viral load suppression was defined as <1,000 HIV RNA copies/mL.
Results: The weighted national HIV prevalence among 15-64 year olds was 10.6% [females (12.8%) and males (8.2%)]. By region, HIV prevalence was highest in the South particularly Blantyre City (18.2%) and lowest in Central East (5.3%) and Central West (5.8%). HIV prevalence in the Lilongwe City (11.8%) was higher than the other two zones in the Centre. Blantyre City had both the highest prevalence and the lowest viral load suppression among adults living with HIV, as seen in table.

Zone	HIV Prevalence % (95% C.I.)	% HIV Population Virally suppressed
North	7.3 (5.8-8.7)	66.9 (60.7-73.1)
Central-East	5.3 (4.0-6.6)	63.7 (51.1-76.3)
Central-West	5.8 (4.9-6.8)	70.4 (63.0-77.9)
Lilongwe City	11.8 (10.4-13.1)	65.5 (60.3-70.7)
South East	15.6 (13.4-17.8)	68.8 (62.3-75.3)
South West	15.9 (14.0-17.8)	70.3 (65.4-75)
Blantyre City	18.2 (16.4-19.9)	59.5 (53.6-65.5)
Total	10.6 (9.9-11.2)	67.6 (65.0-70.2)

[Geographical distribution of HIV indicators in Mal]

Conclusions: The HIV epidemic in Malawi continues to show geographical variation and gender disparities with the Southern Region being the most affected and with some of the largest gaps in achieving the viral load suppression target. This suggests that the HIV program in Malawi needs strengthening in the Southern Region particularly Blantyre City.

TUPEC0878

Critical situation concerning HIV exposure among people who inject drugs in France: results from ANRS-Coquelicot surveys and HIV monitoring system

M. Jauffret-Roustide[1,2], J. Pillonel[3], F. Lot[3], F. Barin[4], F. Cazein[3]
[1]INSERM, Cermes3, Paris, France, [2]Public Health France, Paris, France, [3]Public Health France, Saint-Maurice, France, [4]CHU, Tours, France
Presenting author email: josiane.pillonel@santepubliquefrance.fr

Background: Harm reduction policies has had a marked impact on HIV transmission in PWID (People Who Inject Drugs) but a much more limited impact on HCV. Therefore, harm reduction strategies are currently more focused on HCV prevention. However, some recent indicators presented here show that the French situation concerning HIV dynamic in PWID remains critical.
Methods: We used data from the mandatory HIV surveillance system in France, adjusted for under-reporting, reporting delays and missing values. Diagnoses at an advanced stage of HIV infection were defined as diagnoses with a CD4 count below 200 cells/mm3 excluding HIV acute illness, or with an AIDS defining disease regardless of the CD4 count.
We also used data from the ANRS-Coquelicot cross-sectional surveys that included a sampling plan (Time Location Sampling combined with the Generalized Weight Sampling Method) and were conducted in 2004 and in 2013 among 1,718 PWID who had injected drugs at least once in their life. Socio-behavioral data were collected from face-to-face interviews. Self-finger prick blood samples were collected on dried blood spots.
Results: PWID are more likely to be diagnosed at an advanced stage of infection (38% of new diagnoses in 2015) than MSM (18%) and heterosexually-infected people (34% among men, 27% among women). In 2012, incidence in PWID - who constituted the second most exposed group to HIV - was estimated at 86 per 100 000 person-years and has not decrease since 2003. This incidence was much higher than that in heterosexuals born in France (5/100,000) or abroad (44/100,000). The ANRS-Coquelicot surveys highlight that 26% of PWID declared they shared their syringes at least once during the previous month compared with 13% in 2004. Furthermore, in 2013, 30% of PWID declared difficulties in obtaining syringes, even in big cities as Paris.
Conclusions: All these indicators show that conditions favouring exposure to infectious diseases including HIV in PWID are still present. Our data indicate that France should remain vigilant with respect to the HIV epidemic in PWID. HIV screening is still insufficient and new harm reduction policies, focusing more on socio-structural interventions, are urgently needed.

TUPEC0879

Factors associated with longer engagement in methadone maintenance therapy among HIV-positive people who use illicit opioids

T. Andrusiak[1], E. Wood[2,3], J. Shoveller[2,4], T. Kerr[2,3], J. Montaner[2,3], M.-J. Milloy[2,3]
[1]St. Paul's Hospital, Goldcorp Addiction Medicine Fellowship, Vancouver, Canada, [2]St. Paul's Hospital, BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, Division of AIDS, Department of Medicine, Vancouver, Canada, [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada
Presenting author email: tara.andrusiak@gmail.com

Background: Compared to non-drug using peers, HIV-positive individuals who use illicit drugs exhibit higher rates of suboptimal HIV treatment outcomes. For many with opioid dependence, methadone maintenance therapy (MMT), is required to lower risks of negative health outcomes. Thus far, factors associated with longer engagement in MMT among HIV-positive individuals has not been described. Hence, we set out to describe behavioral, social and clinical factors associated with engagement in MMT among a cohort of HIV positive illicit opioid users in Vancouver, British Columbia.
Methods: Data was obtained from the AIDS Care Cohort to evaluate Exposure to Survival Services (ACCESS), an outgoing prospective cohort of HIV-positive illicit drug users linked to clinical records in universal no-cost HIV treatment and care. The primary outcome of interest was reporting being on MMT at the time of study interview. Baseline characteristics of HIV-positive individuals were obtained and a generalized estimating equation (GEE) with Poisson regression was used to longitudinally estimate relationships between the primary outcome and explanatory variables. In the final multivariate model, all variables with p <0.05 were included
Results: From December 1 2005 to June 1 2015, 586 HIV-positive, antiretroviral therapy (ART) exposed individuals with a history of illicit opioid use or MMT use were recruited. At baseline, there was a positive association between those on MMT and use of ART (OR 2.38, 95% CI:1.44-3.93). Over the study period, a positive association was found between longer engagement in MMT and achieving an undetectable viral load (VL) (ARR 1.30, 95% CI: 1.22-1.38) as well as having at least a high school diploma (ARR 1.14, 95% CI: 1.08-1.21). Engagement in MMT was negatively associated with daily heroin injection (ARR 0.62, 95% CI: 0.56-0.69) and daily methamphetamine use (ARR 0.40, 95% CI: 0.28-0.56).
Conclusions: In this community-recruited cohort of illicit-opioid using HIV-positive individuals, engagement in MMT was associated with positive health and social factors including maintenance of an undetectable viral load, obtaining at least a high school education, and decreased participation in the use of heroin and methamphetamines. These findings strongly reaffirm the use of opioid substitution therapy in the management of HIV-positive individuals with opioid use disorder.

TUPEC0880

Impact of HIV/AIDS on the psychological behavior of children from HIV affected families in Myanmar

M.-M. Mon[1], L.L. Win[1], Y.T.N. Oo[1], S. Saw[1], H.N. Oo[2], P.P.W. Htin[3]
[1]Ministry of Health and Sports, Department of Medical Research, Yangon, Myanmar, [2]Ministry of Health and Sports, National AIDS Program, Nay Pyi Taw, Myanmar, [3]UNICEF, Yangon, Myanmar
Presenting author email: mmyomon@gmail.com

Background: Information on the impact of HIV/AIDS on the psychological behavior of children on a national scale is lacking in Myanmar. Therefore, a nationwide survey was conducted to identify and compare the psychological behaviors of children from HIV affected families with children from neighborhood.
Methods: A community-based, cross-sectional comparative study was done in 30 townships of Myanmar in 2014. Study children were children under 18 years who have/had HIV infected parents regardless of their own HIV status. Age group matched children were recruited from neighborhood. Parents/guardians of 1,511 study children and 1,511 controls were interviewed by using a pre-tested, structured questionnaire. In-depth interviews were conducted with providers and parents/guardians.
Results: Mean age of the children was 8.7±4.1 years and 46.8% of study children were orphans. Higher proportion of study children stayed in extended families (36% vs. 29%). Among 10 to 14 years old children, 8.6% of study children was working for their living compared to 4.4% of the control group (p<0.05). Over 24% of study children were HIV infective and 75% have initiated ART. Psychological behavior was measured by the Strengths and Difficulties Questionnaire (SDQ) which included 22 items organized into emotional, conduct problems, hyperactivity, peer relationship and pro-social behavior. Regarding the total difficulties score, higher proportion of study children were seen in abnormal category than their neighborhood children (13.4% vs. 9.1%, p<0.01). Similarly, higher percentage of study children were in the abnormal emotional behavior (24% vs. 18%, p< 0.01) and abnormal conduct behavior categories (15% vs. 11%, p<0.05). These findings pointed out the higher risk of developing behavioral problems among the study children in comparing to neighborhood children. Many key informants highlighted the issues of vertically HIV infected adolescents including emotional and behavioral problems, ART non-compliance and unmet need of reproductive health information. Many health care providers indicated psychological support as a priority especially for the HIV infected adolescents.
Conclusions: The needs of HIV positive adolescents should be addressed through the provision of psychological support and reproductive health information. In conclusion, long term strategic plans should be drawn up for psychological support for the children from HIV affected families.

HIV serostatus disclosure from partners before sex: results from an online survey of Chinese men who have sex with men

W. Tang[1], B. Cao[2], C. Liu[2], R. Fu[2], S. Pan[2], H. Li[2], W. Ma[3], C. Wei[4], J. Tucker[1], SESH
[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]UNC Project-China, Guangzhou, China, [3]Shandong University, Jinan, China, [4]University of California, San Francisco, San Francisco, United States
Presenting author email: weimingtangscience@gmail.com

Background: HIV serostatus disclosure before sex can facilitate serosorting, condom use and potentially decrease the risk of HIV acquisition. However, few studies have evaluated HIV serostatus disclosure from different partners before sex. We examined the rates and correlates of HIV serostatus disclosure from different types of partners before sex among an online sample of men who have sex with men (MSM) in China.
Methods: An online cross-sectional study was conducted among MSM in eight Chinese cities in July 2016. Participants completed questions covering sociodemographic information, sexual behaviors, HIV testing (including HIV self-testing)

history, self-reported HIV status, post-test violence, and whether or not HIV test results were disclosed between them and their different kinds of most recent partners before sex. Participants or their partners who never tested for HIV were defined as undisclosed.
Results: Overall, 2105 men completed the survey. Among them, 85.9% were never married, and 35.4% had high school or less education. 346/1678 (20.6%) of men received HIV serostatus disclosure from their regular male partners, which was significantly lower than the disclosure rate of the participants to their regular partners (704/1678 42.0%, P<0.001). HIV serostatus disclosure rates from other types of partners were: 17.8% (287/1608) from casual male partners, 16.2% (62/383) from regular female partners, and 16.8% (48/286) from casual female partners. Multivariable analysis indicated that disclosure from regular male partners was associated with a higher likelihood of post-test violence (adjusted OR (aOR) =5.18, 95% CI: 1.53-17.58). Compared to never self-tested participants, participants ever self-tested for HIV were also more likely to receive HIV status disclosure from regular male partners (aOR=1.92, 95% CI: 1.50-2.44).
Conclusions: This study showed that HIV serostatus disclosure from partners was uncommon among Chinese MSM. Interventions and further implementation research to facilitate safe disclosure are urgently needed for MSM.

TUPEC0882

HIV-related stigma, racial discrimination and gender discrimination are associated with reduced antiretroviral adherence and lower health-related quality of life among a national cohort of women living with HIV in Canada

C.H. Logie[1], Y. Wang[1], A. Lacombe-Duncan[1], A.C. Wagner[2], K. Webster[3], A. Kaida[3], T. Conway[4], A. de Pokomandy[5], M.R. Loutfy[4]
[1]University of Toronto, Toronto, Canada, [2]Ryerson University, Toronto, Canada, [3]Simon Frasier University, Vancouver, Canada, [4]Women's College Research Institute, Toronto, Canada, [5]McGill University, Montreal, Canada
Presenting author email: yings.wang@mail.utoronto.ca

Background: HIV-related stigma has well-known deleterious health impacts among women living with HIV (WLWH). Less is known, however, about the effects of multiple, intersectional forms of stigma. The study objective was to examine associations between HIV-related stigma, racial and gender discrimination and WLWH's health outcomes.
Methods: We used baseline data from a national cohort study with WLWH to test a conceptual model of pathways between intersectional stigma (HIV-related stigma, racial discrimination, gender discrimination) and antiretroviral adherence and health-related quality of life (HrQOL) (mental and physical dimensions). We hypothesized that stigma would be associated with reduced antiretroviral (ART) adherence (< 90% adherence vs. ≥90%) and lower HrQOL, and that social support and HIV disclosure concerns would mediate these relationships. We conducted structural equation modeling using maximum likelihood estimation to test the model.
Results: Participant (n=1425) mean age was 42.8 (SD=10.62); 41% of participants were Caucasian, 22% Aboriginal, and 29% African/Caribbean/Black. The confirmatory factor analysis of the intersectional stigma construct demonstrated good model fit with three factors (HIV-related stigma, racial discrimination, gender discrimination) (CFI=0.91, TLI=0.90, RMSEA=0.05). In independent models, HIV-related stigma, racial discrimination and gender discrimination were each associated with: lower social support, reduced mental and physical HrQOL, increased HIV disclosure concerns, and reduced ART adherence. In the simultaneous model, HIV-related stigma had a significant indirect effect on reduced ART adherence, fully mediated by HIV disclosure concerns. HIV-related stigma had significant direct and indirect effects on mental HrQOL, partially mediated by social support and HIV disclosure concerns. HIV-related stigma had a significant indirect effect on physical HrQOL, fully mediated by social support. Racial discrimination had a significant direct effect on ART adherence, partially mediated by social support and HIV disclosure concerns. Gender discrimination had significant direct and indirect effects on mental and physical HrQOL, partially mediated by social support. The model fit the data well (CFI=0.96, RMSEA=0.062).
Conclusions: Associations between intersectional stigma—HIV-related stigma, gender and racial discrimination—and ART adherence and HrQOL are multi-faceted and associated with HIV disclosure concerns and social support. Interventions to increase ART adherence and HrQOL among WLWH must address multiple forms of stigma, HIV disclosure strategies, and build social support.

TUPEC0883

A pilot study comparing sexual risk data collected via smartphone application diaries and online survey questionnaire among at-risk HIV-negative men who have sex with men

M. Musuruana[1,2], B. Koblin[3], D. Lucy[3], G. Ortiz[3], J. McCrossin[3], D. Usher[3], H.V. Tieu[3]
[1]University of Illinois College of Medicine, Peoria, United States, [2]HVTN Research and Mentorship Program Scholar, New York, United States, [3]New York Blood Center, Laboratory of Infectious Disease Prevention, New York, United States
Presenting author email: musurua1@gmail.com

Background: Men who have sex with men (MSM) are disproportionately affected by HIV in the US. Self-reports of sexual risk behaviors among MSM may be biased and unreliable. The study objectives were to test the feasibility and acceptability of using smartphone app-based diaries for collection of sensitive sexual behavioral risk data among MSM in New York City.
Methods: Participants were recruited via online platforms and referral letters. Inclusion criteria were male at birth, anal sex with a man or transwoman in the last month, age 18-50 years, and self-report being HIV negative or unknown status. After informed consent, participants were randomized into 3 study arms with smartphone sex diary entries daily, weekly, or after sex. Participants completed a self-administered online survey at enrollment and at 30 days. Data collected from the surveys were compared with data from the smartphone diaries using kappa statistics.
Results: 30 MSM enrolled in the study; median age was 32 years. Mean number of anal sex partners in the last 30 days was 4. Smartphone diary completion was higher among the weekly arm (97.5%) than the daily (70.6%) (p=.025). When compared to online survey data collected at day 30, agreement in reported number of anal sex partners in the 3 sex app arms was low (kappa range: 0-0.23). The number of protected insertive and receptive anal sex acts reported by the daily study arm showed moderate agreement with the survey (kappa= 0.58 and 0.53, respectively). In the weekly study arm for the same categories, the kappa statistics were 0.231 and 0.318 respectively. Participant feedback was largely positive with 89.3% finding it to be "very easy" or "easy" to complete their sex diaries.
Conclusions: It is feasible to collect sexual risk behavior data using a smartphone app-based diary among MSM. Completion of diaries once weekly is more desirable as participants had a high completion rate. There was low to moderate agreement of data between the diary app and online survey across behaviors. This pilot study supports the use of mobile devices to obtain sensitive behavioral information that may otherwise not effectively be obtained via surveys with longer recall periods.

Background: The COmmunity-BAsed Cohort (COBA-Cohort), implemented in the framework of the Euro HIV EDAT project, aims to collect common data among HIV-negative MSM attending community-based voluntary counselling and testing (CBVCT) services in 6 European countries. The objective of the present analysis was to identify patterns in HIV-testing in the preliminary baseline data of COBA-Cohort.
Methods: All HIV-negative MSM >18 attending one of the 17 participating CBVCT services are invited to participate in COBA-Cohort. The first site started enrolling in January 2015, the last one in October 2016. We performed a Latent Class Analysis (LCA) using 5 categorical variables: time since last HIV test, main reason for the present test, steady relationship type, condomless anal intercourse (CAI)

with the last casual partner, and willingness to use PrEP. The LCA was adjusted for the country of participants (cluster option), and the number of classes relied on information criteria and interpretability of the item-response probabilities.
Results: Among the 3071 HIV-negative MSM enrolled in COBA-Cohort from commencement to 06/30/2016, 21% reported an HIV test < 6 months prior to enrolment, and 15.8% were never tested. Regular control was the main reason for the baseline HIV test (71.4%). 49.2% reported only casual partners in the last 12 months, 12.9% only steady partners and 31.6% both. CAI with the last casual partner was reported by 19.5% of participants and willingness to use PrEP by 40.7%. The first class (58% of all participants) described regular testers reporting condom use at last casual encounter; the second class (18%) grouped regular testers in steady/exclusive relationship; the third class (18%) was composed of regular testers having both CAI and non-CAI with casual partners, but no steady partner; and the last class (6%) grouped men recently tested but not coming on a regular basis, reporting CAI and willingness to use PrEP.
Conclusions: This LCA brings a first insight of HIV testing patterns in relation to several basic risk indicators, and suggests that the most regular testers are not necessarily the most at-risk individuals. Further explorations of the COBA-Cohort's data will allow to better characterise these profiles and identify possible changes over time.

TUPEC0885

Association between self-report measures of treatment adherence and viral suppression among people living with HIV/AIDS in China: optimal recall period and item content

W. Da[1], X. Li[1], S. Qiao[1], Y. Zhou[2], Z. Shen[2]
[1]University of South Carolina, Department of Health Promotion, Education, and Behavior, Arnold School of Public Health, Columbia, United States, [2]Guangxi Center for Disease Control and Prevention, Nanning, China
Presenting author email: shanqiao@mailbox.sc.edu

Background: Strong correlations between self-report treatment adherence measures and HIV viral load have been reported in several studies. Few studies, however, have assessed the ability of treatment adherence measures differing in recall time frames and item contents in predicting viral suppression. This study aims to compare the performance of four self-report treatment adherence measures in predicting viral suppression.
Methods: A cross-sectional study among 2,987 HIV patients recruited from 12 cities/counties in Guangxi, China were used in this study. Medication adherence behaviors were collected by self-administered questionnaires and most recent viral load was obtained from patients' medical records. Adherence was dichotomized at the cut-off of 90%. Viral suppression was defined as having an HIV viral load below 400 copies/ml. Tetrachoric correlation was used to assess the correlation between adherence and viral suppression. The ability to predict viral suppression was evaluated by calculating the area under the receiver-operating characteristic (AUROC) curve. Multivariate logistic regression was used to assess the association between adherence measures and viral suppression controlling for demographics, depression, and HIV risk-related behaviors.
Results: The correlation ranged from 0.49 to 0.73 between the four adherence measures, and from 0.11 to 0.24 between adherence measures and viral suppression. The difference between AUROC curves was not statistically significant. Viral suppression was positively associated with one-month adherence measured by missed doses (aOR = 2.12, 95% CI 1.08, 4.17), but not by missed days (aOR = 1.63, 95% CI 0.80, 3.31). Both 3-day (aOR = 2.12, 95% CI 1.08, 4.17) and weekend (aOR = 2.51, 95% CI 1.14, 5.54) adherence were positively associated with viral suppression. Time on treatment (aOR ranging from 1.02 to 1.03) and injection drug use (aOR ranging from 0.52 to 0.55) were associated with viral suppression.
Conclusions: One-month recall periods can be of similar accuracy in predicting viral suppression compared with shorter periods. Questions asking about number of missed doses may be more accurate than those asking about missed days, which might be due to differences in levels of dosing schedules. Therefore, adherence measurement items may need tailoring to specific dosing regimens.

TUPEC0886

Can regular HIV testing and counselling modify sexual behaviour in HIV-negative Malian MSM? (CohMSM ANRS 12324 - Expertise France)

P.-J. Coulaud[1], B. Mmadi Mrenda[1], L. Sagaon-Teyssier[1], G. Maradan[1], M. Mora[1], B. Dembélé Keita[2], F. Diallo[2], A. Coulibaly[2], A.A. Keita[2], A. Bernier[3], C. Laurent[4], B. Spire[1], The CohMSM Study Group

Presenting author email: pierre-julien.coulaud@inserm.fr

Background: The promotion of safe sex practices is necessary in HIV-negative men who have sex with men (MSM), especially for those who regularly attend sexual health centres. We aimed to assess possible changes in sexual behaviours of MSM in West-Africa, in the context of regular, comprehensive follow-up in healthcare facilities according to international recommendations.
Methods: Data were obtained from an interventional cohort of HIV-negative MSM implemented in Western Africa (CohMSM). Among participants enrolled in Mali, we focused on the first 90 MSM who completed 12 months of follow-up comprising quarterly HIV-testing and counselling. Socio-behavioural data were collected at baseline, 6 and 12 months, using a standardised face-to-face questionnaire. Outcomes of condom use during anal or oral sex, and number of sexual partners in the previous 6 months were used as indicators of sexual risk behaviours. A multistate Markov model was used to predict the evolution of these outcomes over time using estimated transition probabilities between baseline and M12.
Results: 174 MSM were recruited with a median age of 24 years (Interquartile Range=22-27), 90% of them were single and 78% reported financial difficulties. No significant differences were found regarding socio-demographic characteristics between the 90 MSM sub-group and the other Malian participants. Markov modelling highlighted that the probability of participants who practiced condomless anal sex at baseline changing to systematic condom use at M12 was 0.11. In contrast, the probability of participants with systematic condom use during anal sex at baseline stopping condom use was 0.04. With respect to oral sex, the probability of participants adopting systematic condom use was higher than that of stopping condom use (0.07 versus 0.05). MSM with multiple partners at enrolment were more likely to still have multiple partnerships at M12 (i.e., 0.86).
Conclusions: Predictions of risky sexual behaviours at one year of follow-up showed a modest impact of regular HIV-testing and counselling on the sexual practices of HIV-negative MSM. In a context where HIV incidence remains high among MSM, comprehensive biomedical interventions including both early ART and PrEP are needed to have a stronger impact on HIV incidence.

90-90-90 HIV targets will not be enough to achieve global incidence reduction targets

N. Scott[1,2], S. Kelly[1,2], D. Wilson[1], M. Stoove[1,2], M. Hellard[1,2,3]
[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]The Alfred Hospital, Melbourne, Australia
Presenting author email: nick.scott@burnet.edu.au

Background: The UNAIDS 90-90-90 target aims to have 90% of people living with HIV knowing their status, 90% of people diagnosed on treatment, and 90% of people on treatment with suppressed viral loads by 2020. We estimated the HIV incidence reduction in Australia corresponding to:
(1) achieving the UNAIDS 90-90-90 targets by 2020 and;
(2) achieving extended targets of 95-95-95 by 2030, in combination with various scale-ups of HIV testing, primary prevention and pre-exposure prophylaxis (PrEP) among high-risk men who have sex with men (MSM).
These projections were evaluated against the ending AIDS target of achieving a 90% reduction in HIV incidence by 2030 compared to 2010 levels.
Methods: A mathematical model was used to project annual HIV incidence in Australia between 2016 and 2030 for all combinations of HIV care cascade targets, testing frequencies, primary prevention coverages and levels of PrEP scale-up.
Results: Achieving 90-90-90 by 2020 was estimated to reduce incidence by 8% from 2010 levels; however beyond this continued improvements were required to prevent incidence from increasing. Achieving 95-95-95 by 2030 was estimated to reduce incidence by 14% from 2010 levels. This was improved to 29% by testing low- / high-risk MSM two / three times per year respectively; to 39% by including a 5-year scale-up to 30% PrEP coverage among high-risk MSM; and to 55% by increasing condom use with casual partners from an estimated 42% to 60%. However, it was only with 95-95-95, two / three test per year for low- / high-risk MSM, 100% high-risk MSM PrEP coverage and 100% condom use that an 89% reduction in incidence was possible by 2030.

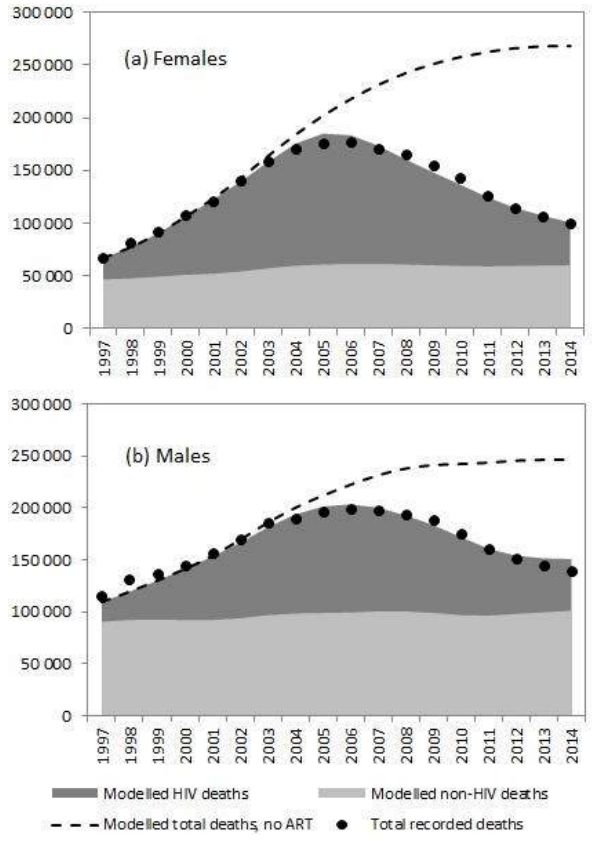
Conclusions: Even if the UNAIDS care cascade targets are met or exceeded, additional coverage of prevention programs will be required to achieve a 90% reduction in HIV incidence by 2030.

TUPEC0888

The impact of antiretroviral treatment on adult mortality trends in South Africa

L. Johnson[1], M. Cornell[1], R. Dorrington[2], A. Boulle[1], M. May[3], M. Egger[4], M.-A. Davies[1]
[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [2]University of Cape Town, Centre for Actuarial Research, Cape Town, South Africa, [3]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom, [4]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland
Presenting author email: leigh.johnson@uct.ac.za

Background: Substantial reductions in adult mortality have been observed in South Africa since the mid-2000s, but there has been no formal evaluation of how much of this decline is attributable to the impact of antiretroviral treatment (ART).
Methods: A combined demographic and HIV model was developed for South Africa. Estimates of mortality rates in ART patients were obtained from the International Epidemiology Databases for the Evaluation of AIDS Southern Africa (IeDEA-SA) collaboration. The model was calibrated to HIV prevalence data and death data from the South African vital registration system, which records 94% of adult deaths, using a Bayesian approach. To evaluate the impact of ART, the model was used to simulate the mortality trend that would have been expected in the absence of ART.
Results: The model matched the recorded death data closely (Figure). In the period up to the end of 2014, 2.73 million adult HIV-related deaths occurred in South Africa. Adult HIV deaths peaked at 232 000 per annum in 2006 and declined to 97 000 in 2014, a reduction of 75% when compared to the scenario without ART (Figure). In the period up to the end of 2014, the South African ART programme is estimated to have saved 6.36 million life years in adults (95% CI: 5.55-6.92 million). This compares with a potential saving of 9.12 million (95% CI: 8.01-9.91 million) life years that might have been achieved had South Africa moved swiftly to implement WHO guidelines and achieved high levels of ART uptake in HIV-diagnosed individuals from 2004.



[Figure: Trends in adult deaths (ages 20-59)]

Conclusions: ART has had a dramatic impact on adult mortality in South Africa, but delays in the rollout of ART, especially in the early stages of the ART programme, have contributed to the loss of 2.8 million life years.

TUPEC0889

Acceptability of male circumcision by women partners in a clinical trial in the Dominican Republic

S. Mayer[1], P. Fleming[2], S. Khosla[3], L. Lerebours[4], Y. Donastorg[5], M. Brito[3]
[1]University of Illinois at Chicago, Infectious Disease, Chicago, United States, [2]University of Michigan, Ann Arbor, United States, [3]University of Illinois at Chicago, Chicago, United States, [4]Clinica De Familia, La Romana, Dominican Republic, [5]Instituto Dematologico, Santo Domingo, Dominican Republic
Presenting author email: smayer75@uic.edu

Background: Voluntary Medical Male Circumcision (VMMC) serves as an effective HIV prevention strategy in high prevalence areas. A recent single arm clinical trial of VMMC in the Dominican Republic (DR) reported high acceptability and low complication rates in circumcised men. Little is known about the acceptability of VMMC in sex partners of circumcised Dominican men. The aim of this study was to assess satisfaction, acceptability, and sexual health in women before and after their partner's circumcision.
Methods: We recruited regular sex partners of men circumcised in a clinical trial of VMMC in the DR. Willing participants either joined focus group discussions or completed a survey on acceptability, sexual practices, and health. Focus groups were audio-recorded, transcribed verbatim, and coded using Atlas.ti software. We analyzed survey data with SAS (v9.3) to generate descriptive statistics bivariate results.
Results: Median age of women surveyed (n=55) was 28 years (IQR 24-34) and 80% had children. Almost universally (98%) women were satisfied with their partner's circumcision and would consider circumcising their sons (98%). The majority of women (89%) were more attracted to their partner after circumcision and 98% were more satisfied with sex after circumcision. Women who reported vaginal and urinary symptoms (dysuria, bleeding, abnormal vaginal discharge, ulcers) prior to their partner's circumcision reported a substantial decrease of these symptoms after circumcision. All women were very satisfied with their partner's hygiene and the majority (>70%) felt more protected against HIV/STI. Almost all (98%) had recommended the procedure to other couples. Focus group data confirmed high levels of acceptability and satisfaction, primarily due to perceived improvements in their sex life and health.
Conclusions: Regular sex partners of circumcised men perceived VMMC to improve sexual health and satisfaction. These findings suggest that VMMC may have a positive impact on women and that they could be engaged to promote VMMC.

TUPEC0890

Impact of TasP, PrEP and condoms on the HIV epidemic among MSM in British Columbia

V.D. Lima[1], I. Rozada[1], N.J. Lachowsky[2], D.M. Moore[1], M.W. Hull[1], R.S. Hogg[1], J.A. Shoveller[1], J.S.G. Montaner[1]
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of Victoria, Victoria, Canada
Presenting author email: irozada@cfenet.ubc.ca

Background: Gay, bisexual and other men who have sex with men (MSM) are disproportionally affected by the HIV epidemic. In British Columbia (BC), the HIV epidemic has decreased among people who inject drugs. However, the same trend has not been observed among MSM. Today, condoms, Treatment as Prevention (TasP), and Pre-Exposure Prophylaxis (PrEP) are highly efficacious HIV prevention strategies that can prevent HIV transmission in MSM. We conducted this study to assess how condoms, TasP and PrEP can be used in combination to prevent further HIV infections among the MSM population in BC.
Methods: We designed a mathematical model that combines individual-based knowledge of clinical, behavioral and epidemiological aspects of the HIV epidemic among MSM in BC. The MSM population was divided into low- and high-risk of acquiring/transmitting HIV, based on the US CDC HIV Incidence Risk Index for MSM. We assessed the effect of increasing condom use and PrEP access. For PrEP, we evaluated universal (all MSM are eligible) and targeted (only high-risk MSM are eligible) scenarios. We studied the effect of increased TasP by decreasing the time to HIV diagnosis, to antiretroviral treatment (ART) initiation, and increasing the time retained on ART. The effect of the interventions at five and ten years was evaluated on HIV incidence, all-cause mortality, HIV prevalence, and the Control Reproduction Number Rc.
Results: Optimizing all aspects of TasP and increased provision of PrEP to high-risk MSM was the most effective strategy (74% reduction in incidence, Rc as low as 0.63). Increasing condom use maintained the effectiveness of the strategy while limiting the extent of targeted PrEP coverage. TasP was the only intervention that significantly decreased mortality. The most influential aspect of TasP was the time individuals were retained into treatment.
Conclusions: The results provided by this model showed that the optimization of TasP, by promoting timely HIV diagnosis, treatment initiation and higher retention,

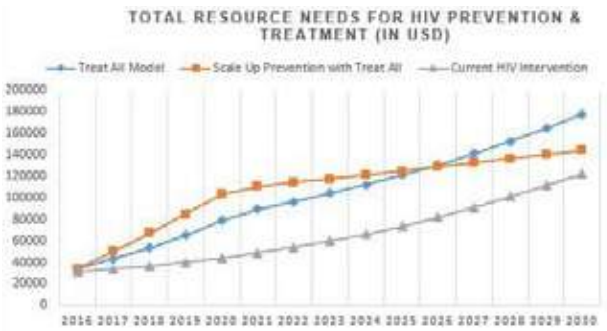
combined with the distribution of PrEP to MSM at high risk of HIV infection was the most successful strategy to control the HIV epidemic among MSM. Consistent use of condoms should continue to be actively promoted to reduce HIV transmission by all MSM.

TUPEC0891

Using the AIDS epidemic model to guide programs of a rapidly increasing epidemic

N.D. Montevirgen[1], A. Aquino[2], A. Balaoing[3], L. Trinidad[3], B. Castaneda[3], K.A. Umali[3], M.J. Zapanta[3], N. Palaypayon[3], G. Samonte[3], I. Asuncion[3], W. Peerapatanapokin[4]
[1]Epidemiology Bureau, Department of Health, Pasay, Philippines, [2]Epidemiology Bureau, Department of Health, Manila, Philippines, [3]Department of Health, Manila, Philippines, [4]Eastwest Center, Bangkok, Thailand
Presenting author email: genesis.samonte@gmail.com

Background: Current treatment guidelines in the Philippines are not aligned with WHO treat all recommendation. The 2016 Philippine AIDS Epidemic Model (AEM) provides a means to determine the potential impact and relevance of a treat all strategy for the country's HIV program. Given the diverse distribution of the HIV epidemic in the country, the Philippine AEM was constructed using sub-national models.
Methods: Five sub-national models were developed and combined to construct the Philippine AEM using key inputs population size estimates, HIV prevalence, risk and protective behaviors, and anti-retroviral (ART) coverage. Unit cost of prevention and treatment interventions were derived from the 2014 Philippine AEM. Adjustments to treatment parameters were done for the treat all scenario, while prevention parameters were sustained. A combined scale up prevention and treat all strategy was modeled by increasing prevention coverage along with treatment adjustments.
Results: The 2016 Philippine AEM estimates 55,005 people living with HIV (PLHIV); only 30% are currently on ART. New infections are estimated to occur at 29 cases daily, and are expected to increase by 607% in 2030 if current efforts are maintained. Meanwhile, a treat all strategy averts 68% of new HIV infections, and prevents 74% of HIV-related deaths. A combination strategy not only averts significantly more new HIV infections (90%) and prevents 10% more HIV-related deaths than a lone treat all approach, it also offers a lower resource need from the program in the long run.



[Figure 1. Total resource needs for HIV prevention & treatment (in USD)]

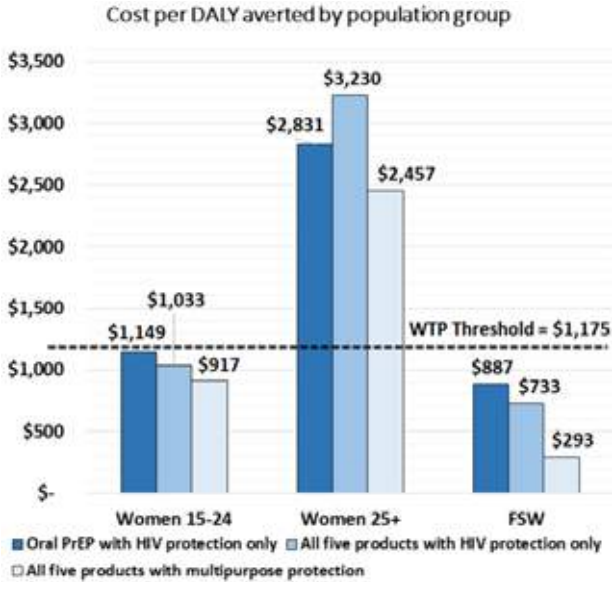
Conclusions: A combined prevention scale up and treat all strategy is highly recommended given the potential it offers for halting and reversing the Philippine HIV epidemic coupled with a more economical resource requirement in the long-term. Current prevention coverage is at 30%, increasing this to 60% will already make a dent in the epidemic, however a 90% coverage was found to be most effective.

TUPEC0892

Valuing the synergistic benefits of multipurpose HIV and pregnancy protection: an economic evaluation of multipurpose prevention products in South Africa

M. Quaife[1,2], F. Terris-Prestholt[1], M.A. Cabrera Escobar[2], R. Eakle[1,2], S. Delany-Moretlwe[2], M. Mvundura[3], M. Kilbourne-Brook[3], P. Vickerman[4]
[1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [2]University of the Witwatersrand, Wits RHI, Johannesburg, South Africa, [3]PATH, Seattle, United States, [4]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom
Presenting author email: matthew.quaife@lshtm.ac.uk

Background: The development of antiretroviral-based HIV prevention products has substantially changed the prevention landscape. A promising area of research is the development of candidate multipurpose prevention technologies (MPTs), products which could offer users protection from HIV, other STIs, or unintended pregnancy. We estimate the cost-effectiveness of a range of potential single- and multi-purpose prevention products.
Methods: We combine a cost model with a simple, static model of product impact to estimate the cost-effectiveness of five MPTs - oral PrEP, intravaginal rings, injectable ARVs, microbicide gels, and SILCS diaphragms used in concert with gel. We account for the preferences of end-users by predicting uptake using a discrete choice experiment (DCE) among 362 general population women (HIV negative, aged 16-45) and 122 female sex workers (FSW) (HIV negative, aged 18-45) in South Africa. DCE results were also used to predict additional uptake for products offering contraceptive properties. Disability-adjusted life years (DALYs) averted per HIV infection were estimated for each group under scenarios of low, median and high HIV incidence as observed in recent trials. The model incorporated costs relating to local and national implementation and MPT development, whilst averted costs included those related to treatment and the avoidance of unintended pregnancies. A sensitivity analysis explores the robustness of estimates to parameter uncertainty.
Results: On average, the cost-effectiveness of MPTs was around 35% better than single-purpose products. All rollout scenarios were cost-effective using a 1xGDP threshold, but only interventions among young women (< 25 years) and FSWs were cost-effective when lower, more methodologically robust thresholds were applied.



[Figure]

Conclusions: Candidate MPTs are attractive to both women in the general population, and female sex workers. Incorporating contraceptive indications into HIV prevention products could increase product uptake, impact, and improve cost-effectiveness. This study provides further impetus for the development of effective and attractive MPTs.

TUPEC0893

National evaluation of option B+ in Malawi: high maternal ART coverage and low early infant transmission in all areas of the country

B. Tippett Barr[1], M. van Lettow[2], M. Landes[3,4], J.J. van Oosterhout[2,5], E. Schouten[6], N. Wadonda[7], S. Gupta[8], T. Kalua[9], A. Jahn[9,10]
[1]Centers for Disease Control and Prevention, CGH/DGHT, Harare, Zimbabwe, [2]Dignitas International, Blantyre, Malawi, [3]University of Toronto, Toronto, Canada, [4]Dignitas International, Toronto, Canada, [5]University of Malawi, College of Medicine, Blantyre, Malawi, [6]Management Sciences for Health, Blantyre, Malawi, [7]Centers for Disease Control and Prevention, CGH/DGHT, Lilongwe, Malawi, [8]Centers for Disease Control and Prevention, Lusaka, Zambia, [9]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [10]University of Washington, ITECH, Lilongwe, Malawi
Presenting author email: joepvanoosterhout@gmail.com

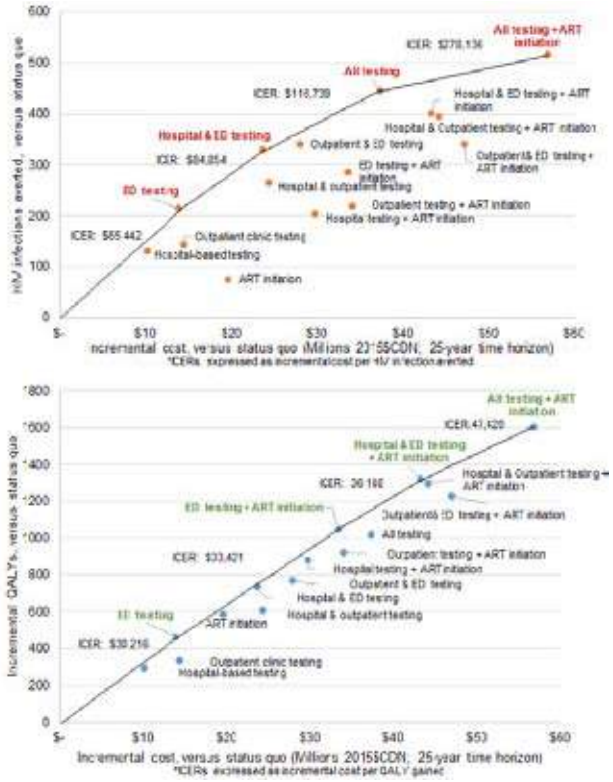
Background: Option B+ was conceptualized and implemented in Malawi in 2011. Routine program data suggest relatively high ART uptake among pregnant women and challenges with retention. HIV testing for exposed children is affected by delays and loss to follow-up. The Ministry of Health has led the implementation of a National Evaluation of Malawi's PMTCT Program (NEMAPP) to provide unbiased nationally representative data on maternal ART coverage and on early and late vertical transmission rates.
Methods: NEMAPP is a 2 year longitudinal cohort study implemented at 54 health facilities in November 2014 using a two-stage cluster sampling design to identify a representative sample of 4-12 week old infants. Mothers were consecutively consented and screened for HIV while attending an under-5 clinic; HIV-exposed infants receive HIV-1 DNA testing at enrolment, 12 and 24 months. Complex weighted survey design analysis was conducted using STATA.
Results: Among 2,125 HIV-positive mothers, 2,082 (96.1%) reported knowing their HIV status before or during pregnancy, and 1,865 (88.5%, 59.4-100% across sites %) were on ART in pregnancy. Overall MTCT was 4.2% (95% CI 2.9-6.1); for women on ART in pregnancy, MTCT was 2.5% (95% CI 1.6-3.9). MTCT was 17.9% (95% CI 13.0-24.2) among women not on ART during pregnancy. MTCT varied from 1.4% (95% CI 0.5-3.9) among women who initiated ART before pregnancy, to 20.2% (95% CI 5.8-50.7) in those starting ART post-partum. Early infant transmission was similar across geographic strata, ranging from 3.2% (95% CI 1.7 - 5.8) to 5.1% (95% CI 3.5-6.3) between strata (Table 1).
Conclusions: Malawi's early MTCT rates are close to those of developed nations. Decentralization of ART services to all ANC clinics and strong program leadership through quarterly supportive site supervision and active supply chain management have resulted in high levels of ART coverage and low early transmission rates in all areas of the country. The number of new pediatric infections are disproportionately contributed to by the small percentage of HIV-positive women not on ART in pregnancy.

TUPEC0894

Using the QALY to evaluate interventions for HIV treatment and prevention: value and ethics

B. Nosyk, J. Min, X. Zang, M. Olding, J. Montaner
BC Centre for Excellence in HIV/AIDS, Vancouver, Canada
Presenting author email: bnosyk@cfenet.ubc.ca

Background: Motivated by the principle of maximizing population health, the use of quality-adjusted life years (QALYs) is ubiquitous in health economic evaluation. An explicit focus on reducing new HIV infections by the US National HIV/AIDS strategy among others has prompted some to consider HIV infections averted in the denominator of the incremental cost-effectiveness ratio (ICER), used to judge incremental value of an intervention.
Our objective is to demonstrate the health and ethical implications of using HIV infections averted, as opposed to QALYs gained, in judging the relative value of HIV treatment and prevention interventions.
Methods: Building off a prior model-based evaluation of HIV care interventions (primary care testing (hospital, emergency department, outpatient) and ART initiation) in British Columbia (BC), we plotted health production functions, showing the highest-valued combinations of strategies for the range of investment levels, with QALYs and HIV infections averted in the y-axes to illustrate differences in valuation. Strategies were compared to the next-most resource intensive, with ICERs <3xGDP per capita considered for funding (BC GDP per capita:$55,405).
Results: With HIV infections averted in the y-axis (top panel), ED testing, ED+ hospital-based testing, all primary care testing and the combined intervention lie on the health production function, with all primary care testing likely to be implemented (ICER:$116,739/HIV infection averted). With QALYs in the y-axis (bottom panel) ED testing, ED testing+ART initiation, ED+hospital testing+ART initiation and the combination intervention lie on the health production function, with the combination intervention likely to be implemented (ICER:$47,420/QALY). This strategy results in an additional 584 QALYs at a cost of $19.5M compared to the strategy selected by focusing on HIV infections averted, with an ICER ($33,421/QALY) well-within international standards.
Conclusions: Using HIV infections averted in the ICER undervalues strategies providing immediate health benefits to PLHIV, resulting in sub-optimal and potentially unethical funding decisions.



[Figure 1. Health production functions]

TUPEC0895

Estimating the potential impact of providing HIV treatment and opioid agonist therapy (OAT) in prison and upon release on HIV incidence among people who inject drugs (PWID) in Tijuana, Mexico

A. Borquez[1], D. Abramovitz[1], S. Strathdee[1], L. Beletsky[1,2], A. Vera[1], C. Magis-Rodríguez[3], P. Vickerman[4], M.C. Boily[5], N.K. Martin[1,4]
[1]University of California San Diego, Medicine, La Jolla, United States, [2]Northeastern University, School of Law & Bouvé College of Health Sciences, Boston, United States, [3]CENSIDA, Mexico, Mexico, [4]University of Bristol, Bristol, United Kingdom, [5]Imperial College London, London, United Kingdom
Presenting author email: natasha-martin@ucsd.edu

Background: Tijuana is a nexus for drug use on the Mexico-US border, with an estimated 10,000 PWID, among whom HIV prevalence is 3.5% and incidence 1 per 100 person-years (although much higher among women than men). Among PWID in Tijuana, access to HIV and harm reduction services is very low (< 3% receiving ART or OAT) and incarceration is frequent. We estimate the potential impact of providing ART and OAT in prisons and upon release on HIV incidence among PWID in Tijuana, using mathematical modeling.
Methods: We developed a deterministic model of injecting and sexual HIV transmission among PWID disaggregated by HIV status (including ART), sex, incarceration status and OAT. We calibrated the model to HIV prevalence and incidence data among PWID in Tijuana, parameterized with local data on incarceration patterns and elevated risk of syringe sharing among recently and non-recently incarcerated. For simplicity, we assumed no coverage of ART or OAT at baseline either in prison or the community. In the counterfactual scenarios, we varied the efficacy of ART in preventing parenteral transmission (relative risk 0.4-0.96) and assumed a drop out rate of 0.1/year in the community. We assumed an efficacy of OAT in reducing HIV acquisition of 0.53 (95%CI: 0.33-0.68) based on a meta-analysis and mean duration of 1 year. We estimated the impact on HIV incidence of providing ART to HIV-infected PWID in prison and on release, OAT to all PWID in prison and on release, or both (OAT+ART) from 2017-2030.

Results: Modeling estimated that between 2017-2030, ART provision in prison and on release could avert 16% (95% Credible Interval (CrI): 8%-28%) of new HIV infections. OAT provision to all PWID in prison and on release could avert 12% (95%CrI: 5%-22%) of HIV infections, and OAT+ART provision could avert 21% (95%CrI: 11%-34%) of HIV infections.
Conclusions: Prisons could provide a valuable opportunity for initiating PWID onto HIV prevention in Tijuana, a population in much need of HIV and harm reduction services. Indeed, a fifth of new HIV infections could be averted between 2017-2030 through the provision of ART and OAT in prison and upon release.

Strategies to Increase Uptake of and Retention in HIV Services

TUPED1185

Minors access to HCT and proxy consent: standing up for their right to highest quality of care

M. Balibago[1], E. Brathwaite[2]
[1]*UNICEF Philippines, HIV and Adolescent Programming, Caloocan City, Philippines,* [2]*ICRC, Carlton, Australia*
Presenting author email: mbalibago@unicef.org

Background: The Philippines is one of the seven countries with increasing HIV cases in the world, with 19 of 29 estimated new HIV infections per day occur among 15 to 24 years old. Restrictive laws remain as significant barriers especially with the recent decision of the Supreme Court on the constitutionality of the Responsible Parenthood Reproductive Health Law that requires below 18 y/o adolescents to obtain written consent from their parents; the same requirement of AIDS Law for HIV testing. With the very low comprehensive knowledge on HIV among the key populations (IHBSS 2015) and the general youth (YAFS 2013), delayed access to services and low condom use among those who engaged in risky behaviors at an early age, and unwillingness to disclose sexual activities to parents, the YOUTH will continue being drivers of the HIV epidemic in the country.
Methods: UNICEF worked with Philippine government to start reverting 62% of HIV cases among youth, thus implemented the Integrated SRH/HIV Service Delivery Model for Adolescents. Capacity of national and local government agencies, civil society organizations (CSO), PLHIV community and youth networks were strengthened on HCT provision, determining "conditions to provide proxy consent", training health providers/social workers providing adolescent friendly health services, review of ethical medical practice and use of case management tools and forms, and establishing a wide network of service delivery referrals on adolescent using standardized operational guidelines.
Results: Improved life skills education and other demand generation activities that is linked to adolescent friendly health services increased service uptake. Frontline service providers are less afraid to provide services through the partnership model. To date, 2 HIV high burden cities have amended HIV ordinance lowering age to consent for HIV testing from 18 to 15 y/o while other cities have ongoing leveraging with mayors to provide HCT services to minors through MOU. Most important is that more than a thousand of adolescent minors as young as 13 years old have accessed HCT; those positive linked to services.
Conclusions: Use of evidence-based data, documentation of experiences, and strong government/CSO/youth partnerships guarantee actions to overcoming legal barriers and other challenges to minors access to services.

TUPED1186

Engagement in care and viral suppression (VS) are not associated with *same-day* versus *delayed* antiretroviral therapy (ART) initiation during pregnancy in Cape Town, South Africa

N. Langwenya[1,2], E.J. Abrams[3,4], T. Phillips[1,2], J. McIntyre[1,5], K. Brittain[1,2], A. Zerbe[3], L. Myer[1,2]
[1]*University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa,* [2]*University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa,* [3]*Columbia University, ICAP, New York, United States,* [4]*Columbia University,College of Physicians & Surgeons, New York, United States,* [5]*Anova Health Institute, Johannesburg, South Africa*
Presenting author email: nontokozo.langwenya@uct.ac.za

Background: Immediate initiation of ART on the same day as eligibility is determined ("same-day initiation") is common in PMTCT services to help maximise time on ART and VS before delivery. However there are concerns that same-day initiation may restrict patient preparation before ART start and contribute to subsequent non-adherence, disengagement from care and raised viral load (VL). We examined whether same-day initiation is associated with engagement and VS in a cohort of women initiating ART during pregnancy.
Methods: At a large primary care clinic, consecutive ART-eligible women were enrolled into an implementation science study at their first antenatal visit, 4/2013-6/2014. During the study, ART eligibility/initiation changed from delayed initiation following CD4-driven eligibility criteria ("Option A", 4-6/2013) to universal same-day initiation ("Option B+" after 6/2013). All women were followed with VL testing for the study, separate from routine care, through 12m postpartum. Postpartum engagement in ART services was measured using routinely-collected clinic, pharmacy and laboratory records.
Results: Of 628 ART-eligible women enrolled (median age=28y; median gestation=21w; 55% newly diagnosed HIV+), 73% started ART same-day; 81% and 19% under "Option B+" and "Option A", respectively; there were no significant demographic differences between same-day and delayed initiators. There were no differences in engagement through 12m postpartum (same-day=76%, delayed=75%, p=0.512). Levels of VS<1000cps/mL at delivery (92%vs90%) and 12m postpartum (75%vs71%) were the same under same-day vs delayed initiation, respectively; similar findings were observed when VS was defined at < 50cps/mL (p>0.200 throughout). Results did not vary after adjustment for demographic/clinical measures, and were consistent across subgroups of age, CD4 and timing of HIV diagnosis (Table).
Conclusions: These data suggest that same-day ART initiation is not associated with lower levels of engagement in care or VS through 12m post-delivery, reassuring findings for PMTCT/ART programmes offering immediate ART initiation.

Subgroup	At delivery [OR (95% CI)]		At 12 months Postpartum [OR (95% CI)]		
	VS<50	VS<1000	VS<50	VS<1000	Engaged in care
All women	0.97 (0.48-1.97)	1.72 (0.69-4.25)	1.33 (0.71-2.53)	1.38 (0.71-2.71)	1.54 (0.82-2.90)
Age: <28 years	1.49 (0.61-3.68)	3.64 (1.16-11.5)	1.20 (0.49-2.95)	1.32 (0.54-3.26)	1.90 (0.83-4.33
Age: ≥28 years	0.80 (0.24-2.60	0.62 (0.12-3.20)	1.56 (0.59-4.14)	1.63 (0.56-4.71)	1.39 (0.49-4.00)
Pre-ART CD4: ≤350	1.05 (0.43-2.60)	1.47 (0.44-4.92)	0.88 (0.35-2.20)	1.12 (0.43-2.88)	1.62 (0.64-4.11)
Pre-ART CD4: >350	0.81 (0.24-2.75)	2.83 (0.69-11.6)	1.70 (0.65-4.47)	1.54 (0.56-4.26)	1.35 (0.53-3.42)
HIV diagnosis: new in pregnancy	0.99 (0.36-2.70)	1.79 (0.53-6.08)	1.52 (0.57-4.02)	1.42 (0.53-3.79)	1.20 (0.53-2.75)
HIV diagnosis: before pregnancy	0.77 (0.26-2.30)	1.47 (0.37-5.87)	1.07 (0.45-2.58)	1.25 (0.48-3.24)	2.09 (0.75-5.86)
All models adjusted for pre-ART VL, time on ART, gestation at ART initiation, marital status and PMTCT Option (A/B+); models with all women also adjusted for CD4, age and timing of HIV diagnosis					

[Adjusted association same-day vs delayed]

TUPED1187

Will HIV test and start be the end of baseline CD4 monitoring? CD4 functionality and impact of transition in a resource-limited setting, Zimbabwe

T. Maphosa[1], K. Webb[1], V. Chitiyo[1], B. Engelsmann[1], J. Murungu[2], S. Page[1], P. Nesara[1], D. Patel[1]
[1]*Organisation for Public Health Interventions and Development, Harare, Zimbabwe,* [2]*Ministry of Health and Child Care, AIDS and TB Program, Harare, Zimbabwe*
Presenting author email: tmaphosa@ophid.co.zw

Background: In 2015, World Health Organization (WHO) released new HIV treatment and care guidelines recommending starting antiretroviral therapy (ART) in all people living with HIV (PLHIV) regardless of CD4 count or clinical stage. In June 2016, Zimbabwe started implementing the new HIV treatment guidelines which still recommend baseline CD4 monitoring. The objectives of the assessment were to describe the availability of CD4 monitoring and identify existing bottlenecks to effective and efficient use of CD4 monitoring equipment.
Methods: Qualitative and quantitative data was collected in 22 purposively sampled districts (5 provinces). Health care staff was interviewed in March 2016 using a structured questionnaire. After Treat All roll out; CD4 utilization pattern was recorded pre- and post-TREAT ALL implementation in June and July 2016 respectively. Stata V12 was used to conduct the data analysis.
Results: At the time of the assessment; 50% (15/30) of conventional and 34% (42/124) CD4 POC machines were not functioning. Average length of break down was 118 days, with most frequently cited reasons for breakdown being error messages, no cartridges or reagents, and results printer down. In the previous 6 months, 81% of all CD4 machines had experienced a reagent stock out, breakdown or both.

The proportion of patients initiated on ART that received baseline CD4 monitoring significantly reduced the month after Treat All began (47% vs. 26%, p <0.001). The table below shows the reported status of the CD4 machines per province.

Province	Total CD4 machines	Number of Point of care CD4 machines	Number of conventional CD4 machines	Number of machines CURRENTLY non-functional (May 2016)	Machines reporting cartridge or reagent stock out	Number of machines reported broken down	Machines reporting breakdown &/or stock out
Bulawayo	13	11	2	3 (23%)	10 (91%)	3 (23%)	11 (85%)
Manicaland	31	26	5	4 (13%)	18 (58%)	8 (26%)	23 (74%)
Masvingo	34	27	7	12 (35%)	17 (50%)	15 (44%)	25 (74%)
Mat. South	31	23	8	20 (65%)	26 (84%)	11 (35%)	29 (94%)
Midlands	45	37	8	18 (40%)	26 (58%)	29 (64%)	36 (80%)
Total	154	124	30	57 (37%)	97 (63%)	66 (43%)	124 (81%)

[Reported CD4 machine status per province]

Conclusions: We report frequent breakdown of both POC and conventional CD4 machines and a significant decline in documented baseline CD4 in newly initiated patients following the start of Treat All in Zimbabwe. As national scale up of VL monitoring continues, we recommend cost-effectiveness analyses to determine optimal investment for improving functionality of existing CD4 equipment to support baseline monitoring of patients on ART as recommended in Zimbabwean national guidelines.

TUPED1188

"PrEP in the Wild": results from a global survey of medical providers' PrEP practices in settings where it is approved and where it is not

J. Galea[1,2], R. Cook[3], J. Pickett[4,5], P. Gorbach[3]
[1]Socios en Salud, Boston, United States, [2]Harvard Medical School, Global Health and Social Medicine, Boston, United States, [3]University of California, Los Angeles, Epidemiology, Fielding School of Public Health & Division of Infectious Diseases, David Geffen School of Medicine, Los Angeles, United States, [4]AIDS Foundation of Chicago, Prevention Advocacy, Chicago, United States, [5]International Rectal Microbicide Advocates, Chicago, United States
Presenting author email: jpickett@aidschicago.org

Background: Some medical providers prescribe PrEP drugs off label ("in the wild") and/or provide related medical monitoring to individuals who procure PrEP drugs on their own. Little is known about the practices of these medical providers.
Methods: During February-December, 2016, an internet survey of PrEP providers was deployed globally in English, French and Spanish. A descriptive analysis of PrEP provider practices was conducted.
Results: 70 surveys were completed by medical providers from 27 countries. Their reported patients included: people who inject drugs (76%); transgender persons (63%); men who have sex with men (91%); and, heterosexual women (84%) and men (86%). 89% of providers reported following established PrEP guidelines including: US CDC (62%); WHO (62%); South African (14%). HIV infection was ruled-out prior to prescribing PrEP by: rapid HIV antibody (70%) or HIV antibody with P24 antigen (53%) tests; ELISA with P24 antigen (54%); PCR/viral load (30%); CD4+ (11%). ARVs prescribed included: Truvada® (80%) or generic TDF/FTC (55%); 3TC+TDF (13%); TDF (5%); Stribild (5%); Atripla (7%); other (10%). Primary ARV dosing schedules prescribed: daily (92%); 1 dose the day before sex, then 1 dose every day of sex, and 1 dose the day after sex (12%); and 1 dose 4x/week (8%). HIV was testing most frequently recommended monthly (7%); quarterly (75%); or bi-annually (7%). Other testing included: gonorrhea (73%); chlamydia (77%); HPV (36%); mycoplasma (23%); syphilis (94%); hepatitis A, B, C (56%, 92% and 76%, respectively); serum creatinine clearance (92%); liver function (74%); bone mineral density (10%); and urine dipsticks (62%). Social services referrals were common (67%). Reasons for refusing to prescribe/support PrEP included: low HIV risk (52%); concerns about reduced condom use (19%); recreational drug use (13%); mental health problems (21%); < 18 years of age (20%); female (17%); transgender (13%); sex worker (11%); current condomless sex (19%); no condomless sex (35%); only heterosexual sex (17%); medication affecting kidneys (57%).
Conclusions: Most "in the wild" PrEP providers followed established guidelines; however, non-recommended PrEP regimens and tests were common. Of concern was refusal to prescribe PrEP to potentially very vulnerable individuals. PrEP approval in countries is critical to the consistent, correct provision of PrEP.

Facilitators and barriers for providing HIV, sexual and reproductive health (SRH) services to adolescent key populations in Kenya: a situational analysis

R. Kimathi[1], M. Kiragu[1], S. Nduta[1], M. Mireku[1], M. Muthare[1], G. Ombui[1], J. Kyongo[1], R. Karuga[1], E. Gitau[2], U. Gilbert[2], H. Musyoki[3], A. Ikahu[1], L. Digolo[1], W. Mukoma[1], L. Otiso[1]
[1]LVCT Health, Nairobi, Kenya, [2]UNICEF, Nairobi, Kenya, [3]NASCOP, Nairobi, Kenya
Presenting author email: rkimathi@lvcthealth.org

Background: AIDS related deaths among adolescents continues to rise in Africa. Key populations contribute to 30% of new infections annually and include adolescent key populations (KPs). However, limited data exists on adolescent key populations in Kenya, limiting sexual and reproductive health (SRH) and HIV policy formulation and service delivery.
In this study, adolescent KPs were defined as adolescents aged 10-19 years who engage in either sex work, same sex relationships or intravenous drug use. The study aimed to identify enablers and barriers to inform provision of HIV/SRH services to adolescent KPs in Kenya.
Methods: A cross sectional study using qualitative methods was conducted between October 2015 and April 2016. A total of 9 focus group discussions and 18 in-depth interviews were conducted with 108 adolescent KPs. Fifteen key informant interviews were conducted with national and county policy makers, 18 with health service providers (clinicians and counsellors) and 18 with key populations' program implementers (program officers and managers) in Nairobi, Mombasa and Kisumu counties of Kenya. The interviews explored perceptions of facilitators and barriers to provision of HIV/SRH services to adolescent key populations by the different groups. Data were recorded digitally, translated, transcribed and coded in NVivo10 prior to a thematic analysis.
Results: Adolescent KPs, health service providers, program implementers and policy makers identified several facilitators in the provision of services namely: a friendly and easily accessible location or environment for provision of HIV/SRH services and integrated health services that minimize referrals ("one-stop-shop"). Barriers to provision of services reported were; limited involvement of adolescent KPs in the design of HIV/SRH programs, negative health care providers' attitudes towards key populations, limited age appropriate information education materials, absence of disaggregated data that helps in decision making on programming, and lack of adolescent key population's policies & guidelines on HIV and sexual reproductive health.
Conclusions: The study has demonstrated existing facilitators and significant barriers to provision of HIV/SRH services for an at risk group for which limited data exist. These results provide a basis for policy review and program redesign involving the adolescent KPs to minimize barriers and facilitate HIV/SRH service access and uptake.

TUPED1190

Interpersonal Communications (IPC) linked with a mobile-based feedback mechanism for voluntary medical male circumcision (VMMC) demand creation: lessons from a 6-month implementation pilot in Zambia

B. Thurston[1], A. Machinda[2], M. Namukoko[3], G. Sishekanu Liche[3], M. Sundaram[4], N. Chintu[2]
[1]Population Services International, Lusaka, Zambia, [2]Population Services International/Society for Family Health, Lusaka, Zambia, [3]Society for Family Health, Lusaka, Zambia, [4]Bill & Melinda Gates Foundation, Seattle, United States
Presenting author email: brittanyt@sfh.org.zm

Background: IPC approaches are the backbone of VMMC demand, facilitating discussions and allowing men to address their unique concerns. Despite relative effectiveness of IPC, most men showing willingness to get circumcised do not get circumcised. Internal programmatic data shows one third of men reached with circumcision messages get circumcised. Most VMMC programs lack structured follow-up strategies for clients missing appointments.
A door-to-door mobilization model, which utilized Community Health Workers (CHWs) equipped with tablets to maximize follow-up, efficiency and effectiveness of contact with potential VMMC clients was implemented over six months in Lusaka.
Methods: Ten CHWs and one supervisor were trained and equipped with pre-configured tablets, given unique identifier codes and assigned to one geographical area. At each household, CHWs electronically submitted client information and booked VMMC appointments through a custom-built application, which generated unique client numbers. These were used to track clients and ultimately for reconciling appointments. Automated reminder messages were sent to appropriate CHW a maximum three times for clients missing appointments.

Results: 70% (121/171) of booked clients were circumcised, 91% of these on first booking, and 9% after follow-up visits. 37% of clients booked through a CHW were circumcised the following day, while 15% were circumcised between 2 to 5 days later, and 19% took 6 to 75 days.
Most of circumcised clients were males between 15-29 years; unmarried (84%); attained a minimum of primary school level education (96%); and unemployed (70%). Clients most likely to go for circumcision after a day were those with tertiary education (50%); heads of households (45%); unmarried (48%); employed (43%); and aged 15-29 years (41%). Conversely, clients requiring more time to get circumcised were those with up to secondary level education only (26%), and aged less than 15 years (23%).
Of the 30% clients missing appointments, most never attended school (71%) and were below 15 years (40%).
Conclusions: An innovative IPC demand creation model using CHWs coupled with a mobile-based feedback mechanism is an effective approach for identifying characteristics of clients who access VMMC services in low resource settings; monitoring client referral success rates; and promoting timely and systematic follow-ups.

Evaluation of lost to follow-up tracing system in integrated HIV care (IHC) program in Myanmar: call for strengthening of current tracing activity

A.M. Ko Ko[1], K.W.Y. Kyaw[2], Z.Z. Oo[1], T. Htun[3], S. Thiha[1], A.C. Min[1], T.K. Aung[1], N.T.T. Kyaw[2], H.N. Oo[4]
[1]International Union against Tuberculosis and Lung Disease (The Union), HIV Unit, Mandalay, Myanmar, [2]International Union against Tuberculosis and Lung Disease (The Union), Operational Research Department, Mandalay, Myanmar, [3]International Union against Tuberculosis and Lung Disease (The Union), Monitoring, Evaluation, Accountability and Learning Deparment, Mandalay, Myanmar, [4]Ministry of Health and Sports, National AIDS Program, Nay Pyi Taw, Myanmar

Background: Access to the antiretroviral therapy (ART) has been rapidly increased during the past ten years in Myanmar as well as in Integrated HIV Care (IHC) Program. Loss-to-follow-up (LTFU) rate 7% was reported in the IHC program in 2012 although the target set by National Program is < 5%. Hence, LTFU, defined as "disengagement from clinic at least 12 weeks from last appointed date" in the program, became one of the critical area to emphasize to improve the treatment outcome in this setting. The systematic tracing of LTFU was implemented in 2015 and 2016 by contacting via phone or by visiting home with monthly interval of at least three times by peer network.
Methods: Retrospective analysis of the tracing outcomes of LTFU patients from three ART Centers of Mandalay General Hospital and one of 300 Bedded Mandalay Teaching Hospital between June 2005 and December 2016.
Results: Of 1,368 LTFU patients from four ART Centers, 733 (54%) were traced with 648 (88%) patients on ART and 85 (12%) on stopped ART at the time of LTFU. The median (interquartile range -IQR) age at time of enrolment was 35 years (30 - 40), while the median duration on ART at the time of LTFU was 7 months (IQR 2 - 19). After tracing, 185 (25.2%) were reported to be alive, 118 (16.1%) were dead, 245 (33.5%) could not reached because of wrong recording or changing of addresses and phone numbers; and 185 (25.2%) patients were reported as family lost connection with patients, loss of record booklet, etc. LTFU patients with CD4≤200 cells/mm^3 were more likely to report dead compared with those who had CD4>200 cells/mm^3 [Odd ratio 3 (95% confidence interval 1.84 - 4.88)].
Conclusions: The current LTFU tracing system is needed to strengthen to cover more LTFU patients, moreover, the recording system of the program is also required to improve to get correct contact details of patients with regular updating of the changes. In addition, it is needed to implement a new innovative strategy for patients with low CD4 count to prevent disengagement from care.

TUPED1192

Impact of household visit schedule of field teams on retention of community-recruited participants in HIV prevention research: perspectives from the HPTN 071 (PopART) study

E. Nkuna[1], N. Mandla[1], R. Hayes[2], H. Ayles[2], P. Bock[1], N. Beyers[1], R. Sloot[1], on behalf of the HPTN 071 (PopART) Study Team
[1]Stellenbosch University, Desmond Tutu TB Centre, Cape Town, South Africa, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom
Presenting author email: eliudn@sun.ac.za

Background: Successful follow-up of community-recruited participants in HIV prevention research could be influenced by the household visit schedule of field teams. The aim of this study is to investigate the impact of different field work shifts on successful follow-up of participants.
Methods: HPTN 071 (PopART) is a community-randomised trial of a household-based HIV-prevention intervention package in South Africa and Zambia. The primary outcome, HIV incidence, is measured in a randomly selected Population Cohort (PC). We used data from the 12 month follow-up survey (July 2015 - June 2016) of the PC in 9 South African communities. Follow-up household visits among individuals consented to participate at baseline were scheduled in three shifts: Midweek (Monday-Friday) shifts (8 hour duration) categorized as early shift if it ended before 4pm; as late shift if it ended after 4pm; and a Saturday shift (5 hours). During each shift, 4 teams (two individuals per team) were active per community. A participant was considered successfully followed-up if the survey was completed during the household visit. The number of successful follow-up visits were calculated for each shift type and standardized to account for variation in shift duration. Poisson regression analysis was used to calculate incidence rate ratio's (IRRs) and 95% confidence intervals (CIs) of number of successful visits. Month of visit was included in the model to account for confounding with calendar time.
Results: 11,720 participants, including 8,251 females (70%), were successfully followed-up during 223 days. The rate of successful visits per hour was 5.1 for early shifts (CI=4.1-6.0), 6.8 for late shifts (CI=5.9-7.6) and 15.7 for Saturday shifts (CI=12.1-19.3). Follow-up visits during Saturday shifts were more successful as compared to visits during early or late midweek shifts (IRR=3.1, CI=2.5-3.9; IRR=2.4, CI=1.9-2.9, respectively). Among males, Saturday shifts resulted in 3.6 times as many successful visits compared to early midweek shifts (CI=2.8-4.5) and 2.9 times as many compared to late shifts (CI=2.4-3.5). Among females, these IRRs were 2.9 (CI=2.3-3.7) and 2.2 (CI=1.7-2.7).
Conclusions: To efficiently follow-up participants, in particular males, more household visits should be scheduled during Saturday shifts instead of midweek shifts. These findings can be used for implementation of community-based research.

Improving documentation of antiretroviral therapy (ART) medication pick-up via electronic pharmacy barcode system in rural Mozambique

S.M.F. Van Rompaey[1], M. Melo[2], J. Viele[3], A. Green[3], H. Machabane[4], A. Muicha[5], C. Magumisse[6], C.W. Wester[3,7]
[1]Friends in Global Health, Quality Improvement, Maputo, Mozambique, [2]Friends in Global Health, Quality Improvement, Quelimane, Mozambique, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Friends in Global Health, Maputo, Mozambique, [5]Friends in Global Health, Quelimane, Mozambique, [6]Direcção Distrital de Saúde, Alto Molocue, Mozambique, [7]Vanderbilt Institute for Global Health, Nashville, United States
Presenting author email: mayra.melo@fgh.org.mz

Background: In 2011 the Mozambican Ministry of Health (MoH) modified the existing paper-based system to register individual medication pick-up for antiretroviral therapy (ART). However, use of the form (known locally as a FILA - Ficha Individual de Levantamentos de ARV) was time consuming and inconsistent, threatening accuracy of ART retention data. Therefore, in 2015 the MoH included electronic FILA systems in its national strategy for quality improvement. In March 2016, the international non-governmental organization Friends in Global Health (FGH) established a user-friendly electronic barcode FILA system (eFILA) with interoperability between its Electronic Patient Tracking System (EPTS) at the rural Alto Molocue Hospital pharmacy in Zambezia province, Mozambique; which averages 48 ART patients a day. We assessed the effect of this innovation on timely registration of patient ART medication pick-up into the EPTS and FILA processing time.
Methods: Analysis of timely registration for patients who picked up ART at the pharmacy throughout 5 consecutive business days during the following periods: March 10-16, 2016 (pre-implementation) and September 14-20, 2016 (during implementation). We triangulated data for patient pick-up date, ART regimen and dosage between the prescription, paper-based FILA, eFILA and EPTS, with timely registration in EPTS defined as no more than two days beyond the inclusion period. We also assessed, from the time a patient was attended by pharmacy staff: a) time of paper-based FILA completion, and b) time of registration into the eFILA system, to calculate mean FILA processing time.
Results: Before implementation, timely registration of ART pick-up in EPTS was noted for 173 (71%) of 243 patients. During implementation, timely registration was noted for 299 (98%) of 305 patients. Prior to eFILA implementation, the mean processing time for paper-based FILAs was 162 minutes, compared to 47 minutes (71% reduction) for paper-based FILAs and 2 minutes for eFILA following implementation.
Conclusions: The electronic barcode system, with its user-friendly scanning device and EPTS interoperability, shows great potential to improve timely registration of ART pickup in Mozambique. Future analyses are planned to explore the system's impact on retention data.

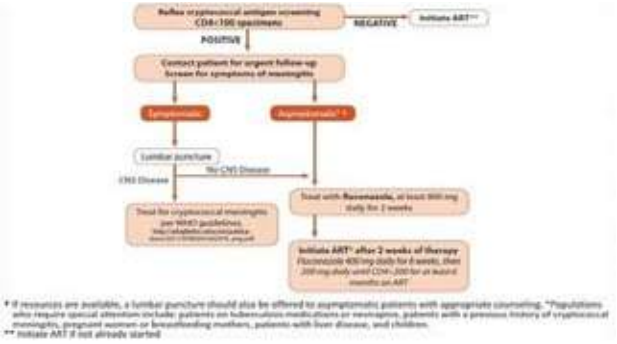
Challenges in managing cryptococcal meningitis in resource-limited settings

G. Gonese[1], A.F. Bochner[2], R. Makurumidze[1], T. Apollo[3], B. Makunike[1], E. Meacham[2], F. Petracca[2], R. Levine[2], S. Balachandra[4], P. Nyika[4], A. Downer[2]
[1]International Training and Education Center for Health (I-TECH), Harare, Zimbabwe, [2]International Training and Education Center for Health (I-TECH), University of Washington Department of Global Health, Seattle, United States, [3]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [4]U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe
Presenting author email: tsitsiapollo2@gmail.com

Background: Cryptococcal meningitis remains a major cause of mortality and morbidity among HIV-infected individuals. The Zimbabwe national HIV guidelines recommend screening all HIV positive clients for cryptococcal infection. I-TECH Zimbabwe, with funding from the U.S. Centers for Disease Control and Prevention, supports the Ministry of Health and Child Care's roll-out of cryptococcal antigen (CrAg) screening as standard HIV care. Prior to implementation, a baseline assessment was conducted, and we report our findings.
Methods: The baseline assessment was performed in September 2016 at seven hospitals, purposively sampled in Zimbabwe. The assessment tool contained questions assessing the capacity of sites to perform CrAg screening, other laboratory services used in the diagnosis and management of meningitis cases, and the availability of commodities. Key informants at each facility were interviewed, and the assessment took approximately a half day to complete.
Results: Five district hospitals and two provincial hospitals participated in the assessment. Two facilities assessed were currently offering CrAg screening. At facilities not performing CrAg screening, lack of test kits, reagents, and trained staff were reported as barriers to service provision. Both of the facilities offering CrAg screening reported insufficient quantities of reagents. All facilities had functional lumbar puncture packs and four facilities had the necessary reagents to perform CSF microscopy, culture, and sensitivity. Six facilities had Fluconazole available; Amphotericin B was unavailable at all sites. All sites offered haematology, six had functional CD4 services, and three offered urea and electrolytes chemistry.



[CrAG Screening Algorithm (Adopted from WHO)]

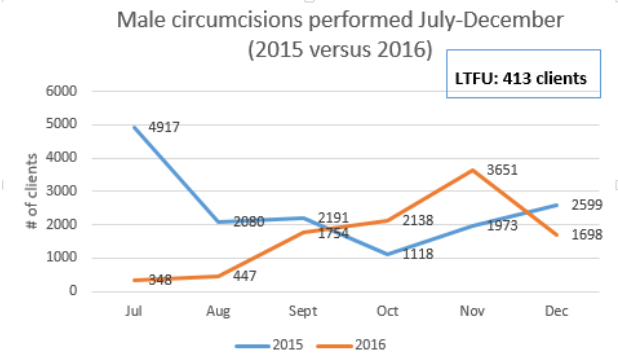
Conclusions: The majority of hospitals lacked capacity to offer CrAg screening and manage cryptococcal meningitis cases. The baseline assessment identified ways in which hospitals would need to be supported to implement CrAg screening and manage cryptococcal meningitis cases within acceptable standards. Additional support to hospitals through staff training and increased availability of commodities has the potential to reduce the morbidity and mortality caused by cryptococcal meningitis.

TUPED1195

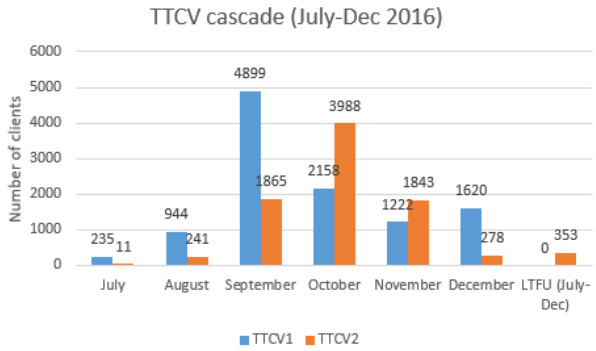
Trends in tetanus immunization and VMMC uptake in 12 districts in Rwanda

E. Rugwizangoga[1], A. Ntakirutimana[1], E. Tayebwa[1], J. Sinzahera[1], J.M.V. Kabalisa[2], E. Zimulinda[3], R. Favero[4], J. Reed[4], K. Curran[4], B. Mukarugwiro[1], S. Mutwiwa[1]
[1]Jhpiego, Rwanda, Kigali, Rwanda, [2]RDF/Medical Regiment, Kigali, Rwanda, [3]DoD, Kigali, Rwanda, [4]Jhpiego, Baltimore, United States
Presenting author email: eugene.rugwizangoga@jhpiego.org

Background: By 2014, thirteen tetanus cases were reported across Sub-Saharan Africa VMMC programs. Consequently, WHO advised administering two tetanus toxoid containing vaccine (TTCV) doses prior to VMMC procedure. The impact of this new guidance on VMMC programs is unknown. This documentation assesses the trend of VMMC uptake before and after implementation of the new WHO TTCV advice issued in June 2016.
Methods: Vaccines were provided by the Ministry of Health and providers were oriented on new WHO advice. The population was sensitized on TTCV through public media and counseling. Data were included from the same months (July-December) in 2015 (before the WHO advice) and 2016 (after). All males screened for VMMC in 7 RDF sites and 13 sites in priority districts were included. Data were collected from registers, client forms, and monthly reports. There were no reported stock outs of vaccine or VMMC commodities during the assessment. Data will be collected through December 2017.
Results: Fewer VMMC procedures were performed during July-Sept 2016 vs. July-Sept 2015. 353 clients were lost to followup (LTFU) after TTCV1 and an additional 60 lost after TTCV2. Immunization rates decrease 3 months after the initial swell of clients are immunized and the program enters holidays.



[VMMC uptake]



[TTCV uptake]

Conclusions: Programs should expect a decline in VMMC procedures immediately following initiation of the pre-VMMC tetanus immunization. Clients receiving TTCV2 and VMMC were lower than initially screened, implying a need for close monitoring to minimize LTFU. There were more VMMC procedures done compared to clients completing TTCV2, indicating potential contribution from partners.

TUPED1196

HIV and tuberculosis in Malawian prisons: a comprehensive prevention, screening and management programme

S.C. Mendelsohn, C. Aluda, R. Ortuno, A. Shigayeva, K. Hilderband, E. Goemaere
Medecins Sans Frontieres, Brussels, Belgium
Presenting author email: simonmendelsohn@gmail.com

Background: Maula and Chichiri maximum security prisons in Malawi currently hold 2,757 and 1,936 inmates respectively, over 240% of their intended capacities. Congested cells, lack of infection control measures, and prevalent malnutrition result in a high transmission setting for tuberculosis (TB). Prior to any interventions, a limited antiretroviral therapy (ART) programme was the only healthcare service provided by inadequately trained prison staff.
A 2011 study estimated HIV (41%) and TB (4.4%) point prevalence in central Malawian prisons. In 2014 Médecins Sans Frontières' (MSF) introduced a comprehensive package of interventions to prevent, screen, treat, and monitor HIV and TB in these prisons according to the Southern African Development Community minimum standards for prisons. Auxiliary care includes a nutrition programme, hepatitis B vaccination, mental health screening, outpatient care and referral, health promotion, and advocacy.
This research outlines the unique programmatic tools and structural interventions implemented by MSF, and the impact of these interventions on HIV care and TB transmission in the prisons.

Methods: An overview of the programmatic interventions introduced by MSF between June 2014 and December 2016 in Maula and Chichiri prisons. Data were captured in TIER.Net, analysed using Stata 12.1, and results reported until 31/12/2016.
Results: The HIV point prevalence at Maula and Chichiri prisons was 13.7% (95% CI: 12.4-15.1%) and 20.6% (18.8-22.5%) respectively. There have been no confirmed cases of HIV transmission in the prisons. The UNAIDS 90-90-90 HIV cascade indicators are summarised in the table below:

	Maula Prison	Chichiri Prison
Prisoners screened for HIV in past 6 months	2334/2359 (98.9%; 95% CI: 98.4-99.3%)	1780/1807 (98.5%; 95% CI: 97.8-99%)
HIV positive on ART	363/378 (96.0%; 95% CI: 93.5-97.8%)	397/399 (99.5%; 95% CI: 98.2-99.9%)
On ART eligible for viral load with viral load taken	180/241 (74.7%; 95% CI: 68.7-80.1%)	244/281 (86.8%; 95% CI: 82.3-90.6%)
Viral load <1000 copies/ml	165/180 (91.7%; 95% CI: 86.6-96.2%)	229/244 (93.9%; 95% CI: 90.1-96.5%)

[UNAIDS 90-90-90 HIV cascade indicators in prisons]

The number of inmates with active TB on treatment was 33 (1.2%; 95% CI: 0.8-1.7%) in Maula and 22 (1.1%; 0.7-1.7%) in Chichiri with HIV-TB co-infection of 24.2% (8/33) and 59.1% (13/22) respectively.
Conclusions: The model of care implemented in this challenging setting has been effective in helping to achieve the UNAIDS 90-90-90 goal and can be replicated in similar prison contexts. Active TB case finding and infection control efforts (including isoniazid preventative therapy) need to be intensified to curb transmission.

Internalized homophobia, HIV/AIDS responsibility beliefs, and HIV knowledge amongst men who have sex with men: correlates of HIV/AIDS discrimination in a setting of institutionalized homophobia

R.K.J. Tan[1], B. Teerawichitchainan[2]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]Singapore Management University, School of Social Sciences, Singapore, Singapore
Presenting author email: e0145771@u.nus.edu

Background: Men who have Sex with Men (MSM) in Singapore are disproportionately represented in the proportion of prevailing HIV infections, relative to the general population. However, there exists a paucity of research on the psychosocial dimensions of the HIV/AIDS epidemic amongst MSM in non-Western settings such as Singapore due to the criminalization of gay sex and prevailing homosexual stigma. The present study addresses this gap by investigating the significant demographic and psychosocial correlates of HIV/AIDS discrimination amongst MSM. The results will serve to highlight psychosocial barriers to the reduction of HIV/AIDS discrimination against People Living with HIV/AIDS (PLWHA) which is associated with poor antiretroviral adherence, increased risky sexual behaviors, and poor mental well-being when internalized.
Methods: 164 responses from self-identified MSM were obtained through purposive and convenience sampling methods by employing a web-based survey disseminated by two voluntary welfare organizations. Surveys were self-administered and responses were anonymized to protect participants from possible legal repercussions in Singapore, where gay sex is criminalized. The survey sought to measure discrimination against PLWHA, and its association with internalized homophobia, HIV/AIDS personal responsibility beliefs (HAPRB) and HIV knowledge. An ordinary least squares regression model, using a sequential modelling approach, was employed for analysis.
Results: Results indicate that internalized homophobia is positively associated with discrimination against PLWHA. Age and living in private housing are negatively associated with internalized homophobia. Personal income, perception of strong community support, and having no religion are positively associated with HIV knowledge. Being HIV-positive and personal income are positively associated with HAPRB, while having no religion or perceiving strong community support are negatively associated with HAPRB. Internalized homophobia also mediates the relationship between HAPRB and discrimination against PLWHA [Mediated Effect = .24, SE = .11, 95% CI = .03, .46]. This study validates a 13-item internalized homophobia scale (Cronbach's alpha = .86), and a 3-item discrimination against PLWHA scale (Cronbach's alpha = .79) amongst Singaporean MSM.
Conclusions: Community-based interventions in settings of prevailing institutionalized homophobia should recognize internalized homophobia as a barrier to the effectiveness of programs targeted at reducing HIV/AIDS discrimination amongst MSM, which in turn has wider implications for HIV prevention efforts.

TUPED1198

What prevents central Asian migrant workers from accessing HIV testing? Implications for increasing HIV testing uptake in Kazakhstan

A. Davis[1,2], A. Terlikbayeva[3], D. Terloyeva[3], S. Primbetova[3], N. El-Bassel[2]
[1]Columbia University Medical Center, HIV Center, New York, United States, [2]Columbia University, School of Social Work, New York, United States, [3]Columbia University Global Health Research Center of Central Asia, Almaty, Kazakhstan
Presenting author email: ad3324@cumc.columbia.edu

Background: Several barriers prevent key populations, such as migrant workers, from accessing HIV testing. The success of the UNAIDS 90-90-90 goals hinges on the ability to drastically increase the number of people being tested for HIV, particularly among key affected populations with low HIV testing uptake, such as migrant workers. There is a dearth of HIV research on migrants in Central Asia, a region that has one of the fastest growing HIV epidemics in the world. Central Asia also has high levels of migration flows, which may complicate controlling the HIV epidemic in the region. This study identifies the determinants of HIV testing among Central Asian labor migrants (from Kyrgyzstan, Tajikistan, and Uzbekistan) in Kazakhstan.
Methods: Using data from a cross-sectional study among 623 migrant workers (22% female, 78% male) in Kazakhstan, we examined factors associated with HIV testing. Participants completed surveys containing questions related to demographic, economic, legal, sexual risk, and health care access factors. We assessed associations between independent variables and HIV testing using bivariate logistic regression. Significant variables in the bivariate models were simultaneously entered in the multivariate model to identify variables that remained significantly associated with HIV testing.
Results: Overall, 48% of participants had ever received an HIV test. Being female (AOR 2.56; (95% CI [1.48-4.45]), having temporary registration (AOR 1.69; (95% CI [1.12-2.56]), having an employment contract (AOR 2.59; (95% CI [1.58-4.23]), being able to afford health care services (AOR 3.61; (95% CI [1.86-7.03]) having a medical check-up in the past 12 months (AOR 1.85; 95% CI [1.18-2.89]), and having a regular doctor (AOR 2.37; 95% CI [1.20-4.70]) were associated with having an HIV test.
Conclusions: HIV testing uptake among migrants in Kazakhstan falls far short of the UNAIDS 90-90-90 goals. Intervention strategies to increase HIV testing among this population may include initiatives that focus on improving outreach to undocumented migrants, making health care services more affordable, and linking migrants to health care.

Financial and behavioral economic factors associated with uptake of free HIV testing in AIDS-affected adolescents and households in Uganda: a cross-sectional analysis

L. Jennings[1], F. Ssewamala[2], L.M. Michalopoulos[3], P. Namatovu[4]
[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]Columbia University School of Social Work, International Center for Child Health and Development, New York, United States, [3]Columbia University School of Social Work, Global Health and Mental Health Unit of SIG, New York, United States, [4]Columbia University School of Social Work, International Center for Child Health and Asset Development, New York, United States
Presenting author email: lm2996@columbia.edu

Background: Provision of free HIV counseling and testing services (HCTS) is perceived to remove financial barriers to seeking care. Yet, little is known on whether uptake of free HCTS by households impoverished by AIDS is influenced by financial and behavioral economic factors. Research suggests that individuals experiencing financial distress may be reluctant to seek HCTS with high opportunity costs, but this has not been examined in adolescents and families.
Methods: We used baseline data from the Suubi-Maka randomized experiment in the Rakai and Masaka districts of Uganda. Three hundred forty-six (n=346) AIDS-affected adolescents, aged 10 - 17, and their guardians were enrolled. Multivariate, hierarchal logistic regression was used to examine the association of prior HIV testing with traditional financial measures, such as employment, savings, food and income insecurity. We also examined whether guardians in households affected by AIDS with "present-bias" preferences were more likely to seek free HCTS for themselves, their adolescent orphans, and other household adults. Present-biased individuals were defined by behavioral economics as those who disproportionately weighted the present while discounting the future.
Results: HIV testing was low for adolescent orphans (8%), guardians (59%), and households with at least one non-guardian adult (41%). Household savings were not associated with adolescent testing (OR=0.88, CI:0.32 - 2.46). However, ado-

lescents cared for by present-biased guardians were more likely to be HIV tested (OR=2.64, CI:1.04 - 6.70) than adolescents cared for by guardians who weighted future gains. This suggests that present-biased guardians may have valued HIV testing given the rapid results. Conversely, omitting adolescent HIV testing may have been consistent with future-biased guardians' preferences to avoid present-day costs and reserve resources for the future. Guardians (OR=2.02; CI:1.19 - 3.41) and non-guardian adults (OR=2.38; CI:1.30 - 4.34) in households with cash savings were also more likely to have been tested. Financially-insecure households (OR=0.59, CI:0.35 - 0.97) and those with an employed non-guardian adult (OR=0.49, CI:0.25 - 0.97) were less likely to be tested.
Conclusions: Interventions that address would-be HIV testers' economic needs, including present- or future-behavioral economic biases, may prove beneficial. More research is needed to understand how costs and household economies impact HIV testing behaviors.

TUPED1200

The role of gender norms and masculinity on men's engagement in the HIV care continuum in sub-Saharan Africa: a systematic review

K. Sileo[1,2], R. Fielding-Miller[2], S. Dworkin[3], P. Fleming[4]
[1]San Diego State University Graduate School of Public Health, San Diego, United States, [2]University of California, Division of Global Health, School of Medicine, San Diego, United States, [3]University of California, School of Nursing, San Francisco, United States, [4]University of Michigan School of Public Health, Department of Health Behavior & Health Education, Ann Arbor, United States

Background: Men living with HIV/AIDS in sub-Saharan Africa have worse outcomes throughout the HIV care continuum compared to women. Gender norms and masculinity have been hypothesized as key factors in men's poor engagement in HIV care.
Methods: We conducted a systematic review and qualitative synthesis to examine how masculinity influenced men's HIV care engagement in sub-Saharan Africa. In May 2016, we systematically searched PubMed, Web of Science, and PsychInfo for quantitative and qualitative studies examining masculinity/gender norms and HIV care engagement outcomes (HIV testing, support-seeking, linkage to care, treatment adherence, clinic attendance). Studies were first screened for eligibility by title and abstract, then full articles reviewed, and data extracted, with consensus obtained across authors. A content analysis approach was used for qualitative analysis.
Results: Our review yielded a total of 23 qualitative studies from 10 countries that met inclusion criteria. Masculinity was defined similarly across settings, and common themes demonstrated how notions of masculinity can serve both as barriers and facilitators to care engagement across all stages of care. The articles identified several masculine norms as barriers to care engagement: being physically and mentally strong, independent, emotionally inexpressive, and sexually successful with women; and fear that HIV would threaten men's social relationships including their role as husband, father, head of household, provider, worker, and peer. HIV stigma was found to threaten men's fulfillment of these masculine gender roles. Facilitators to HIV care/treatment included: perceptions that care/treatment could restore masculinity through regained physical strength, ability to work/provide, and potential for marriage and children. Studies found that over time some men were able to adopt new masculine identities and roles in the community that were conducive to care engagement.
Conclusions: Our review identifies evidence across sub-Saharan Africa that masculinity plays an important role in men's decision to seek and remain in HIV care. These findings suggest a need for further cross-sectional and longitudinal work to establish the relationship between masculinity related norms and HIV care. Future research should consider integrating a gender-transformative approach into HIV counseling to help reduce the masculinity-related barriers to care.

TUPED1201

Barriers to ART uptake experienced by healthy clients in Malawi under test and treat

K. Dovel[1,2], K. Phiri[2], A. Schooley[1,2], M. Bellos[2], E. Sanudi[2], D. Chasweka[2], R. Hoffman[1,2]
[1]University of California, Department of Infectious Disease, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi
Presenting author email: kdovel@mednet.ucla.edu

Background: Malawi is one of the first countries in sub-Saharan Africa to implement antiretroviral therapy (ART) regardless of clinical stage or CD4 cell count (Test and Treat). We evaluated barriers and facilitators to ART uptake from the perspective of both asymptomatic newly HIV+ clients and HIV service providers during the first 6 weeks of program implementation.
Methods: Routine data from 5 ART clinics were reviewed to identify clients ≥ 18 years of age testing HIV+ between July 14-September 23, 2016. Individuals were screened to determine if they were asymptomatic at time of testing. In-depth interviews were conducted with asymptomatic clients. Twelve focus group discussions were completed with ART providers (n=31), HIV counselors (n=19), and community-based support staff (n=29).
Results: One hundred and fifty-three clients tested HIV+ and of those 22% (n=33) were asymptomatic. Ninety-one percent of clients identified as asymptomatic completed in-depth interviews (n=30). The most common barriers to ART uptake identified by clients were fear of disclosure (63%, n=19), fear of experiencing side effects while healthy (57%, n=17), work schedules or other commitments that conflict with clinic hours (33%, n=10), and needing time to accept their diagnosis before initiating ART (30%, n=9). Dominant facilitators to ART initiation included the desire to stay healthy to provide and/or care for family members (70%, n=21), motivation to prevent unwanted disclosure by becoming sick (23%, n=7), the desire to extend one's life (43%, n=13), and personal knowledge of others who died from AIDS due to delayed treatment (37%, n=11). Providers identified fear of disclosure, lack of privacy at ART clinics, and poor knowledge about benefits of early ART as primary barriers to uptake among asymptomatic clients. Additionally, providers raised concern that asymptomatic men may not engage in HIV care.
Conclusions: Concern about HIV disclosure, lack of privacy, fear of side effects, and facility hours may limit ART uptake among asymptomatic clients. Patient- and provider-reported barriers closely align. Interventions that improve privacy, support disclosure, increase patient knowledge, and improve access to ART may facilitate ART uptake among asymptomatic HIV+ individuals under Test and Treat.

TUPED1202

Out-of-pocket expenditures associated with HIV treatment and care in the Dominican Republic: results of a community-based research

C.G. Véronique Chaumont, A. de León
ITPC LATCA, Guatemala, Guatemala

Background: Though treatment is free for most people in the Dominican Republic, there are external factors that inhibit individuals to procure treatment or to assist to their regular checkups, such as the inability to pay for transportation, meals, and childcare. Evidence from other countries shows that out-of-pocket (OOP) expenditures can generate significant barriers to access and retention in care for persons living with HIV. The objective of this research was to estimate OOP expenses incurred by persons with HIV, and to analyze characteristics associated with them, including socio-demographic characteristics, current treatment options, vital status, use of health services, and impact of opportunistic infections.
Methods: Data was collected between October and November 2015 with a community based participatory research (CBPR). The sample consisted in 191 randomly selected adults living with HIV, enrolled in ART or pre-ART services across 10 sites in and around Santo Domingo. Researchers conducted individual face-to-face interviews with different themes: demographic characteristics, current visit at health facility, vital status, and OOP expenditures associated with HIV services in the last six months.
Results: Individuals interviewed reported an average total spending on health for the last six months corresponding to US$ 153. Besides, individuals reported an average of US$ 28 spent on transport and housing to access HIV services. When looking at how out-of-pocket expenditures were spent, the two most important categories were hospital stay and nutrition complements, which corresponded to US$35 and US$43 respectively. These important expenses can lead individuals to rely on external financial sources. 17% reported having to sell personal belongings to pay for health expenditures, 35% having to ask a personal loan from family or friend, and 31% having to take a loan from someone outside their personal and family circle.
Conclusions: The costs of transport and housing to access HIV services appeared to be significant for a vast majority of the individuals surveyed (85%). Our results suggest that while the majority of people with HIV reports limited amount of OOP expenditures, the latter could be a significant barrier to access and retention to HIV care and treatment for a minority of individuals facing important expenses in the Dominican Republic.

TUPED1203

Can adolescents and youth in Kenya afford free HIV testing services? A cost analysis

A. Wagner[1], K. Wilson[1], J. Babigumira[1], C. Mugo[2], P. Maingi[3], D. Wamalwa[2], D. Bukusi[3], G. John-Stewart[4], P. Kohler[5], J. Slyker[1]
[1]*University of Washington, Global Health, Seattle, United States,* [2]*University of Nairobi, Pediatrics and Child Health, Nairobi, Kenya,* [3]*Kenyatta National Hospital, HIV Prevention Unit, Nairobi, Kenya,* [4]*University of Washington, Global Health, Pediatrics, Medicine, Epidemiology, Seattle, United States,* [5]*University of Washington, Global Health, Nursing, Seattle, United States*
Presenting author email: anjuliwagner@gmail.com

Background: Voluntary HIV testing among adolescents is critical to curb transmission and limit morbidity and mortality. Although HIV testing is free, other costs to adolescents may be barriers.
Methods: Adolescents and youth ages 14-24 who completed voluntary HIV testing and counseling (VCT) at a large public hospital in Nairobi, Kenya were recruited. Direct non-medical costs (transportation, childcare, and food), indirect costs (missed income), and lost school time were collected. Per capita GDP ($115USD/mo) was used as a proxy for wages for unpaid work. Median and interquartile ranges (IQR) presented for participants with non-zero costs.
Results: Among 189 adolescents, 121(64%) reported non-zero costs; 118(62%) had direct non-medical costs, 19(10%) had indirect costs. Among those with non-zero costs, the median total cost was $1.98. Median direct costs were $1.73. Food and transport were the largest components of direct costs: 79(42%) paid for food (median: $1.98), 98(52%) paid for their own transport (median: $0.59), and 20(11%) paid another person's fare (median: $0.50). Median indirect costs were $7.97; 19(10%) missed a half or full day of work. 78(42%) missed a half or full day of school. Monthly income ranged; 25(13%) of adolescents had any income. Among those with income, median monthly income was $198; 52% reported no income but incurred direct costs; 35% reported no income and no direct costs.
In sex-stratified analyses, males (34%) were more likely to have direct and indirect cost than females (78% vs 53%, 15% vs 7%, respectively). They had similar sources of income, but males were more likely to have a salaried job (15% vs 10%). Males were more likely to pay for their transport than females (63% vs 45%).
Conclusions: The costs of HIV testing may influence adolescent care seeking and HIV detection. Interventions to address cost of seeking HIV testing and time away from school or work should be considered.

N=189	n	%	median	25th percentile	75th percentile
Any direct non-medical costs	118	(62)	1.73	0.69	2.97
Any indirect costs	19	(10)	7.97	5.01	11.38
Has salaried job	23	(12)	148.51	54.46	297.03
Has non-salaried (casual labor) job	15	(8)	49.50	19.80	99.01
Does unpaid work	86	(46)	--	--	--
Has other source of income	11	(6)	19.80	4.95	49.50
Any food and drink outside the house	79	(42)	1.98	0.99	1.98
Paid own transportation costs	98	(52)	0.59	0.40	0.99
Paid another person's transportation costs	20	(11)	0.50	0.30	0.84

[Costs of adolescent care seeking]

TUPED1204

Rethinking the value of pill counts: poor performance of pill counts in correlating with viral suppression in HIV-infected patients on ART at the Mbeya, Tanzania COE

J. Bacha[1,2,3], L. Campbell[1,2,3], M. Chodota[3], V. Mng'ong'o[3], R. Mgimba[3], B. Kasambala[3], L. Mwita[3]
[1]*Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States,* [2]*Baylor College of Medicine, Pediatrics, Houston, United States,* [3]*Baylor College of Medicine Children's Foundation, Pediatrics, Mbeya, Tanzania, United Republic of*
Presenting author email: bacha@bcm.edu

Background: Pill counting is a labor-intense, time-consuming and logistically challenging process to implement efficiently at high volume clinics. It is susceptibility to unintentional calculation and human errors at the facility and patient level. Given the time consuming nature of the practice, it is important to evaluate the utility of pill counting in our resource limited settings. We evaluated the performance of pill counting in correlating with viral suppression in patients on ART in Mbeya, Tanzania.
Methods: Retrospective review of pill count data and VL results was extracted between January 2015 and May 2016 at the Baylor College of Medicine Children's Foundation - Tanzania centre of excellence in Mbeya, Tanzania. "Viral suppression" was defined as VL <1000 copies. Pill count value of "95-105%" was used to define test result of interest. Pill count data was extracted from the same visit the VL testing was performed. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) was calculated to evaluate the performance of pill count of "95-105%" to identify viral suppression.
Results: Between January 2015 and May 2016, 903 patients had both a documented pill count and VL. Of these, 59% (530/903) were virologically suppressed. In correctly identifying virologically suppressed patients, pill count of "95-105%" had 64% sensitivity, 40% specificity, 60% PPV and 44% NPV. For patients during the routine VL testing era that started February 2016 (n= 575), 63% (364/575) were fully suppressed, and "95-105%" pill count had 63% sensitivity, 38% specificity, 64% PPV and 38% NPV.
Conclusions: Pill count value of "95-105%"performed poorly in identifying virologically suppressed patients on ART. Sensitivity, specificity, PPV and NPV were all low. Clinicians need to be aware of these limitations of pill counts, and critically consider the utility of this practice. Pill counts may be an additional tool, but is not a standalone replacement for adherence monitoring, and our findings should bring to light the risks and pitfalls of relying too heavily on pill counts as the sole measure of adherence.

TUPED1205

Community-based support reduces the risk of virological failure among children with HIV infection: results of the ZENITH trial

R. Ferrand[1,2], V. Simms[1], E. Dauya[2], T. Bandason[2], G. Mchugh[2], P. Chonzi[3], J. Busza[1], K. Kranzer[1,4], H. Weiss[1], R. Hayes[1]
[1]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [2]*Biomedical Research and Training Institute, Harare, Zimbabwe,* [3]*Harare City Health Services, Harare, Zimbabwe,* [4]*Research Centre Borstel, Hamburg, Germany*
Presenting author email: rashida.ferrand@lshtm.ac.uk

Background: Children have poorer HIV treatment outcomes than adults. We conducted a randomized controlled trial to investigate the impact of community-based support on viral suppression and retention in care.
Methods: Children aged 6-15 years with newly-diagnosed HIV attending 7 primary health clinics (PHC) in Zimbabwe were randomized to receive routine (PHC-based) care (control arm) or routine care plus structured support visits by lay workers (LW) (intervention arm) over 18 months. Primary outcomes were proportion who i)died or had an unsuppressed HIV viral load (VL) (>400 copies/ml) at 12 months post antiretroviral therapy (ART) initiation (only in those who started ART within 6 months of enrolment, and ii)missed ≥2 scheduled clinic appointments within 18 months (all participants). The secondary outcome was a composite of death, VL>400 copies/ml, not initiating ART and loss-to-follow-up at 18 months. Odds ratios for outcomes were estimated using mixed-effects logistic regression, with adjustment for age and sex, LW and clinic and any variables with imbalance between arms at baseline.
Results: We randomised 334 participants (166 intervention; 168 control); median age 11 years and 53% female. Trial retention rates were similar between arms (Table):

	Intervention arm(n=166)	Control arm(n=168)
	n(%)	
Transferred to another clinic	30(18.1%)	23(13.7%)
-Planned	***-28***	***-14***
-Client did not inform clinic	***-2***	***-9***
Died	5(3.0%)	7(4.2%)
Withdrew from trial	0	1(0.6%)
Lost-to-follow-up	6(3.6%)	11(6.5%)

[Trial retention rates]

Within 6 months of randomization 122 intervention arm and 115 control arm participants started ART, and at 12 months post ART initiation in this group the proportion of participants with VL >400copies/ml or death was lower in the intervention arm compared to control arm participants (33.0% vs 48.2%; aOR=0.47, 95%CI 0.24-0.91; p=0.03). There was also a significant difference between trial arms in the proportion who met the composite outcome (43.8% in intervention arm vs 58.0% in control arm; aOR=0.50; 95%CI 0.28-0.89; p=0.02). There was no difference by arm in proportion who missed >2 clinic appointments (17.4% vs 18.2%, aOR=0.92, 95%CI 0.49-1.74; p=0.79).
Conclusions: This is the first trial of an intervention that reduces risk of HIV virological failure in children in resource-limited settings, and has high potential for scaleability.

TUPED1206

Development of a risk score-based on patient's individual factors for predicting non-adherence to antiretroviral therapy

H. Knobel[1], A. Guelar[1], S. Calzado[1], A. Retamero[2], M. De Antonio[2], J. Vila[3], I. Subirana[3], R. Guerri[1], G. Casamayor[1], E. Lerma[1], J. Villar[1], A. Gonzalez[1], S. Luque[2]

Presenting author email: hknobel@parcdesalutmar.cat

Background: Adherence remains a key factor in the effectiveness of antiretroviral therapy. Patient-related individual factors that influence adherence are well known. However, we do not have a useful tool to predict adherence considering several risk factors together. The aim of the study was to develop a model to predict the risk of non-adherence in people living with HIV.
Methods: We retrospectively evaluated 349 HIV-infected patients who started antiretroviral therapy in 2012-2015 from a University Hospital in Barcelona, Spain. Adherence was evaluated every 2 months by pharmacy refills and by self-reports. A patient with < 90% of prescribed dose and / or ART interruption for more than one week was considered non-adherent. To test the association of risk factors with non-adherence univariate and multivariate logistic regression (LR) was used. The best cut-off was obtained by means of bootstrapping methodology. To develop an ease to use predictive score, we assigned the risk factors identified by multivariate analysis weighted points proportional to the β regression coefficient values. C statistic was evaluated as measure of performance.
Results: During a median follow-up of 23.13 months, 104 patients (29.8%) were considered non-adherents.
Seven independent risk factors were identified, and each was assigned a value proportional to its regression coefficient: alcohol use (20); current substance use (11); language and cultural barrier (24); unstable housing (13); concerns and negative beliefs about treatment (28); loss of previous appointments (28); Psychiatric disorder (depression, psychosis) (9). We calculated risk scores for each patient adding the values of each risk factor. The optimal cutoff point calculated was 29.7, and to predict non-adherence we found sensitivity 0.87, specificity 0.87, positive predictive value 0.74, and a negative predictive value 0.94. The C statistic was 0.91 (95% CI 0.87-0.94). Viral load < 20 copies / ml was achieved at follow-up by 92.7% versus 33.7% of patients in the adherent and non-adherent group respectively (p:0.000).
Conclusions: A simple risk score was developed to predict non-adherence to antiretroviral treatment with high sensitivity and high specificity. Once validated in another population could be a useful tool to identify the resources needed to achieve the optimal treatment goals.

Background: Missed clinic visits can lead to poorer HIV treatment outcomes and higher risk of mortality. Knowing the determinants of missed visits will allow for appropriate counselling and intervention strategies to ensure continuous engagement in care.
Methods: Patients from TAHOD who have initiated antiretroviral therapy (ART) were included in the analyses. A missed visit was defined as having no clinical visits or laboratory assessments in a six-monthly time period, up to five years after ART initiation. Patients who were lost to follow-up were counted as having a "missed visit" up until 12 months after their last visit date then removed from the analysis dataset. Repeated measures logistic regression (GEE) was used to analyse factors associated with missed visits.
Results: A total of 7100 patients were included from 20 sites in 12 countries in Asia with 2676 (37.7%) having at least one missed visit. There were 4967 males (70%) and 2133 females (30%). The median follow-up time was 5.1 years (IQR 3.2 - 7.4). ART adherence information in the first six months was available in 2541 patients (35.8%). Multivariate analyses indicate that patients with early suboptimal self-reported adherence < 95% in the first six months were more likely to have a missed visit compared to those with adherence ≥95% (OR=2.55, 95% CI(1.81-3.61)). Other significant factors associated with having a missed visit were homosexual (OR=1.45, 95%CI(1.27-1.66)) and other modes of HIV exposure (OR=1.48, 95%CI(1.27-1.74)) compared to heterosexual exposure; using PI-based (OR=1.33, 95%CI(1.15-1.53) and other ART combinations (OR=1.79, 95%CI(1.39-2.32)) compared to NRTI+NNRTI combinations; and being hepatitis C co-infected (OR=1.27, 95%CI(1.06-1.52)). Patients aged older than 30 years (31-40 years OR=0.81, 95%CI(0.73-0.89); 41-50 years OR=0.73, 95%CI(0.64-0.83); and >50 years OR=0.77, 95%CI(0.64-0.93)); female sex (OR=0.81, 95%CI(0.72-0.90)); and being from upper middle (OR=0.78, 95%CI(0.70-0.80)) or high-income countries (OR=0.42, 95%CI(0.35-0.51)), were less likely to have missed visits.
Conclusions: Missed visits occurred in almost 40% of our TAHOD patients. Early ART adherence was an indicator of subsequent clinic visits. Intensive counselling and adherence support should be provided at ART initiation in order to optimise long term clinic attendance and maximise treatment outcomes.

"Because my life is more important": findings from a qualitative study on adherence to second and third-line antiretroviral therapy regimens in rural Malawi and Kenya

R. Burns[1], P. Blasco[2], M. Kibogo[3], A. Vandenbulcke[4], E. Szumilin[2], I. Mukui[5], D. Magalasi[6], B. Schramm[1], T. Kalua[7], E. Pasquier[2], A. Wringe[8]
[1]Epicentre, Paris, France, [2]Medecins Sans Frontieres, Paris, France, [3]Medecins Sans Frontieres, Homa Bay, Kenya, [4]Medecins Sans Frontieres, Nairobi, Kenya, [5]Ministry of Health, Nairobi, Kenya, [6]Medecins Sans Frontieres, Chiradzulu, Malawi, [7]Ministry of Health, Lilongwe, Malawi, [8]London School of Hygiene and Tropical Medicine, London, United Kingdom
Presenting author email: alison.wringe@lshtm.ac.uk

Background: Little is known about treatment adherence behaviours amongst second- and third-line patients who may have unique experiences associated with reaching ,the end' of their treatment options. We explored influences on adherence to second- and third-line regimens among patients enrolled in HIV programmes supported by Médecins sans Frontières in rural Malawi and Kenya.
Methods: Repeated in-depth interviews were conducted with 29 HIV patients on second- or third-line antiretroviral therapy and 10 HIV health workers with different roles in Chiradzulu, Malawi and Homa Bay, Kenya. Patients were purposively sampled from second and third-line patients receiving their current regimen for 6 months minimum, and ensuring maximum diversity in terms of age, sex, residence, virological outcomes and regimen type. Observations took place in clinics including group education sessions. Interviews were audio-recorded, transcribed and translated into English. Following coding, themes were derived deductively and inductively.
Results: In both settings, many patients' engagement with second and third-line treatment was shaped by experiencing life-threatening illnesses prior to switching regimens and fearing they had reached ,the end' of treatment options, before being given "a final chance at life". These events often catalyzed changes in patients' attitudes to treatment-taking and prompted feelings of responsibility for managing their disease. Transformations reported by patients included giving up drinking, reducing sexual encounters, changing jobs that interfered with treatment-taking, becoming involved in leadership positions in the community and overcoming stigma. This was more evident in the Kenyan programme where the counsellor had received more training in working with patients after regimen changes. Nevertheless, many patients reported the persistence of multiple and interrelated social, economic and health systems challenges that had undermined their adherence to first-line treatments.
Conclusions: While well-established barriers to adherence remain for many second- and third line patients, others experienced a resurgence of hope as they overcame debilitating HIV-related illnesses associated with prior treatment failure. Although this can initially encourage renewed efforts to adhere, the effects may wane over time. Regular, patient-centred counseling or peer-led mentoring following regimen change may help promote and sustain these life transformations and build resilience among patients, supporting adherence and thereby prolonging the life-span of second and third-line regimens.

Presenting author email: yohooaha@gmail.com

Background: International emphasizes the need of early uptake of antiretroviral therapy (ART) for all HIV-infected patients at any CD4 cell count. Understanding individual´s readiness to initiate lifelong treatment is essential. The study purpose was to determine patient's readiness to take ART impact on HIV viral suppression.
Methods: A prospective longitudinal study was conducted at seven AIDS designated hospitals of Taiwan. Eligible patients were over 20 years old, newly diagnosed with HIV after 2014, and not currently taking antiretroviral medication.
Readiness to take ART is measured by the 10-item HIV medication readiness scale (HMRS) and the score >31.5 referred to ready to take ART.
Readiness and HIV viral load were repeated measured at three time points: baseline, one month (T1) and 6 months (T2) after taking ART.
Generalized estimating equation analysis was used to estimate relationships among readiness, adherence and viral suppression.
Results: A total of 283 patients newly diagnosed with HIV were enrolled, of them 146 (51.6%) had initiated of ART. Of the 137(48.4%) patients received ART, 58.4% had the HMRS score >31.5 referred to ready to take ART, 44.9% had achieved viral load suppression in T2. Factors associated with taking ART were: readiness (OR, 2.07; 95% CI, 1.24-3.46, p=0.005) CD4 cell counts lower than 350 counts/mm3 (OR, 0.567; 95% CI, 0.33-0.98, p=0.042), and viral load >100,000 copies/ml (OR, 1.89; 95% CI, 1-05-3.39; p=0.034). Eighty (54.8%) patients completed three times repeated measure, readiness increased from 61.6% in baseline, 86.2% in T1, and 88.9% in T2. After taking HAART, adherence ≥90% increased from 41.6% in T1 to 92.9% in T2, and viral suppression rate increased from 9.8% in T1 to 44.9% in T2. Factors associated with viral suppression after taking ART were: Readiness (β=0.43, p=0.08), CD4 cell 350-500 counts/mm3 (β=1.11, p=0.07) and greater than 500 counts/mm3 (β=1.82, p=0.002).
Conclusions: Readiness is the key of initiation of ART among people newly diagnosis with HIV, but not the major factors of achieving viral suppression after taking ART. Preparing individual's readiness to initiate lifelong treatment is essential in the era of " treat-for-all".

Adherence to maternal ART during the 18 months post-delivery in South Africa

A. Larsen[1,2], V. Magasana[3], K. Ayalew[4], M. Cheyip[4], W. Chirindra[5], T.-H. Dinh[6], D. Jackson[7,8], C. Lombard[9,10], N. Ngandu[5], G. Kindra[11], A. Goga[5,12]
[1]US Centers for Disease Control and Prevention, Epidemiology and Strategic Information, Pretoria, South Africa, [2]Fred Hutchinson Cancer Research Center, Seattle, United States, [3]South African Medical Research Council, Health Systems Research Unit, Pretoria, South Africa, [4]US Centers for Disease Control and Prevention, Pretoria, South Africa, [5]South African Medical Research Council, Pretoria, South Africa, [6]US Centers for Disease Control and Prevention, Atlanta, United States, [7]United Nations Children's Fund, New York, United States, [8]University of Western Cape, Cape Town, South Africa, [9]South African Medical Research Council, Cape Town, South Africa, [10]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [11]US Centers for DIsease Control and Prevention, Pretoria, South Africa, [12]University of Pretoria, Department of Paediatrics, Pretoria, South Africa
Presenting author email: vuyolwethu.magasana@mrc.ac.za

Background: Despite improved policies to prevent mother-to-child HIV transmission (MTCT), adherence to maternal antiretroviral therapy (ART) is low in South Africa. We describe ART adherence amongst a cohort of HIV-positive mothers from six weeks until 18 months post-delivery and identify risk factors for nonadherence.
Methods: Data were collected in 2012-2014 through a nationally representative survey of PMTCT effectiveness. Mother-infant pairs were enrolled during the infant's first immunization visit at 6 weeks. Mothers and HIV-exposed infants (2,811 pairs) were followed to 18 months at 3-month intervals. Mothers who self-reported being on ART at 6 weeks postpartum (N=1572 (55.9%)) were eligible for this analysis and information about their adherence was captured at each interview they attended thereafter. We defined nonadherence within each 3-month interval as self-report of missing >5% of daily ART doses, estimated cumulative adherence using Anderson & Gill analysis for recurring events, and identified risk factors for nonadherence with an extended Cox regression model (separately for mothers and infants) in Stata 13. Results are as yet not adjusted for the study design or non-response and not weighted for live-births.
Results: Cumulative adherence to ART until 18 months was 63.6% among mothers reporting ART use at 6 weeks (95% confidence interval (CI): 60.9-66.2) based on 483 nonadherence events during the 480,715 days of person-time contributed. Risk factors for nonadherence to maternal ART, controlling for other factors, included single status (single vs. married, adjusted Hazard Ratio (aHR): 1.6, 95% CI: 1.1-2.3), young maternal age (16-24 years vs. >35 year aHR: 1.5, 95% CI: 1.1-2.1), and nondisclosure of HIV status to anyone (nondisclosure vs. disclosure: aHR: 1.5, 95% CI: 1.2-1.9).
Conclusions: Maintaining ART adherence until 18 months postpartum remains a crucial challenge with maternal ART adherence <65%. Young, single, and mothers who do not disclose their status should be targeted with messages to improve adherence.

TUPED1211

Impact of mobile technology in improving tracking outcomes in Northern Nigeria

A. Okafor[1], N. Ndulue[2], B. Saidu[1], A. Yakubu[1], M. Dauda[1], E. Nwabueze[3]
[1]Management Sciences for Health, Care and Support for PLHIV, Abuja, Nigeria, [2]Management Sciences for Health, HIV Prevention, Treatment, Care and Support, Abuja, Nigeria, [3]Management Sciences for Health, HIV Treatmment, Abuja, Nigeria
Presenting author email: nndulue@msh.org

Background: Retention in ART has remained a serious challenge for HIV treatment programs in northern Nigeria among patients on ART. High rate of Lost to Follow Up (LTFU) among clients on ART constitute a significant challenge to the success of achieving 90% retention rate. This is as a result of difficulty in physically tracking the clients back to treatment due to distance and hard to reach terrains. Thus, most PLHIV who default on ART and are eventually lost to follow up.
Methods: With funding from USAID, MSH's Pro ACT project provided mobile phones to select trained adherence counsellors and trackers in select supported health facilities. These mobile phones are used to track clients who default on appointment and those LTFU. Counseling services are also provided to defaulters and LTFU clients via mobile phones. List of defaulters and LTFU clients are generated from supported health facilities by data clerks and handed over to trained trackers and adherence counsellors for onward tracking using mobile phones. The trackers and adherence counsellors reach the defaulters and LTFU clients at least twice a week through mobile phones. These interventions were conducted in supported health facilities across Kwara, Sokoto and Kebbi states in North Central and North Western Nigeria. A total of 4315 clients comprising of defaulters and LTFU were tracked. This number comprised of 1425 males and 2830 females.
Results: After twelve months of intervention, a total of 2956 clients comprising of defaulters and LTFU were tracked back to ART. This number comprised of 1020 males and 1936 females. Thus, 68.5% of defaulters and LTFU clients were returned to ART using mobile technology.
Conclusions: The use of mobile technology in tracking and provision of adherence counseling services improves clients retention on ART especially among clients from far distance and hard to reach terrains. Thus, there is a need to scale up this intervention especially in rural communities.

TUPED1212

Client and provider perceptions of factors affecting adherence to antiretroviral therapy in Côte d'Ivoire

K. Ouattara[1], E. Bazant[2], G. Furlane[2], D. Burke[2], A. Dia Lou[1], D. Bassalia[3], S.C. Stender[4]
[1]Jhpiego, Abidjan, Cote D'Ivoire, [2]Jhpiego, Baltimore, United States, [3]Ministry of Health, Abidjan, Cote D'Ivoire, [4]Jhpiego, Cape Town, South Africa
Presenting author email: ouattara.kiyali@jhpiego.org

Background: HIV is the leading cause of death in Côte d'Ivoire and adult prevalence is 3.5%. In 2012 it was estimated that only 67% of clients were alive and on treatment 12 months after initiation of antiretroviral therapy (ART). A 3-year pilot of an integrated model of chronic care aiming to improve retention and adherence began in 2015 in 42 government facilities across 2 regions of the country. A qualitative evaluation was undertaken to understand patient and provider perceptions of barriers and enablers to adherence to care.

Methods: In May 2016, we conducted a cross-sectional qualitative assessment in one hospital and one health center in one region where the model was being implemented, with matched facilities in a neighboring control region. This included in-depth interviews and focus group discussions with clients, and in-depth interviews with providers. A total of 108 participants were interviewed during 36 discussions after consent was obtained. Ritchie's Framework analysis approach was used to ascertain themes deductively and inductively, and coding of verbatim transcripts occurred in Atas-ti.
Results: Service-level enablers identified included improved access to medicines, provider follow-up with clients, counselling that emphasizes HIV as a chronic condition, confidentiality, presence of a clinical care team, appointment scheduling and encouragement of partner disclosure of HIV status. Client-level barriers included difficulty disclosing status, stigma, missing appointments for social responsibilities; traditional healers discouraging ART use; and transport costs. Service-related barriers were related to staffing and wait times. Facility staff and clients articulated the perception that HIV is a condition that one can live with, similar to other chronic conditions.
Conclusions: The integrated chronic care model has potential to improve social support for PLHIV, facilitate disclosure of HIV status among couples, and may reduce perceived stigma that, for many PLHIV, contributes to difficulties with adhering to treatment. The model aims to decentralize care, contributing to the reduction of transport costs as a barrier, as well as improve facility-level care through instituting appointment systems and integrating services, leading to decreased waiting times and uncoordinated visits for clients.

TUPED1213

Use of digital gaming and Wisepill dispenser technology to measure adherence among HIV-infected adolescents and young adults

C. Griffith[1,2], A. Castel[2], D. Greenberg[3], N. Ellenberger[1,2], B. Lewis[2], N. Hussein[1,2], T. Howard[2,4], N. Rakhmanina[1,2,5]
[1]Children's National Health System, Washington, United States, [2]George Washington University, Washington, United States, [3]Media Rez, Washington, United States, [4]Howard University, Washington, United States, [5]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States
Presenting author email: cgriffit@childrensnational.org

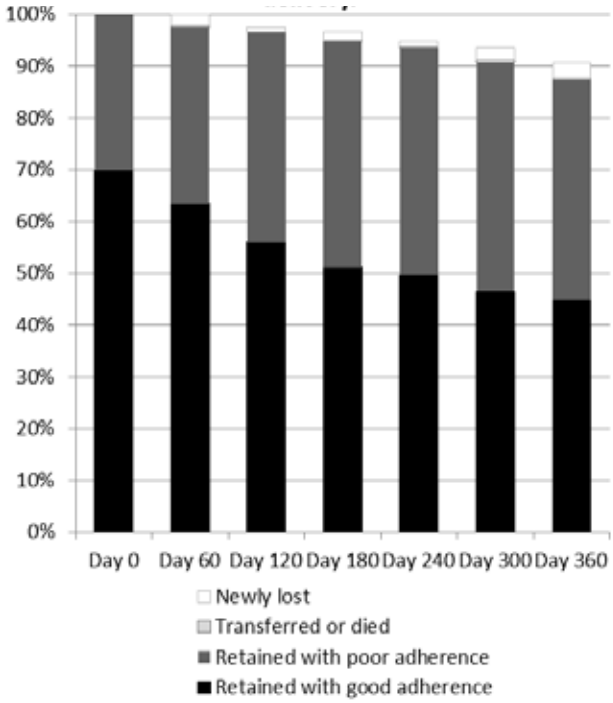
Background: There is an unmet need for effective interventions to improve adherence to antiretroviral treatment (ART) among HIV-infected adolescents and young adults (AYAs). Interventions that utilize user-friendly gaming with motivational components have shown promise for behavior change in AYAs. Currently, the data on the role of gaming and real-time medication adherence monitoring of ART adherence remain limited. This study examined the uptake of interactive smartphone based games interlinked with medication-monitoring device (Wisepill dispenser) among a cohort of HIV-infected AYAs on ART.
Methods: HIV-infected AYAs ages 13-24 years with suboptimal ART adherence (defined as detectable HIV viral load) were eligible. Participants were provided with smartphones containing three digital games with varying levels of difficulty and a Wisepill dispenser, which openings were linked to in-game incentives. Gameplay data, including the numbers of levels completed and Wisepill dispenser openings were tracked using wireless technology. Descriptive statistics were used for data analysis.
Results: Twenty-four participants (mean age=18 years; 12M/12F) were recruited; 17 (10F/7M) completed the 3-month follow up. Participants opened their Wisepill dispensers only 23% of the time based on the prescribed ART frequency (501 actual/2169 prescribed openings). On time Wisepill dispensers' openings (within two hours of self-reported daily medication ingestion times) were observed only 5% of the time (118 actual/2169 prescribed openings). Nearly three-fourths (71%; n=17) decreased the number of Wisepill openings during the study period. Available game data among 3-month follow up participants (n=12; 7M/5F) showed overall little gameplay (mean=12% completion). There were no differences in amount of gameplay by age; however, females showed slightly higher completion compared to males (14% vs. 10%). Among the three games, higher degree of difficulty was associated with lower degrees of completions.
Conclusions: Although a real-time, electronic ART adherence monitoring system interlinked with smartphone gaming was technically feasible, we observed low uptake of this technology among this cohort of HIV-infected AYAs with suboptimal ART adherence. Data from ongoing exit surveys will be used to modify gaming and adherence monitoring design.

TUPED1214

Antiretroviral therapy adherence among HIV-positive breastfeeding women in an implementation research study in Malawi

J. Joseph[1], T. Tchereni[2], A. Gunda[2], T. Farley[3], A. Erlwanger[4], V. Mwapasa[5]
[1]Clinton Health Access Initiative, Applied Analytics Team, Boston, United States, [2]Clinton Health Access Initiative, Lilongwe, Malawi, [3]Sigma3 Services SÀR, Nyon, Switzerland, [4]Clinton Health Access Initiative, Harare, Zimbabwe, [5]College of Medicine, Postgraduate Studies and Research, Blantyre, Malawi
Presenting author email: jjoseph@clintonhealthaccess.org

Background: Option B+ has changed the landscape for prevention of mother-to-child-transmission of HIV (MTCT), offering antiretroviral therapy (ART) to all HIV-infected pregnant women for life. To achieve virtual elimination of MTCT, efforts must include evaluating retention in care and adherence to ART. This analysis examines adherence of ART medication possession ratio (MPR) among HIV-positive breastfeeding mothers in Malawi.
Methods: Data from clinical records abstracted as part of the Promoting Retention among Infants and Mothers Effectively (PRIME) study (a cluster randomized controlled trial that examined post-partum retention in care), conducted May 2013-August 2016, were pooled and reanalyzed. Using ART attendance dates, number of pills dispensed, transfers and deaths for every woman, at every visit, the proportion of women with good adherence was assessed, defined by MPR ≥95% of the time while in care, from delivery through 360 days.
Results: Among the 1084 women on ART and in care at delivery (day 0), 70% had good adherence. This proportion decreased to 63% on day 60, 51% on day 180, and 45% on day 360 (p< .001), with the overall proportion retained on day 360 decreasing to 87% (figure 1). By day 360 2% died or transferred and 11% were lost. Women who initiated ART during pregnancy (61%) were more likely to be lost by day 360 than those already on ART prior to pregnancy (14% vs. 6%, RR 2.05, p=0.001). Similarly, women already on ART were more likely to have good adherence (51% vs. 41%, RR 1.24, p=0.002).



[Figure 1. Evolution of good ART adherence (medication possession ratio ≥95%) and retention in care from days 0 to 360 post-delivery]

Conclusions: Although most women were retained in care one year after delivery, less than half had good adherence, much lower than Malawi's goal of achieving good adherence among 90% of patients by 2020. Interventions to keep women in care and ensure good adherence must begin during the antenatal period and be maintained through the postpartum and breastfeeding period.

TUPED1215

Understanding treatment failure amongst patients on second-line antiretroviral therapy regimens: a mixed methods study in Médecins sans Frontières-supported HIV programmes in rural Malawi and Kenya

B. Schramm[1], R. Burns[1], P. Blasco[2], J. Oruko[3], A. Vandenbulcke[4], E. Szumilin[2], I. Mukui[5], E. Pasquier[2], D. Ardiet[1], V. Carnimeo[1], A. Rakesh[6], T. Zimba[6], T. Kalua[7], A. Wringe[8]
[1]Epicentre, Paris, France, [2]Medecins Sans Frontieres, Paris, France, [3]Medecins Sans Frontieres, Homa Bay, Kenya, [4]Medecins Sans Frontieres, Nairobi, Kenya, [5]National AIDS and STIs Control Programme, Nairobi, Kenya, [6]Medecins Sans Frontieres, Chiradzulu, Malawi, [7]Ministry of Health, Lilongwe, Malawi, [8]London School of Hygiene & Tropical Medicine, London, United Kingdom
Presenting author email: birgit.schramm@epicentre.msf.org

Background: Patients' understanding of the relationship between viral load and antiretroviral therapy may influence their adherence to treatment, particularly among those who have experienced treatment failure. We investigated second-line patients' understanding of HIV, treatment and viral load and its association with viral load suppression.
Methods: Quantitative: Adult patients receiving second-line antiretroviral therapy regimens for at least 6 months in Médecins sans Frontières-supported programmes in Chiradzulu (Malawi) and Homa Bay (Kenya) underwent viral load testing and were interviewed to assess knowledge about HIV, treatment and viral load. A knowledge score was calculated by summing the number of correct answers to 9 true/false questions on antiretroviral therapy.
Qualitative: In each site, repeated in-depth interviews were conducted with a purposive sample from the survey participants (Kenya:n=16) and (Malawi:n=13) and 5 health workers to explore experiences and understanding of second-line medication. Interview data were transcribed, translated and coded. Content analysis identified emerging themes from the data.
Results: Quantitative: In Kenya, 299 (51% female) and in Malawi 212 (59% female) were surveyed. Knowledge about antiretroviral therapy was high in both sites, whereas understanding of viral load was more limited, with some differences by site (table 1).

	KENYA			MALAWI		
	VL < 1000 copies/ml	VL ≥ 1000 copies/ml	p value	VL < 1000 copies/ml	VL ≥ 1000 copies/ml	p value
	n(%)	n(%)		n(%)	n(%)	
Total surveyed n (%)	**256(86)**	**43(14)**	**n/a**	**188(89)**	**24(11)**	**n/a**
Good ART knowledge: (8/9 questions correct)	192(75)	31(72)	0,67	186(99)	24(100)	0,61
Doesn't know if ever had VL test	39(15)	9(20)	0,56	9(5)	1(4)	0,64
Doesn't know what VL test is for	43(17)	15(35)	0,006	28(15)	4(17)	0,76
Knows that VL test can check if ART is working	57(22)	7(16)	0,37	122(65)	1(71)	0,56
Knows that VL test can monitor adherence	11(4)	0()		72(38)	9(36)	0,94

[Table 1. Results Knowledge questions]

Qualitative data revealed that moralistic messages from health workers in both settings meant that some patients believed that high viral load results and treatment failure were due to unprotected sex, use of traditional medicine or witchcraft, particularly in Malawi. Many patients did not explicitly link viral load results to their own pill-taking or the effectiveness of their treatment.
Conclusions: Despite excellent knowledge about antiretroviral therapy, many second-line patients have limited understanding of viral load and its relationship to adherence and treatment failure. Counselling sessions should address the missed opportunity to explain this relationship which may promote regular pill-taking. Supportive counselling approaches should be favoured rather than blaming patients' sexual behavior or use of traditional medicine for treatment failure.

Design of a user-centered strategy to improve ART adherence among MSM living with HIV in Mexico

Z. Andrade-Romo[1], L. Chavira-Razo[1], B. Crabtree-Ramírez[2], L.F. Barraza-Araiza[1], J.S. Andrade-Pérez[3], S.G. Sosa-Rubí[1], T. Aramburo-Muro[1], S. Bautista-Arredondo[1,4]
[1]National Institute of Public Health, Health Economics, Cuernavaca, Mexico, [2]Instituto Nacional de Nutrición y Ciencias Médicas Salvador Zubirán en la Ciudad de México, Infectious Diseases Department, Mexico, Mexico, [3]Hospital Civil de Guadalajara Dr. Juan I. Menchaca, Infectious Diseases Department, Guadalajara, Mexico, [4]UC Berkeley, School of Public Health, Berkeley, United States
Presenting author email: brenda.crabtree@infecto.mx

Background: Globally, studies show that adherence levels to antiretroviral therapy (ART) among people living with HIV are not optimal. High adherence to ART is key to improving survival rate and reducing AIDS related complications among patients, while also reducing HIV-transmission. The objective of this study was to design a user-centered strategy to improve adherence to ART among MSM living with HIV in Mexico.
Methods: Between October and November 2016, 37 MSM participated in six focus groups discussions held in two Mexican cities, and 9 semi-structured interviews were conducted with health care providers of two HIV-clinics. A team discourse analysis approach was first used to identify themes using MAXQDA software. A "design thinking" approach was then used in order to identify the best elements to design the strategy.
Results: We identified multiple barriers and facilitators to ART adherence, and strategies used by patients to improve their medication intake. We found that these strategies vary in time as patients adjust their routines over the course of treatment. Two key moments were identified as crucial to intervene: treatment initiation and a period of readjustment after an intake routine is established. The former is a stage in which most of the adherence barriers first emerge and is crucial for newly diagnosed patients; the latter is essential for those who have already achieved a routine of medication intake, but this routine is discontinued or about to be.
To address this, we designed a multi-stage intervention strategy. For the first, we focused on the formation of skills to overcome key barriers. For the second, we reinforcement key information regarding HIV and ART, strengthen communication with health personnel, and create safe spaces for MSM living with HIV to share experiences with peers.
Conclusions: Barriers and facilitators to adherence are not static, and might undergo changes throughout different stages of adjustment to ART, thus, different moments and strategies that can be used to improve medication intake should be considered by health personnel.
Daily routine, social context, and cultural factors should be taken into account while designing a strategy to improve ART adherence in MSM in order to make it relevant and effective.

Presenting author email: kovalti@ukr.net

Background: HIV-infected women are very affected through stigmatization, social problems and drug abuse. Women initiating ART during pregnancy before implementation of Option B+ have high rates of dropout, particularly after delivery. In this study, we aimed to explore the HIV cascade care in Ukraine and potential barriers to retention HIV infected women.
Methods: We analyze data from medical documentation a retrospective cohort of 839 women who were observed in HIV outpatient clinic in Poltava region of Ukraine in 2003-2016. Three outcome measures related to involvement and retention in care were considered - (1) duration of contact with the HIV-care institution after the initial registration, (2) time of the first CD4 count analysis, (3) start of ART.
Results: Among 839 study participants, were registered in care 121 in 2005 or earlier, 226 in 2006-2008 and 492 in 2009 or later. Proportion of women who were registered in care and not seen by health workers in subsequent years was 25.7% overall and lower (13.2%) in earlier years. Women who inject drugs and those who diagnosed during the pregnancy had higher rates of dropout (OR=1.6, 95%CI 1.1-1.8; OR=1.9, 95%CI 1.5-2.3). Staying in care was best predicted by having any of the clinical complications including oropharyngeal candidiasis (OR=0.6, 95%CI 0.3-0.7), any unknown opportunistic infection (OR=0.5, 95%CI 0.3-0.9), tuberculosis (OR=1.2, 95%CI 1.1-2.8), herpes zoster (OR=0.5, 95%CI 0.3-0.8). Likewise,

patients with diagnosed HIV-infection stage 4 at admission were less likely to drop out (OR=0.5, 95%CI 0.3-0.8). Among those who stayed in care, 538 (64.1%) had their CD4 test within same or next year after registration, 205 (24.4%) did so later on, and 96 (11.4%) never got their CD4 counts. Younger women (29 years or less) had greater risk to never get CD4 counts and to postpone getting the test. Analysis of start ART showed that if any of the above listed symptoms were present, odds of getting ART were greater: OR=2.2, 95%CI 1.4-3.4.
Conclusions: The main predictors of retention in HIV care were revealed appearance of severe opportunistic infections, low level of CD4 counts, older age, drug abuse and diagnosing HIV during the pregnancy before implementation of Option B+.

TUPED1218

The role of peer-to-peer model in achieving 90-90-90 among female sex workers in East Central Uganda

H. Ndagire, F.H. Kazibwe, F. Ajok, A. Mugume
(JSI) and World Education, Inc. / Strengthening TB and HIV&AIDS Responses in East Central Uganda (STAR-EC), Technical, Kampala, Uganda
Presenting author email: ndagireh2002@yahoo.com

Background: Female Sex workers (FSWs) have an increased risk of HIV infections due to a number of behavioral and structural drivers. In Uganda, HIV prevalence among FSWs is estimated between 33 and 37 percent, much higher than the national average of 7.3 percent. The objective of presented work was to assess engagement of FSWs in HIV care continuum within Strengthening HIV&AIDS and Tuberculosis Responses in East Central Uganda (STAR-EC) program.
Methods: STAR-EC supported access to and use of TB and HIV services within the East Central Region for the period 2014-2016. The project targeted different populations, including Key populations. STAR-EC trained peer-to-peer- mentor buddies, identified and registered FSWs in brothels, bars, lodges, and truck stops. Registered FSWs were referred to reproductive health and HIV services, including family planning, STI risk reduction counselling, HTC, ART, and adherence counselling, offered at health facilities and outreach clinics. Follow up by health workers to HIV-negative FSWs on a monthly basis was conducted and HIV-positive FSWs received retention support services including CD4 and viral load testing.
Results: A total of 2,815 FSWs were reached by STAR-EC during October 2014 - June 2016. Among them 2,318 FSWs were tested for HIV for the first time and 608 tested HIV positive. Among 608 HIV positive FSWs, 577 (95%) linked to ART, 537 (88%) remained active on ART within the region, 430 (71%) received CD4 and viral load testing and 318 (52%) were virally suppressed.
Conclusions: Peer-to-peer ,mentor buddies' program helped to diagnose HIV positive persons and link them to care. Additionally, the model helped FSWs to be retained on ART program. A lot more is still required to ensure everybody accesses viral load testing and mechanism to be put in place to ensure viral load suppression for FSWs in order to achieve the 90 90 90.

TUPED1219

"I can do this myself": investigating the acceptability of a web-based, HIV self-testing service in South Africa

P. Smith[1], R. Marcus[1,2], M. Atujuna[1], N. Madubela[1], L.-G. Bekker[1]
[1]Desmond Tutu HIV Centre, Socio-behavioural, Cape Town, South Africa, [2]Barts Health NHS Trust, Department of Infection and Immunity, London, United Kingdom
Presenting author email: philip.smith@hiv-research.org.za

Background: While HIV testing rates have improved in South Africa, the majority of HIV positive individuals (65% male, 45% female) are unaware of their seropositivity, which negatively impacts the potential for universal HIV treatment. HIV self-testing (HIVST) has been shown to have high fidelity, feasibility and acceptability, and therefore has the potential to provide testing to individuals who may not use traditional healthcare services, with subsequent opportunities for timely HIV care. This study evaluated individual acceptability of a web-based HIVST delivery service.
Methods: Self-selected participants above 18 years old logged onto the iTest website via a web search. After viewing text and video study information, participants requested an HIVST and were presented with referral options. Following online consent, a courier was notified to deliver the iTest HIVST to the participant's address. A researcher administered a telephonic acceptability questionnaire within two weeks of the HIVST delivery.
Results: 205 (55%) of 372 participants who enrolled were successfully contacted. 141 of these participants (58% female) had completed the HIVST, and 7% were first-time (debut) testers. No adverse experiences were reported. The majority (97%) reported satisfaction with delivery times, which ranged from 2-5 days, with 7 participants reporting non-delivery. Nearly all participants considered the service to be confidential (94%), with an easily understood video (97%) and written information (96%). The service was rated 4.7 out of 5 with 115 (82%) stating that their experience of self-testing was better than facility based testing.
Conclusions: This study demonstrated high acceptability for the web-based HIVST service, with no adverse events reported. The number of debut testers was surprisingly low. Further qualitative research may elucidate the reasons for seemingly lower uptake from debut testers. The study indicates that HIVST available online can complement existing HIV testing strategies by offering a rapid and confidential testing environment.

TUPED1220

Engagement of traditional birth attendants for scaling-up PMTCT coverage in Abia and Taraba States, Nigeria

B. Olakunde[1], S. Wakdok[1], Y. Olaifa[1], F. Agbo[1], U. Essen[1], O. Ojo[1], M. Okeh[2], S. Ibi[3]
[1]National Agency for the Control of AIDS, Abuja, Nigeria, [2]Abia State Ministry of Health, Umuahia, Nigeria, [3]Taraba State Ministry of Health, Jalingo, Nigeria
Presenting author email: boolakunde@yahoo.com

Background: Slow effort at integrating Traditional Birth Attendants (TBAs) care has been identified as one of the barriers to scaling up prevention of mother-to-child transmission of HIV (PMTCT) in Nigeria. Under the National Agency for Control of AIDS Comprehensive AIDS Programme with States, we engaged TBAs to scale-up PMTCT coverage in Abia and Taraba States.
Methods: Mapping: Officers-in-charge (OIC) or the PMTCT focal persons in the Primary Healthcare Centres (PHCs) were asked to identify TBAs within their environs.
Capacity building: A two-day meeting was held to train the TBAs on universal precaution and safe assisted delivery and to also get a buy-in on the engagement.
Network formation: Referral and linkage networks were established between TBAs and PHCs.
Service provision: From July to September 2016, the OICs or PMTCT focal persons in the PHCs conducted monthly outreaches while the TBAs mobilized their clientele for the outreaches. The OICs were provided with stipend for the outreaches and the TBAs were also provided with communication stipend to facilitate referral and linkages with the PHCs.
Monitoring and Evaluation: Ad hoc forms were developed for reports on the outreaches. Data were also captured using the national M & E tools and register as appropriate.
Results: A total of 720 TBAs were mapped (Abia 407; Taraba 313). Three hundred and ninety nine TBAs who participated in the capacity building meeting were linked to 115 PHCs in Abia State while 245 TBAs were linked to 27 PHCs in Taraba State. In three months, the outreaches contributed 17% to the number of pregnant women counselled tested and received result (CTRR) (table 1) and 15% to the total positive women identified (table 2). All the positive pregnant women were enrolled into care.

State	TBA outreach	Facility	Total CTRR	% contribution from TBA outreach to total CTRR
Abia	2,053	9,073	11,126	18%
Taraba	1,892	10,154	12,046	16%
Total	**3,945**	**19,227**	**23,172**	**17%**

[Table 1: Pregnant women CTRR]

State	TBA outreach	Facility	Total positive	% contribution from TBA outreach to total positive
Abia	58	270	328	18%
Taraba	22	174	196	11%
Total	**80**	**444**	**524**	**15%**

[Table 2: Pregnant women who tested positive]

Conclusions: If effectively engaged, TBAs can improve the uptake and coverage of PMTCT services by bridging the gap between the communities and the health facilities.

TUPED1221

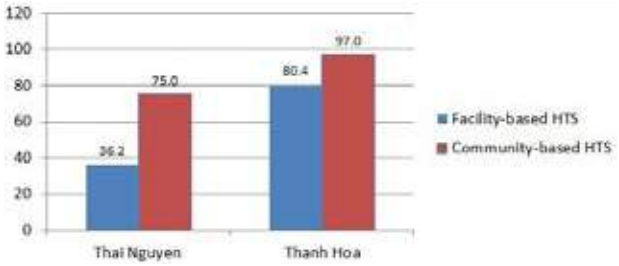
Effectiveness of community-based HIV testing and counseling in identifying HIV-positive cases and linking to care in a concentrated epidemic in Viet Nam

V.T.T. Nguyen[1], T.T.H. Phan[2], T.S. Le[3], B.M. Truong[4], D.N. Vu[3], T.T.H. Nguyen[4], H.S. Vo[2], N. Ishikawa[5], T.H. Ho[6], M. Kato[1]
[1]World Health Organization, Country Office in Viet Nam, Hanoi, Vietnam, [2]Viet Nam Authority for HIV/AIDS Prevention and Control, MOH, Hanoi, Vietnam, [3]Thanh Hoa Provincial AIDS Centre, Thanh Hoa, Vietnam, [4]Thai Nguyen Provincial AIDS Centre, Thai Nguyen, Vietnam, [5]World Health Organization, Western Pacific Regional Office, Manila, Philippines, [6]Hanoi School of Public Health, Hanoi, Vietnam
Presenting author email: nguyenva@who.int

Background: Uptake of HIV testing and counseling services (HTS) at health facilities has been limited among key populations in Vietnam due to various reasons, e.g. fear of discrimination, stigma, need to travel long distance. Community-based HTS (CBHTS) was piloted to test the hypothesis that CBHTS is acceptable to key populations and effective in identifying HIV positive cases and linking them to treatment.
Methods: Pilot description: The pilot was started in January 2015 in Thanh Hoa and in August 2015 in Thai Nguyen province. CBHTS was delivered by trained village health workers in 12 communes in Thanh Hoa, and by trained PWID and MSM peer educators at three sites in Thai Nguyen.
Pilot assessment: A review on CBHTS was conducted in November 2016 to assess the outcomes of the pilot including feasibility and acceptability of CBHTS. Quantitative data were obtained through the reviews of HTS and treatment logbooks. Qualitative data were collected though 33 in-depth interviews and 2 focus group discussion sessions
Results: A total of 1,711 clients received HTS in communities. Forty-four clients were diagnosed as HIV positive and 40 (91%) were linked to ART (Table 1). Better linkage from HIV testing to treatment was achieved compared to facility-based HTS (Figure 1). Both clients and lay providers reported CBHTS is convenient for clients, enhancing demands for HTS; reaching "unreached" key populations, providing prompt and accurate results while ensuring privacy and confidentiality, and supportively linking to care and treatment services.

Clients	# tested	# HIV+ cases (%)	# received ART (%)
Key populations	834	34 (4.1)	30 (88.2)
Partners/children of people living with HIV/people who inject drugs	472	8 (1.7)	8 (100)
Other	405	2 (0.5)	2 (100)
Total	1711	44 (2.6)	40 (90.9)

[Table 1. Results of CBHTS in two piloted provinces]



[Figure 1. Linkage from HIV testing to care and tre]

Conclusions: The results of this pilot demonstrated the appropriateness, effectiveness and feasibility of CBHTS as an additional approach for increasing testing uptake. The results of this pilot informed development of national guidelines for HIV testing in which CBHTS was recommended.

TUPED1222

Provider-initiated testing and counseling: is it still high yield? Yield of routine HIV testing in pediatric and adult inpatient wards in central and southern Malawi

K. Simon[1,2], M. Montandon[1,2], S. Ahmed[1,2], E. Wetzel[1], R. Sabelli[1], T. Beyene[1,2], E. Kavuta[1], C. Chikoti[1], K. Namachapa[3], P. Kazembe[1,2], M. Kim[1,2]
[1]Baylor College of Medicine Children's Foundation, Lilongwe, Malawi, [2]Baylor International Pediatric AIDS Initiative at Texas Children's Hospital, Baylor College of Medicine, Houston, United States, [3]Malawi Ministry of Health, Department of HIV/AIDS, Lilongwe, Malawi
Presenting author email: ksimon@tingathe.org

Background: Routine HIV testing at health facilities (provider-initiated testing and counseling, PITC) is recommended at presumed high yield venues like inpatient wards. Limited recent data exist on testing yield in settings like Malawi with mature Option B+ and active HIV case finding programs. We evaluated inpatient PITC yield at three hospitals in central and southeastern Malawi.
Methods: Data on PITC in inpatient wards (adult, pediatric, pediatric nutritional rehabilitation units (NRU)) were collected from July-Dec 2016 (Salima) and Oct-Dec 2016 (Balaka, Mangochi) using dedicated PITC registers. Per national guidelines, patients one year of age and older underwent rapid antibody testing to determine HIV status; mothers of infants less than one year (or if unavailable, infants) underwent rapid HIV testing to determine HIV exposure. Patients were offered testing if they had never tested for HIV, tested negative >3 months ago, or had no documentation of prior testing. HIV status (known or newly ascertained) and testing outcomes for patients one year of age or older were analyzed to determine ward HIV prevalence and testing yield.
Results: Of 7664 inpatients (3526 pediatric, 4064 adult, 74 NRU) admitted during the evaluation period, 6266 (82%) were assessed for testing eligibility. Of those assessed, 4742 (76%) did not have documented HIV status (including those never tested) or tested negative >3 months ago and were offered testing. Refusal rate was 1.6%.

	Ward prevalence: Known and new HIV+ / (Total Known Status + Total Newly Tested >1yo)	Testing Yield:New HIV+ / (Total Newly Tested >1yo)
NRU	25.5% (13/51)	12.5% (4/32)
Pediatric Inpatient	3.5% (75/2118)	1.1% (19/1799)
Adult Inpatient	23.7% (787/3327)	4.8% (102/2141)

[Ward Prevalence and Testing Yield]

The majority of HIV-positive inpatients knew their HIV status prior to admission (87% in adult wards, 75% in pediatric wards, 69% in NRU). Inpatient ward HIV prevalence was higher than national population HIV prevalence (1.6% 0-14y and 10.6% 15-64y) (Malawi Population-based HIV Impact Assessment 2016). Yield of new HIV testing among inpatients (excluding NRU) was lower than population prevalence.
Conclusions: PITC remains an important approach for HIV case finding and is critical for prompt treatment initiation, however in the setting of Option B+ and active HIV case finding, yield may be decreasing. Contemporary data on PITC yield in various settings and identification of novel high-yield case finding strategies are needed.

TUPED1223

After achieving 90-90-90 in the SEARCH study: who is not achieving viral suppression?

D. Kwarisiima[1,2], M. Kaur[3], F. Mwangwa[4], J. Ayieko[5], A. Owaraganise[4], D.M. Byonanebye[4], T. Liegler[3], L. Brown[3], D. Black[3], T.D. Ruel[6], V. Jain[3], C.R. Cohen[7], E.A. Bukusi[5], E.D. Charlebois[3], T.D. Clark[3], M.L. Petersen[8], D.V. Havlir[3], M.R. Kamya[4,9]
[1]Infectious Disease Research Collaboration, SEARCH Trial, Kampala, Uganda, [2]Makerere University Joint AIDS Program, HIV Prevention, Kampala, Uganda, [3]University of California, Division of HIV, Infectious Diseases & Global Medicine, San Francisco, United States, [4]Infectious Diseases Research Collaboration, SEARCH Trial, Kampala, Uganda, [5]Kenya Medical Research Institute, Nairobi, Kenya, [6]University of California, Department of Pediatrics, San Francisco, United States, [7]University of California, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [8]University of California, Berkeley, Berkeley School of Public Health, San Francisco, United States, [9]Makerere University, School of Medicine, College of Health Sciences, Kampala, Uganda
Presenting author email: bkdalsone@yahoo.co.uk

Background: HIV viral suppression (VS) on a population level can accelerate elimination of new HIV infections. The SEARCH HIV test-and-treat study (NCT01864603), achieved 97% HIV tested/93% on ART/89% suppressed after 2

years in 16 intervention communities (~10,000 persons each). Population-level viral suppression among HIV+ persons was 80%. We assessed demographic and care characteristics to better understand factors contributing non-suppression in the 20% of adults who remain viremic.
Methods: We studied HIV+ adults (≥15 years) in 16 SEARCH intervention communities using streamlined HIV care that included:
(1) nurse-driven triage,
(2) multi-disease care,
(3) viral load (VL) testing and counseling,
(4) 3-month ART refills,
(5) appointment reminders and patient tracking, and;
(6) telephone access to clinicians.
VLs were measured at during annual campaigns and clinical follow-up (June, 2013 - November, 2016). Predictors of viremia (most recent VL>500 copies/ml) were sought with multivariate logistic regression.
Results: Among 8299 HIV+ adults, 5705 (69%) were ≥30 years and 2594 (31%) were aged 15-29 years. Among the 7968 (96%) adults with at least one VL measurement, 1603/7968 (20%) were viremic. Among these viremic adults: 980 (61%) were female, 869 (54%) were ≥30 years, 1082 (68%) were married, 1257 (78%) had attained primary education, 831 (52%) were farmers and 1131 (71%) resided in Kenya. In total, 494 (31%) had never been in care, 512 (32%) were linked to care but lost to follow up (LTFU), and 597 (37%) were actively engaging in care. Predictors of viremia included: age 15-29 years (OR= 2.29 vs. age ≥30, 95% CI 2.02-2.58); male (OR=1.43, 95% CI 1.26-1.61); working in transport (OR=1.49 vs farming, 95% CI 1.01-2.19); being a student (OR=2.27 vs farmer, 95% CI 1.70-3.04), and residing in Kenya (OR= 1.24 vs. residing in Uganda, 95% CI 1.09-1.40).
Conclusions: In the SEARCH Study, after 2 years of a universal HIV test-and-treat intervention, 20% of HIV+ adults remained viremic. One third had never linked to care, 1/3 LTFU and 1/3 were still engaged in care. Youth—in particular young men—and students were the most at risk for viremia. Targeted interventions to support viral suppression are urgently needed for these sub-populations.

TUPED1224

Barriers and facilitators of HIV testing among female sex workers in rural pastoralist communities in Northern Kenya

C. Akolo[1], S. Ochieng'[2], P. Edonga Ekuam[3], B. Ediedu Ogwang'[2], N. Njuguna[2]
[1]Family Health International (FHI 360), LINKAGES Project, Washington DC, United States, [2]Family Health International (FHI 360), LINKAGES Project, Nairobi, Kenya, [3]Turkana Pastralist Development Organization, LINKAGES Project, Lodwar, Kenya
Presenting author email: cakolo@fhi360.org

Background: Female sex workers (FSWs) in Turkana County, Kenya, are disproportionately affected by HIV compared to the general population and other FSWs in Kenya (36% versus 6% and 29%, respectively). HIV testing is a critical first step in linkage to care and yet uptake is low in this region.
We sought to increase HIV testing through peer-led outreach and determine reasons for low testing uptake among FSWs in Turkana West subcounty, a rural pastoralist community in Northern Kenya.
Methods: The USAID and PEPFAR funded LINKAGES project, in collaboration with TUPADO, conducted hotspot mapping exercises in Turkana West subcounty. We estimated the number of FSWs in the region and formed a community advisory board consisting of FSWs and project staff to help identify a suitable location for a drop-in center (DIC). We trained 30 peer educators to mobilize their peers for intensified HIV testing at least once every quarter. FSWs were tested through referrals to the DIC or through outreach events. We analyzed data collected during programmatic activities for accelerating HIV testing in the run-up to World AIDS Day 2016. Descriptive statistics are used to summarize HIV testing uptake.
Results: A total of 28 hotspots with 1,465 FSWs were identified from October to December 2016. Of 851 FSWs (58%) offered HIV testing services, 162 (19%) accessed the HIV testing centers, of whom 147 (17%) received an HIV test. Sixty-five percent of FSWs tested were ages 15-24 years. The most common reason cited for testing was a need to confirm their HIV negative status. Of the 15 FSWs who accessed the testing center but declined an HIV test, seven (47%) reported a condom burst without access to post-exposure prophylaxis in the previous three months. The most commonly cited reason for not testing was fear of others knowing their status and desire for heightened anonymity.
Conclusions: HIV testing uptake continues to be low among FSWs in this high HIV prevalence region. HIV stigma reduction interventions and heightened confidentiality measures during testing are urgently needed to increase uptake of HIV testing and prevention services among high risk FSW.

TUPED1225

High virological suppression and retention in HIV-infected patients initiated on ART with CD4 above 500 in a program setting in Uganda

D.M. Byonanebye[1,2], F.C. Semitala[2,3], J. Katende[3], I. Arinaitwe[2], A. Bakenga[2], I. Nahamya[3], P. Musinguzi[4], P. Kyambadde[5], M.R. Kamya[1,2]
[1]Infectous Diseases Research Collaboration, Resaerch, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]Makerere Joint AIDS Program, Kampala, Uganda, [4]Mulago Hospital, STD/HIV Clinic, Kampala, Uganda, [5]Most at Risk Populations Initiative, Kampala, Uganda
Presenting author email: dathan@idrc-uganda.org

Background: The World Health Organization recommends antiretroviral therapy (ART) for all HIV-infected patients. However, there are concerns that healthy patients especially key populations (KPs) accessing ART in programmatic settings may have poorer rates of virological suppression. We sought to determine the prevalence of lost to follow up (LTFU) and define predictors of viral suppression among HIV infected adult patients initiated on ART with baseline CD4 cell count >500 cells/µl at two high volume urban clinics in Kampala, Uganda.
Methods: In this cross-sectional study, we enrolled patients attending two PEPFAR supported clinics, one of which exclusively serves KPs. Eligible patients were aged ≥18 years, baseline CD4>500 and on first line ART for ≥six months. We obtained data on socio-demographics, ART history, clinic and reasons for ART; using interviewer-administered questionnaires. Plasma HIV RNA was determined with Abbott Real-time© HIV-1assay.Predictors of virological suppression (HIV RNA< 75 copies/ml) were determined using multivariate logistic regression.
Results: Between August 2015 and March 2016, 228 consecutive participants were eligible of which 25 (11%) were LTFU (no visit in prior 90 days). Of the 203 enrolled patients, 106 (52.2%) were sex workers, 9 (4.4%) men who have sex with men, 17 (8.4%) discordant couples, 45 (22.2%) pregnant or lactating women and 26 (12.8%) were other high-risk populations. The median age (IQR) was 30 (25-35) years, median duration (IQR) on ART14.2 (8.4-16.2) months and baseline CD4 (IQR) was 662 (547-774) cells/µl. Virological suppression was achieved in 173/203 (85%; 95% CI, 80.3-90.1) patients, and 192/203 (95%, 95% CI 90-97) had HIV RNA< 1000 copies/ml. In a model adjusting for age, sex, adherence, prior HIV RNA test, reason for ART initiation and clinic, the factors associated with virological suppression were prior HIV RNA monitoring test(s) (aOR 6.98; 95% CI 2.63-18.50; p value < 0.001) and receiving care from a non-KP clinic (aOR 5.41; 95% CI 1.52-19.27; p=0.009). Of the 25 LTFU, 10 were alive and 60% (6/10) of these patients had stopped ART.
Conclusions: HIV infected patients with high CD4 counts including KPs, achieved excellent virological suppression and retention in care in a routine program setting. VL monitoring and clinic type were associated with suppression.

TUPED1226

Why do people delay seeking healthcare for advanced HIV? A qualitative study from a low-coverage setting in Kinshasa, Democratic Republic of Congo (DRC)

E. Venables[1], S. Spiers[2], I. Casteels[2], E. Goemaere[1], M. Mashako[2], G. van Cutsem[1]
[1]Medecins Sans Frontieres, Southern Africa Medical Unit, Cape Town, South Africa, [2]Medecins Sans Frontieres, Kinshasa, Congo, Democratic Republic of the
Presenting author email: msfocb-kinshasa-sida-pmr@brussels.msf.org

Background: HIV prevalence in DRC is estimated to be 1.2%, and access to HIV testing and treatment remain low across the country. National ART coverage is among the lowest worldwide (23% in 2014). While 64% of the population lives below the poverty line, 43% of health expenditure is made by households. User fees severely limit health-care access, and many people with HIV start ART late or interrupt treatment due to cost. At the Centre Hospitalier Kabinda (CHK) in Kinshasa, median CD4 count at admission was 74 cells/uL and in-patient mortality was 25%; 70% of patients were previously on ART and 50% had interrupted treatment for more than 6 months and 20% were treatment failures not managed accordingly. A qualitative study was conducted to explore why patients arriving at CHK delayed seeking treatment.
Methods: 24 in-depth interviews were carried out with currently- and previously-hospitalised patients, relatives/care-givers of patients and health-care workers in CHK. Patients included those who were ART-naïve and non-naïve. Participant observation was also conducted. Interviews were conducted in French and Lingala. All interviews were translated into English, entered into NVivo, coded and thematically analysed.
Results: Patients, care-givers and health-care workers gave similar reasons for late arrival of patients including lack of training amongst health-care workers on treatment failure management; religious leaders encouraging people not to take ART; poor patient understanding of diagnosis/treatment; stigma and lack of economic

resources to pay for consultations. Stigma prevented patients from disclosing and seeking support from their relatives. Health-care workers felt HIV testing was not offered early enough and that adherence support was insufficient. Clinics were described as ‚boutiques' where every intervention had an additional - often unaffordable - cost.
Conclusions: Cost, stigma, lack of patient and health-care worker knowledge and misinformation by religious leaders causes delays in seeking health-care. These factors jeopardise the assumption that lifelong HIV treatment is feasible in low-coverage settings, and contribute to explain ongoing persistence of advanced HIV disease. Access to free HIV-testing, ART and treatment of opportunistic infections; counselling (disclosure, adherence, treatment failure); training of health-care workers and counsellors; support for care-givers and stigma reduction strategies with churches are urgently needed.

TUPED1227

Access to prevention of mother to child transmission (PMTCT) of HIV service cascade through integrated active case management in 15 operational districts in Cambodia

S. Samreth[1], T. Delvaux[2], V. Ouk[1], V. Keo[1], R. Tep[1], S. Leang[1], A. Ke[1], B. Ngauv[1], S. Mam[1], P.S. Ly[1]
[1]National Center for HIV/AIDS, Dermatology and STD (NCHADS), Phnom Penh, Cambodia, [2]Institute of Tropical Medicine (ITM), Antwerp, Belgium
Presenting author email: sovannarith@nchads.org

Background: Aiming to achieve the goal of virtually eliminating mother-to-child HIV transmission by 2025, Cambodia has implemented integrated active case management (IACM) approach since 2014. This approach is expected to improve detection of HIV positive cases and assure that all HIV positive pregnant women and their HIV-exposed infants receive the full package of PMTCT services. This study aimed to analyse PMTCT cascade data in 15 operational districts (ODs) implementing the IACM in Cambodia.
Methods: A retrospective cohort study design was used to analyse data obtained from IACM program database from 15 ODs implementing IACM between 1 January 2014 and 31 December 2016. We measured key PMTCT cascade indicators including HIV infected pregnant women identified, maternal antiretroviral treatment (ART) during pregnancy, infant antiretroviral (ARV) prophylaxis, infant cotrimoxazole prophylaxis, and early infant diagnosis (EID) of HIV infection by DNA PCR test.
Results: During the study period, 895 HIV positive pregnant women were identified. Among them, 237 (26.5%) were tested HIV positive during pregnancy, 9 (1%) were tested HIV positive at delivery, and 649 (72.5%) were HIV positive women already on treatment who became pregnant. By 31 December 2016, 501 women in the cohort had given birth to 502 infants, as one woman had twins. Among these 502 infants, 496 were live birth infants and 486 reached 6 weeks old or older. PMTCT cascade analysis shows that 92.3% (826/895) of the identified women had access to ART during pregnancy, 85.3% (423/496) of live birth infants received ARV prophylactic treatment, and that 72.8% (354/486) and 70.4% (342/486) of the infants aged 6 weeks or older received cotrimoxazole prophylaxis and DNA PCR test, respectively. Among infants who received DNA PCR test, 2.6% (9/342) was HIV positive.
Conclusions: Gaps in accessing PMTCT of HIV service cascade were still significant in these ODs implementing IACM. Many HIV positive women and their HIV-exposed infants were still not able to receive treatment, prophylaxis, and early diagnosis of HIV. Further research is needed to identify the determinants of access to PMTCT service cascade.

A program implemented to expand access to HIV testing finds high prevalence and incidence among young MSM in four provinces in Thailand

S. Ongwandee[1], C. Manopaiboon[2], M. Wasantioopapokakorn[1], T. Phoorisri[1], F. Langkafah[2], U. Kritsanavarin[2], P. Visavakum[2], B. Jetsawang[2], S. Nookhai[2], N. Jongchotchatchawal[2], A. Sukkul[2], M. Martin[2,3]
[1]Ministry of Public Health, Bureau of AIDS, TB and STIs, Nonthaburi, Thailand, [2]Thailand Ministry of Public Health-U.S. CDC Collaboration (TUC), Division of Global HV and TB (DGHT), Nonthaburi, Thailand, [3]Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/AIDS, Atlanta, United States
Presenting author email: sumet_o@yahoo.com

Background: HIV prevalence and incidence among men who have sex with men (MSM) remain high in Thailand but HIV testing, an entry point to care, is low. We launched a four-year pilot program to promote HIV testing and link HIV-infected MSM to care in September 2011 in Bangkok, Khon Kaen, Phuket, and Udon Thani, four high-HIV prevalence provinces in Thailand.
Methods: MSM were recruited and trained to promote HIV testing among their peers. Mobile and clinic-based sites were identified to provide HIV testing using three rapid HIV tests, consistent with national guidelines. MSM who tested HIV-positive were referred for care. During HIV testing, health care providers collected demographic and HIV testing history information using a standardized form. We used Poisson regression to determine trends in annual HIV testing and calculated incidence, per 100 person-years of observation, using data from participants who initially tested HIV negative and tested at least one more time (there were 68 incident HIV infections), assuming a uniform probability distribution throughout the interval between the last negative and first positive HIV tests.
Results: A total of 5,629 MSM agreed to HIV testing. Testing increased from 458 in fiscal year (FY) 2012 to 1,832 in FY 2016 (p<0.001). Participant's median age at enrollment was 24 years, 2,299 (41%) were referred by peers, 1,923 (34%) tested at mobile clinics, and 3,412 (61%) were testing for the first time. Almost 100% (5,606) received their HIV test results. HIV prevalence was 21% in FY 2012 and decreased to 17% in FY 2016 (p<0.001). Among HIV-positive MSM, 63% had a CD4 test and the median CD4 count was 284 (interquartile range 143-420) cells/mm^3. The overall HIV incidence was 6.2 per 100 person-years (95% CI, 4.8-7.9) but higher among MSM 15-19 years old (10.1 per 100 person-years) and 20-24 years old (10.9 per 100 person-years) than among MSM >24 years old (3.8 per 100 person-years).
Conclusions: We successfully implemented an HIV testing program among MSM. HIV prevalence and HIV incidence among MSM remains high, particularly among young MSM, highlighting the urgent and ongoing need for comprehensive HIV prevention services for this population.

TUPED1229

Toward the first 90: identifying and testing younger populations for HIV at community outreach events in Kenya

N.A. Okoko[1], M.A. Guzé[2], S. Ndolo[1], G. Nyanaro[1], E.A. Bukusi[1], C.R. Cohen[2], J. Penner[3], J.L. Kulzer[2]
[1]Kenya Medical Research Institute (KEMRI), Family AIDS Care and Education Services (FACES), Center for Microbiology Research (CMR), Kisumu, Kenya, [2]University of California, Department of Obstetrics, Gynaecology and Reproductive Sciences, San Francisco, United States, [3]University of British Columbia, Vancouver, Canada
Presenting author email: awuornicollate@gmail.com

Background: Low HIV status awareness among children and adolescents, 12,940 new HIV infections among children and rising adolescent AIDS-related deaths in Kenya is a cause for concern given the association of delayed HIV identification with poor health outcomes. This study examined HIV testing outcomes and characteristics of younger (age < 19) populations attending targeted community outreach events (TCOEs).
Methods: In Homa Bay, Migori, and Kisumu counties in Kenya 492 TCOEs with HIV testing and identification were conducted in 148 health facility catchment areas supported by the HIV program Family AIDS Care & Education Services (FACES) over five months from July - December 2015. Aggregated HIV testing (mean number tested), yield (mean number identified HIV positive), and gender among eligible children (age < 15) and adolescents (age 15-19) at TCOEs were captured in a REDCap database. Negative binomial models were used to assess age and gender differences in HIV testing and yield.
Results: Among 14,603 individuals tested at TCOEs, 67% (N=9788) were children (age < 15) and 33% (N=4815) were adolescents (age 15-19). Among children, 54% (N=5291) were female with 0.2% (N=10) HIV positive; 46% (N=4497) were males including 0.2% (N=8) HIV positive. Among adolescents, 51% (N=2457) were female with 0.5% (N=13) HIV positive; 49% (N=2358) were male including 0.2% (N=4) HIV positive. Adolescents were less likely to be tested at TCOEs compared to children (IRR: 0.46; 95% CI: 0.34, 0.62; p<0.01). Although fewer males than females tested overall (IRR: 0.85; 95% CI: 0.78, 0.93; p<0.01), the decrease in males testing from the children age group to the adolescent age group was smaller than in females (IRR: 1.13, 95% CI: 1.02, 1.25, p=0.02). There was no significant difference in age and gender among those testing positive.
Conclusions: Targeted community outreach events reached twice as many children as adolescents for HIV testing and identification and female HIV testing declined in adolescence. The TCOE approach appears useful in reaching children, however a better understanding of what type of community approaches would draw adolescents, particularly females, is needed.

Gender and power dynamics of social relationships shape willingness to participate in biomedical HIV prevention research among South African adolescents and young adults

L. Lee[1], J. Dietrich[2], L. Greener[3], L. Makhale[2], P. Smith[1], S. Hornschuh[2], T. Mathenjwa[3], M. Brockman[1], M. Beksinska[3], G. Gray[2], J. Smit[4], A. Kaida[1], on behalf of the AYAZAZI research team
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]Perinatal HIV Research Unit, University of the Witwatersrand, Bio-Behavioural Research Division, Soweto, South Africa, [3]MatCH Research Unit (MRU), University of the Witwatersrand, Faculty of Health Sciences, Durban, South Africa, [4]MatCH Research Unit (MRU), University of the Witwatersrand, Faculty of Health Sciences, Dept. of Obstetrics and Gynaecology, Durban, South Africa
Presenting author email: jsmit@matchresearch.co.za

Background: Adolescents and young adults (AYA) are a priority population for HIV prevention initiatives. We explored the social relationships at intimate, family, community and institutional levels that influence AYA participation and potential adherence to protocols in HIV prevention research (e.g., PrEP, vaccine trials, mucosal sampling, medical male circumcision).
Methods: Eight age- and gender-stratified (16-18; 19-24 years) focus group discussions (FGDs) were conducted with 33 male and 42 female participants enrolled in AYAZAZI, a youth-centred HIV prevention study among AYA in Soweto (April-May 2015) and Durban (July 2016). FGDs were co-facilitated by trained qualitative researchers and youth interviewers in English, Sesotho, or isiZulu, audio-recorded and translated verbatim. Data were analysed using grounded theory and ecological systems theory.
Results: Across all levels, gender and power dynamics of AYA's social relationships shaped willingness to participate in research. At an intimate level, vaccine trials and PrEP were favoured by women for access to female-controlled discrete options to protect themselves against HIV and by men who desired to protect themselves and sexual partners (i.e against unfaithfulness; when condoms weren't used).
At the family level, AYA feared that to parents, study participation would suggest risky sexual behavior and expressed concerns about a lack of privacy if asked to collect vaginal or seminal samples at home.
At the community level, AYA feared stigmatization from neighbors and peers for participating in research and men feared physical abuse and teasing. Learning about sexual risks and sharing knowledge with friends to protect them was a motivator to participate for men and women. Some men feared marginalization from their community if they chose medical over traditional circumcision.
Institutional: Both men and women were motivated by the desire to help society. Positive relationships with health care teams (trust, safety, non-judgmental, listening ear) were also motivators to participate in such research.
Conclusions: Large numbers of AYA will be required to demonstrate efficacy and feasibility for future biomedical HIV prevention research. Recruitment and retention efforts are likely to be enhanced through adopting a multi-level relational and gendered approach that considers collective decision making processes such as support, opposition or judgment of family, partners and community regarding study participation.

TUPED1231

High yields attained through HIV household index case testing in Zimbabwe: the case of the FHI 360 Zimbabwe HIV care and treatment project

N. Mahachi[1], A. Muchedzi[1], T. Moga[1], T. Tapfuma[1], C. Dziwa[1], T. Chimbidzikayi[1], S. Gonouya[1], O. Chakubili[2], K. Torpey[3]
[1]FHI 360, Programmes, Harare, Zimbabwe, [2]FHI 360, Global, Durham, United States, [3]FHI 360, Global Technical, Washington, United States
Presenting author email: nyikadoc@yahoo.com

Background: FHI360 in Zimbabwe is implementing a USAID-funded, Zimbabwe HIV Care and Treatment Project (ZHCT), to increase the availability and quality of care and treatment services for persons living with HIV (PLHIV), through community-based interventions.
This project compliments the Government of Zimbabwe efforts towards achievement of the first and the third 90s of the UNAIDS Strategy aimed at ending AIDS by 2030.
Methods: The ZHCT project primarily provides household index-case testing (HICT) specifically targeting adolescents, young women, pregnant and breastfeeding women, men and sexual partners. In 2016, ZHCT project was implemented in communities around health facilities with more than 175 patients enrolled on ART in eight districts in 2 provinces of Zimbabwe. Between March and December 2016, HIV- positive index-cases were identified at various service delivery points at these health facilities and were followed up by trained nurse testers. HIV testing services (HTS) were then provided to their sexual partners and children at household levels. Those identified to be HIV-positive were linked to care and confirmed by being recorded in the health facility pre-ART register.
Results: A total of 25,930 people tested for HIV during the period under review and 4383(16.9% yield) were newly identified to be HIV-positive. The yield increased from 8% to 39% over the first year of implementation. A total of 13,057 (50%) of those that tested for HIV were men while (48%) were aged 25-49 years. A total of 1579 (75%) of those identified to be HIV-positive were linked for HIV care.
Conclusions: These findings show that HICT gives a higher yield of HIV-positives identified and linked to HIV care than traditional community based HTS approaches like door to door or outreach. In this project HICT reached the sexually active age group and more men with HIV testing services compared with ~10% at heath facility levels. Based on these findings HICT should be scaled up with a focus on testing of sexual partners and exploring the sexual network in Zimbabwe as the country moves towards attainment of the 90x 90x90 targets and thus reach individuals less likely to test within the conventional health facility testing stream.

TUPED1232

Index client testing: is this the magic bullet to better testing yield in the journey towards the first 90?

M. Kitheka[1], S. Gitia[2], S. Bii[3], M. Mudany[1]
[1]Jhpiego, Nairobi, Kenya, [2]LVCT Health, Nairobi, Kenya, [3]USAID, Nairobi, Kenya
Presenting author email: moses.kitheka@jhpiego.org

Background: There are estimated 1.6 million Kenyans living with HIV, with 101,560 new HIV infections annually in 2016. Kenya has adopted UNAIDS' 90-90-90 goals, as outlined in the Kenya AIDS Strategic Framework. In order to achieve these, beginning with the first "90", Kenya has embraced innovative HIV testing strategies that target highest risk populations and aim to identify more people living with HIV. Among this was index client testing which is a strategy to identify untested sex partners/spouses and family members of people living with HIV and offer them HIV testing services.
Methods: APHIAPLUS KAMILI is a USAID funded project led by Jhpiego supporting HIV Prevention, Care and Treatment in Eastern and Central Kenya, including HIV testing services (HTS). In year 2016, the project began offering index client testing in 62 HTS sites. Health facility staff and HTS counselors were mentored on the approach, and roles and responsibilities for each were outlined. Client records were reviewed during routine facility visits to identify family members (spouse and children) with unknown HIV status. Clients were educated on the importance of family member testing, and were requested to bring them for testing during their next appointment. In some cases where the client was unable to visit, HTS counselors offered family member testing in the clients' home.
Results: Between January and September 2016, a total of 4,561 HIV client records were reviewed as the index cases. Of these, 8,876 contacts/family members were identified, of which 1,529 had a known HIV status and were excluded. Of the 7,347 with unknown HIV status, 6,047 (82%) were tested, 397 (7%) tested HIV positive, and 363 (91%) were successfully linked with treatment. This yield is significantly higher than the 2.1% HIV positivity at outpatient and 2.5 % at Inpatient HTS observed during the same time period.
Conclusions: The index client testing strategy is a high yield and effective approach to identify undiagnosed HIV-positive clients. This enables programs reach people with a high likelihood of being HIV positive to optimise on HTS services. Jhpiego and other programs should scale up this approach as part of the strategy to achieve the UNAIDS 90-90-90 goals.

TUPED1233

Uptake of HIV services in rural Mozambique: factors associated with retention in care after community-based ascertainment of 12-month outcomes

E. Lopez-Varela[1,2], L. Fuente-Soro[1,2], O. J. Augusto[1], C. Sacoor[1], A. Nhacolo[1], E. Bernardo[1,3], E. Karajeanes[4], P. Vaz[4], D. Naniche[1,2]
[1]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [2]Barcelona Institute for Global Health (ISGLOBAL), Barcelona, Spain, [3]Manhiça District Health Services, Manhiça, Mozambique, [4]Fundação Ariel Glaser Contra o SIDA Pediátrico, Maputo, Mozambique
Presenting author email: elisa.lopez@isglobal.org

Background: In order to end the HIV/AIDS epidemic by 2030, the current gap in case detection needs to be closed through HIV counseling and testing strategies that are locally appropriate and effective in linking patients into care. We aimed to compare the linkage rates between different testing modalities in a semi-rural area in southern Mozambique.

Methods: Between May 2014 and June 2016, a prospective cohort study conducted in the Manhiça District Health Demographic Surveillance System consecutively enrolled adults with a first positive HIV result from three testing modalities: voluntary and provider initiated (VCT and PICT) and home based testing (HBT). Linkage and retention data was extracted from patient clinical charts. Determinants of lost to follow-up (LTFU) at each step of the cascade were evaluated through the Fine and Gray competing risk model. The true attrition rate was ascertained through home visits after 12 months' follow-up.
Results: Among the 1122 enrolled patients, 56.1% were female with a median age of 33 years and 43.7% had linked to care, defined as having a CD4 count available within three months of diagnosis. Among them, median CD4 cell count was 291/mm3 (IQR 173-450) and 69% were ART eligible. When conditioned on the previous step, the testing venue showed no significant difference in linkage, although, it did influence significantly initial enrollment in care (98%, 91% and 36% enrollment for VCT, PICT and HBT respectively, p<0.01). Other factors associated with increased linkage included older age (adjusted sub-distribution hazard ratio (aSHR) 1.56; 95% CI: 1.17-2.09), having a previous HIV test more than a year ago (aSHR 1.85; 95%CI: 1.15-2.27), and being tested with other family/friends (aSHR 1.32; 95%CI: 1.01-1.73). Whereas decreased linkage was associated with showing no intention to disclose their HIV status to partner (aSHR 0.64; 95%CI: 0.43-0.95). One fourth of participants initiating anti-retroviral treatment were LTFU after 12 months of initiation. Among them, 22% were deaths, an additional 29% were transfers and migrations, thus reducing the proportion of true LTFU by half.
Conclusions: Improved linkage will require multiple cascade step-specific interventions and adequate monitoring including ascertainment of true LTFU.

TUPED1234

Contact tracing of HIV-infected individuals, an innovative approach to increase HIV case finding in Angola (pilot project)

M.L. Furtado[1], I. Fortes[1], F. Alberto[2], A.G. Ngulu[2], S. Ngonyani[3], S. Kelbert[4], M. Gurdian[3], J. Juarez[3], K. Curran[4], M.J. Cardoso[5], A.S. Tamele[5], L.V. Vemba[3]
[1]National AIDS Institute Angola, Luanda, Angola, [2]Viana I Health Center, Luanda, Angola, [3]Jhpiego, Luanda, Angola, [4]Jhpiego, Technical Leadership Office, Baltimore, United States, [5]Jhpiego, Maputo, Mozambique
Presenting author email: silvia.kelbert@jhpiego.org

Background: Angola has a generalized heterosexually-driven HIV/AIDS epidemic with an estimated HIV prevalence of 2.41% in adults aged 15-49. An estimated 317,206 people are living with HIV in Angola, more than 50% of whom do not know their HIV status. To achieve the UNAIDS 90-90-90 goals by 2020, additional efforts are needed to identify HIV-positive persons and link them to HIV care and treatment services. Contact tracing has shown success in achieving this goal.
Methods: Strengthening Angola Systems for Health (SASH), a USAID-funded project, together with the National AIDS Institute (INLS), Luanda Health Directorate, and Viana Municipal Health Directorate, implemented a contact tracing pilot project in Viana I Health Center October-December 2016. The goal was to increase the number of HIV-positive individuals who know their HIV status and link them to care and treatment services. All index cases, or ICs, (i.e. all persons newly diagnosed with HIV and/or recently admitted into HIV care) included in the project received counseling and information about the importance of testing contacts. ICs provided healthcare workers with information to reach their sexual contacts and consented verbally to home visits. Contacts were reached via phone or home visits and offered HIV testing at home or at the health facility.
Results: 60 ICs were enrolled in the pilot project, with 80% between 25-49 years. 67% were female. 131 contacts were identified: 64 sexual partners (37 primary partners), 48 children, 2 parents of child/adolescent ICs, and 17 other family members. Male ICs were more willing to provide information about their sexual partners. 50 contacts (38%) were HIV-positive: 30 sexual partners (47%), 8 children (17%), 2 parents of IC children (100%), and 10 other family members (59%). Linkage to HIV care and treatment was successfully documented in 42 (84%) HIV-positive contacts; 30 initiated ART (71.4%).
Conclusions: Contact tracing is an innovative strategy for testing persons at high risk of HIV infection and increasing the number of HIV-positive individuals diagnosed and linked to HIV care and treatment. Contact tracing should be offered to all ICs, although additional work may be necessary to increase future tracing of sex partners, who may be at highest risk.

TUPED1235

Pilot of a community-based hybrid HIV testing program as a strategy to saturate testing coverage in Western Kenya

H.-H.M. Truong[1], E. Akama[2], F. Otieno[2], D. Ogindo[2], E. Wandera[2], P. Ntwali[3], M. Guzé[3], S. Obabo[2], D. Bushman[3], K. Kadede[2], E.A. Bukusi[2], P. Oyaro[2], C.R. Cohen[3]
[1]University of California, Department of Medicine, San Francisco, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]University of California, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States

Background: Increasing access and uptake of HIV testing services (HTS) is a critical first step for linking individuals to prevention, care and treatment services. In 2015, Homabay County had the highest HIV incidence in Kenya and HIV prevalence was 4.5 times higher than nationally. We piloted a community-based "Hybrid" HTS program entailing community mapping, household census, multi-disease community health campaigns (CHCs) and home-based HTS.
Methods: The pilot was implemented in July-September 2016. HTS eligibility (not previously-diagnosed HIV-positive, age ≥15 years, sexually-active youth <15) and antiretroviral therapy (ART) initiation were based on 2016 national guidelines. Services provided at CHCs included HTS, and screening/referral for tuberculosis, malaria, hypertension and diabetes. Enumerated residents not attending CHCs were tracked to offer home-based HTS. Demographic factors associated with accepting HTS were assessed by multivariate logistic regression.
Results: The Hybrid program reached a total of 28,460 persons: 24,608 enumerated Rusinga and Lambwe residents, and 3,852 non-residents. There were 19,291 persons reached through CHCs (n=14,018) and tracking (n=5,273). Of the 11,352 HTS-eligible individuals, 9,487 (84%) accepted testing, of which 854 (9%) were first-time testers and 124 (1.3%) were newly-diagnosed with HIV. Persons ages 25-34 (aOR=0.86; p=0.047) and those with no prior testing history (aOR=0.23; p<0.001) were less likely to accept HTS. Among eligible residents, HTS was achieved in 76% of adults and 100% of children, yielding 94 new diagnoses. These new diagnoses represent 7% of total 1,336 HIV cases (newly- and previously-diagnosed) among residents attending CHCs or tracked. Sixty-one percent of newly-diagnosed persons identified at the CHCs initiated ART the same day as part of the campaign.
Conclusions: The Hybrid HTS program diagnosed Homabay County residents previously unaware of their HIV-positive status, thereby enabling linkage to care and same-day treatment and reducing onward transmission risk. The pilot was among the first programs in Kenya to implement new national guidelines of ART initiation upon diagnosis. The brief implementation timeframe limited the number of CHCs and duration of tracking activities. Increasing HTS uptake among individuals who never tested or potentially at-risk for infection remains challenging. Lessons learned from this pilot will inform future implementation of HIV testing approaches in sub-Saharan Africa.

TUPED1236

Participant reasons for not initiating antiretroviral treatment despite compelling evidence following early unblinding of the Strategic Timing of Antiretroviral Treatment (START) trial

C. Rappoport[1], S. Sharma[2], G.M. Corbelli[3], S. Meger[2], S. Collins[4], D. Munroe[5], S. Schwarze[6], P. Aagaard[7], M. Meulbroek[8], M. Turner[9], F. Gordin[10], INSIGHT START Study Group
[1]University of California, Division of AIDS, ID and Global Medicine, San Francisco, United States, [2]University of Minnesota, Division of Biostatistics, Minneapolis, United States, [3]European AIDS Treatment Group, Rome, Italy, [4]HIV i-BASE, London, United Kingdom, [5]INSIGHT Community Advisory Board, New Orleans, United States, [6]European AIDS Treatment Group, Berlin, Germany, [7]Copenhagen HIV Programme, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [8]Projecte dels NOMS-Hispanosida, Barcelona, Spain, [9]Washington DC Veterans Affairs Medical Center, Washington DC, United States, [10]Washington DC Veterans Affairs Medical Center, Washington, United States
Presenting author email: giuliomariacorbelli@gmail.com

Background: START, an international randomized clinical trial, investigated whether immediate initiation of antiretroviral treatment (ART) at CD4 cell counts > 500 cells/μL was superior to deferral until CD4 < 350 cells/μL or development of AIDS in terms of morbidity and mortality. After 3.0 years average follow-up, the data safety and monitoring board (DSMB) unblinded the study due to significant clinical benefit in favor of immediate ART initiation. The DSMB recommended that ART be offered to all participants in the deferred arm not yet on therapy. Despite the DSMB's recommendations, some participants elected not to initiate ART.
Methods: A case report form (CRF) was developed to capture why participants in the deferred arm declined ART. The CRF listed multiple possible reasons, and site staff completed the form following discussion with the participant. The CRF

was available over a 6-month period to allow sites time to contact participants and discuss the study results.
Results: Of the 4685 randomized participants, 2359 were in the deferred arm. At the time of unblinding in May 2015, 48% (1134) of the deferred arm were on ART; six months later, 454 (19%) participants were not known to have initiated ART and were requested to complete the CRF. Of these, 33% (148) reported not wanting to begin ART, 40% (181) elected to or had already initiated ART, and 28% (125) were not able to be contacted.
Of the 148 who declined ART the most common reasons were: not ready to begin ART (57%); high CD4 cell count (37%); low HIV viral load (20%); and, concern about side effects (19%). 40% of participants provided 2 or more reasons. Reasons were consistent across geographic regions.
Conclusions: In START, despite strong evidence of clinical benefit from initiation of ART at high CD4 cell counts, some participants were reluctant to begin ART. The most common reason reported was not being ready to begin ART, which indicates that patient approaches to treatment are more complex than clinical evidence alone. More effort is needed to fully understand why some individuals decline ART. Further study should investigate individuals' personal reasons for making treatment decisions.

Bridging the HIV treatment gap using a door to door strategy: experience from the community care program in Benue state Nigeria

F. Ogirima, R. Muhammed, G. Agada, P. Christopher Izere, I. Abutu, E. Udeh, P. Jwanle, M. Ashie, B. Ameh, J. Ujah, B. Oyeledun
Center for Integrated Health Programs, Abuja, Nigeria
Presenting author email: fogirima@gmail.com

Background: To close the HIV treatment gap and facilitate achievement of the UNAIDS 90-90-90 goal, there is need to decentralize HIV services. PEPFAR selected 32 high HIV burden local government areas (LGA) for scale up and saturation of HIV services in a 'test and treat' pilot. The Center for Integrated Health Programs (CIHP) an indigenous non-governmental organization, was mandated to scale up HIV services in 5 of the LGAs in Benue state. To increase antiretroviral treatment (ART) coverage we instituted a door to door initiative across 58 ward councils of the 5 LGAs.
Methods: CIHP mapped the existing HIV treatment clinics and communities within the wards. Door-to-door community care program (CCP) protocol was developed in line with the WHO 'test and treat' strategy. Integrated community engagement approaches were undertaken to get buy-in of the community gate keepers. Community care volunteers (CCVs), which included a pool of unemployed but certified community health extension workers, were engaged and trained to provide HIV services. From January-September 2016, door to door HIV testing were conducted by groups of 3-4 CCVs and newly diagnosed HIV positives started on ART using the 'test and treat' strategy, then linked to the clinics for follow up. Newly diagnosed HIV positive persons were screened for tuberculosis and presumptive cases referred to the clinics. Contact tracing systems were instituted to enhance completion of referrals. Programmatic oversight was provided by trained LGA officials and CIHP technical staff.
Results: Seventy four percent of the communities (1,192/ 1,603) were reached in 9 months of intervention. 385,534 (48% males and 52% females) were tested for HIV and 90% (4,191/ 4,656) of HIV positive started on ART by the CCVs. 93% (3,912/ 4,191) of those initiated on ART were successfully linked to the clinics for follow up HIV care services. 88% (1,647/ 1,870) of the patients linked to the clinics remained in care 6 months post ART initiation.
Conclusions: The door-to-door CCP is a feasible way to take HIV services to underserved communities and bridge the HIV treatment gap. However targeting high risk populations will increase the efficiency of door to door HIV testing.

TUPED1238

Tracking lost to follow-up patients for ART initiation after the introduction of test and start in the North of Haiti

V.A. Francois
Jhpiego, HIV/TB, Cap-Haitian, Haiti
Presenting author email: valerie.francois@jhpiego.org

Background: The incidence of HIV in Haiti is among the highest in the Caribbean but has decreased in the past decade from 6.6% to 2.2%. Despite great progress in the HIV response, retention in care is a national concern as many people living with HIV (PLHIV) are considered lost to follow up (LTFU). In 22 health facilities in northern Haiti supported by MCSP-SSQH/USAID, only 25% (4773) of PLHIV enrolled in care were receiving ART in July 2016. The launch of Test and Start that same month prompted improved efforts between July-September 2016 to track HIV patients LTFU and support them to be initiated on ART.
Methods: A tracking tool was developed and airtime/transportation fees were provided to community health workers/Peer Educators to actively search for and bring back those patients.. The total number of patients active in care and number of clients who were LTFU were inconsistent, and a triangulation between pharmacy, EMR and appointment book registries was necessary. LTFU was defined as patient that missed more than 3 visits. The list of clients who were LTFU was updated weekly as patients returned to the clinic.
Results: As of September 2016 a total of 1182 HIV patients were active in care and 1354 were LTFU. 836 (62%) of patients LTFU had been contacted through phone calls or home visits.225 (27%) were found, and more than 209 (25%) returned for treatment. We were unable to trace 81 patients due to absence of contact information, and the remaining had reportedly travelled to nearby countries in the Caribbean for economic reasons.
Conclusions: In light of the new policy to treat all PLHIV, it is critical to ensure HIV clients who are already in care but were LTFU are re-engaged in care and initiated on ART. Additional efforts are needed to track those clients and reintegrate them back into care to contribute for epidemic control.

TUPED1239

Role of support persons in adolescent and youth voluntary counseling and testing for HIV

J. Neary[1], A. Wagner[2], C. Mugo[3], P. Maingi[4], D. Bukusi[4], G. John-Stewart[1,2,5], D. Wamalwa[6], P.K. Kohler[2,7], J. Slyker[1,2], DASH Team Study Group
[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Nairobi, Nairobi, Kenya, [4]Kenyatta National Hospital, Nairobi, Kenya, [5]University of Washington, Medicine & Pediatrics, Seattle, United States, [6]University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya, [7]University of Washington, Department of Psychosocial and Community Health, Seattle, United States
Presenting author email: anjuliw@uw.edu

Background: HIV incidence and mortality are high in adolescents and youth (AY), but testing rates remain low. Understanding how support persons influence HIV testing decisions of AY may improve the uptake and quality of testing.
Methods: AY aged 14-24 seeking HIV testing in Nairobi, Kenya completed a post-test survey which assessed the role of support persons in HIV testing. Correlates were evaluated using chi-square tests and multivariate relative risk regression.
Results: Among 1,062 AY, median age was 21 (IQR: 19-23); 306 (29%) were younger (14-19 years), and 756 (71%) were older (20-24 years). Overall, 12.4% reported their decision to test was influenced by a parent, 20% by a partner, and 22% by a peer. Older AY were more likely than younger AY to be influenced to test by partners (23% vs 12%, p<0.001), and less likely by parents (7% vs 27%, p<0.001), health care workers (11% vs 16%, p=0.048), or counselors (9% vs 19%, p<0.001).
Half of AY were accompanied for HIV testing (10% with parent, 11% partner, 23% peer, 4% others, and 2% with multiple types). Support persons were involved in all aspects of testing: 57% were present for pre-test counseling, 64% for finger prick/blood draw, 33% in disclosure of results, and 33% for post-test counseling.
Older AY were more likely than younger AY to present alone (58% vs 32%, p<0.001) or with a partner (12% vs 7%, p<0.001), and less likely to present with a parent (2% vs 31%, p<0.001). Similar proportions of younger and older AY came with a peer or in a group.
Correlates of presenting with a support person included: younger age (RR=1.63 [95%CI=1.37-1.94]), female sex (aRR=1.45 [95%CI=1.21-1.73]), and school enrollment (RR=1.43 [95%CI=1.07-1.92]). Accompanied and unaccompanied AY had similar HIV transmission and prevention knowledge and similar proportions previously tested for STI (p>0.05).
Conclusions: Support persons play an important role in Kenyan AY's HIV testing experience, however support person involvement may vary with age. Leveraging AY support persons may provide interventional opportunities to enhance the uptake and quality of HIV testing for this population.

TUPED1240

Determinants of voluntary HIV testing among female sex workers and men who have sex with men in India: a cross-sectional study

P. Mathew[1], E. Daniel[1], N. Raghunathan[2], S. Kumar[3], S. Karkal[4], P. Patel[5], S. Shyam[1]
[1]Swasti Health Resource Centre, Monitoring, Evaluation and Learning, Bangalore, India, [2]Catalyst Management Services, Bangalore, India, [3]Swasti Health Resource Centre, Bangalore, India, [4]Swasti Health Resource Centre, Sexual Reproductive Health and Rights, Bangalore, India, [5]Catalyst Management Services, Monitoring, Evaluation and Learning, Bangalore, India

Background: Regular HIV testing plays a critical role in the HIV prevention effort. Regular testing is not only an indicator of heightened awareness of one's HIV status but also a gauge to assess ownership of his/her own sexual health. However regular HIV testing among High-Risk groups (HRGs) fails to take precedence in certain settings. This study investigates factors associated with HIV testing among FSWs and MSM in the AVAHAN phase-3 project areas in South and Western India.
Methods: A Systematic survey was conducted by field workers in their respective intervention areas using existing lists available with CO and TI and Snow balling technique.The Cross-sectional study was conducted during April - September 2015. It covered 109,366 FSWs and 8594 MSM in the five high-risk states of India. Socio-demographic characteristics, sex work related factors and community involvement were used as independent variables. Outcome indicator used was HIV testing at least twice a year. Multiple regression analysis was applied which was stratified based on the type of HRG.
Results: The Study revealed poor HIV testing behavior among both FSW and MSM groups approximately 63% and 62% respectively. Factors negatively associated with HIV testing among FSW and MSM groups included Younger age(< 25 years), Low monthly income (< 5000Rs), living with parents or alone and alcohol consumption. Factors such as increased years in sex work, higher client load per week were positively associated. Increased involvement with a community organization was strongly associated with testing as per the norm in both FSW AOR (1.464, CI (1.422-1.508) and MSM AOR (2.76, CI (2.37-3.20). FSWs who frequently changed the site of sex work were more likely to go for tests. In contrast among MSM, HIV testing was higher among those who had never changed the place of sex work.
Conclusions: Regular HIV testing among HRGs remains dismal. Special attention needs to be paid on actively engaging with the younger and newer entrants into commercial sex work. Addressing alcohol use among HRGs will be an essential component to consider in the HIV prevention program. The study clearly reiterates the potential of community organizations in improving voluntary testing.

TUPED1241

Improving access to HIV testing among hard to reach and hidden sex workers in India: will uptake of HIV test increase if testing services are provided at the door-step?

S. Godbole[1], A.V. Kadam[2], S. Deshpande[3], A. Lokhande[1], S. Karkal[4], R. Gangakhedkar[1]
[1]National AIDS Research Institute (ICMR), Pune, India, [2]ICMR-National AIDS Research Institute, Department of Health Research, Ministry of Health and Family Welfare, Bhosari, Pune, India, [3]Consultant, Pune, India, [4]SWASTI, Bangalore, India
Presenting author email: akadam@nariindia.org

Background: To meet the first UNAIDS 90-90-90 target; India, with a low-level, concentrated but high-burden HIV epidemic, needs to focus on testing most-at-risk populations, who are least likely to test. India's updated National guidelines (Dec 2016) for HIV Counseling and Testing Services (HCTS), provide an enabling environment for novel interventions. We conducted a rapid field-assessment in a high-burden state in western-India, to explore needs, develop and understand feasibility of a community-based HIV testing (CHT) model among female sex workers (FSWs) as a new intervention to "test the untested".
Methods: Between June-September 2016; 3 group-discussions (GD) with FSWs in Kolhapur (urban), Ichalkaranji (semi-urban) and Gadahinglaj (rural) and 2 among Government Integrated Counseling Testing Centre (ICTC) staff and FSW-peers from Targeted Intervention (TI) sites were held. GDs were taped after seeking consent.
Results: Most FSW "accepted" the importance of HIV testing. Urban, semi-urban and rural FSWs availed public-facility based HCTS differentially. Although urban-FSWs, living elsewhere and working in the city, reported high levels of bi-annual HCTS in public-facilities; the testing was primarily driven by ‚peers' from TI programs. Semi-urban FSWs were less likely to access ICTC in public-facility due to "fear of recognition" and all knew many "hidden/secret" FSW who neither interacted with TI nor got tested. Secretive-FSW from less-populous rural areas, said that attending the "highly publicized" ICTC at rural-hospitals, was potentially stigmatizing and a deterrent to testing. All expressed a strong need for community-based anonymous opportunities for screening and opined that "if we are healthy, we can serve better". FSW accepted trained-peers providing pre-HIV-test education; but would not accept a ‚trained-peer' to perform the HIV screening test in the community.
Conclusions: FSW continue to remain less likely to self-initiate conventional HIV-Testing, especially at public facilities, even in the urban ambience offering anonymity. Secretive semi-urban and rural FSWs are less likely to access government HCTS and strongly favor anonymous community-based testing services.These data have helped develop a CHT model, leveraging the local networking of secretive-FSW, to provide anonymous HIV-screening opportunities at conveniently timed, small social-gatherings to "reach the unreached and test the untested" FSWs in rural areas. A demonstration study is planned in 2017-18.

A user costs analysis for HIV testing among rural communities in Malawi

L. Sande[1], C. Mangenah[2], L. Mwenge[3], H. Maheswaran[4], M. Neuman[5], C. Johnson[6], P. Indavudh[1], M. d'Elbée[5], K. Hatzold[7], L. Corbett[5], F. Terris-Prestholt[5]
[1]Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [3]Zambart, Lusaka, Zambia, [4]University of Warwick, Conventry, United Kingdom, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]World Health Organisation, Geneva, Switzerland, [7]Population Services International, Harare, Zimbabwe
Presenting author email: cmangenah1@gmail.com

Background: HIV prevalence remains high in Malawi, with adult rates of infection at 9% and high testing gap among men. Even if no user fees are charged, direct and indirect user costs of attending health services are increasingly recognized as a barrier to access. We estimated user costs in terms of direct costs, such as transport, and indirect costs such as lost income and child care costs of accessing HIV testing in rural Malawi as part of the HIV Self-Test Africa (STAR) project and analyzed their key determinants.
Methods: A baseline household survey was conducted in southern Malawi as part of a cluster randomized trial of HIV self-testing. The questionnaire was administered to adults (15-49 years) of randomly selected households (n=5,556), of which 25% were randomly allocated an extended HIV testing questionnaire (n=1,387). Further, the respondents who reported having at least one HIV test in the preceding 12 months (14%) completed a module on costs associated with their last test (n=749). To estimate the impact of user and service level characteristics on patient expenditures, while accounting costs being censored at $0, a Tobit model was applied.
Results: Fifty-nine percent of respondents had previously accessed HIV testing at a health facility, 29% reported no user costs. Of those reporting costs, the median cost was $2.08: $2.98 for men and $1.39 for women. Both user and service characteristics were important drivers of costs. Overall, individuals who tested at health care facilities spent twice as much as those who tested within their communities (mobile clinic) with each additional hour spent at the facilities leading to an average of 24% increase in user costs, ceteris paribus.

[Regression Results]

Conclusions: Observed user costs in rural Malawi were significant, approximately equal to 154% of average daily earnings. This financial burden may provide insights into the existing HIV testing gap, particularly among men.

TUPED1243

Normalizing HIV testing to reach the first 90: PITC at clinic reception - Zambezi NAPPA Clinic, Namibia

T. Chakare[1], M. Strachan[2], A. Christensen[3]
[1]Jhpiego, Windhoek, Namibia, [2]Jhpiego, Washington, United States, [3]Jhpiego, Dar es Salaam, Tanzania, United Republic of
Presenting author email: tafadzwa.chakare@jhpiego.org

Background: An estimated 28% of people with HIV in Namibia do not know their HIV status and provider-initiated testing and counselling (PITC) is one of several strategies to achieve UNAIDS 90-90-90 goals. Namibia Planned Parenthood Association (NAPPA) operates a clinic in Zambezi region, offering sexual and reproductive health (SRH) services targeted at adolescents and young people. The majority of clients are women and girls seeking family planning and HIV Testing Services (HTS). Despite efforts to boost provider initiation, HTS was largely client-initiated with low uptake and frequent retesting. It failed to reach highest-risk individuals including adolescents.
Methods: In December 2015, PITC was integrated into the clinic registration process for all clients, in an effort to improve HTS uptake and increase case finding. Clients receive group pre-test information, then individually proceed to a private room for registration procedures including blood collection via finger prick. HIV results are given individually along with the services originally sought. Waiting times are the same for all clients, including those who opt out of HIV testing. Clients with negative results in the past 12 months were only retested if they insisted. Data from HTS monthly reports was reviewed, comparing six pre-intervention months (June-November 2015) to the six post-intervention months (December 2015-June 2016). There was no HTS in April 2016 due to test kit unavailability.
Results: In comparison to the pre-intervention period, the post-intervention months showed a remarkable increase in the total number of HIV tests conducted (1211 vs 571), number of provider initiated tests (661 vs 117), number of first time testers (634 vs 276) and most importantly, the number of positive results (119 vs 72). There was a small increase in the number of males tested (212 vs 181). However, a lower positivity yield (9.8% vs 12.6%) was recorded post-intervention. While there was an overall 210% increase in HTS uptake post-intervention, the greatest increase (302%) was observed among persons aged 15-19 years.
Conclusions: Integrating PITC to standard clinic registration process remarkably increased HTS uptake and HIV case finding among SRH clients. The prominent impact observed among middle and late adolescents suggests an added adolescent appeal.

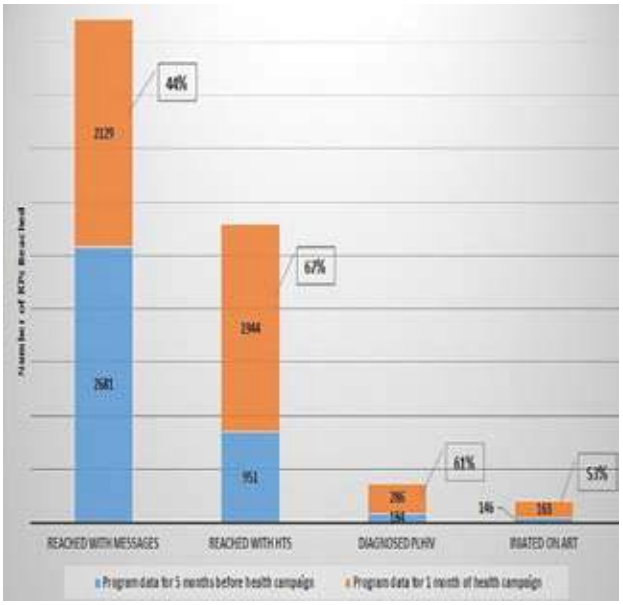
TUPED1244

Targeted health campaign for key populations improves access to HIV testing and initiation on antiretroviral therapy (ART) in Botswana

M.D. Seretse[1], M. Merrigan[1], V. Ranebennur[2], M. Gilbert-Lephodisa[1], W. Dikobe[1], C. Akolo[3], S. Gaosenkwe[1]
[1]FHI 360, Gaborone, Botswana, [2]FHI 360, Mumbai, India, [3]FHI 360, Washington, United States
Presenting author email: mseretse@fhi360.org

Background: The traditional hot-spot based outreach approach often used to reach key populations (KPs) - including men who have sex with men and female sex workers - with HIV prevention interventions has resulted in low uptake of HIV testing and low positivity yield because of limited penetration of KP networks.
To improve access to new KP networks and increase uptake of HIV testing services (HTS) and ART services by KPs, the USAID- and PEPFAR-funded LINKAGES project conducted a 1 month KP health campaign in the 4 LINKAGES Botswana districts.
Methods: The campaign used social network strategy (SNS), a respondent-driven sampling, to find KPs and link them to clinical services. The strategy used an initial purposive selection of 39 peer outreach workers and mobilizers/recruiters as 'seeds', who were each given 4 referral coupons to share with members of their social networks. When KP members presented with a coupon, they were enrolled in the program, received phone airtime incentive (approximately $10), received a basic package of clinical services, and were given coupons to recruit other KPs. A small airtime incentive was also provided to the recruiter for each KP successfully referred to the campaign site.

Results:



[Campaign results vs project results]

In the 5 months of project implementation prior to the campaign, 951 KPs were tested for HIV and 146 were initiated on ART. During the campaign, 1944 KPs (1665 FSW and 279 MSM), newly tested for HIV. 163 (155 FSW and 8 MSM) were initiated on ART. Incomplete referrals were limited as comprehensive services were available in one spot.
Conclusions: The combination of SNS-based health campaign and same-day service provision increased coverage and uptake of HTS, identified more KPs living with HIV, and improved linkage to ART services among KPs in Botswana. SNS has proven to produce results and other KP focused programs can implement it.

Saved by angels: a SHIPS for MARPS approach for partner notification services (PNS)

S. Isigbo[1], M. Ojo[2], O. Agwagah[3], C. Ndukwe[4], B. Abusaeed[5], S. Molokwu[6], R. Ugbena[2], S. Ikani[2], S. Faruna[2], S. Iwuagwu[7]
[1]Centre for the Right to Health-CRH, Monitoring and Evaluaion Unit, Abuja, Nigeria, [2]Society for Family Health, Monitoring and Evaluation Unit, Garki, Nigeria, [3]Society for Family Health (SFH), Program Management, FCT, Nigeria, [4]Society for Family Health, Program Management, Garki, Nigeria, [5]Society for Family Health, Community Intervention, Garki, Nigeria, [6]Centre for the Right to Health, Community Intervention, Garki, Nigeria, [7]Centre for the Right to Health-CRH, Program Management, FCT, Nigeria
Presenting author email: ugosylvia56@yahoo.com

Background: Partner Notification Services is the act of notifying the sexual partner(s) of a MARP, known as the "index case", who has been newly diagnosed with HIV. It involves contact tracing and index testing of the MARPs partners. In response to the UNAIDS 90:90:90 objective, the SHIPS for MARPs project adopted an index testing strategy into its program implementation in order to ensure that the first and second 90 objective is achieved.
Methods: Once a MARP is tested positive during HIV Testing Services, s/he is provided with post counseling during which their disclosure plan is discussed. The moment the MARP declines or presents fear of status notification to partners due to Intimate Partner Violation, partners Contacts and best time of partner availability are elicited while s/he is linked to the One Stop Shop (OSS) for further management. Cluster testing is conducted in the spots/neighborhood at the times provided by the MARP. Upon identification of the INDEX case, disclosure plan is equally discussed and if the Index client decline, same process is followed.
Results: The project commenced Partner Notification Services in quarter 3 of the Fiscal Year16. The table below shows her progressive achievement in HTS and ART through PNS only;

INDICATOR	QTR 3	QTR 4	QTR 1, FY17
No of elicited partners tested	226	525	413
No of elicited partners tested positive	21	54	219
No of elicited partners enrolled on ARV	1	27	212

[PNS Result]

Conclusions: Great effort and emphasis should be laid on cluster testing for Partner Notification Services as it has proved effective in reducing incidence/cases of Intimate Partner Violation, improved MARPs early knowledge of their status and initiation on treatment (ART) as well as enhanced level of confidence bearing.

TUPED1246

The use of risk-tracking snowball approach to increase HIV testing and HIV case detection among hard-to-reach individuals at higher risk of HIV infection

S. Chhim[1], J. Macom[2], C. Pav[1], N. Nim[1], P. Yun[3], S. Tuot[4]
[1]FHI 360, Phnom Penh, Cambodia, [2]FHI 360, Bangkak, Thailand, [3]Chhouk Sar Association, Phnom Penh, Cambodia, [4]KHANA, Phnom Penh, Cambodia
Presenting author email: tsovannary@khana.org.kh

Background: This implementation study is to tests whether a Risk Tracing Snowball approach (RTSA) at Non-Governmental Organization (NGO) clinics result in a higher testing and HIV detection rate than among people walked in.
Methods: Between March and August 2016, at two NGO clinics in Phnom Penh Cambodia, RTSA adopted from respondent driven sampling was used to reach hard-to-reach individuals at higher risk of HIV infection. All clients who presented for HIV testing and counselling services, were given the opportunity to be seeds who will recruit other high-risk individuals to get tested for HIV. If recruited individuals presented at either HIV NGO clinic with a valid coupon, screened as being "at risk" for HIV infection, and completed HIV testing, their seeds received $2.5 USD compensation. Recruited individuals were then given the same opportunity as initial clients to be recruiters. Study participant criteria were everybody who came for HIV testing—general population, men who sex with men, transgender women, and female sex workers—and aged 18 years or older, and never tested for past three months. Simple descriptive analysis was used to examine client's type of population, referral network, and study outcome (rate of newly identified HIV positive).
Results: During the implementation period, 2,293 HIV tests were conducted at these two clinics—721 walked-in clients, and 1,572 clients referred by seeds/recruiters. Among tests conducted, newly HIV identified positive via RTSA was lower than walked-in clients (1.8% vs. 3.2%, p-value=0.002). However, the number of total HIV cases were increased compared to the same six-month period prior RTSA implementation (32 vs 52). Also, the rate of newly identified HIV positive cases among those recruited in RTSA were about six times higher than the rate among 35,398 tests of key populations tested by outreach workers at community in 2016 (1.8% vs. 0.6%, p-value <0.001).
Conclusions: RTSA was a promising alternative approach to increased HIV testing uptake (surplus on the routine HIV test), but not increased the newly identified HIV positive rate. However, the HIV case detection rate in RTSA is still an acceptable rate, given the low HIV case detection rate among key population tested by outreach workers at community.

TUPED1247

Making mobile HIV testing available for high-risk MSM in saunas

P. Krisintu[1], M. Avery[1], T. Sattayapanich[1], A. Arunmanakul[1], S. Janyam[2], D. Linjongrat[3]
[1]FHI 360, USAID LINKAGES Project, Bangkok, Thailand, [2]Service Workers in Group (SWING), Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand
Presenting author email: pkrisintu@fhi360.org

Background: Men who have sex with men (MSM) account for roughly half of all new HIV infections in Thailand, but only 1/3 of HIV-positive MSM know their status, which limits the potential impact of HIV treatment as prevention. We aimed to improve testing uptake and HIV case finding in Bangkok, Thailand by offering on-site HIV testing in saunas where high-risk MSM gather to seek partners and engage in sex on the premises.
Methods: Community-based organizational partners identified 4 high-volume men's saunas and, with the support of the venue owners, provided venous blood-based, rapid mobile testing at each venue once per month, following a three-test confirmatory algorithm. Uniformed outreach workers recruited clients in the public areas of the sauna, and a private space was set aside for counselors and laboratory specialists. Standard operating procedures (SOPs) were developed to ensure that mobile testing met quality guidelines, protected clients' confidentiality and did not interfere with sauna operations. All clients were registered and tracked with a Unique ID Code.
Results: From July-December 2016, community partners conducted 20 sauna testing sessions at 4 saunas and tested 224 clients, finding 36 new HIV-positive cases (16.1%), compared to an 10.6% yield for all facility-based testing clients in Bangkok during the same period. 8 clients (22%) were successfully referred to ART services and initiated ARV treatment. 30 clients were screened syphilis reactive using a TPHA rapid syphilis screening test (19 of whom were also HIV-positive); however, only 7 were successfully referred for VDRL confirmation and treatment. Sauna-based testing clients included a higher-than-usual proportion of migrant and non-Thai individuals who were less open to follow-up by community-based organizations.
Conclusions: Sauna-based HIV testing was more accepted than originally anticipated by sauna owners and patrons, though existing SOPs should be modified to accommodate a higher volume of clients with restricted time and space. Elevated seropositive rates indicate testing in these venues access higher-risk subpopulations of MSM. However, ensuring successful referrals to both ARV and STI treatment are significant challenges. Where sauna-based testing is supported, care and support staff should be integrated into the mobile testing team, with rigorous follow-up protocols.

Comparison of testing of index-case networks with outreach in community hotspots for identification and linkage of HIV-positive clients into care

K.P. Nyalali[1], L. Mphuru[1], J. McMahan[2], C. Viadro[2], D. Nelson[2], J. Wesson[3], D. Mbilinyi[4], K.J. Kazaura[4]

Presenting author email: jwesson@intrahealth.org

Background: Despite aggressive global targets to raise awareness about HIV status among 90% of people living with HIV (PLHIV), HIV testing and counselling (HTC) interventions have not reached most of this group. Tanzania's country operation plan (2014) showed that only 4.3% of PLHIV were being identified through facility-based HTC outlets. In 2016, with CDC funding, IntraHealth International piloted and compared two community-based HTC approaches: 1) Outreach in community hotspots, and 2) home-based index-case testing.
Methods: HTC and treatment databases and participatory social mapping with local leaders were used to identify high transmission areas and social networks. Outreach in community hotspots targeted people with high-risk behaviours for testing with their consent, while the index-case approach started with known HIV-positive clients, contacted by service providers for linking up with their social networks. Individuals who tested HIV-positive were offered an escort for clinic follow-up and enrolment into care and treatment.
Quarterly service data were used to analyse trends in HTC service uptake and enrolment of HIV-positive clients into treatment. Using Excel, manual calculations generated the proportion of clients as well as enrolment rates by service delivery model, age, and sex.
Results: Both community-based approaches were acceptable, but home-based testing of index-case networks was more logistically feasible in urban and semi-urban versus rural settings. Overall, the hotspot approach allowed four times more clients to be tested (117,511) than the index-case approach (27,827).
However, home-based testing of index-case client networks was more sensitive in identifying HIV-positive clients (7.6% of those tested) than testing in hotspot areas (4.3%). Outreach in homes with people sick for unidentified reasons was better for reaching children below 15 years and couples who had never been tested. Both models were effective in enrolling clients into care (82%), but slightly more index-case clients were enrolled into care (79%) compared to individuals in hotspot areas (72%).
Conclusions: Both community approaches are promising to reach people outside clinics for HIV testing, but the index-case approach may be more sensitive in identifying HIV-positive clients.

HIV care & support program review for India: longitudinal trends in enrolment for antiretroviral therapy (ART)

M. Bamrotiya[1], R.S. Gupta[1], Y. Bansal[2], V. Purohit[3], P. Goyal[2], K. Sharma[2], S. Sinh[1], R. Rana[4], N. Garg[1]
[1]National AIDS Control Organization, New Delhi, India, [2]Clinton Health Access Initiative, New Delhi, India, [3]Independant Public Health Consultant, New Delhi, India, [4]Former National AIDS Control Organization, New Delhi, India
Presenting author email: bamrotiya.manish@gmail.com

Background: The Indian ART program began in 2004 and has grown from 8 to 528 ART centers. It has enrolled approximately 2 million patients and currently provides care to 1.2 million people. Access to treatment has been increased by adopting mul-

tiple strategies like scale-up of treatment centres, revision of national guidelines as per international recommendations, awareness creation activities etc. This paper seeks to
(a) quantify the changes in program performance over time for metrics enumerated below and
(b) evaluate demographic factors that may impact these metrics in order to assist the programme in formulating future strategizing.
Methods: A retrospective analysis was conducted on program data comprised of 15,40,133 (out of 18,01,678) adults (>15 years old) registered into care from January 2004-September 2015 in 519 government ART centres with complete patient records. The annual movement in
(a) patient registrations,
(b) CD4 count at registration,
(c) ART initiations, and
(d) time to ART initiation after registration for eligible patients were evaluated. Eligible patients were defined as patients who were eligible for ART initiation (as per prevailing ART guidelines) at registration based on their CD4 count.
Results: Annual patient enrolments increased from 37,849 in 2005 to 2,03,747 in 2014. Median CD4 counts at registration increased from 165 cells/mm^3 in 2005 to 253 cells/mm^3 in 2015 and proportion of patients presenting with CD4 counts greater than 350 cells/mm^3 increased from 21% to 35%, including 19% with >500/cmm. For all years analysed, it was observed that older and male patients registered with lower median CD4 counts than younger and female patients. 80% (6,93,057) of the 56% (8,68,010) eligible patients were initiated on ART. The proportion of eligible patients initiated increased from 73% to 85% while their median time to initiation decreased from 16 to 6 days.
Conclusions: The program has been successful in diagnosing and treating patients considerably earlier. However, a large proportion of patients still register at a later disease stage (CD4< 350) and males more often than females, necessitating customised strategies and deeper evaluation of causal social factors that needs to be considered before Test and Treat.

[1]Pangaea Global AIDS, Strategic Information Unit, Harare, Zimbabwe, [2]International Training and Education Center for Health, University of Washington Department of Global Health, Seattle, United States, [3]U.S. National Institutes of Health, Fogarty International Center, Bethesda, United States, [4]U.S. Centers for Disease Control and Prevention (CDC), Harare, Zimbabwe, [5]International Training and Education Center for Health (ITECH), University of Washington Department of Global Health, Seattle, United States, [6]International Training and Education Center for Health (I-TECH), University of Washington Department of Global Health, Seattle, United States, [7]Ministry of Health and Child Care, AIDS and TB Program, Harare, Zimbabwe, [8]Zimbabwe Association of Church Related Hospitals (ZACH), HIV Care and Treatment Program, Harare, Zimbabwe, [9]Zimbabwe Association of Church Related Hospitals, HIV Care and Treatment Program, Harare, Zimbabwe
Presenting author email: peter.kilmarx@nih.gov

Background: Provider-initiated HIV testing and counselling (PITC) and linkage to care are key interventions towards UNAIDS' 90-90-90 objectives in Zimbabwe. A facility-based PITC model was implemented at 3 mission hospitals, deploying dedicated nurse counsellors to offer HIV testing to patients in hospital outpatient departments (OPDs). An "OPD HIV testing tracking tool" was administered from October 1, 2015, to July 31, 2016, capturing clients > 18 years of age attending the OPD, with known HIV-positive status or eligible for testing, the proportion tested, positives identified and linked into care.
Methods: Summary descriptive statistics were used to report the HIV test acceptance and linkage rates, comparing average number of tests performed and positives identified 12 months before and after PITC implementation. Forty-two qualitative interviews were conducted with health care providers, adult clients who declined testing, and key stakeholders. Interviews were thematically analysed to assess respondents' experiences.
Results: Of the 6,951 clients attending OPD and not in OI/ART care we tracked, 95.3% (6,621) accepted HIV testing, with 631 (9.5%) testing positive, and 617 (97.8%) being linked to care. The average number of HIV tests performed per month at the 3 facilities increased from 623 (SD=134.6) in the 12 months prior to introducing PITC, to 1,009 (SD=246.8) in the 12-month period post PITC initiation (p <0.0001). The average number of positives identified per month also increased from 73.8 (SD=13.8) to 89 (SD=19.2), (p=0.0363). Themes from qualitative analysis suggested that primary reasons for refusing testing included patients' preference to consult with partner first, not feeling ready, or the perception that they were not at risk.

Facility performing HIV tests	Pre-PITC Mean (±SD)	Post-PITC Mean (±SD)	Mean Difference	p-value
Makonde Mission Hospital	182.8 (48.8)	336.2(77.9)	153.4	<.0001
St. Paul´s Mission Hospital	182.1 (80.5)	324 (112.7)	141.9	0.0018
St. Luke´s Mission Hospital	258.3 (118.4)	349 (150.6)	90.7	0.1149
Total	623 (134.6)	1,009.2 (246.8)	386.2	<.0001
Facility identifying HIV-positives	Pre-PITC Mean (±SD)	Post-PITC Mean (±SD)	Mean Difference	p-value
Makonde Mission Hospital	22.75 (7.7)	27.3(6.9)	4.55	0.1394
St. Paul´s Mission Hospital	23.8 (2.6)	29.5 (2.67)	5.7	0.144
St. Luke´s Mission Hospital	27.2 (12.5)	32.2 (13.4)	5	0.354
Total	73.8 (13.9)	89 (19.2)	15.2	0.0363

[Average number of tests performed and positives id]

Conclusions: Strengthening PITC resulted in a 62% increase in testing, 21% increase in positives identified and a 97.8% linkage rate. Programs to increase PITC coverage in OPD departments can play a role in reaching UNAIDS´ 90-90-90 objectives in Zimbabwe.

Values and preferences of adolescent girls and young women in Kenya for three HIV prevention approaches: PrEP, HIV self-testing and HIV partner notification

F.A.A. Anam[1], R. Matheson[2], C. Payne[3], C. Figeroa-Guerrero[3], F. Koechlin[3], S. Dalal[3], M. Rodolph[3], C. Johnson[3], R. Baggaley[3], M. Happy[4], D. Chihenyo[4], C. Opiyo[4]
[1]The International Community of Women Living with HIV (ICW), Advocacy and Communication, Nairobi, Kenya, [2]The International Community of Women Living with HIV, Advocacy and Communication, Nairobi, Kenya, [3]World Health Organization (WHO), Geneva, Switzerland, [4]International Community of Women Living with HIV (ICW), Nairobi, Kenya
Presenting author email: advocacy@iamicw.org

Background: Adolescent girls and young women are especially vulnerable to HIV infection in high prevalence settings, underscoring the need to ensure the acceptability and accessibility of HIV testing and preventative services among this population. This study explores the values and preferences of adolescent girls and young women in Kenya for PrEP, HIV self-testing and partner notification.
Methods: This mixed methods study was conducted in five high HIV prevalence counties in Kenya (8.6%-27.1%): Homabay, Siaya, Kisumu, Mombasa and Nairobi. Females 18-24 years old were eligible for the study. Participants were recruited through national and county networks of PLHIV, youth groups, sex workers and PWID. Data was collected from structured questionnaires and focus group discussions (FGDs). FGDs were conducted in a mix of health facilities and community sites. Standard thematic analysis was applied to qualitative transcripts.
Results: 489 adolescent girls and young women participated in structured questionnaires and 240 participated in 20 FGDs. Prior to the study, less than half of all participants had heard of PrEP, HIV self-testing or partner notification. However, respondents reported that all three approaches were acceptable for preventing HIV or learning your HIV status. 59% of respondents felt at risk for HIV. 89% had previously tested for HIV. 49% of 18-19 year-old participants and 29% of 20-24 year-olds did not know their partners' HIV status. 11% of participants reported previously using PrEP. Participants discussed possible adherence challenges for PrEP. It was also observed that many participants confused PrEP with PEP. Lack of confidentiality at health facilities was considered a barrier to accessing services. Participants felt HIV self-testing would provide much-needed privacy. However, some participants worried about forced testing, increased risk behaviors and the potential for oral HIV self-tests to revive misconceptions that HIV is spread through saliva. Partner notification was largely seen as beneficial for both partners to know their status and support each other to access treatment, but there were concerns it could influence household breakups.
Conclusions: Adolescent girls and young women in Kenya had overall positive perspectives on PrEP, HIV self-testing and partner notification. Supportive, confidential service delivery could improve uptake of HIV prevention approaches for this population.

Men are absent across the HIV continuum of care in a rural area of southern Mozambique

L. Fuente-Soro[1,2], E. López-Varela[1,2], O. J. Augusto[1], C. Sacoor[1], A. Nhacolo[1], E. Bernardo[1,3], E. Karajeanes[4], P. Vaz[4], D. Naniche[1,2]
[1]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [2]Barcelona Institute for Global Health (ISGLOBAL), Barcelona, Spain, [3]Manhiça District Health Services, Manhiça, Mozambique, [4]Fundação Ariel Glaser Contra o SIDA Pediátrico, Maputo, Mozambique
Presenting author email: laura.fuente@manhica.net

Background: Loss-to-follow up (LTFU) along the HIV continuum of care leads to increased morbidity and mortality which is not distributed equally by gender. In sub Saharan Africa (SSA), the female-male gap in adult life expectancy has nearly doubled since the scale-up of antiretroviral treatment (ART) in 2004. Although the incidence of new HIV infections is higher in women in SSA, mortality is higher in men.
Methods: Between May 2014 to June 2016, a prospective cohort study conducted in the Manhiça District Health Demographic Surveillance System (HDSS) in southern Mozambique consecutively enrolled 1,122 adults with a first positive HIV result from three testing modalities: voluntary and provider initiated (VCT and PICT) and home based testing (HBT). Linkage and retention data was extracted from clinical charts and demographic data from the HDSS database.
Results: Of the new HIV diagnoses, 43.9% were male with a median age of 33 years. The proportion of males among total clients was higher in PICT and HBT as compared to VCT (39.1%, 34.1% and 26.2% respectively, p=0.05).
However, in a random sample of 10,897 households visited for HBT, men were 3 times more likely than women to be absent from the household (p<0.01) and 1.2 times more likely to have emigrated (p<0.01). Furthermore, the acceptance of HBT was significantly higher in women (84%) than in in men (77%) (p<0.01).
After initial linkage to care, men were twice as likely to be in WHO stages III/IV at first visit (p<0.01) and the median CD4 count was lower (209 vs. 281 c/μL, p=0.03). Of those initially ART eligible, a similar proportion of men and women initiated treatment (81 and 86%, respectively). Both had similar odds of LTFU at pre-ART stage but women were more likely to be retained in ART after 12 months (82.5% vs. 69.9%, p<0.01).
Overall 12 month mortality was almost twice as high in men as compared to women (5.9% vs. 3.2%, p=0.03).
Conclusions: Decreasing the female-male gap in mortality and achieving the 90-90-90 targets will require gender-based strategies. Male-friendly approaches for testing and retention across the continuum care are needed to control the epidemic.

TUPED1253

Linkage Expert Program facilitates timely linkage to care and promotes early retention for people living with HIV

R.A. Sabelli[1], K.R. Simon[1,2], P.N. Kazembe[1,2], S. Ahmed[1,2], M. Kim[1,2]
[1]Baylor College of Medicine Abbott Fund Children's Clinical Center of Excellence, Lilongwe, Malawi, [2]Baylor International Pediatric AIDS Initiative at Texas Children's Hospital, Baylor College of Medicine, Houston, United States
Presenting author email: saeeda@bcm.edu

Background: Timely linkage between HIV diagnosis and treatment services is critical for the health of people living with HIV and transmission prevention. Recent literature demonstrates high rates of loss to follow-up between diagnosis and treatment initiation or enrollment in HIV care services. We developed and evaluated the impact of a novel Linkage Expert Program to facilitate prompt linkage to and retention in HIV care.
Methods: The program was implemented from June 2015 to November 2015 in two government-funded health facilities in central Malawi. Immediately following an HIV+ diagnosis, patients were referred to a community health worker designated as the focal linkage person, or Linkage Expert (LE), who provided intensified post-diagnosis counseling and an escort to HIV services. Patient data was recorded in a linkage register and their enrollment into HIV services tracked. For patients who did not enroll, at least two tracing attempts were made via phone and home visit to follow up.
Results: A total of 515 patients were enrolled in the program, median age (IQR) was 34 (26-42) years and 215 (41.8%) were male. The majority were referred from the voluntary testing and counselling department (51.1%). At the time of identification, 117 (22.7%) reported knowing their HIV+ status, but had not initiated treatment. Of all enrolled patients, 449 (87.2%) were eligible for ART; 384 (85.5%) initiated in a median time (IQR) of 7 (1-10) days. Of those initiated on ART, 345 (89.9%) remained in care three months post enrollment.

Enrolled in Linkage Expert Program	Khombedza Health Centre N= 101 (%)	Salima District Hospital N=414 (%)	Total N=515 (%)
Eligible for ART			
Yes	88 (87.1)	361 (87.2)	449 (87.2)
No	13 (12.9)	46 (11.1)	59 (11.4)
Unknown*	0 (0.0)	7 (1.7)	7 (1.4)
Started ART, n	*n= 88*	*n=361*	*n=449*
Yes	87 (98.9)	297 (82.3)	384 (85.5)
No	1 (1.1)	64 (17.7)	65 (14.5)
Enrolled in HIV Services			
Yes	100 (99.0)	330 (79.7)	430 (83.5)
No	1 (1.0)	84 (20.3)	85 (16.5)
3 Month Outcome			
Alive, enrolled in pre-ART care	9 (8.9)	32 (7.7)	41 (8.0)
Alive, on ART	71 (70.3)	274 (66.2)	345 (67.0)
Died	3 (3.0)	16 (3.9)	19 (3.7)
Refused	5 (5.0)	48 (11.6)	53 (10.3)
Stopped	1 (1.0)	3 (0.7)	4 (0.7)
LTFU	8 (7.8)	26 (6.3)	34 (6.6)
Transferred Out	3 (3.0)	15 (3.6)	18 (3.5)
Missing	1 (1.0)	0 (0.0)	1 (0.2)

*Person was lost to follow up before assessment of ART eligibility.

[Table. Outcomes of patients enrolled in the Linkage Expert Program by health facility]

Conclusions: These findings suggest that in settings with sub-optimal rates of linkage from testing to treatment initiation, a dedicated LE can promote prompt linkage from identification to HIV care with high rates of early retention. Further characterization of clients with known HIV+ status who have not yet initiated treatment may inform development of better strategies to increase treatment coverage.

TUPED1254

High HIV positivity rate in Index Case Testing in Malawi

L. Khongonyowa, A. Zakaliya, A. Abdallah, E.J. Schouten
Management Sciences for Health, Malawi Program, Lilongwe, Malawi
Presenting author email: lkhongonyowa@msh.org

Background: In partnership with the Malawi government, the CDC funded DHSS project, implemented by Management Sciences for Health (MSH) and partners, aims to identify people living with HIV and enroll and sustain them in care and treatment. Overall HIV prevalence in Malawi is 10.6%, but HIV positivity rate of HIV testing has declined to less than 5%. This is the result of a high coverage rate of 70% of all people living with HIV on ART.
To increase the HIV positivity rate or yield DHSS introduced Index Case contact testing. All patients attending HIV Care or ART Clinics are encouraged to bring their family members (children, spouses, siblings, and parents) for HIV testing during family testing days organised at each health facility, facilitated by a Family Referral Slip (FRS) which is given to the first member of the family identified (Index Case).
Methods: Routinely collected data from HIV testing registers were used to prepared monthly ‚Index Case Testing' reports from each of the 41 health facilities. We used these reports for further analysis for this paper.
Results: From August - December, 2016, a total of 7,680 adults and children from families living with HIV/AIDS were tested in 41 Facilities in four districts in the south of Malawi (Blantyre, Chiradzulu, Thyolo and Neno). The table gives an overview of the number of tests done, the number HIV positive, and the HIV positivity rate (yield).

	Male			Female			Total		
Age Group	Tested	Positive	Positivity Rate	Tested	Positive	Positivity Rate	Tested	Positive	Positivity Rate
1-4	822	54	7%	870	37	4%	1692	91	5%
5-9	276	38	14%	372	40	11%	648	78	12%
10-14	208	25	12%	236	32	14%	444	57	13%
15-19	181	39	22%	474	66	14%	655	105	16%
20+	2081	789	38%	2160	855	40%	4241	1644	39%
Total	3568	**945**	**26%**	**4112**	**1030**	**25%**	**7680**	**1978**	**26%**

[Results]

Conclusions: Our results indicate that Index Case testing in the Malawi setting shows good results. A positivity rate of 26% is high compared to the overall prevalence and the number of men reached was encouraging. Therefore, case finding through index patients is a promising strategy to maximize HIV case detection.

TUPED1255

Association between a novel telehealth intervention and utilization of HIV services among transgender women of color in Washington, DC, U.S.A

M. Magnus[1], E. Edwards[1], A. Dright[1], L. Gilliam[1], A. Brown[1], V. Criss[1], M. Levy[1], N. Sikka[1], M. Siegel[1], E. Machtinger[2], C.C. Watson[3], I. Kuo[1]
[1]George Washington University, Washington, United States, [2]University of California, San Francisco, San Francisco, United States, [3]George Washington University (at Time of this Work), Washington, United States
Presenting author email: manyadm@gwu.edu

Background: Transgender women of color (TWC) are an underserved population who often experience HIV and barriers to care, as well stigma, violence, and trauma. Novel ways to improve access for TWC are urgently needed. Telehealth can engage TWC in care, yet this approach has been unexamined. The purpose of this study was to develop a TWC-specific telehealth intervention to increase access to care and assess feasibility of the intervention among TWC.
Methods: Participants were ≥18 years, male at birth, transgender or female identified, a racial/ethnic minority, and with at least one study-defined barrier to healthcare in the last 6m. Following a 3m pre-intervention phase, participants received a 3m intervention with secure, remote access to trained peer health consultants (PHC) via video, email, text, and phone. Utilization of the intervention and outcomes were assessed monthly. Intention to seek care and receipt of care were modeled using generalized estimating equations (GEE) from data obtained from PHC and participants via Computer Assisted Self-Interview (CASI).
Results: Of 25 participants, most were Black (96%), >25y (69%), living with HIV (52%), and reported recent depressive symptomatology (67%).The intervention was acceptable and well-utilized based (Table 1). The intervention was associated with significantly ($p < 0.05$) increased odds of intention to seek TWC-specific care [aOR 1.76 (1.00-3.08)] compared to each person's baseline, while participants with depressive symptoms were significantly more likely to have intention to seek specialty care [aOR 10.53 (1.42-77.97)], HIV-specific care [aOR 2.56 (1.27-5.17)], and mental health care [aOR 2.56 (1.27-5.17)] post intervention. Participants with depressive symptoms had significantly greater odds of having sought HIV care in the past month [aOR 2.31 (1.31-4.06)] post intervention relative to those without.

Characteristic--> Intention to seek type of care in the next month	Post Intervention Period (vs. Pre-Intervention Period) Adjusted OR (95% CI)	Elevated CES-D-8 (vs. Lower CES-D-8) Adjusted OR (95% CI)
Primary care	0.91 (0.52-1.57)	0.99 (0.58-1.70)
Specialty care	0.39 (0.10-1.59) p=0.188*	10.53 (1.42-77.97) p=0.02**
Transgender-specific care	1.76 (1.001-3.08) p=0.049**	1.52 (0.87-2.65) p=0.142*
HIV-specific care (prevention or treatment, as applicable)	0.97 (0.53-1.77)	2.56 (1.27-5.17) p=0.009**
Mental health care	***0.63 (0.28-1.40)***	***2.80 (1.22-6.43) p=0.015****
N=16 with baseline evaluation plus at least one post-intervention assessment		
**p<0.05 *0.05<p<0.25 shown due to hypothesis-generating nature of pilot study.		

[Correlates of Intention to Seek Care]

Conclusions: These data suggest telehealth may be facilitated by PHCs who provide immediate non-clinical consultation; this may be effective in overcoming barriers and improving health of TWC. Telehealth may be an innovative solution to improve outcomes for TWC with barriers to care.

Finding the hard to reach HIV-infected: respondent-driven sampling as a public health intervention for PWID and MSM

S.S. Solomon[1,2,3], A. McFall[2], G. Lucas[1], A. Srikrishnan[3], D. Celentano[2], M.S. Kumar[3], S. Anand[3], J. Wong[4], S. Solomon[3], S.H. Mehta[2], The NCA Study Group
[1]Johns Hopkins University School of Medicine, Medicine, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]YR Gaitonde Centre for AIDS Research and Education, Chennai, India, [4]Tufts University School of Medicine, Boston, United States
Presenting author email: sss@jhmi.edu

Background: HIV treatment-induced viral suppression is the most efficacious prevention tool available, so all HIV programs should seek to minimize prevalence of viremia in a community. However, to achieve viral suppression, HIV-infected persons need to be identified, linked and maintained on ART. In hard-to-reach populations such as MSM and PWID, identifying out of care HIV-infected persons remains the biggest deficiency in the HIV care continuum. We hypothesized that respondent driven sampling (RDS) to identify viremic individuals would be cost-effective by leveraging social network connectedness in MSM and PWID.
Methods: Between 9/12-12/13, we recruited 14,481 PWID and 12,022 MSM across 27 sites in India (n~1000 per site) through RDS. To estimate costs, we identified costs from site operations (e.g., rent, staffing), RDS (e.g., compensation for recruiting participants), and HIV testing (market pricing) and excluded research costs (e.g., investigator salaries, travel, sample storage). Cost per viremic person identified was calculated as the total non-research costs at each site divided by the number of viremic persons identified at the site.
Results: From 56 seeds recruiting 26,447 individuals, RDS identified 4,065 HIV-infected individuals (median: 197 per PWID site and 86 per MSM site) of whom 2,825 were viremic (median: 141 per PWID site and 50 per MSM site) and 2,329 were unaware of their HIV infection. The median site cost per viremic individual identified was USD 349 (range: 117-1344). This varied from USD 233 (range: 117-820) for PWID sites to USD 481 (range: 291-1344) for MSM sites. The prevalence of viremia and speed of recruitment were positively associated with the cost per viremic individual identified. The median site costs per unaware HIV-infected PWID and MSM identified were USD 147 and 437, respectively. The additional median cost of identifying a HCV-infected PWID unaware of his/her status was USD 11 (site range: 7-142).
Conclusions: RDS is an efficient way to identify hard to reach viremic HIV-infected MSM and PWID with the potential to transmit HIV, particularly in communities with high HIV burden, poor ART access and strong interconnectedness. RDS appears more cost-effective in PWID compared to MSM, potentially explained by higher HIV burden and poorer ART access.

TUPED1257

Community involvement and targeted approach: increase uptake of HIV testing among family members of PLHIVs - experience from the Global Fund-Supported Vihaan Programme in India

V. Arumugam[1], H. Rosenara[2], R.M. Saravanan[1], A.K.s. Parihar[1], M. Bamrotiya[3], U. Chawla[2], R.S. Gupta[3], S. Mehta[2]
[1]India HIV/AIDS Alliance, Strategic Information, Delhi, India, [2]India HIV/AIDS Alliance, New Delhi, India, [3]National AIDS Control Organisation, Delhi, India
Presenting author email: aviswanathan@allianceindia.org

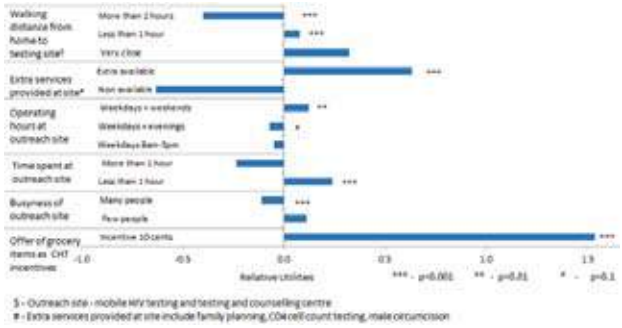
Background: India HIV/AIDS Alliance implements the Global Fund supported Vihaan programme to deliver care and support services for people living with HIV (PLHIV) through its 361 community-based Care & Support Centres (CSC) across India from 2013 to 2017. Around 1 million PLHIVs were provided care and support services through CSCs. Care and support helps increase treatment adherence, improves quality of life and ensures healthy life for PLHIV. Partner notification and partner testing including family members for HIV still remains challenge.
Methods: Screening to firm up the eligible family members were carried out among 1,019,667 registered clients through 361 CSCs till June 2016. Data were collected using structured client registration form after obtaining consent from the client. Eligible clients were approached individually by 2021 field level outreach workers and peer counsellors for linking with HTC for testing through proper referral slip. Outcome were updated and documented in the CSCs. Clients were followed up to ensure HIV testing and receive results. Intervention also ensured all newly diagnosed PLHIV are linked with treatment center for medication.
Results: Family size of the 1,019,667 registered clients were 2.2 with total family members of 2,276,326. Mean duration of having connected with treatment center is more 3.2 years. 9.4% (n=2,13,298) of family members were identified as eligible for HIV testing but not tested for more than one year or ever. Majority of the eligible family members were spouse/partners (57%), female and age group of 15-45 years. Through regular counselling and motivated family notification, 38% (80,476) of eligible clients were tested for HIV and received results with 10.3% positivity. As a continuum of care, 73% (6,091 vs 8,329) of the newly diagnosed HIV positive clients were linked with ART center for care and treatment.
Conclusions: HIV positivity among family members is higher than the key populations and so focus on this group is most warranted. Community based intensified focused approach on family members especially spouses and partners improve the uptake HIV testing and early linkage with treatment center. Vihaan model may be replicated across world as it yielded high result.

TUPED1259

How should we configure services to maximise uptake of couples HIV testing: results of a qualitative study and discrete choice experiment from rural Zimbabwe

E.L. Sibanda[1], G. Maringwa[1], N. Ruhode[1], C. Madanhire[1], M. Tumushime[1], C. Watadzaushe[1], S. Napierala Mavedzenge[2], S. Gudukeya[3], S. Bautista-Arredondo[4], H. Thirumurthy[5], K. Hatzold[3], F. Terris-Prestholt[6], F.M. Cowan[1,7]
[1]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [2]RTI International, San Francisco, United States, [3]Population Services International, Harare, Zimbabwe, [4]National Institute of Public Health, Mexico, Mexico, [5]University of North Carolina at Chapel Hill, Chapel Hill, United States, [6]London School of Hygiene and Tropical Medicine, London, Zimbabwe, [7]Liverpool School of Tropical Medicine, Liverpool, United Kingdom
Presenting author email: euphemiasibanda@yahoo.co.uk

Background: Despite numerous health benefits, uptake of couples HIV testing (CHT) is suboptimal. We conducted a mixed-methods study to identify and evaluate relative preferences for CHT services in a rural Zimbabwean community.
Methods: We systematically identified attributes to explore in the discrete choice experiment (DCE): we conducted mixed-gender focus group discussions (FGDs) and in-depth interviews to explore barriers and facilitators to CHT and identify preferred service delivery characteristics. We used these findings along with structured discussions with programmers/implementers to finalise DCE attributes. The piloted paper-based DCE questionnaire was illustrated pictorially and administered among adults >18 years. DCE data were analysed using the multinomial logit model allowing for preference heterogeneity.
Results: We conducted four FGDs with 8-9 participants each (n=34, 17 women), and 29 in-depth interviews (16 women). Barriers to CHT included:
1) difficulty broaching the subject of CHT for cultural reasons (females not expected to bring up sexuality issues) and discomfort with associated implications of distrust/infidelity;
2) fear of relationship dissolution in case of HIV-positive diagnosis;
3) conflicting work schedules. Men reportedly resisted CHT more than women.
Interventions that "put pressure" to test together, such as CHT at antenatal clinics, reportedly facilitated CHT. Small non-monetary incentives were suggested as CHT facilitators.
We enrolled 300 DCE participants, including 174 women. The final DCE attributes and levels and their relative strength of preferences identified people's optimal CHT service attributes: a nearby, not busy, integrated facility that has short waiting times with weekend opening (figure).



[Relative Utilities for CHT Program Characteristics]

Non-monetary incentives for CHT were highly attractive. Even low value incentives could compensate for perceived shortcomings in other program attributes. In subgroup analysis women had stronger preferences for incentives than men.
Conclusions: Broaching the subject of CHTC is challenging especially for women. Paying attention to strengths of preferences may ensure design of programs which improve CHT. Incentives may help overcome identified barriers.

TUPED1260

Values and preferences of PLHIV and key populations in HIV self-testing (HIVST) and partner notification (PN) in the Middle East and North Africa (MENA)

J. Hermez[1], G. Eid[2], R. Haddad[3], G. Azzi[4], C. Khoury[4], E. Ballan[4], C. Johnson[5], C. Figueroa[5], C. Payne[5], A. Verster[5], G. Riedner[1]
[1]World Health Organization - Regional Office for the Eastern Mediterranean, HIV-STI-Hepatitis, Cairo, Egypt, [2]Regional/Arab Network against AIDS (RANAA), Beirut, Lebanon, [3]Independent Public Health Consultant, Beit Chabab, Lebanon, [4]Arab Foundation for Freedom and Equity (AFE), Beirut, Lebanon, [5]WHO, HIV, Geneva, Switzerland
Presenting author email: hermezj@who.int

Background: In 2016, WHO issued guidelines recommending HIVST and PN. In this context, the WHO Regional Office for the Eastern Mediterranean conducted an assessment of the values and preferences of key populations (KP) in collaboration with two regional networks, RANAA and AFEMENA. The results of the assessment will be used to address low access to HIV testing services (HTS) and antiretroviral therapy in the region.
Methods: Focus group discussions and in-depth interviews were conducted by trained service providers in Morocco, Tunisia, Lebanon and Jordan. Forty people who inject drugs, 34 female sex workers (FSW), 24 men who have sex with men, 24 transwomen (TG) and 72 people living with HIV (PLHIV) were recruited using a convenience sample. Consultation with service providers was conducted virtually. All answers were categorized and analyzed thematically.
Results: HIVST was known to a minority of participants, including service providers. A large proportion of the participants perceived HIVST as beneficial to increase access to HTS and overcome stigma and discrimination (S&D). TG were more skeptical due to lack of awareness in the community. PLHIV with prior bad experiences with HTS favoured HIVST while those with positive experiences tended to reject it. Unacceptance of HIVST was due to overprotection of PLHIV, distrust in rapid testing, fear of self-harm, and lack of counselling and linkage.
Overall, assisted and unassisted HIVST were acceptable especially if supported by population-tailored information and delivered through NGOs, peers via outreach programs, pharmacies or health services.
PN was considered essential by all groups, but less so by FSW due to the difficulty of reaching clients, fear of violence and income loss. Barriers include S&D, limited awareness, loss of partner's trust and fear of HIV status being known by others.
The preferred approaches to PN were dual and contract referral due to the protection and support by the service provider. Few empowered and independent participants preferred the passive referral.
Conclusions: Introduction of HIVST and PN in MENA is acceptable to KP, service providers and PLHIV. Implementation will require advocacy, raising awareness and building capacity among communities and service providers, along with tailoring service delivery to community needs and context.

TUPED1261

Improving quality of care for patients by introducing atazanavir/ritonavir as the preferred second-line protease-inhibitor in Togo

S. Zekeng[1], F. Kossi[2], A. Dagnra[2], B. Assimadzi[2], A. Singo-Tokofai[2], A. Zakillatou[2], F. Boubakari[2], B. Caldwell[3], C. Middlecote[3], B. Stewart[3], N. Sugandhi[3]
[1]Clinton Health Access Initiative, Dakar, Senegal, [2]Togo National AIDS Control Programme, Lomé, Togo, [3]Clinton Health Access Initiative, Boston, United States
Presenting author email: szekeng@clintonhealthaccess.org

Background: In 2010, Togo had 24,635 patients on treatment and 5% on second-line (2L). 98% of 2L patients were on LPV/r-containing regimens despite challenges such as poor tolerability, twice-daily dosing schedule, and high pill burden. A new protease-inhibitor, atazanavir/ritonavir (ATV/r), became available in 2013 with benefits over LPV/r including: smaller pill size, decreased pill burden, once-daily dosing, and improved tolerability. ATV/r was also less costly compared to LPV/r.
Methods: In December 2010, the Clinton Health Access Initiative supported the Togo Ministry of Health to develop a comprehensive product introduction process for national rollout of ATV/r in Togo. A National Technical Committee for ARV's and other related commodities for the management of HIV was established and tasked with drafting and disseminating dispensing guidelines for ATV/r administration. A progressive switch of 70% of patients from LPV/r to ATV/r was planned from January 2015 to December 2017. The National Anti-AIDS Committee used mentors to actively engage with facilities to monitor the rapid uptake of ATV/r through dispenser reports providing site-level breakdown.
Results: Starting with 100 patients on ATV/r in the second quarter of 2011, Togo expanded to 2,216 patients on ATV/r by the end of 2014. Between 2010 and 2014, approximately 1,500 patients on 2L treatment switched from LPV/r to ATV/r. By

the end of 2014, 60% of 2L patients were on ATV/r. The success of the ATV/r roll-out was tied, in part, to engagement with community groups as part of the national adoption framework. Additionally, Togo achieved over $1,232,705 in savings from 2011-2014 by preferring ATV/r to LPV/r in 2L.
Conclusions: Successful uptake of new products requires more than adoption into national guidelines. Key interventions in Togo contributing to successful uptake included: comprehensive planning and engagement with stakeholders; a strong regional approach; the use of mentors who had a deep understanding of the realities in the field; and periodic supervisory site visits to monitor dispensation reports, identify sites not implementing, and develop solutions to resolve any bottlenecks.

TUPED1262

Increasing ART initiations with a community outreach health information intervention, a cluster-randomized trial from Zomba, Malawi

L. Derksen[1], A. Muula[2], A. Matengeni[3], M. van Lettow[3], S. Sodhi[4], J.J. van Oosterhout[2,3]
[1]*University of Toronto, Toronto, Canada,* [2]*University of Malawi, College of Medicine, Blantyre, Malawi,* [3]*Dignitas International, Zomba, Malawi,* [4]*Dignitas International, Toronto, Canada*
Presenting author email: joepvanoosterhout@gmail.com

Background: Treatment as prevention is a potentially effective strategy to end the AIDS epidemic in southern Africa. ART is widely available upon diagnosis; in Malawi a test and (immediate) treat policy has recently been implemented. Evidence-based policy to increase uptake of ART is necessary in order to successfully scale up treatment as prevention. We evaluated a community outreach information campaign as a policy to increase HIV testing and ART uptake.
Methods: We conducted a cluster-randomized controlled trial in a rural area of Zomba district, Malawi, with two arms: control villages (n=122) and intervention villages (n=62). In late 2013, we held a 45-minute community health information meeting, conducted by a trained community educator, in every intervention village. On average, 64% of adults attended the meeting (total attendance =7375 adults). We provided the information that ART prolongs life, reverses HIV/AIDS symptoms by suppressing viral load, and is available at a specific nearby health facility.
Results: We collected health facility data on village-level outcomes collected during 12 months post-intervention. We find a significant effect on HIV diagnoses (aOR 1.39, 95% CI 1.04-1.86, control arm mean =2.4 diagnoses/village) and ART uptake (aOR 1.33, 95% CI 1.02-1.75, control arm mean =1.4 initiations/village). The effect of the intervention on ART uptake was heterogeneous, and was larger for villages with higher pre-intervention rates of HIV testing (p=0.06) and ART uptake (p=0.05), and for villages that were further from a health facility (p=0.06). The mean age of clients who initiated ART in the intervention arm was two years younger (p=0.14) and they were 9 percentage points more likely to have a CD4 count taken (p=0.08), which was only indicated for individuals in WHO-stage I or II, suggesting that the intervention may have encouraged early ART initiation. Clients who initiated ART did not differ significantly by gender or weight between the intervention and control arms.
Conclusions: The results demonstrate that lack of information about the benefits and availability of ART is a barrier to ART uptake among adults in rural Zomba, Malawi. An inexpensive, one-time community outreach information campaign is an effective policy to increase ART uptake.

Men's perspectives of their HIV risk and vulnerability in KwaZulu-Natal, South Africa: formative findings of the 'linkage of men to HIV care' study

J. Chikovore[1], H. van Rooyen[2], L. Bruns[3], T. Ngubani[2], T. Coates[3]
[1]*Human Sciences Research Council, HIV/AIDS, STIs & TB, Durban, South Africa,* [2]*Human Sciences Research Council, Human and Social Development, Sweetwaters, South Africa,* [3]*University of California, Los Angeles, Centre for World Health, Los Angeles, United States*
Presenting author email: jchikovore@hsrc.ac.za

Background: Treatment-as-Prevention requires that a substantial proportion of HIV-positive persons be diagnosed, linked to, and maintained in care. Substantially fewer men than women in sub-Saharan Africa are tested and linked to treatment; addressing this will reduce men and women's risk and vulnerability to HIV. This is one of a handful of studies rigorously evaluating evidence-based strategies to diagnose, link and retain HIV-infected men in care in a high-prevalence context.
Methods: Using a cluster randomized design, eight communities in KwaZulu-Natal, South Africa will be randomised to receive one of:
(1) male-centred mobilization,
(2) a small incentive and male-focused testing, or
(3) standard-of-care health services. Once tested, HIV-positive men will be individually randomized to:
(1) standard-of-care ART,
(2) point-of-care CD4 testing, or
(3) point-of-care CD4 testing combined with personalized male linkage to care.
Finally, we will estimate the joint effect of the structural and individual-level interventions and conduct cost-effectiveness analysis. Formative data were collected in May-July 2016 through key informant interviews with stakeholders working with men (n=10; ages 25-58) to understand risk concepts, potential linkage barriers, and possible intervention strategies. Five focus group discussions were conducted with men (n=42; ages 25-49) to explore gender norms and barriers to HIV testing and treatment. Data were transcribed and translated verbatim, then analysed both inductively and deductively to identify, refine and consolidate emerging themes.
Results: Men articulated their HIV vulnerability as being tied to several complexly interconnected factors, namely
i) unemployment and related struggles with role reversal and failure, lost respect and waning power in sexual relationships;
ii) social disconnectedness and lack of platforms to share and discuss challenges,
iii) inability to engage women partners or healthcare workers about physical, sexual or psychological health problems;
iv) health systems that were experienced as alienating, and where consultations carried huge direct and opportunity costs amid poverty; and v) high alcohol use in a context of stress, poverty and unemployment.
Conclusions: In this setting, determinants of men's HIV vulnerability intersect in complex ways, reiterating that multi-strategy interventions could be the key to effectively diagnosing, linking and retaining men in HIV care.

TUPED1264

Association between intimate partner violence and the prevention of mother to child transmission of HIV

M. Gichane[1], K. Moracco[1], H. Thirumurthy[2], E. Okitolonda[3], F. Behets[4,5], M. Yotebieng[5,6]
[1]*University of North Carolina at Chapel Hill, GIllings School of Global Public Health, Health Behavior, Chapel Hill, United States,* [2]*University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Health Policy and Management, Chapel Hill, United States,* [3]*University of Kinshasa School of Public Health, Kinshasha, Congo, Democratic Republic of the,* [4]*University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Epidemiology, Chapel Hill, United States,* [5]*University of North Carolina at Chapel Hill School of Medicine, Social Medicine, Chapel Hill, United States,* [6]*Ohio State University, College of Public Health, Epidemiology, Columbus, United States*
Presenting author email: warugich@live.unc.edu

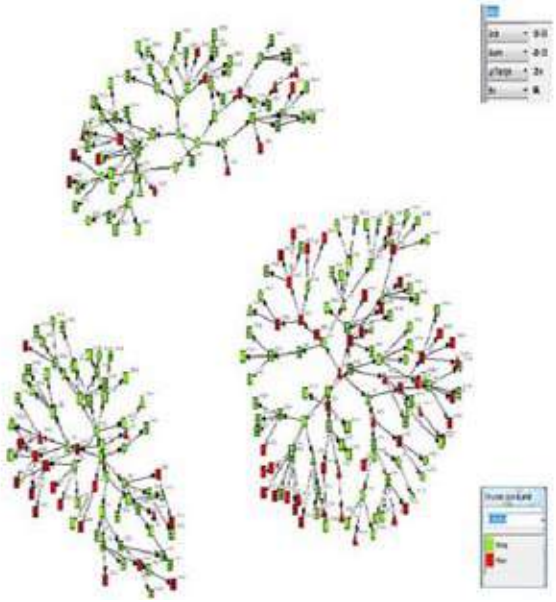
Background: Prevention of mother to child transmission of HIV (PMTCT) has been prioritized as a key component in ending HIV/AIDS transmission in Sub-Saharan Africa. Intimate partner violence (IPV) is a risk factor for non-adherence to HIV treatment for women, however the evidence on the impact of IPV specifically on uptake of PMTCT services is inconclusive. The aim of this study is to assess the effect of IPV on uptake of PMTCT services and retention in care.
Methods: We used data from a randomized controlled trial that evaluated the effect of conditional cash transfers on retention in and uptake of PMTCT services in which newly diagnosed HIV-infected women, ≤32 weeks pregnant, were recruited at antenatal care clinics in Kinshasa, Democratic Republic of Congo, between April 2013 and August 2014 and follow-up through 6 weeks postpartum. Participants were asked about their IPV experiences in a face-to-face interview at enrollment. The outcome assessed was uptake of PMTCT services (attend all scheduled clinic visits and accept proposed services) through six weeks postpartum and LTFU (loss to follow-up).
Results: Of the 433 participants who were enrolled and randomized, approximately half of the sample (51%) had experienced some form of IPV; 35% had experienced emotional abuse, 29% physical abuse, and 19% sexual abuse. At six weeks postpartum, the proportion of participants who attended all clinic visits and accepted proposed services was 61% and the proportion LTFU was 15%.There were no significant differences between women who had experienced IPV and those who had not experienced IPV in adherence to the PMTCT cascade (61.5% vs. 59.4% (Adjusted Odds Ratio [AOR] =1.14; 95% confidence interval [CI]: 0.77-1.69) or LTFU (15.4% vs. 15.6% AOR= 0.98; 95% CI: 0.58-1.65), controlling for age, marital status, and education level.
Conclusions: Findings from this study indicate that experiencing IPV does not reduce pregnant women's engagement in PMTCT services. The high prevalence of IPV in this population suggests that IPV screening and intervention should be included as part of standard care for PMTCT.

TUPED1265

Utilisation of the social network strategy to reach hidden female sex workers (FSWs) with HIV and health services in Francistown, Botswana

M.D. Seretse[1], V. Ranebennur[2], M. Gilbert-Lephodisa[1], M. Merrigan[1], W. Dikobe[1], S. Gaosenkwe[1]
[1]FHI 360, Gaborone, Botswana, [2]FHI 360, Mumbai, India
Presenting author email: mseretse@fhi360.org

Background: The USAID- and PEPFAR-funded LINKAGES project aims to increase reach to key populations most at risk for HIV, promote HIV testing and counseling, and enroll and retain those with HIV into care and treatment. In Botswana, The LINKAGES team attempted to reach female sex workers (FSWs) with HIV prevention messaging and HIV counselling and testing at "hotspots" where they congregate through peer outreach workers (POWs), but faced challenges identifying HIV+ FSW. To address this, a Social Network Strategy (SNS) was applied to increase access to hard to reach FSWs.
Methods: The SNS followed a respondent driven sampling approach to recruit FSWs within POW networks. POWs, acting as initial ‚seeds' in 4 districts, were given 4 referral coupons to give to FSWs in their social networks. FSWs who presented with coupons at LINKAGES-supported health facilities received clinical services including HIV testing and ART. FSWs received a small incentive of approximately $10 USD airtime for participation. They were also given 4 coupons to recruit additional FSWs in their network, with an added incentive of $5 USD for each successful new FSW referred.
Results:



[Fig 1: Spread of network through SNS strategy]

Data presented here are from Francistown district where three POWs acted as initial seeds. Through SNS, 282 FSWs were recruited within 4 weeks. A total of 261 (93%) were newly tested, 85 (30.1%) diagnosed HIV positive and, of those, 50 (59%) initiated on ART. More HIV+ FSWs were identified as the waves increased within the network. (fig 1)
Conclusions: The SNS method that relies on peers referring others into the program was effective in identifying new FSWs, increasing testing, and enhancing initiation of HIV+ FSWs on treatment. LINKAGES is currently supporting partners with acceleration activities using the same approach to identify new FSWs. The approach can be replicated across LINKAGES countries as it has proven to yield results.

Does HIV treatment availability improve HIV status knowledge and progression through the cascade of care?

E. Moscoe[1], J. Bor[2], F. Tanser[3,4], D. Pillay[3,5], T. Barnighausen[3,6]
[1]Harvard T H Chan School of Public Health, Global Health and Population, Somerville, United States, [2]Boston University School of Public Health, Department of Global Health and Department of Epidemiology, Boston, United States, [3]Africa Health Research Institute (AHRI), Mtubatuba, South Africa, [4]University of KwaZulu-Natal, Durban, South Africa, [5]University College London, London, United Kingdom, [6]University of Heidelberg, Institute of Public Health, Heidelberg, Germany
Presenting author email: tbaernig@hsph.harvard.edu

Background: Expansion of HIV treatment may increase disclosure, reduce stigma, and increase testing leading to improved progression through the cascade of care. However many HIV-infected persons in South Africa, especially men, do not know their status and many patients are lost along the cascade of care. We estimate how a person's ART eligibility affects their household member's HIV status knowledge and progression through the cascade of care.
Methods: We conducted a regression discontinuity analysis that exploits the CD4 count threshold for ART eligibility in South Africa to evaluate the causal intent-to-treat (ITT) effect of ART eligibility. Using data from a large population-based cohort, we compared outcomes among household members of patients who had a CD4 count just below the 200-cell threshold (eligible for ART) with those just above the cut-off (less likely to be eligible for ART). We assessed effects on knowledge of HIV status, and further research will assess cascade of care outcomes including CD4 count of household members when enrolling in pre-ART services, and time to ART enrollment once eligible.
Results: ART led to a 17 percentage point increase in HIV status knowledge among the patient's male household members relative to a baseline level of 7% (17 pp, 95% CI 12, 22). The results were robust to variation in bandwidths and inclusion of covariates. We hypothesize that loss to follow up in enrolling on ART and CD4 count at the time of pre-ART enrollment will be improved by living with an ART-eligible household member, results forthcoming.
Conclusions: Living with someone who is eligible for ART increased men´s likelihood of reporting that they knew their HIV status. Although prior studies have noted a correlation between ART expansion and testing rates, this study is among the first to causally link ART initiation to increased awareness of HIV status among household members. This effect may be due to increased testing, or to updating of beliefs about HIV status based on partner´s status. Ongoing research will determine whether this effect leads to improved progression through the cascade of care.

TUPED1267

The last mile toward elimination of mother to child HIV transmission in Zimbabwe: optimizing resources for subpopulations most at risk

M.-S. Kang Dufour[1], S. McCoy[2], A. Mushavi[3], A. Mahomva[4], N.S. Padian[5], F. Cowan[6,7]
[1]University of California, San Francisco, Department of Medicine, San Francisco, United States, [2]University of California Berkeley, School of Public Health, Berkeley, United States, [3]Ministry of Health and Child Welfare, Harare, Zimbabwe, [4]Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe, [5]University of California, Berkeley, School of Public Health, Berkeley, United States, [6]Centre for Sexual Health, HIV & AIDS Research, Harare, Zimbabwe, [7]Liverpool School of Tropical Medicine, Liverpool, United Kingdom
Presenting author email: mi-suk.kangdufour@ucsf.edu

Background: The first coverage target required for validation of "virtual elimination" of mother-to-child HIV transmission is ≥95% antenatal care (ANC) attendance. Achievement of this target will require strategic allocation of limited resources. We identified subgroups most at need for intervention for the final push toward elimination of PMTCT in Zimbabwe.
Methods: We analyzed data from a 2014 evaluation of the National PMTCT Program that collected population representative data. Eligible women were ≥16 years and had infants born 9-18 months before the interview. Participants were tested for HIV and interviewed about service utilization during pregnancy. We examined the proportion of mothers who would be targeted by various strategies, the number of outreached mothers needed in each strategy to reach one mother without ANC, and the impact on population ANC attendance if 50% of those mothers without ANC were successfully engaged in ANC. We also looked at uptake of other services among women who did not attend ANC.
Results: Two of the five provinces surveyed failed to meet ANC the target, with 6.2% of mothers in Harare and Manicaland reporting no ANC visits. The targeting strategy with the highest impact on overall ANC attendance in these provinces was outreach to mothers of Apostolic religion (reduction from 6.2% to 4.1%). However, 37% of mothers were Apostolic. An alternate strategy, also allowing these prov-

inces to reach the target (reduction from 6.2% to 4.5%), was to target mothers in those provinces with 3 or more previous pregnancies or a previous non-institutional delivery. This group targets only 18% of mothers. Mothers with no ANC were also more likely to have missed other services including; institutional delivery (62.6% vs 11.9%, p<0.0001), immunization (33.5% vs 0.1%, p<0.0001), and EID (48.6% vs 28.8%, p=0.003).
Conclusions: Reaching the last group of women who do not attend ANC will require a significant effort. Women in this group are also less likely to uptake other health services, and targeted outreach to these mothers may have additional benefits if they are engaged in healthcare. These findings demonstrate a data driven approach to optimizing resources to target populations outreach for ANC services.

TUPED1268

Barriers and facilitators of HIV care in recently diagnosed men who have sex with men (MSM) in Lima, Peru: qualitative analysis of bi-directional text messages from an mHealth intervention

L. Menacho[1], E. Bayona[2], F. Roman[1], C. Tristán[1], C. Arroyo[1], M. Cassolato[3], R. Cabello[4]
[1]VIA LIBRE, Research Department, Lima, Peru, [2]University of California, Los Angeles, United States, [3]International HIV/AIDS Alliance, Brighton, United Kingdom, [4]VIA LIBRE, Lima, Peru
Presenting author email: lmenacho@vialibre.org.pe

Background: Mobile phone technology in HIV care (mHealth) is a promising tool to increase HIV treatment adherence and retention in the HIV care continuum for high-risk populations. A thorough understanding of barriers and facilitators of engagement and retention in care from the perspective of newly diagnosed MSM is critical to targeting effective mHealth interventions in Lima, Peru.
Methods: From June-December 2015, 28/40 MSM participants were linked to HIV care with an mHealth intervention within 3 months of HIV diagnosis at Via Libre clinic. For 12 weeks, participants agreed to receive weekly short message service (SMS) from an assigned HIV counselor. Text messages were tailored to elicit barriers and facilitators of HIV care while encouraging engagement in conversation. We coded and thematically analyzed 4,559 messages.
Results: Mean age of participants was 29.8 years (2050); with 70% reporting some post-high school education and 73% self-identifying as homosexual. Five categories captured 16 themes related to barriers and facilitators of care that emerged from the data:
1) Psychosocial issues,
2) Medication concerns,
3) Follow-up support,
4) Interpersonal dynamics, and
5) HIV/AIDS knowledge.
Upon engagement in care, psychosocial themes emerged most often. In messages about assimilating an HIV-positive diagnosis, most participants conveyed that "adapting to a new life is the most difficult thing" to overcome. For the majority of participants, "fear of the effects of the drugs they [I] will take" was a barrier to retention. In fact, most patients prescribed antiretroviral therapy (ART) did experience mild to moderate side effects including gastrointestinal upset, headaches, dizziness, and body rashes. The ability to send pictures and ask questions at symptom onset mitigated this retention barrier for most participants and simultaneously facilitated their engagement in care. Proactive themes of re-scheduling appointments and asking about follow-up lab work helped participants navigate their care, with most expressing the sentiment "now I know I am not alone."
Conclusions: For newly diagnosed MSM entering the HIV care continuum, psychosocial and medication related barriers to engagement and retention merit further study. Future mHealth interventions may benefit from anticipating these barriers and producing built-in facilitators to address these concerns.

Early lessons from a regional scale-up of test and treat in Lubombo, Swaziland

M. Calnan[1], M. Mkhontofo[1], S. Ginindza[1], S. Haumba[2]
[1]University Research Co.,LLC, Mbabane, Swaziland, [2]University Research Co., LLC, Mbabane, Swaziland

Background: The Ministry of Health of Swaziland in compliance with WHO HIV management guidelines released in 2015 scaled up "Test and Treat" to all people living with HIV (PLHIV) starting October 2016. Prior to this time, "Test and Treat" was only available to targeted populations. The country ART coverage was 66% The Test and Start initiative serves to increase ART coverage to meet the UNAIDS 90-90-90 targets leading to a reduction in the estimated 8,658 new infections and 3200 AIDS related deaths annually in Swaziland. This paper sought to describe early lessons from the scale up of "Test and Treat" in the Lubombo region.
Methods: Following a national position statement by the Health Ministry, a national mentors training on Test and Start was conducted by the National AIDS Program. In the Lubombo region, a modular training curriculum for test and start was developed for use onsite. A Regional training calendar was developed to improve the coordination of the training, on site trainings were held and post training mentoring support for service delivery and documentation was provided. The public was sensitized through key messaging and community dialogues. Facility support for supply chain management was also provided to cater for the anticipated additional prescriptions.
Results: ART coverage in the region increased from a baseline of 65% at the end of 2015 to 71% by the end of December 2016. Between October and December, ART initiations increased by 20% with 17% of new initiations taking place on the same day as the HIV test. 90% of the health care facilities received training on Test and Start within October 2016 and 85% of health care providers were trained during this time.
Conclusions: A region wide coordinated effort of training and information provision that targeted both providers and recipients of HIV care enhanced the scale up of "Test and Treat". Both clients and providers received targeted messaging enabling demand creation for the service.

Predictors of loss to follow-up among HIV exposed children within HIV prevention of mother to child transmission cascade, Kericho County, Kenya, 2016

H. Taabukk Kigen[1], R. Too[2], T. Galgalo[1], J. Wamicwe[3,4]
[1]Kenya Field Epidemiology Training Program, Health, Nairobi, Kenya, [2]Moi University, Biostatistics and Epidemiology, Eldoret, Kenya, [3]Ministry of Health-Kenya, NASCOP, Nairobi, Kenya, [4]Ministry of Health, NASCOP, Nairobi, Kenya
Presenting author email: taabukk@gmail.com

Background: In 2014 >2.3 million children <15 years were HIV infected with >240,000 new infections occurring annually and majority (>90%) are in sub Saharan Africa. Morbidity and mortality from HIV remain high in Kenya partly due to lost to follow up (LTFU). LTFU results in no or delayed treatment. The study had sought to determine predictors of LTFU among HIV exposed children in Kericho County, Kenya, 2016.
Methods: A hospital based frequency matched case-control study was conducted. Study recruited 44 cases who had missed 3 months of clinic appointments and 88 controls who had adhered to all appointments. HIV exposed infant (HEI) hospital register for the months of September 2014 through February 2016 was used. A structured questionnaire was administered to both cases and controls. Consent was required. Predictor factors were identified using chi-square tests (X^2) at 95% significant levels and logistic regression model to determine independent predictors.
Results: Of the 132 HEIs 71(54%) were male. Median age was 59 weeks (26-93 weeks), cases ranged 29-91 weeks and controls 27-90 weeks. Majority 81 (61%) were aged 12-18 months. A total of 124 (94%) caregivers were biological mothers, 79 (60%) aged < 30 years with 94 (71%) delivering in a hospital. Independent factors associated with mother-infant pair loss to follow up were: fear knowing HEI status (aOR= 12.7 [CI 3.2-50.2]),lack of knowledge HEI are followed up to 18 months (aOR= 12.0 [CI 2.9-48.8]),not wanting partners know HEI status (OR= 11.3 [CI 2.9-44.0]),using traditional treatments (aOR= 6.4 [CI 1.8-22.9]).Protective of HEI status were: HEI mothers knowing own HIV status pre-pregnancy (aOR= 0.2 [CI 0.05-0.71]) and households having health insurance
(aOR= 0.11 [CI 0.01-0.76]).
Conclusions: Non-disclosure of infant exposure status to partner, lacking knowledge of HEI follow up duration and use of traditional treatments significantly contribute to clinic non-adherence. Increased early HIV testing among mothers, disclosure support, health education and partner involvement is advocated. Encouraging households enroll in health insurance schemes could be beneficial. Further qualitative studies to understand care givers knowledge, attitudes and practices relating children HIV and a survey to get the magnitude, impact and reasons for using home treatments.

TUPED1271

The impact of structured mentor mother support on PMTCT retention and viral suppression at 6 months postpartum among HIV-positive women in rural Nigeria

C. Fan-Osuala[1], C. Isah[1], H.O. Ramadhani[2], S. Erekaha[1], U. Anaba[1], M. Charurat[2], H. Galadanci[3], N.A. Sam-Agudu[1,2]
[1]Institute of Human Virology Nigeria, International Research Center of Excellence, Abuja, Nigeria, [2]Institute of Human Virology, University of Maryland School of Medicine, Epidemiology and Prevention, Baltimore, United States, [3]Bayero University, Department of Obstetrics and Gynaecology, Kano, Nigeria
Presenting author email: homari@ihv.umaryland.edu

Background: Nigeria has the 2nd-highest burden and widest gaps in PMTCT globally. Poor PMTCT uptake and adherence remain major challenges. Peer support has reportedly improved PMTCT outcomes; however, evidence on its impact on retention-in-care is limited. Retention implies consistent engagement and treatment adherence. The MoMent study evaluated the impact of structured peer support on postpartum retention and viral load (VL) suppression among rural Nigerian women.
Methods: A total of 497 HIV-positive pregnant women were consecutively recruited at 10 primary healthcare centers (PHCs) with structured Mentor Mother (MM) support (close supervision, detailed documentation of MM activities, close client tracking), and 10 pair-matched PHCs with routine but ad-hoc peer support (PS). Retention was defined by clinic attendance during the first 6 months postpartum. Participants with ≥ 3 of 6 expected monthly visits were considered retained. Women with a 6-month postpartum plasma VL of < 20 copies/mL were considered suppressed. A logistic regression model with generalized estimating equation to account for clustering was used to assess the effect of MMs on retention and viral suppression.
Results: Exposure to structured MM support was associated with higher odds of retention than routine PS (aOR=5.9, 95% CI 3.0-11.6) (Table 1).

Characteristics	All, N=497	Retained in Care n (%)	Multivariate Analysis (aOR, 95% CI)	
Routine PS	237	59 (24.9)	1.0	--
MM Support	260	161 (61.9)	**5.9**	**3.0-11.6**
<secondary education	252	115 (45.6)	1.0	--
≥secondary education	245	105 (42.9)	1.1	0.6-1.9
Muslim	178	66 (37.1)	1.0	--
Christian	319	154 (48.3)	1.1	0.7-1.9
Previously HIV diagnosed	197	95 (48.2)	1.0	--
Newly HIV diagnosed this pregnancy	299	125 (41.8)	1.0	0.6-1.6
aOR=adjusted odds ratio; CI=confidence interval; PS=peer support; MM=Mentor Mother				

[Factors Associated with Retention at 6m Postpartum]

Similarly, the odds of viral suppression at 6 months postpartum were higher for MM-supported women (aOR=4.9, 95% CI 2.6-9.2) (Table 2).

Characteristics	All, N=497	Viral Suppression (n=130); n(%)	Multivariate analysis (aOR, CI)	
Routine peer support	237	22 (9.3)	1.0	--
Mentor Mother support	260	108 (41.5)	**4.9**	**2.6-9.2**
<secondary education	252	51 (20.2)	1.0	--
≥ secondary education	245	79 (32.2)	1.6	1.0-5.6
Efavirenz-based regimen	330	86 (26.1)	1.0	--
Nevirapine-based regimen	156	38 (24.3)	1.0	--
Lopinavir-based regimen	11	5 (45.5)	**3.7**	**1.0-13.2**
Not retained	277	43 (15.5)	1.0	--
Retained	220	87 (39.5)	**2.1**	**1.2-3.5**

[Factors Associated with Viral Suppression]

Conclusions: Closely-supervised, outcomes-focused Mentor Mother support significantly improved postpartum PMTCT retention and viral suppression among HIV-positive women in rural Nigeria. Introduction of structure and close supervision into peer support interventions can significantly improve outcomes of women and children in PMTCT care.

TUPED1272

Trends in the implementation of national policies to improve retention in HIV care: evidence from national policy reviews and health facility surveys in six sub-Saharan countries

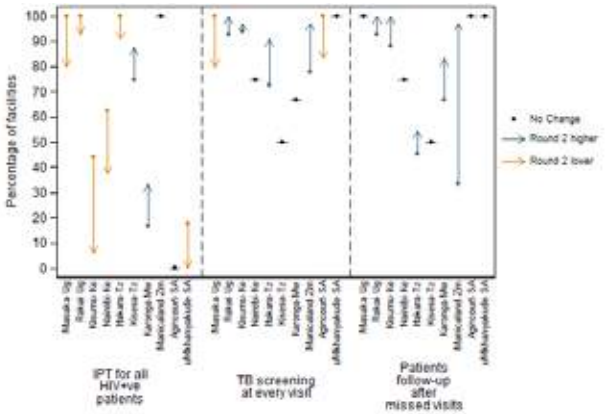
Presenting author email: alison.wringe@lshtm.ac.uk

Background: Sub-optimal retention in HIV care in African settings may undermine efforts to reach the "90-90-90" targets. We describe national policies relating to retention in care, and investigate their implementation in selected health facilities between 2013 and 2016.
Methods: A policy extraction tool was used to summarise 120 national HIV policy documents published in Kenya, Malawi, South Africa, Tanzania, Uganda, and Zimbabwe between 2003 and 2016. 145 purposively-sampled health facilities in ten health and demographic surveillance sites in the same countries were surveyed in 2013-15 and 2015-16 using a structured questionnaire to document HIV service provision. A conceptual framework was used to develop 16 indicators to compare policies influencing retention in care with health facility implementation. For each indicator, we assessed whether national policy was explicit or implicit/absent, and calculated the proportion of facilities per site that reported its implementation in each round.
Results: Policy gaps relating to retention in care were observed in all countries in 2013, with little change by 2016. The most frequent policy gaps included referrals for home-based care, nutritional support for HIV patients and drug pick-ups by a designee (noted in 3 or more countries in each case). Only three policies were explicit in all countries by the latter round: home visits/phone calls to patients following missed clinic appointments, tuberculosis screening at every visit, and intermittent preventative therapy for all HIV-positive patients. However, the proportion of health facilities implementing these policies varied across sites and over the two rounds (figure 1).



[Figure 1. Changes in implementation of national policies to promote retention in care from 2013-16]

Furthermore, stock-outs of antiretroviral therapy drugs increased in 5/10 sites, with 34% of all facilities reporting stock-outs in the past year by round 2 (+22%).
Conclusions: Addressing policy implementation gaps and reducing the occurrence of drug stock-outs will be essential if retention in care is to be improved, and HIV elimination goals are to be achieved.

AllyQuest: engaging HIV+ young MSM in care and improving adherence through a social networking and gamified smartphone application (App)

L. Hightow-Weidman[1], K. Knudtson[1], K. Muessig[2], M. Srivatsa[3], E. Lawrence[3], S. LeGrand[4], H. Kirschke-Schwartz[1], D. Lemos[5], C. Balthazar[5], S. Hosek[5]
[1]University of North Carolina-Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill School of Public Health, Health Behavior, Chapel Hill, United States, [3]Ayogo, Vancouver, Canada, [4]Duke University, Duke Global Health Institute, Durham, United States, [5]Hektoen Institute, Chicago, United States
Presenting author email: lisa_hightow@med.unc.edu

Background: HIV disproportionately impacts young men who have sex with men (YMSM) who experience disparities across the HIV care continuum. Technology-based interventions allow the delivery of tailored content specific to each user's context, and offer the unique capability for broad diffusion across geographic locations within the US and globally.
Methods: AllyQuest is a novel, theoretically-based, smartphone app intervention designed to improve engagement in care and antiretroviral therapy (ART) adherence among HIV+ YMSM (target age 16-24 years). The app features address barriers to care among youth, including low HIV health literacy, lack of social support, and internalized stigma. AllyQuest was built on an established gamification platform for patient engagement that embeds social networking and fundamental game mechanics, such as challenges, points, and rewards (unlocking story collections). A medication tracker provides reminders to promote ART adherence via personalized adherence strategies that are user and context specific; a calendar allows for reflection on adherence over time. After iterative development with input from two Youth Advisory Boards, usability testing was conducted to assess app functionality, comprehension of the educational content, use of intervention features, and overall impressions of app relevance and appeal. A 28-day pilot trial was conducted with 20 HIV+ YMSM to evaluate intervention feasibility and acceptability.
Results: Mean age of participants was 21.8 years (range 19-24), 95% were non-white. Mean time using the app was 143 minutes, with a mean of 36.2 log-ins and a mean 21 days of use. There were 225 posts to the daily discussion social wall and 275 total health-focused quests completed. Feasibility and acceptability ratings were high. Overall, participants found the app easy to use and navigate, not intrusive, and had few reported technical issues. Most (15/17) reported greater confidence in reliably taking their ART and feeling more connected to other HIV+ YMSM (14/17). Qualitative exit interviews identified areas for improvement including the need for additional tailoring and personalization.
Conclusions: AllyQuest represents a new, highly scalable solution that is well-suited to meet the specific prevention and care needs of HIV+ YMSM. The development of this intervention is both timely and vital given the urgency of the ongoing HIV epidemic among YMSM.

TUPED1274

Protocol guided adherence counseling by trained patients taking ART: does it make a difference?

A. Teklu[1,2], A. Nega[3], K. Yirdaw[3]
[1]St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [2]Center for International Reproductive Health Training, Addis Ababa, Ethiopia, [3]MERQ, Addis Ababa, Ethiopia
Presenting author email: ateklu72@gmail.com

Background: Retention on an Anti-Retroviral Treatment (ART) program and adherence to medication are key to survival of AIDS patients. Shifting of selected tasks, such as counseling, to People living with HIV (PLHIV) is believed to be one way to increase adherence and retention. However, PLHIV-provided counseling services may lack structure or key content useful for encouraging patients to take their medicine and stay on treatment.
Methods: To assess the effectiveness of protocol guided adherence counseling provided by ART-experienced PLHIV in reducing attrition and improving adherence; a two arm cluster randomized, controlled trial with partial blinding was used. Random assignment was made to intervention or control arm at hospital level first. Eligible patients in the intervention hospitals were consented and those who agreed were provided with protocol guided counseling by peer educators. The study subjects were selected from among those who consented and who got the protocol guided counseling randomly. Neither the health care providers nor the peer counselors knew who will be enrolled during the intervention, thus were blinded. In the control sites, standard of care was provided which included counseling by peer educators without the protocol. Retention and adherence to medication were compared at month 2 and 6.
Results: Six hospitals were included in each arm. 433 patients were enrolled in the study (226 in the intervention arm). A significant difference in attrition rates was seen at month-six: 19.4 vs. 37.5 per 100 person-years on treatment in the intervention and control arms respectively (incidence rate ratio 0.52, 95% CI 0.28 - 0.92, P = 0.02). After adjusting for multiple factors, the intervention group had a lower risk for attrition than control group (adjusted IRR 0.47, 95% CI 0.27 - 0.82, P=0.01). The chance of missing medication was much lower in the intervention group at month six (Adjusted IRR 0.44, 95% CI 0.22 - 0.90, P = 0.03).
Conclusions: Retention and adherence to medication were significantly higher among ART patients who were provided protocol-guided adherence counseling compared to those who were provided with unstructured counseling. Provision of protocol guided adherence counseling by ART experienced patients should be considered in all ART settings.

TUPED1275

Navigation and linkage to care outcomes among not-in-care HIV-infected patients identified by three referral sources: clinical providers only, HIV surveillance only and a combination model

D. Sachdev, E. Mara, R. Kohn, E. Antunez, A. Hughes, S. Scheer, S. Cohen
San Francisco Department of Public Health, San Francisco, United States
Presenting author email: darpun.sachdev@sfdph.org

Background: The US CDC supports the use of HIV surveillance data to identify not-in-care (NIC) patients and re-link them to care ('Data-to-Care'). Since 2012, the SFDPH LINCS navigation program has re-linked NIC patients, but the optimal strategy for identifying patients for Data-to-Care is unknown.
Methods: Eligible NIC patients met one of the following criteria: their last viral load (VL) was >1500 and >4 months ago, or they had no VL in 12 months. Referred NIC patients came from three sources:
1) Clinical providers;
2) A query of the SFDPH electronic medical record cross-matched with the SFDPH HIV surveillance registry to remove patients who were already in care (AIC) or who had migrated (EMR-surveillance) or;
3) A surveillance-generated list.
Patients who were incarcerated, psychiatrically unable to participate, had a case manager or who had migrated were considered ineligible for navigation.
Two outcomes were evaluated:
1) Enrollment in LINCS defined as initiating navigation services and;
2) Linkage to care defined as VL or CD4 count reported to surveillance after enrollment.
Results: From 10/1/2015-9/30/2016, LINCS navigation enrolled 40% (127/320) of provider referrals, 30% (32/106) of EMR-surveillance referrals and 9% (17/195) of surveillance-generated referrals (p<0.0001.) Over a quarter of surveillance-generated referrals were AIC, compared to 13% and 2% of referrals from providers and the EMR-Surveillance list, respectively. Of the 176 patients enrolled in navigation, 82% were male, 27% were Black, 27% were Latino, 24% were homeless, and 38% used methamphetamines. Within 90 days of enrollment, 77% of them re-linked to care and 35% were virally suppressed. There were no differences in linkage rates based on gender, race, housing status, drug use, or referral source.

	Clinical Provider		EMR Identified Patients Matched to Surveillance		Surveillance Generated List	
	Frequency	Percent	Frequency	Percent	Frequency	Percent
Enrolled	127	39.7	32	30.2	17	8.7
Already in Care	42	13.1	2	1.9	54	27.7
Refused	35	10.9	11	10.4	13	6.7
Not located	52	16.3	28	26.4	39	20.0
Ineligible	64	20.0	33	31.2	72	36.9
Total	320	100	106	100	195	100

[Linkage Outcomes by Referral Source,10/2015-9/2016]

Conclusions: Provider-identified NIC referrals were more likely to be enrolled in navigation compared to both surveillance-generated and EMR-surveillance referrals. In order to improve the efficiency of Data-to-Care strategies, health departments should consider working closely with clinical providers and refining eligibility criteria for surveillance-generated lists prior to attempting navigation.

TUPED1276

The effect of a mobile health intervention on patient retention during the first year of HIV care: a randomised controlled trial (WelTel Retain)

M. van der Kop[1,2], S. Muhula[3], J. Kimani[4], L. Gelmon[4], R. Gichuki[3], P. Nagide[3], L. Thabane[5], P. Awiti[2], L. Kyomuhangi[3], E. Mills[6], A. Patel[1], D. Ojakaa[7], K. Kinagwi[3], B. Abdunah[3], A.M. Ekström[2], R. Lester[1]
[1]University of British Columbia, Vancouver, Canada, [2]Karolinska Institutet, Stockholm, Sweden, [3]Amref, Nairobi, Kenya, [4]University of Nairobi, Nairobi, Kenya, [5]McMaster University, Hamilton, Canada, [6]Global Evaluative Services, Vancouver, Canada, [7]Brim Consulting, Nairobi, Kenya

Background: Patient retention in the first year of HIV care is critical to ensure the timely initiation of anti-retroviral therapy (ART) and to maximise health outcomes; however, a substantial proportion of individuals in sub-Saharan Africa are lost during the early stages of HIV care. We conducted an open, parallel group randomized controlled trial to determine whether a weekly text-message intervention improved retention during the first year of care.
Methods: Between April 2013 and June 2015, adults testing HIV-positive were recruited at two clinics in low-income areas of Nairobi, Kenya. Participants were randomly allocated to the intervention or control arm at a 1:1 ratio. Intervention arm participants received a weekly text-message check-in and were asked to respond within 48 hours ("OK" or "problem"). Healthcare providers contacted those who responded "problem" or did not respond. The primary outcome was retention in care at 12-months (attendance at the 12-month visit). Participants who did not attend this visit were telephone or community traced. Those in care elsewhere were considered retained. The key secondary outcome was retention in Stage 1 care (the proportion of participants who returned to the clinic within three weeks to complete their ART-eligibility assessment). This trial was unblinded.
Results: Of 1,068 participants screened, 700 were recruited: 349 were allocated to the intervention arm and 351 to standard care only. Out of 17,422 text messages sent, there were 9,303 "OK" responses, 401 indicated a problem, and 7,718 instances of non-response. At 12 months, 276/349 (79.1%) intervention arm participants were retained in care compared to 285/351 (81.2%) control arm participants (non-retention risk ratio (RR) 1.11, 95% confidence interval (CI) 0.826 to 1.499). In Stage 1 care, 301/349 (86.2%) in the intervention arm were retained compared to 310/351 (88.3%) in the control arm (RR 0.98, 95% CI 0.923 to 1.033). The median time to initiation of ART for those eligible at baseline was 27 days in both groups (Kaplan-Meier log-rank test p-value 0.947).
Conclusions: Preliminary analyses indicate that the WelTel intervention did not improve retention in the first year of HIV care. Other secondary outcomes, including satisfaction with care and level of social support, will be presented elsewhere.

TUPED1277

The role of triggering events as a cause of attrition in a cohort of lost to follow-up patients in the DREAM program in Malawi

S. Mancinelli[1], F. Ciccacci[2], A. Doro Altan[2], E. Buonomo[1], P. Scarcella[1], G. Guidotti[2], P. Germano[2], H. Sangare[3], S. Orlando[1], E. Abramo[1], K. Nielsen-Saines[4], G. Liotta[1], L. Palombi[1], M.C. Marazzi[5]
[1]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [2]DREAM Program, Roma, Italy, [3]DREAM Program, Blantyre, Malawi, [4]University of California at Los Angeles, David Geffen School of Medicine, Los Angeles, United States, [5]LUMSA University of Rome, Rome, Italy
Presenting author email: fausto.ciccacci@gmail.com

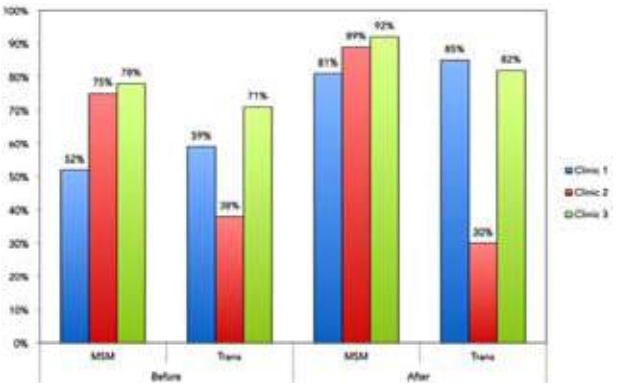
Background: Retention in care is crucial for achieving success in HIV programs. A deeper understanding of potential challenges is needed to design appropriate strategies. DREAM is a public health program for HIV care in Malawi. Medical care, laboratory monitoring and adherence interventions (counselling, peer-to-peer educators, phone calls, computerization) are free of charge; these factors lead to retention rates >95%.
Methods: The objective of this study was to investigate the reasons for attrition. Research was conducted in 12 DREAM centres in Malawi (1 in the urban area of Blantyre, 11 in rural settings). Lost-to-follow-up (LTFU) was defined as >90 days from the last visit for a client on ART and was identified through software available within health centres. Community health workers traced every client LTFU and questionnaires were administrated.
Results: From 15.099 clients [10.732 females (71%), 8.561 urban residents (56.7%)] registered before 2. 014, 202 (1.3%) were LTFU in 2014, including 148 females (73%). Tracking results demonstrated that 56 clients were untraceable (37 moved, 19 possibly gave erroneous contact information), 18 died, 26 (12.8%) transferred care to another clinic. Among 102 clients disengaged from care who were interviewed, 51(50%) experienced a "triggering event": a new job, work-related move, marriage, divorce or death of partner, incarceration or acute illness. These events were registered mostly in urban settings (75.4%) and drove to change of residency and difficulty in reaching our clinic. Other reasons were behaviour-related: belief they were in good health (20); turning to traditional healers/prophets (9); failing to disclose his/her status (4). These reasons were mainly reported in rural areas (43% of LTFU), while in clients from urban areas the attrition was due to job related issues in 32% of cases. After the interview, 20 clients (19.6%) returned to care.
Conclusions: In our cohort, 21.7% of clients reported as LTFU were dead or had transferred care, demonstrating the need for further investigation of LTFU. A model of "triggering events" could better explain the LTFU process even in previously adherent patients. HIV treatment programs should take these challenges into account.

TUPED1278

Comprehensive management provision of anal and HPV-related diseases as an HIV retention strategy in low-middle income countries

R. Paulino-Ramirez[1], A. Benitez[1], E. Sanchez[1], M.V. Castaños[1], M. Muñoz[2], J. Clase[3], R.M. Rodriguez-Lauzurique[1,3]
[1]Universidad Iberoamericana, Instituto de Medicina Tropical & Salud Global, Santo Domingo, Dominican Republic, [2]Centro de Orientación e Investigacion Integral, Santo Domingo, Dominican Republic, [3]Centro de Orientacion e Investigacion Integral, Santo Domingo, Dominican Republic
Presenting author email: paulinor.robert@gmail.com

Background: HIV Prevalence in Dominican Republic is estimated of 0.8%; however, this local epidemic is considered to be concentrated among key populations, like Gays, Transgender, and other Men who have sex with men (GTM). This concentrated prevalence reflects an absence of specific services addressing the needs of these populations. The purpose of this analysis was to evaluate the cascade of care among GTM living with HIV that received a comprehensive package of services that included a holistic approach of anal health, and early detection of HPV-related malignancies.
Methods: We selected six (6) HIV clinics from three provinces in the DR (Puerto Plata, Santiago, and Santo Domingo). Out of the total patients we have characterized GTM populations to look over the HIV cascade of care. A training covering anal and HPV health, was offered to all providers in those units. Also, after training a series of mentoring visits were provided, as well as follow-up and referral discussion after the pathology department provided anal results. We used as set point the moment of anal screening, and a 12-month based follow-up was used as a determinant for viral suppression.
Results: We characterized a total of MSM and Trans living with HIV in Puerto Plata (n=33), Santiago (n=128), and Santo Domingo (n=96). None of those before intervention were achieving the 90% goal of HIV viral suppression. After anal screening started we revaluated the HIV cascade of care in Puerto Plata between 82%-92% achieved the 90% goal, in Santiago (30%-89%), and Santo Domingo (85%-81%).



[Figure 1. Cascade of care before and after comprehensive interventions in MSM and Trans populations]

Conclusions: This study suggests that population-specific services for GTM populations can increase opportune ART initiation, linkage to care, and retention in care. Anal screening services, and HPV-related malignancies management in friendly environments seems to induce a better virological suppression among those living with HIV.

Background: In Haiti, UNAIDS estimates[1] that in 2013 the number of people living with HIV (PLHIV) between ages 15-49 was between 130,000 and 150,000 with a prevalence rate of approximately 2%. Haiti has a target to place and retain 80% of PLHIV on antiretroviral therapy (ART) by 2017 as part of its effort to reach PEPFAR's 90-90-90 goals. SSQH-Nord was a USAID-funded project (2013-2015) implemented by University Research Company (URC) which supported the MOH in Haiti in north.
The number of PLHIV lost to follow-up (LTFU) after being enrolled in ART has been rising in Haiti over the past years; PEPFAR Haiti indicates that 7000 patients were LTFU in 2013[2]. The SSQH-Nord project launched an investigation to track these clients as well as to better understand the causes for the LTFU, as a first step to reconnecting these clients to care and treatment (C&T).
Methods: The SSQH-Nord team conducted site visits to the three facilities with the highest volume of PLHIV on treatment between May and June 2015. The team worked with health providers and affiliated Community Health Workers (CHW) to identify the reasons for LTFU and propose ways to return clients to C&T. A list of all clients 822 LTFU were cross checked with medical records. CHWs participated in focus groups to identify reasons that clients discontinued C&T and proposed solutions. Focus groups with providers (doctors, nurses, lab technicians) discussed facility-level reasons for LTFU, mapped the treatment process for PLHIV at the site, identified bottlenecks, quantified the resources allocated to each step and proposed solutions to strengthen their processes. Quality improvement teams analyzed the medical records with the providers to assess the quality of care LTFU received.
Results: Client tracking at the community level and care process improvement at the facilities resulted in locating more than 601 LTFU, re-engaging them and decreasing the percentage of those LTFU. The experience was disseminated and decreased LTFU rate in northern Haiti by August from 26% to 17%[3].
Conclusions: The site visits and associated focus groups show that community-level outreach as well as improved site- and department-level monitoring are key to reducing and maintaining low LTFU.

TUPED1280

HIV ART outreaches achieve more than 90% viral suppression and more client retention compared to the ART clinic in Eastern Uganda

M. Muddu[1], J. Kiwanuka[2], M. Ojur[3], J. Baligobye[3], I. Okeba[3], P. Olinga[3], D. Ofaso[3], J. Opio[3], J. Ssali[3], B. Lydia[4]
[1]AIDS Healthcare Foundation, Medical, Kampala, Uganda, [2]AIDS Healthcare Foundation, M&E, Kampala, Uganda, [3]AIDS Healthcare Foundation, Kampala, Uganda, [4]Aids Healthcare Foundation, Africa Bureau, Kampala, Uganda
Presenting author email: lydia.buzaalirwa@aidshealth.org

Background: An efficient antiretroviral therapy (ART) delivery system is necessary for viral suppression. This is a requirement by the UNAIDS 90-90-90 goals to end the AIDS epidemic by 2030 in particular the 3rd 90. HIV ART Outreach is a care model targeting stable patients in the community designed to implement an efficient delivery system to encourage long term retention into care by supporting patients.
The aim of this study is to compare HIV viral suppression and retention among patients receiving care from the ART clinic and outreach and also determine factors associated with detectable viral loads.
Methods: Data from HIV positive patients receiving ART from Soroti clinic and ART outreaches who had had a viral load test by June 2016 were included in the study. Patients' files and open MRS were used to extract clinical and demographic information. Patients were considered lost to follow up if they spent at least ≥91 days without returning to the ART clinic or outreach. Logistic regression was used to determine the factors associated with detectable viral loads.
Results: Of the 447 participants, 293(65.5%) were receiving care from the ART clinic and 154(34.5%) from ART outreaches. HIV viral suppression was achieved in 93.7% overall, being 95.2% in the ART clinic and 90.9% in the ART outreach. There was no statistical difference virological suppression in the ART clinic and outreach, P=0.118. Participants in the ART clinic registered more loss to follow up 22(7.5%) as compared to 1(0.7%) in the ART outreach, P-value 0.002. The independent factors associated with detectable viral load were age, 41-50 years [HR 0.13(95% CI: 0.03-0.56), P=0.006], current WHO stage 3 and 4 [HR 5.12(95% CI: 1.19-22.07), P=0.029], baseline ART regiment containing AZT [HR 4.22(95% CI: 1.14-15.68), P=0.031] and baseline ART regimen containing D4T [HR 5.89(95% CI: 1.16-29.97), P=0.033].
Conclusions: Patients in HIV ART outreaches are achieving more than 90% viral suppression surpassing the UNAIDs target. The same group registered more retention in care compared to clients in the ART clinic. Therefore we need to scale up HIV ART outreach services to suitable populations in order to end the AIDS epidemic by 2030.

TUPED1281

Strengthening community-health facility linkages using expert patients to track and trace HIV-positive clients defaulting ART in Zimbabwe: towards achievement of the third 90 of the UNAIDS targets

A. Muchedzi[1], N. Mahachi[1], T. Moga[1], T. Tapfuma[1], C. Dziwa[1], T. Chimbidzikayi[1], S. Gonouya[1], O. Chakubili[2], K. Torpey[3]
[1]FHI 360, Harare, Zimbabwe, [2]FHI 360, Global, Durham, United States, [3]FHI 360, Global Technical, Washington, United States
Presenting author email: nyikadoc@yahoo.com

Background: The FHI360 Zimbabwe HIV Care and Treatment Project (ZHCT) is a USAID-funded project implementing community-based interventions with the overall goal of strengthening community-health facility linkages and community level systems to monitor, track and retain PLHIV in care. ZHCT interventions contribute to national efforts towards achieving the last 90 of the UNAIDS targets.
Methods: Between March and December of 2016, ZHCT was implemented in communities around PERFAR Tier-1 and 2 health facilities in eight districts in 2 provinces of Zimbabwe. ZHCT, in partnership with health facilities, identified ART clients who had defaulted on treatment. Expert-patients, who are HIV positive community-based cadres, were trained by ZHCT to track defaulters in their communities and evaluate their ART status in order to link them back to care as necessary. Outcomes were recorded for each defaulter reached and defaulters who were not reached in 3 home visits were considered lost to follow up trained by the ZHCT project.
Results: A total of 8,343 clients who were registered as ART defaulters at the 126 health facilities. Of these 8,143(97%) were tracked while 5,918 (73%) were tracked and traced. A total of 1,492/8,343 (25%) of the clients identified were confirmed to be still in care and 2,430/8,343 (29%) was either lost to follow, dead or had self transfered to other health facilities. Of the 4118 true ART defaulters, 3,144 (76%) were successfully returned to care.
Conclusions: These findings show that using expert patients in this context to strengthen community-health facility linkages achieved high rates of ART defaulters returned back to care. Clients still in care but registered as ART defaulters suggest poor documentation at facility levels. The ZHCT will support health facilities in updating registers such as appointment diaries, pre-ART and ART registers to minimise this challenge as the country moves towards attainment of the 90x 90x90 targets.

Barriers and facilitators to retention in HIV care and treatment among patients on antiretroviral therapy at the Communicable Disease Centre in Singapore

Y.Y. Chan[1], L.P. Ho[2], M.A. Ibrahim[1], C.S. Wong[3], C.M. Wong[4]
[1]Institute of Infectious Disease and Epidemiology, Clinical Epidemiology, Singapore, Singapore, [2]Tan Tock Seng Hospital, Care and Counselling, Singapore, Singapore, [3]Tan Tock Seng Hospital, Infectious Disease, Singapore, Singapore, [4]FHI 360, Behavioral and Epidemiological Sciences, Durham, United States
Presenting author email: yinying.chan@gmail.com

Background: As the national referral centre for HIV management in Singapore, the Communicable Disease Centre (CDC) plays an important role in providing clinical care, counselling and support to people living with HIV. In 2014, the clinic observed approximately 15% of missed clinic appointments by patients enrolled in HIV care. To develop interventions to improve retention in HIV care, this qualitative study was conducted to understand the motivators and barriers to accessing and retention in HIV care.
Methods: Twenty-seven in-depth interviews (IDIs) were conducted with healthcare providers and peer support leaders (n=11), people living with HIV who are consistent in care (n=9) and lost to care at CDC (n=7), from April to December 2016. Semi-structured interview guides were used to elicit participants' experiences with linkage to and quality of care at CDC, reasons for staying at or not returning to CDC and recommendations on strategies to improve access and retention in care.

Results: All patient participants reported high quality of care at CDC and that healthcare providers are supportive and caring. However, barriers to care include high costs of antiretrovirals despite financial assistance, perceived stigma associated with visiting CDC which is a known HIV facility, presence of other priorities in life such as work, and long waiting times at the clinic. Patient participants (n=12) shared that they are buying medications from informal sources at much lower prices and thus did not see the need to return to care. To enhance retention in care, healthcare providers reported a need to streamline clinic workflows so as to maximise the value of each patient visit. Use of videoconferencing technology as part of routine clinical consultation (n=13), extended clinic operating hours (n=16) and the use of case managers (n=20) to trace patients lost to care were cited as useful interventions to assist people living with HIV in returning to care.
Conclusions: This study highlights the structural barriers and social factors that needs to be addressed in order to improve retention in care. Healthcare providers at CDC should evaluate current clinic services and explore the implementation of novel methods to enhance access to and retention in HIV care.

Expert client contribution to achieving the 90-90-90 targets: the Malawi experience

Z. Chirwa[1], F. Kayambo[1], C. Chitsulo[2], L. Oseni[1], D. Wendo[3], R. Nyirenda[4], T. Kalua[5], S. Stender[6], K. Curran[6], N. Aufi[7]
[1]Jhpiego Malawi, HIV/TB, Lilongwe, Malawi, [2]Jhpiego Malawi, SSDI-M & E, Lilongwe, Malawi, [3]Jhpiego Malawi, SSDI, Lilongwe, Malawi, [4]Ministry of Health - Malawi, HIV & AIDS Department, Lilongwe, Malawi, [5]Ministry of Health, HIV & AIDS Department, Lilongwe, Malawi, [6]Jhpiego, HIV/TB, Baltimore, United States, [7]Jhpiego Malawi, M&E, Lilongwe, Malawi
Presenting author email: zengani.chirwa@jhpiego.org

Background: In 2015 Malawi adopted UNAIDS 90-90-90 treatment targets and instituted the universal test and treat approach. Despite increased identification of HIV-positive individuals and earlier initiation on antiretroviral treatment (ART), retention in HIV care remains sub-optimal, especially in asymptomatic clients. Malawi MOH reports 1 year retention rates on ART of 71%.
Methods: Jhpiego supported the MOH to deploy 619 Expert Clients (ECs) to 52 facilities in 4 districts-Nsanje, Chikwawa, Lilongwe, and Salima—to strengthen retention of clients on ART and re-engage clients lost to follow-up (LTFU). ECs received a 1-week training on HIV basics, HIV testing, ART, PMTCT, early infant diagnosis, viral load testing, adherence counselling, and tracing clients LTFU. ECs utilized ART/PMTCT clinic appointment books, master cards and registers to identify clients LTFU, traced clients by phone/home visits, and physically escorted clients to the clinic. ECs were provided with bicycles, phones, monthly airtime, t-shirts, umbrellas, gumboots and stationary.
Results: Out of 14,426 clients LTFU, ECs traced 8,929 (62%) clients within 12 months of deployment to health facilities in the 4 districts. Of these: 6,187 (69%) were reinitiated on ART; 844 (9%) had died; 1,063 (12%) had silently transferred to another health facility; and 835 (9%) were traced but refused to come back to care. The majority of the 38% of untraceable clients were reported to be Mozambican nationals. Feedback from clients suggests they related to ECs as peers who understood their situation.

District	Total Defaulters	Total Defaulters traced	Total brought back to care/ re-initiated on ART	Total Died	Total Transferred out (silent transfers)	Traced but refused to come back
Chikwawa	4,815	3,628(75%)	2,924(81%)	177(5%)	339(9%)	188(5%)
Lilongwe	3,306	897(27%)	358(40%)	184(21%)	275(31%)	80(9%)
Nsanje	5,545	3,831(69%)	2,469(64%)	448(12%)	383(10%)	531(14%)
Salima	760	573(75%)	436(76%)	35(6%)	66(12%)	36%(6%)
Totals	**14,426**	**8,929(62%)**	**6,187(69%)**	**844(9%)**	**1,063(12%)**	**835(9%)**

[Back to care outcomes per district]

Acknowledgement of ECs by traditional leaders facilitated their acceptance in the community. Their participation in support groups and training gave ECs the knowledge and confidence to talk to clients about the importance of ART adherence.
Conclusions: ECs can play an important role in achieving the UNAIDS 90-90-90 goals, and should be used to re-engage ART clients who are LTFU in all districts in Malawi.

Retention in HIV care for patients on ART in military health facilities in Zambia

J. Banda[1], J. Mwale[1], S. Banda[1], T. Chisanga[1], N. Kasonka[1], R. Chilima[1], L. Aladesanmi[1], E. Lifuka[2], E. Banda[3], K. Asiedu[1], S. Kelbert[4]
[1]Jhpiego, Lusaka, Zambia, [2]Department of Defence, Lusaka, Zambia, [3]Defense Force Medical Services, Lusaka, Zambia, [4]Jhpiego, Baltimore, United States
Presenting author email: joseph.banda@jhpiego.org

Background: In responding to the 90-90-90 UNAIDS global targets, the Zambia Defense Force (ZDF) increased the number of sites providing ART resulting in an exponential increase in the number of clients on treatment from 3,208 in 2009 to 6,059 in September 2016. While enrollment into care at ZDF facilities has increased by 53%, retention in care remains a challenge: national rates in Zambia public facilities have been reported to be approximately 75% while retention in care at 12 months after ART initiation at ZDF sites have still not been documented.
Methods: We retrospectively examined routine data (using ART registers and patient files) of HIV positive clients that were enrolled into care from October 2014 to September 2015 at 14 ZDF military sites supported by Jhpiego. The objective was to assess client's outcomes 12 months after ART initiation: retention in care, (defined as client alive and currently active on treatment) as well as, lost to follow up rates, deaths and documented transfers. Data was disaggregated by age and sex.
Results: A total of 1134 (males - 40%, females - 60%) HIV positive clients were initiated on ART in the period October 2014 to September 2015. 93% (1054) of the clients were above the age of 15 years. At 12 months after initiation, retention in care was 91% (1034 clients). Retention rates were similar - 91% in both males (417/458) and females (617/676).
Conclusions: Retention of clients on ART at military health facilities in Zambia supported by Jhpiego is much higher than in the public sector. There is need to further investigate the factors influencing retention at these site and create platforms for sharing learning with public health facilities that provide ART services.

TUPED1285

Characterizing patients´ attrition in a primary healthcare clinic practising test and treat

J. Kiwanuka[1,2], N. Kiwanuka[3], F. Matovu Kiweewa[3,4], J. Gonzalez Perez[5], J. Kitonsa[2,6], J. Waila Mukulu[7]
[1]AIDS Healthcare Foundation, Kampala, Uganda, [2]Makerere University School of Public Health, Kampala, Uganda, [3]Makerere University School of Public Health, Epidemiology and Biostatistics, Kampala, Uganda, [4]Makerere University John Hopkins Research Collaboration, Kampala, Uganda, [5]AIDS Healthcare Foundation, Kigali, Rwanda, [6]Medical Research Council - Uganda Virus Research Institute, Masaka, Uganda, [7]Makere University School of Public Health, Kampala, Uganda
Presenting author email: jkiwanuka74@gmail.com

Background: Expanding access to diagnosis, treatment and strengthening linkage and retention in care are critical to achieve the 90-90-90 UNAIDs targets. To date, a number of HIV programs report elevated rates of patients' attrition from care. Presently, limited information is available characterising patients' attrition in a test and treat (T&T) setting. We sought to determine the cumulative incidence of loss to follow up (LTFU) and incidence rate of mortality in a primary healthcare clinic practising T&T.
Methods: We retrospectively sampled 600 patients from routine patients' data for HIV patients enrolled into HIV care from January 2012 to December 2014 at Masaka regional referral hospital - Uganda Cares clinic. Cumulative incidence of loss to follow up and incidence rate of mortality were determined and compared across different patients' baseline characteristics using survival analysis and stata version 13.
Results: Of 600 patients in the sample, 50% had initiated antiretroviral therapy (ART) instantly and 64.67% were females with median (IQR) 30.4 (23.8-37.1) years. The overall cumulative incidence of LTFU at 12 months was 8.48% (95% CI, 6.26-11.12%). Compared to the T&T group (12.26%, 95% CI=7.90-17.51 %), cumulative incidence of LTFU was 5.89% (95% CI=3.57-9.02%) in the deferred group (p=0.023). Overall mortality rate was 5.23/100 person years of observation (pyo). Mortality incidence rate was 7.51/100 pyo in males against 3.95/100 pyo in females (p=0.027). Higher mortality was observed in those aged ≥45 years (9.53/100 pyo) than those <18 years (2.91/100 pyo). Furthermore, higher mortality rate was observed in those with a baseline WHO stage of 3 or 4 at baseline (25.15/100 pyo) against WHO stage 1&2 (2.55/100 pyo, p< 0.001). Compared to those with a baseline CD4 of <350 cells/ ml (6.37/100 pyo), mortality rate was 3.49/100 pyo in those with CD4 cell count of 350-499 cells/ml while we observed no mortality case in those with baseline CD4 cell count of ≥ 500 cell/ml.
Conclusions: This study identified higher cumulative incidence of LTFU in those who begun ART instantly. We observed lower incidence rate of mortality in females, patients starting ART with higher CD4 cell count and in those with early stage of HIV infection.

TUPED1286

Retention of HIV-infected children in antiretroviral treatment programs in Benue State, Nigeria: a retrospective review of medical records

F. Ogirima, H. Ezeofor, B. Osibo, O. Alo, I. Udenkwo, E. Udeh, P. Jwanle, I. Abutu, B. Oyeledun
Center for Integrated Health Programs, Abuja, Nigeria
Presenting author email: fogirima@gmail.com

Background: Retention in HIV care programs are key determinants to successful treatment outcomes. Retaining children infected with HIV in care remains a major challenge in Nigeria where the antiretroviral treatment (ART) coverage remains very low. We conducted a review of medical records of HIV infected children in high burden HIV treatment facilities in Benue. In 2014, Benue state had the highest HIV sero-prevalence of 15.4% in Nigeria.
Methods: From July to November 2016, medical records of HIV infected children were reviewed in 3 large HIV treatment facilities in Benue state, Nigeria; General Hospital Otukpo, GH Ugba and GH Adikpo. Retention was defined as proportion of children alive and presenting at the clinics 6, 12, 24 and 36 months post ART initiation; lost to follow up was defined as absence from clinic for more than 6 months. Retention on ART post initiation and factors associated with lost to follow up were estimated through 3 years using descriptive statistics (frequency and proportion), chi square, T-test and binary logistic regression.
Results: Medical records of 455 children across 3 health facilities were reviewed; median age was 48 months (range= 2-169 months). 53.8% (246) of the participants were male while 46.2% (211) were female. The median CD4 count was 470 (range: 123- 2,879). Out of 455 participants, 79.8% (363) were retained at 6 months, 76.7% (349) at 12 months, 73.8% (336) at 24 months and 60.7% (276) at 36 months. There was a statistically significant difference between time spent in getting to the facility and retention at 6 months (p< 0.001), 12 months (p=0.02), 24 months (p< 0.001); Children were less likely to be retained at 6 months (OR=0.99, 95% C.I= 0.987-0.997), 12 months (OR=0.99, 95% C.I= 0.989 - 0.999) and 24 months (OR= 0.99, 95% C.I= 0.990 - 0.999) for every unit increase in the time spent getting to the clinics. There were no significant associations between CD4 levels, age and sex and retention in care.
Conclusions: Retention of children in HIV care programs decreases over time. Reducing distances travelled to the clinics may improve retention of children in care programs.

TUPED1287

SMS messaging to improve adherence to PMTCT/ART: demand for overt HIV-related content among peripartum HIV-infected women in Kenya

K. Ronen[1], J.A. Unger[1], A.L. Drake[1], T. Perrier[1], P. Akinyi[2], L. Osborn[2], D. Matemo[2], G. O'Malley[1], J. Kinuthia[2], G. John-Stewart[1]
[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya
Presenting author email: keshet@uw.edu

Background: There is growing evidence that mobile health (mHealth) approaches including short messaging service (SMS) can improve antiretroviral therapy (ART) adherence. Concerns about SMS privacy have raised questions about how HIV-related information should be communicated to patients to balance benefits of delivering clear, detailed information against risks of status disclosure. Most interventions have delivered SMS that do not overtly refer to HIV or ART.
Methods: In formative work for the ongoing Mobile WACh-X randomized controlled trial (RCT) evaluating the impact of one-way and two-way SMS on prevention of mother-to-child-transmission (PMTCT) adherence and retention, we conducted 10 focus group discussions (FGDs) with 87 HIV-infected peripartum Kenyan women to determine desirability and preferred terminology of HIV-related content. SMS content for the RCT was developed based on FGD findings.
Results: Roughly half of FGD participants expressed that women would want to receive SMS containing overtly HIV-related terms, such as ‚HIV' and ‚medication'. Participants favoring overt HIV-related content expressed desire for detailed educational messages about ART and PMTCT. Those opposed to overt content expressed concerns about confidentiality. Many participants argued that acceptability of HIV-related content depended on the recipient's disclosure status and others' access to her phone. Based on these findings, both covert and overt SMS were developed. RCT participants who own their phone or have disclosed their HIV status to anyone who accesses their phone may choose one of three options: (1) covert SMS only, (2) overt SMS, only in response to HIV-related questions from the participant, (3) overt SMS routinely, initiated by the study. To date, 545 participants have enrolled in the RCT, of whom 519 (95%) were eligible to receive overt SMS. Of these, 318 (61%) opted to receive routine overt SMS and 64 (12%) to receive participant-initiated overt SMS.
Conclusions: These findings show there is demand for clear, overt HIV-related information by SMS, which outweighs confidentiality concerns if women have disclosed their HIV status or have their own phone. As programmatic efforts to improve ART adherence increasingly incorporate mHealth interventions, our findings highlight that consultation with recipients is key to developing message content that balances confidentiality with delivery of HIV-related information.

TUPED1288

Predictors of loss to follow-up from antiretroviral therapy in Namibia

S. Hong[1,2], N. Mutenda[3], T. Nakanyala[3], N. Hamunime[3], T. Mekonen[3], T. Roy[2], P. Odonkor[4], C. Wanke[1,2], M. Jordan[1,2], A. Tang[2]
[1]Tufts Medical Center, Division of Geographic Medicine and Infectious Diseases, Boston, United States, [2]Tufts University School of Medicine, Department of Public Health and Community Medicine, Boston, United States, [3]Republic of Namibia Ministry of Health and Social Services, Directorate of Special Programmes, Windhoek, Namibia, [4]University of Namibia, Windhoek, Namibia
Presenting author email: shong@tuftsmedicalcenter.org

Background: Nearly one-third of people living with HIV in sub-Saharan Africa have unknown treatment outcomes within two years of starting ART and are classified as lost to follow-up (LTFU). 18 million PLHIV are on ART globally and as this number continues to increase, the challenge of retaining patients on ART is of paramount importance. LTFU presents a major challenge in achieving high levels of treatment success. Patients LTFU are at high risk for virologic failure due to treatment interruption and for development of drug resistance, both of which increase morbidity and mortality.
Identifying predictors and developing interventions to mitigate LTFU is critical in order for countries to achieve the UNAIDS goals of 90-90-90 and to eliminate HIV/AIDS as a public health threat by 2030.
Methods: An observational cohort study was conducted at seven ART sites selected randomly from seven geographic regions in Namibia. 524 consecutive ART starters in 2012 were administered a baseline survey to collect data on demographic and socioeconomic variables. 12-month outcomes were assessed using clinic records and tracing. Multivariable logistic regression analysis was used to determine independent predictors of LTFU.
Results: The mean age was 36 and 61% were female. 40% had less than secondary school education and 75% reported a monthly income of N$1000 (US$75) or less. Mean baseline CD4 cell count was 222 cells/mm^3, 17% had WHO clinical stage 3 or 4, and 14% were started on efavirenz-based regimen.
In the final multivariable model, significant factors associated with LTFU were: younger age (odds ratio (OR)=1.03; 95% confidence interval (CI)=1.00 to 1.06), male sex (OR=2.34; 95% CI=1.34 to 4.06), difficulty leaving work or home to attend clinic (OR=2.55; 95% CI=1.40 to 4.65), and baseline efavirenz-based regimen (OR=2.35; 95% CI=1.22 to 4.51).
Conclusions: Among a representative sample of HIV patients starting ART in Namibia, several factors were significant predictors of LTFU at 12 months. Interventions to improve retention should be targeted to younger men, especially those who find it difficult to leave their work or home to attend clinic. Efavirenz-based regimens may be a risk factor for LTFU potentially due to side-effects.

TUPED1289

Positive health dignity and prevention (PHDP): an imperative intervention for achieving the second and third 90s of the UNAIDS 90-90-90 goals

A. Okafor[1], N. Ndulue[2], M. Dauda[3], B. Saidu[4], A. Yakubu[5], E. Nwabueze[6], F. Adams[7], J. Audu[8]
[1]Management Sciences for Health, Care and Support for PLHIV, Abuja, Nigeria, [2]Management Sciences for Health, HIV Prevention, Treatment, Care and Support, Abuja, Nigeria, [3]Management Sciences for Health, Care and Support for PLHIV, Ilorin, Nigeria, [4]Management Sciences for Health, Care and Support for PLHIV, Birnin-Kebbi, Nigeria, [5]Management Sciences for Health, Care and Support for PLHIV, Sokoto, Nigeria, [6]Management Sciences for Health, HIV Treatmment, Abuja, Nigeria, [7]Management Sciences for Health, Care and Support for PLHIV, Gusau, Nigeria, [8]Management Sciences for Health, Care and Support for PLHIV, Mminna, Nigeria
Presenting author email: nndulue@msh.org

Background: PLHIV default on ART and are eventually lost to follow up (LTFU). There is a significant need to improve the provision of quality community-based PHDP services to PLHIV.A significant challenge to the success of achieving 90% retention rate among clients eligible for ART and subsequent achievement of 90% viral suppression among clients on ART is poor adherence. This is partly a result of service providers' low technical capacity to provide quality Positive Health Dignity

and Prevention (PHDP) services covering risk reduction counseling, condom services, adherence on ART, partner counseling and testing services, and STI and family planning services to PLHIV.
Methods: With funding from USAID, MSH's Pro-ACT project provided small grants to Community-Based Organizations to facilitate the provision of community-based PHDP services to PLHIV at the community level using PLHIV support groups and PHDP home visits. Lists of LTFU clients were compiled from supported health facilities by data clerks and given to trained community-based PHDP volunteers who visit LTFU clients at home, provide them with home-based PHDP services, and link them to support groups. Interventions were conducted in supported communities across Niger, Kwara, Sokoto, Zamfara, and Kebbi states in North Central and North Western Nigeria.
Results: After six months of intervention, 3,490 LTFU clients (1,293 males; 2,197 females) were reached with home-based PHDP services and linked to support groups. 682 LTFU clients (244 males; 438 females) returned to the health facility to continue with ART while a total of 1,154 LTFU clients (334 males; 820 females) joined support groups. 19.5% of LTFU clients returned to ART while 33% of LTFU clients joined support groups. This represents an increase of 12.3% of clients returned to ART and 23.2% of clients who joined support groups when compared to the baselines of 7.2% and 9.8% respectively.
Conclusions: Community-based PHDP interventions can improve clients' retention on ART when strategically tailored to address the factors directly hindering PLHIV from accessing ART and care. There is need to scale up and sustain the provision of community based PHDP for PLHIV in order to achieve the 90-90-90 goals.

Same-day antiretroviral therapy initiation under the "Treat-All" approach is associated with inferior treatment outcomes in rural Swaziland

B. Kerschberger[1], Q. Mpala[1], R. Nesbitt[1], M. Pasipamire[2], N. Lukhele[2], A. Telnov[3], N. Staderini[3], R. Teck[3,4], E. Mabhena[1], S.M. Kabore[1], C.G. Edwards[1], B. Rusch[3], I. Ciglenecki[3]
[1]Medecins Sans Frontieres, Mbabane, Swaziland, [2]Swaziland National AIDS Program (SNAP), Mbabane, Swaziland, [3]Medecins Sans Frontieres, Geneva, Switzerland, [4]Medecins Sans Frontieres, Southern Africa Medical Unit (SAMU), Cape Town, South Africa
Presenting author email: munyapassy@yahoo.com

Background: Antiretroviral therapy (ART) initiation at the day of HIV diagnosis and/or HIV care registration reduces pre-treatment loss to HIV care. Randomized controlled trials indicated improved retention in HIV care while PMTCT option B+ cohorts showed increased ART attrition. We compared treatment outcomes for patients initiating ART same-day vs deferred under routine conditions following the WHO Treat-All programmatic approach.
Methods: This is a prospective cohort study of newly diagnosed HIV+ patients (≥16 years) initiated on ART irrespective of CD4/WHO staging criteria in 9 public-sector facilities in rural Swaziland, from 10/2014 to 09/2015. ART initiation was done by clinicians on the day of HIV diagnosis and/or HIV care registration (same-day) or thereafter (deferred). Kaplan-Meier estimates were used to describe ART retention and Cox-proportional hazards models to assess the risk of all-cause ART attrition, adjusted for socio-demographic, clinical (pregnancy, CD4, WHO staging, body-mass-index, TB) and facility factors. We also described the six-month viral load (VL) suppression (< 1,000 copies/ml).
Results: Of 853 patients initiating ART, 634 (74.3%) were females, 248 (29.1%) were pregnant, the median age was 29 (IQR 24-36) years and CD4 count 289 (IQR 133-447) cells/mm^3. 459 (53.8%) patients deferred ART initiation to a median of 10 (IQR 7-21) days after HIV care enrolment and 14 (IQR 8-28) days after HIV diagnosis. The crude retention on treatment was inferior for same-day ART (6 months: 77.6%, 95%CI: 73.1-81.4; 12 months: 74.8%, 95%CI: 70.1-78.8) when compared to deferred ART (6 months: 86.4%, 95%CI: 82.9-89.3; 12 months: 83.4%, 95%CI: 79.6-86.6). In multivariate analysis, patients initiating same-day ART were 62% (adjusted Hazard Ratio: 1.62, 95%CI: 1.11-2.37; p=0.01) more likely to be lost to care. Among 429 patients with a VL test result, VL suppression was similar in both groups (same-day: 92.4%; deferred: 91.6%; p=0.78). It was inferior for same-day ART (53.2% vs 66.0%; p< 0.01) when patients without VL test results and lost to care were assumed virologically non-suppressed.
Conclusions: Same-day ART initiation was associated with inferior treatment outcomes in this public-sector programme applying the "Treat-All" programmatic approach. Timing of ART initiation should be tailored to the patient needs taking patient's choice and ART readiness into account.

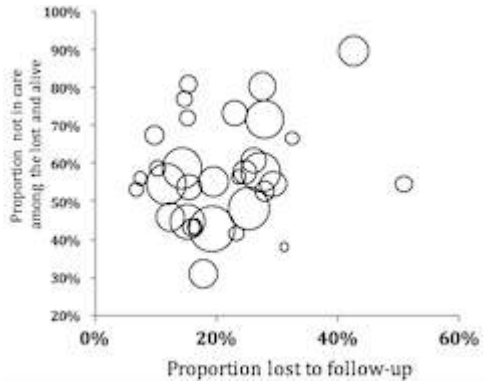
A sampling-based approach to evaluate retention and its barriers across clinics in Zambia

I. Sikazwe[1], C.B. Holmes[1,2], K. Sikombe[1], N. Czaicki[1,3], N. Padian[3], I. Wilson[4], P. Somwe[1], S. Simeza[1], C. Bolton-Moore[1,5], E. Geng[6]
[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]Johns Hopkins University, Baltimore, United States, [3]University of California, Berkeley, United States, [4]Stellenbosch University, Cape Town, South Africa, [5]University of Alabama at Birmingham, Birmingham, United States, [6]University of California, San Francisco, United States
Presenting author email: isikazwe@gmail.com

Background: Understanding the frequency, length and reasons for lapses of retention in HIV treatment can drive improvements in the care cascade. We undertook a systematic assessment of outcomes among a random sample of patients lost to follow up (LTFU) of 31 clinics in Zambia to understand the incidence of silent transfers, disengagement from care, as well as to identify patient reported reasons for loss.
Methods: We intensively traced a simple random sample of patients who were LTFU (>90 days from last scheduled visit) as determined from clinic-based electronic medical records (EMR) from a probability sample of facilities. Among patients alive and found in person, we solicited reasons for either stopping or switching care. We coded reasons into structural, psychosocial and clinic based barriers.
Results: Among 54,172 patients starting ART between July 1 2013 and July 31 2015 (63% female, median age 35 years, median CD4 level 266 cells/ul), median LTFU was 26% (IQR: 22-24, range 20 to 40). We randomly traced 18% of lost patients and successfully contacted 75%. Using only data from EMR, retention estimated across all sites was 61% at one year and 42% at two years. After incorporating outcomes ascertained through tracing, retention at one and two years was 86% and 78%. The difference between EMR and corrected estimates did not differ by clinic, unlike the prevalence of patient reported barriers . Among the patients who were not in care, the median prevalence for patient reported structural, psychosocial and clinic level barriers was 45%, 31% and 40% respectively, and were highly variable across facilities.



[Fig 1: Proportion lost to follow-up (x-axis) is not strongly associated with the fraction of alive patients who are not in care (y-axis). Size of marker proportional to clinic volume.]

Conclusions: True patient retention in care is higher than what is estimated across clinics in Zambia. The EMR LTFU estimates do not reflect the actual degree of patient disengagement. Understanding levels of disengagement, facilitators and barriers to care unique to each clinic is needed to improve retention.

TUPED1292

Linkage to ART in an outpatient treatment center in Dakar, Senegal from 1998 to 2016: delay and missed opportunities

N.F. Ngom Gueye[1,2], K. Ndiaye[1], M. Ndiaga Diop[1], A. Cournil[3], E. Delaporte[3]
[1]Fann Hospital, Centre de Traitement Ambulatoire, Dakar, Senegal, [2]Université Alioune Diop de Bambey, Bambey, Senegal, [3]Institut de Recherche pour le Développement, UMI 233 - TransVIHMI, Montpellier, France
Presenting author email: ndeyetouti98@gmail.com

Background: Delaying ART initiation is associated with increased morbidity and mortality and with increased risk of transmission. We describe delay and missed opportunities from eligibility to antiretroviral treatment (ART) initiation among ART-naïve people followed in an outpatient treatment center since the onset of ART access program in 1998.
Methods: This is a retrospective analysis of ESOPE-software computerized medical file data. A total of 3693 ART-naïve individuals aged above 15 years, entering the Fann Hospital outpatient center in Dakar, Senegal from august 1998 to june

2016 were included. Four time-periods were considered according to successive HIV guidelines revisions. Eligibility was defined as clinical stage 3 or 4 or as clinical stage 1 or 2 and CD4 count below 200, 350 or 500 cells/µl for periods 1998-2003 and 2004-06, 2007-10 and 2011-16, respectively.
Results: Out of 2874 ART-eligible individuals, 1720 initiated ART (60%) in the center. Linkage to ART improved markedly with time and reached 87% in the more recent period. Median delay from eligibility to ART initiation was reduced from 4 months during the first time-period (1998-2003) to 2 months in the last one. But the delay is greater than 9 months for at least one quarter of the individuals in all periods. Overall, only 19% initiated treatment immediately, and 14% had at least 5 visits (missed opportunities) from eligibility to ART initiation, even in the last period (2011-2016).
Conclusions: Despite significant progress in linkage to care, strategies to reduce delay and missed opportunities in initiation of ART need to be implemented to achieve the UNAIDS target of 90% of ART coverage. These strategies, based on education campaign, should highlight the benefit of timely linkage to ART to reduce transmission and help end the AIDS epidemic.

	Time-periods				
	1998-2003	2004-06	2007-10	2011-16	Total
ART-naïve, n (%)	1488	969	831	405	3693
ART-eligible, n (%)	991(67%)	784 (81%)	738 (89%)	361 (89%)	2874 (78%)
Linked to ART, n (%)	426 (43%)	456 (58%)	524 (71%)	314 (87%)	1720 (60%)
Median delay [interquartile range]	4 [2-9]	4 [2-9]	3 [1-11]	2 [1-9]	3 [1-9]
Number of additional visits after eligibility					
No visit	17%	17%	14%	33%	19%
1 to 4 visits	72%	69%	67%	52%	66%
5 + visits	11%	14%	19%	15%	15%

Contributing factors to attrition amongst key and priority population PrEP users: a cross sectional qualitative study of PrEP demonstration project participants in Kenya

A. Ngunjiri[1], J. Kyongo[1], R. Karuga[1], T. Mwangi[1], C. Ngunu[2], J. Thiomi[1], M. Kiragu[1], W. Mukoma[1]
[1]LVCT Health, Nairobi, Kenya, [2]Ministry of Health, Nairobi County Health Services, Nairobi, Kenya
Presenting author email: angunjiri@lvcthealth.org

Background: A major programmatic concern in the delivery of PrEP for HIV prevention to key populations at risk of HIV infection is their retention in PrEP programs. For effective prevention of HIV with minimal risk of drug resistance and seroconversion in PrEP programs, retention needs to be sustained. There is limited literature on reasons why PrEP users choose to withdraw from PrEP programs and solutions to address the attrition. This study aimed to describe the reasons for attrition among clients in a PrEP demonstration project in Kenya, and give recommendations on how to address the challenges.
Methods: A cross sectional qualitative study was conducted in November 2016 among 531 PrEP users (166 female sex workers, 103 men who have sex with men and 262 young women) who had missed their monthly appointments by three to ninety days in the PrEP demonstration project. Health service providers (HSPs) at implementing sites contacted the defaulted PrEP users by phone or face to face to document their reasons for missing appointments. In-depth interviews were also conducted with six HSPs on contributing factors that led to the attrition. Data was analysed using open coding approach.
Results: Individual factors that led to defaulting scheduled appointments were: reduced self-perception of risk where project participants reported they were not sexually active at the time (sex break), negative perceptions of PrEP usage, partner discouragement of appointment attendance, non-disclosure of PrEP use to sexual partner and forgetfulness. Socio-economic factors included: relocation from PrEP dispensing site, lack of transport monies and competing time priorities due to employment. Health system factors mentioned were complicated PrEP initiation and follow up process and procedures and long waiting times at the health facility.
Conclusions: These findings are important for program managers in the context of national PrEP rollout in Kenya to address the challenges raised through practical interventions such as correct PrEP messaging during mobilisation, sexual partner engagement and development of simplified standard operating procedures on initiation and follow up of PrEP users clients. Client education on self-risk perception is equally important to ensure retention during actual seasons of high HIV infection risk.

National-level assessment of patient retention and loss to follow-up under PMTCT test and treat using a random sample of health facilities in Côte d'Ivoire

S. Gloyd[1,2], S.A. Granato[1], C. Konan[1], V. Kourai[1], A. Billy[1,2], S. Kouyate[1,2], J. Robinson[1,2,3], V. Djety[4], S. Kalibala[5], A. Koné[1,2]
[1]Health Alliance International, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Washington, School of Social Work, Seattle, United States, [4]Ministère de la Sante et la Lutte contre le SIDA, Programme National de Lutte contre le SIDA, Abidjan, Cote D'Ivoire, [5]Population Council, Washington, United States
Presenting author email: valerie.kourai@hai-ci.org

Background: Loss to follow-up (LTFU) in PMTCT test and treat programs may occur at multiple stages of antenatal and post-partum care. We estimated the proportion of HIV-positive pregnant women with known retention in care to better understand both LTFU and the information gap between ARV delivery in antenatal care and continued ARV use at and after childbirth.
Methods: We randomly selected a nationally representative, stratified sample of 50 health facilities providing PMTCT services in Côte d'Ivoire. Data collection teams abstracted quantitative data from routine facility-based monthly reports, registries, and patient charts, to estimate the magnitude of LTFU under Option B. We combined data from these sources to determine the proportion of PMTCT patients with documented retention status at childbirth and 6 months post-enrollment.
Results: From November 2014 to October 2015, 92% of pregnant women attending first antenatal care visits had a recorded HIV test; 79% of HIV-positive women were reported to have received ARVs during their antenatal care. Among all HIV-positive women identified in ANC in 2014 and 2015 in our sample, 49% had a patient chart available at the health facility; 72% of 1,207 eligible patient charts had proof of active patient retention at childbirth; and 65% had proof of active retention 6 months from enrollment in care. Variability between health facilities was high for all indicators. Combining the lost to follow up in all of the above steps, the overall aggregate proportion of all HIV-positive women in the sample with a documented active retention 6 months from delivery of ARVs was 29%.
Conclusions: Documented retention in among women on ART in pregnancy is far lower than estimated retention rates based on initiation of treatment. We believe that a focus on improving data quality to understand true retention could improve the effectiveness of service delivery interventions. The high degree of variability among health facilities in LTFU at each stage of the cascade suggests that targeted health facility interventions may provide opportunities to improve performance and reduce LTFU. These may include early interventions to improve data collection quality, consistency, and regular data review.

TUPED1295

Active patient tracking can improve patient retention under PMTCT test and treat: results from a national intervention project in Côte d'Ivoire

S. Gloyd[1,2], S.A. Granato[1], J. Robinson[1,2,3], C. Konan[1], V. Kourai[1], A. Billy[1,2], S. Kouyate[1,2], V. Djety[4], K. Abo[4], S. Kalibala[5], A. Koné[1,2], G. Ouattara[6]
[1]Health Alliance International, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Washington, School of Social Work, Seattle, United States, [4]Ministère de la Sante et la Lutte contre le SIDA, Programme National de Lutte contre le SIDA, Abidjan, Cote D'Ivoire, [5]Population Council, Washington, United States, [6]Health Alliance International, Yamoussoukro, Cote D'Ivoire
Presenting author email: gbossouna.ouattara@hai-ci.org

Background: Test and treat models of antiretroviral treatment delivery (including Option B/B+ for the prevention of mother-to-child transmission of HIV (PMTCT)) greatly increase the numbers of HIV-positive women in lifelong antiretroviral therapy. Côte d'Ivoire has faced challenges to retention in care among HIV-positive mothers, including effective measurement of retention.
Methods: This study used a nationally representative sample of 30 health facilities providing PMTCT services in Côte d'Ivoire. An active patient tracking (APT) intervention was rolled out monthly to six-site clusters following a stepped-wedge study design. The APT included a training workshop and an APT data toolkit to be used by an inter-professional APT team made up of site-based health workers. Quantitative data were collected from HIS reports and patient charts to measure changes in on-site chart availability and to estimate changes in patient retention among available charts. Interviews were conducted monthly to record strategies identified as a result of the intervention.
Results: On-site patient chart availability increased significantly (p=0.001) from 57% pre-intervention to 76% during the intervention. The proportion of patients actively in treatment among available charts did not change significantly. Sites

experienced varied fidelity to the intervention with staff enthusiasm and heavy patient load cited as key barriers to implementation and doctor and community counsellor engagement cited as key facilitators. Sites with higher fidelity to the intervention identified new strategies for improving maternal retention, including new tasks/duties, improved information sharing, increased service offerings, and strengthening data systems and sharing.
Conclusions: The APT intervention increased the number of patient charts available to health workers for management of retention. Since the proportion retained in the additional was similar to the smaller number of charts available before the intervention, the overall proportion of patients who were considered actively in treatment increased significantly. The intervention, focusing on collaboration and use of patient chart data, encouraged staff at health facilities to work together to identify strategies to improve patient retention.

TUPED1296

The burden of gynecomastia among men on antiretroviral therapy in Zomba, Malawi

V. Singano[1], A. Amberbir[1], D. Garone[1], C. Kandionamaso[1], J. Msonko[1], M. van Lettow[1,2], K. Kalima[1], Y. Mataka[1], G. Kawalazira[3], G. Mateyu[1], A. Kwekwesa[1], A. Matengeni[1], J. van Oosterhout[1,4]
[1]Dignitas International, Zomba, Malawi, [2]University of Toronto, Dala Lana School of Public Health, Toronto, Canada, [3]Malawi Ministry of Health, Zomba District Health Office, Zomba, Malawi, [4]College of Medicine, Department of Medicine, Blantyre, Malawi
Presenting author email: v.singano@disgnitasinternational.org

Background: Many Africans who are on life-saving ART face challenges from a variety of toxicities. After the introduction of a standardized first-line efavirenz-containing ART regimen, reports of gynecomastia in Malawian popular media caused concern, however data on the prevalence and risk factors for gynecomastia from studies in African are scarce
Methods: We conducted a cross-sectional study in males ≥18 years registered on ART at the HIV clinic in Zomba Central Hospital, south-east Malawi. Men who reported to have ever experienced breast or nipple enlargement received a standard questionnaire and underwent physical examination. Questions included perceptions and concerns about gynecomastia. Clinicians confirmed the presence of gynecomastia and severity was determined with a validated score. Routinely collected data on current and previous ART regimens, CD4 count, WHO clinical stage at ART initiation, anthropometric measurements and history of tuberculosis were extracted from the electronic database. We used multivariable logistic regression analysis to determine risk factors for gynecomastia.
Results: We enrolled 1,027 men with median age of 44 years (IQR: 38-52 years). The median ART duration was 57 months (IQR: 27-85); 46.7% were in WHO stage III/IV at ART initiation, 88.2% had exposure to efavirenz and 9% were overweight or obese. The prevalence of self-reported gynecomastia was 6.0% (62/1027) (95%-CI: 4.7-7.7%). Of men with gynecomastia 83.6% reported nipple enlargement and 98.4% enlarged breasts (85.5% bilateral). One-third said they had not previously reported gynecomastia to a health care provider. Over three-quarters mentioned that gynecomastia was an important problem for them, while more than half were embarrassed by it. On examination, gynecomastia was present in 90% (confirmed gynecomastia prevalence of 5.5%; 95%-CI: 4.2-7.0%) and 51.8% had severity grade III or IV. Only history of tuberculosis treatment was independently associated with gynecomastia; adjusted OR 2.51 (95%-CI: 1.05-6.01).
Conclusions: The burden of gynecomastia among men on ART in Malawi was higher than previously reported, and was associated with adverse psychological consequences, calling for increased awareness, a proactive diagnostic approach and thorough clinical management.

TUPED1297

Retention in care of children living with HIV in resource constraint setting: the case of Nepal

K. Deuba[1,2], U. Shrestha[1], R. Shrestha[3], B.P. Shrestha[4], B.B. Rawal[5], R.P. Khanal[5], T. Paudel[5]
[1]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [2]Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, [3]Public Health and Environment Research Center, Kathmandu, Nepal, [4]Save the Children International, Kathmandu, Nepal, [5]National Centre for AIDS and STD Control, Kathmandu, Nepal
Presenting author email: keshab.deuba@savethechildren.org

Background: The need for efficient retention in HIV care is more evident than ever because of the expansion of earlier ART initiation and the shift towards ‚Test and Treat'. This study assesses different steps of HIV care cascade (from diagnosis to viral load suppression) among children living with HIV (CLHIV) in Nepal. We also examined retention in care, mortality and Loss To Follow-Up (LTFU) over time by age (0-4 and 5-14 years) and gender.
Methods: We calculated the number of CLHIV using UNAIDS developed Spectrum and Epidemic Projection Package using census, surveillance data and national programme data. We reviewed the program data of all HIV-infected children (1363) registered till the end of 2015 in 65 ART centres in 59 districts of Nepal. The retention in care was defined as the percentage of children alive and on ART at 12, 24, 36 and 48 months. LTFU was defined as having not visited ART centre for 90 days.
Results: Of 1589 estimated CLHIV, 815 (51.3%) were male, and 774 (48.7%) were female. 1363 (86%) of the total estimated children were diagnosed with HIV by the end of 2015. Of the total estimated CLHIV, 76% linked to HIV care. Only half of the CLHIV have access to ART, and one-third (35%) had tested for viral load. Only one-quarter of CLHIV remained virologically suppressed (≤1000 copies/mL) at their most recent tests. The retention rate was 94%, 94%, 89% and 84% at 12 months, 24 months, 36 months and 48 months respectively. No substantial difference in the retention in care was observed by gender, but the difference was observed by age group. LTFU was increased from 3% in 2012 to 6% in 2016, and the substantial difference was observed by age group (≤4 years vs. 5-14 years: 11% vs. 2% at 12 months). Similarly, we found a significant difference in mortality rate over time by age group (≤4 years vs. 5-14 years: 14% vs. 6% at 36 months).
Conclusions: Young children (≤4 years) are experiencing higher LTFU and mortality than children 5-14 years old. Future efforts should improve access to and retention in care of young CLHIV in Nepal.

TUPED1298

Assessing long-term retention in care for patients on antiretroviral therapy in the northern part of Zambia: a cohort study

T. Malebe[1,2,3]
[1]FHI360/ ZPCT II, Technical Department (PMTCT/CT), Lusaka, Zambia, [2]FHI 360, Technical Department, Lusaka, Zambia, [3]University of Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa
Presenting author email: tmalebe@fhi360.org

Background: Zambia has made significant progress in scaling up antiretroviral therapy (ART) programs in the last decade. Retention in care is critical to achieving HIV viral suppression, improved health outcomes and reduced HIV related morbidity and mortality. This evaluation presents findings from a cohort of 4,417 patients on cART as we seek to define predictors for retention in care.
Methods: This was a retrospective review of medical records of patients initiated on cART between January and December 2009 and followed up for 60 months at nine 2nd level provincial hospitals in Zambia. Kaplan Meier curves were used to determine retention at 12, 24, 36, 48 and 60 months. Retention was defined as not having experienced death, loss to follow up, transfer out or stopped ART. Cox regression was used to determine the predictors of retention and the magnitude of their effect on retention. Factors examined included age, baseline WHO clinical stage, education level, marital status and gender.
Results: The retention rates were 77%, 69%, 61%, 54% and 47% at 12, 24, 36, 48 and 60 months respectively. Females had higher retention at 60 months (50% vs 44%) compared to males: aHR: 0.84 (95% CI: 0.76 - 0.92). Retention was positively associated with various factors such as lower baseline WHO clinical stage I and II: aHR: 0.66 (95% CI: 0.60 - 0.74) and primary education: aHR 0.89 (95% CI: 0.81 - 0.99).
Conclusions: Retention rates for patients in ART care was at 77% after 1 year but dropped to 47% at 5 years of follow up. Patients who are male, with WHO stage III or IV disease and with secondary or tertiary education require intensive adherence counselling and follow up to improve retention in care.

TUPED1299

Sub-group effect heterogeneity of conditional food and cash transfers provided to HIV-infected adults in improving adherence to antiretroviral therapy and retention in care in Shinyanga, Tanzania

J.L. Kadota[1], S.I. McCoy[1], C. Fahey[1], P.F. Njau[2], N. Kapologwe[3], N.S. Padian[1], W.H. Dow[1]
[1]University of California, Berkeley, Berkeley, United States, [2]Ministry of Health and Social Welfare, Dar es Salaam, Tanzania, United Republic of, [3]Regional Medical Office, Shinyanga, Tanzania, United Republic of
Presenting author email: jill.kadota@berkeley.edu

Background: We recently concluded a randomized study in Tanzania which found that short-term conditional cash and food transfers significantly improved HIV-infected patients' possession of antiretroviral therapy (ART) and reduced loss to follow-up (LTFU). We examined whether the transfers had differential effects within key subgroups.
Methods: In the parent study, 805 individuals were randomized to standard of care (SOC) HIV services or food or cash transfers, valued at approximately $11 USD/month and provided for ≤6 months, conditional on clinic visits. Eligibility criteria were: 1) ≥18 years; 2) HIV-infected; 3) food insecure; and 4) initiated ART ≤90 days before enrollment. We compared achievement of 6-month medication possession ratio (MPR) ≥95% and 12-month LTFU between patients receiving the SOC and those receiving food or cash (combined). Heterogeneity was assessed by comparing intervention effects expressed as risk differences (RD) within the following subgroups: sex, age (18-35, ≥35 years), wealth (poorest quartile vs. all others), and time elapsed between HIV diagnosis and ART initiation (≥90, < 90 days).
Results: The intervention improved MPR≥95% and reduced LTFU in subgroups, although effects did not significantly differ between most subgroups (see Table). For example, the intervention's effect on MPR≥95% was non-significantly stronger among females compared to males; those poorest vs. wealthier; and significantly greater for participants with < 90 days elapsed between diagnosis and ART initiation compared to those with ≥90 days. For 12-month LTFU, the effect was non-significantly stronger amongst those poorest vs. wealthier; and in participants with ≥90 days elapsed between diagnosis and ART initiation compared to those with < 90 days.

	Males	Females	Age: 18-35	Age: 35+	< 90 days elapsed between diagnosis and ART initiation	≥ 90 days elapsed between diagnosis and ART initiation	Lowest wealth quartile	Wealthier quartiles
Intervention Effect on 6-Month MPR ≥ 95% (RD, 95% CI)	13.9% (-2.1, 29.8)	21.4% (8.9, 34.0)	16.1% (2.5, 29.7)	21.8% (7.1, 36.6)	24.0% (12.4, 35.7)	3.0% (-14.6, 20.6)	28.2% (5.3, 51.1)	16.4% (5.2, 27.5)
Test for homogeneity	p = 0.51		p = 0.64		p = 0.039		p = 0.27	
Intervention Effect on 12-Month LTFU (RD, 95% CI)	-13.7% (-29.6, 2.2)	-6.4% (-15.7, 2.9)	-9.9% (-21.6, 1.9)	-7.5% (-19.2, 4.1)	-6.8% (-16.2, 2.6)	-15.0% (-32.5, 2.5)	-18.3% (-39.7, 3.1)	-6.4% (-15.2, 2.3)
Test for homogeneity	p = 0.58		p = 0.83		p = 0.13		p = 0.27	

[Table]

Conclusions: This analysis provides preliminary data suggesting that targeting interventions at patients more recently diagnosed with HIV, whose HIV healthcare habits are still being formed, may be worthwhile. Although not powered for subgroup analyses, study results suggest that food or cash transfers may have stronger beneficial effects on HIV care in marginalized population members, particularly the poorest and in women. Future studies to detect subgroup effects with larger sample sizes are warranted.

TUPED1300

Have patient outcomes in South Africa's ART program improved with age? Evidence from an urban HIV clinic under three different sets of ART guidelines

C. Hendrickson[1], S. Pascoe[1], K. Shearer[1,2], A. Moolla[1], M. Maskew[1], L. Long[1], M.P. Fox[1,3,4]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]Boston University, Department of Global Health, Boston, United States, [4]Boston University, Department of Epidemiology, Boston, United States
Presenting author email: ksheare5@jhu.edu

Background: As HIV treatment programs in resource-limited settings transition to "treatment-for-all", it is important to take stock of successes thus far to guide retention-in-care priorities as larger numbers of healthier patients start treatment. We evaluate short-term outcomes of patients initiating antiretroviral therapy (ART) in South Africa under various treatment guidelines since program inception in 2004.
Methods: We conducted a prospective cohort analysis of ART-naïve adults (≥18) initiating standard first-line ART at a large, public-sector HIV clinic from 04/2004-12/2015. We used Cox proportional hazards regression to evaluate the association between attrition (mortality and loss to follow-up [LTF: ≥3 months late for a scheduled visit] combined) and three ‚guidelines' cohorts: 04/2004-08/2011 (C1:CD4≤200mm^3); 08/2011-12/2014 (C2:CD4≤350mm^3); 01/2015-12/2015 (C3:CD4≤500mm^3). Patients were followed from ART initiation until the earliest of death, LTF, transfer or 12-months follow-up.
Results: 23,654 adults were followed for 19,961 person-years. Median age at ART initiation increased from 36.3 (IQR:31.0-42.8) (C1) to 38.7 (IQR:32.5-46.3) (C3). The proportion of men increased from 37.0% (C1) to 43.1% (C3) and median baseline CD4 count increased from 94 cells/mm^3 (IQR:35-166) (C1) to 156 cells/mm^3 (IQR:50-305) (C3). Attrition at one year declined across the guidelines cohorts from 24.4% to 18.0% (Table 1).

		C1: CD4 ≤200 guidelines N (%)	C2: CD4 ≤350 guidelines N (%)	C3: CD4 ≤500 guidelines N (%)
Patients enrolled		16794 (71.0)	5723 (24.2)	1137 (4.8)
12-month outcomes	Alive, on treatment	12091 (72.0)	4078 (71.3)	825 (72.6)
	Dead	1314 (7.8)	337 (5.9)	67 (5.9)
	Lost to follow-up	2786 (16.6)	855 (14.9)	137 (12.1)
	Transferred	603 (3.6)	453 (7.9)	108 (9.5)
Total Person Years		14,159	4,826	976
Attrition rate per 100 person years**		29.0	24.7	20.9

*≤200 guidelines: April 2004 to August 2011; ≤350 guidelines: September 2011 to Dec 2014; ≤500 guidelines: January 2015-March 2015. **Attrition is defined as those who are dead or LTF

[Table 1: 12-month outcomes of patients initiated on ART at the Themba Lethu Clinical HIV Cohort in Johannesburg, South Africa between 1 April, 2004 and 31 December 2015 by South African ART guidelines]*

However, after controlling for sex, age, anaemia, and baseline ART regimen, no association was observed between attrition and guidelines cohort within CD4 count categories (Table 2).

		Baseline CD4 count <100		Baseline CD4 count 101-200		Baseline CD4 count 201-350		Baseline CD4 count 351-500	
		n/N (%)	aHR (95% CI)	n/N (%)	aHR (95% CI)	n/N (%)	aHR (95% CI)	n/N (%)	aHR (95% CI)
CD4 treatment guidelines**	≤200	2273/7969 (28.5)	1.00	1046/5243 (20.0)	1.00	343/1775 (19.3)	1.00	31/141 (22.0)	1.00
	≤350	448/1708 (26.2)	0.96 (0.84, 1.09)	193/1167 (16.5)	1.01 (0.83, 1.23)	186/1545 (12.0)	0.76 (0.60, 0.96)	26/189 (13.8)	0.51 (0.24, 1.09)
	≤500	75/330 (22.7)	0.84 (0.65, 1.07)	30/155 (19.4)	1.21 (0.82, 1.77)	26/200 (13.0)	0.84 (0.55, 1.29)	15/123 (12.2)	0.50 (0.22, 1.16)

*Models are adjusted for sex, age and anaemia at ART initiation and baseline ART regimen

[Table 2: Adjusted HR for 12-month attrition by baseline CD4 count]*

Conclusions: Overall, immune status of patients initiated under the three guidelines has improved at this facility; however, we still observe high rates of attrition within 12 months on treatment. As South Africa implements "treatment-for-all", focus should be early retention in care to ensure long-term success.

TUPED1301

Evaluating the WelTel service's Grand Challenges Canada "transition-to-scale" for HIV care in Kenya's northern arid lands

R. Lester[1], K. Kinagwi[2], M. Budd[1], P. Boutet[1], K. Smillie[1], B. Tilahun[1], K. Bardosh[3], G. Wangalwa[2]
[1]University of British Columbia, Infectious Diseases, Vancouver, Canada, [2]Amref Health Africa, Nairobi, Kenya, [3]University of Florida, Anthropology and Emerging Pathogens Institute, Gainesville, United States
Presenting author email: rlester.id@gmail.com

Background: The original WelTel Kenya1 randomized controlled trial showed that weekly text messaging communication between healthcare providers and individuals with HIV improved ART adherence and outcomes. As part of the Canadian Grand Challenges program, in partnership with Amref Health Africa and the USAID-funded APHIAplus IMARISHA project, we implemented and evaluated the WelTel service for HIV patients in Kenya's remote northern arid lands, a pastoral region with major health access issues.
Methods: Patients with mobile phone access seen between April 2015 and September 2016 at the Isiolo County Hospital's Comprehensive Care Clinic (CCC) were prospectively offered enrollment in WelTel. We tracked the number of monthly enrollments, responses to weekly check-in messages, and CCC visit attendance during the study period. Demographic information (age, sex, marital status, individual/shared phone access, and urban/rural residency) was obtained from the hospital's electronic medical records.
Results: Overall, 1,131 patients with demographic information available were seen at the CCC during the study period. Of these, 563 (50%) agreed to receive WelTel, with the majority of participants (350/563, 62%) enrolled within three months. A total of 32,595 messages were sent, with an overall response rate of 36%. Uptake was highest among patients aged 25-49 years (392/711, 55%), those with individual phone access (397/699, 57%), and married patients (277/512, 54%). Uptake was lowest among those aged < 18 years (33/142, 23%), those with shared phone access (42/101, 42%), and single individuals (111/275, 40%). There were no differences based on sex or urban/rural residency. A median of 4 CCC visits were scheduled per patient. As a group, patients on WelTel attended a higher proportion of their visits as scheduled (mean ± standard deviation: 57 ± 30%) than those not on WelTel (52 ± 31%, p=0.02). Patients on WelTel also defaulted on a smaller proportion of their clinic visits than those not on WelTel (8 ± 18% and 12 ± 22% respectively, p=0.01).
Conclusions: The WelTel mobile health program successfully reached half the population of a remote HIV clinic and reduced defaulting. It has been sustainably adopted in additional clinics in northern arid lands.

Tracking of lost to follow-ups PLHIVs towards increased retention in HIV care: experience from the Global Fund-supported Vihaan Programme in India

A.K.s. Parihar, P.K. Shetty, V. Arumugam, H. Rosenara, R. Chauhan, S. Chakraborty, B.B. Ubarhande, U. Chawla, S. Mehta
India HIV/AIDS Alliance, New Delhi, India
Presenting author email: aviswanathan@allianceindia.org

Background: 2,068,097 people registered with ART center for treatment of which 15% are on lost to follow-up (LFU) for the treatment. Bring back the LFU clients for treatment remains challenge. India HIV/AIDS Alliance implements the Global Fund supported Vihaan programme to deliver care and support services for people living with HIV (PLHIV) through its 361 community-based Care & Support Centers (CSC) across India and supports national programme to bring back LFU clients for treatment.
Methods: LFU clients list were shared with CSCs to bring back to the treatment through ART-CSC coordination and data sharing process on monthly basis. LFU clients include ART LFU, Pre-ART LFU, ART missed clients, clients who are eligible but not started ART and missed CD4 testing. Data sharing tool has been developed and used across India uniformly. 2,023 outreach workers and peer counsellors were trained on LFU tracking and tools. Field level community workers tracked back LFU clients and documented the outcome. Brought back line lists were compiled nationally and analysed. Data quality were ensured through on-site data verification and supervisory visits. Descriptive analyses of brought back clients and trend analyses for LFU were carried out.
Results: 256,011 LFU clients were brought back to ART center for treatment and health monitoring between 2013 and 2016. Of which 67% LFU and missed clients on ART and 37% were clients not on ART. On an average, frontline workers of CSC were able to bring clients back to ART centre within 2 months. Among clients brought back to ART centre, average age is 33 years. More than 60% clients are in 20-40 years age category and about 9.3% belongs to < 20 years. Among brought back 54% were male and 46% were female. Through regression analyses of LFU clients for last 2 years showed the there is a significant decrease (p< 0.001) in clients not on treatment (Pre-ART clients) and stabilisation on clients on-ART.
Conclusions: Collaborative effort between national ART progamme and community led outreach programme is effective in bringing back the alive LFU clients for treatment. Long term of this continued efforts will sustain the increased adherence and retention in HIV care.

Low retention in care among recently diagnosed women enrolled in Option B+ care in Mozambique

K.H. Ásbjörnsdóttir[1,2], A. Silvis Rustagi[1], J. Coutinho[2], S. Gimbel[2,3], F. Cuembelo[4], M. Nhumba[2], C. De Schacht[2], G.C. John-Stewart[1,5,6,7], K. Sherr[1,2,7]
[1]University of Washington, Global Health, Seattle, United States, [2]Health Alliance International, Beira, Mozambique, [3]University of Washington, Family and Child Nursing, Seattle, United States, [4]Universidade de Eduardo Mondlane, Department of Community Health, Maputo, Mozambique, [5]University of Washington, Medicine, Seattle, United States, [6]University of Washington, Pediatrics, Seattle, United States, [7]University of Washington, Epidemiology, Seattle, United States
Presenting author email: kasbjorn@uw.edu

Background: Mozambique adopted the Option B+ strategy in 2013-2014. Reported rates of HIV testing and ART initiation during pregnancy are >90%; however, retention in care has been poor, potentially resulting in uncontrolled viral load (VL) and continued mother-to-child HIV transmission.
Methods: From 07/2015-03/2016, we enrolled an unselected population of Option B+ eligible women from antenatal care at ten clinics in Central Mozambique. Sociodemographic data, medical and obstetric history, and data concerning ART knowledge and self-efficacy were collected at enrollment. Follow-up data were collected by clinic nurses during routine visits at delivery, six weeks and six months post-partum; VL samples were collected at delivery. Retention in care was defined as completion of a routine visit within 45 days of the scheduled date. Baseline factors associated with subsequent retention in care and VL suppression to < 500 copies/mL were identified using generalized estimating equations with clustering by clinic.
Results: 1576 women were enrolled at a median gestational age of 5.9 months. Prior to enrollment, 57% of women had been diagnosed with HIV and 47% had initiated ART. By six weeks post-partum, 46% of women were lost to follow-up; by six months post-partum, 68% were lost to follow-up. Retention in care was associated with presenting to care after the first trimester (OR=1.26,(95%Confidence Interval:1.07-1.47)), and HIV diagnosis prior to study enrollment (OR=1.56,(1.25-1.94)). Of 535 women with samples analyzed to date, 290 (54%) had suppressed VL. Suppression was associated with HIV diagnosis (OR=2.06,(95%CI:1.42-2.98)) and ART initiation (OR=1.49,(95%CI:1.07-2.08)) prior to enrollment. Greater than median self-efficacy score at enrollment was associated with both retention in care (OR=1.31, (95%CI:1.05-1.64) and VL suppression (OR=1.62,(95%CI:1.20-2.18).
Conclusions: Early loss to follow-up from routine care in our study was extremely high, and recently diagnosed women were at particular risk of loss to follow-up and unsuppressed VL. Enhanced strategies are needed to promote retention in care and ART adherence under Option B+ in Mozambique; self-efficacy assessments may provide an opportunity to identify at-risk women.

Exploring patent medicine vendors (PMVs) in the context of community ART programs in resource poor settings using rural areas of Benue state as case study

H. Sagay[1], B. Akpa[1], P. Jwanle[1], E. Udeh[1], H. Ezeofor[1], L. Inyama[1], M. Ojeikpo[1], O. Daramola[1], I. Kuku[1], J. John-Baba[1], T. Mmanger[2], B. Oyeledun[1]
[1]Center for Integrated Health Programs, Abuja, Nigeria, [2]Benue State Ministry of Health, Benue, Nigeria
Presenting author email: heltisa@gmail.com

Background: Background
To scale up Antiretroviral Therapy (ART) in 5 PEPFAR prioritized LGA of Benue State, access to HIV treatment must be at the reach of the endemic population in the communities. Patent Medicine Vendors (PMVs) are outlets for selling over-the-counter drugs. Literature review reveals that PMVs are the first point of contact when members of the community become ill. The objective of the study is to examine the contextual factors of involving PMVs in community ART programs
Methods: .A cross-sectional community based survey was conducted across five local government areas in Benue state in December 2015. A total of 191 Patent medicine vendors across 41 ward councils of Tarka, Logo, Gwer West, Katsina Ala and Konshisha LGA were assessed. Data collection was done using a structured questionnaire and analysed using SPSS

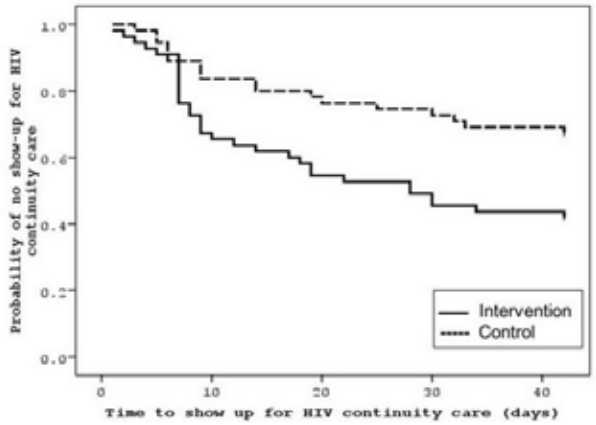
Results: A review of the 191 PMVs assessed in the 5 LGs revealed 47.1% had secondary school certificate, 2.6% had tertiary education, and 15.7% had no formal education. No PMVs had record of adverse drug reactions. Hygiene standards revealed 2% had hand washing and 15% had toilet facility respectively. Dispensing worksheet was not in use with only 3% using adhoc drug register to document drugs dispensed. Assessment of Basic Infrastructure to support ART drug pick-up showed that only 24.1% have rooms with audio-visual privacy while 27.2% have adequate patient waiting area. Only 20.9% have PCN (Pharmacists council of Nigeria, the regulating and licencing body in Nigeria) licence while 93.2% were registered with NAPPMED (National Association of Patent and Proprietary Medicine Dealers, the association of medicine vendors in Nigeria)
Conclusions: The study findings demonstrates that PMVs have obvious limitations in participating in community ART programs due to legal issues of PCN licensing, poor infrastructural support and inconsistent level of formal education. Other observations include PMVs retailing alcoholic beverages/ household materials, traditional concoctions and tobacco. To incorporate PMVs into community ART program, effort would be needed to build capacity, provide infrastructural support and advocacy on appropriate licencing for practice

TUPED1305

A randomized controlled study of intervention to improve continuity care engagement among HIV-infected jail detainees

T. Khawcharoenporn[1,2], J. Cole[2], J. Claus[2], T. Bell[3], A. Lewis[2], C. Zawitz[3,4], H. Kessler[2]
[1]Thammasat University, Infectious Diseases/Internal Medicine, Bangkok, Thailand, [2]Rush University Medical Center, Chicago, United States, [3]The Ruth M. Rothstein CORE Center, Chicago, United States, [4]Cermak Health Service Division, Chicago, United States

Background: Short-term stay, multiple jail admissions and social and financial difficulties are significant obstacles for continuity care engagement (CCE) after release among HIV-infected jail detainees. The rate of CCE within 6 weeks after jail release has been previously reported to be 25-68%. However, no study has been conducted to evaluate strategies to improve CCE.
Methods: All HIV-infected detainees at Cook County Jail were enrolled during 2011-2014. The detainees were randomly assigned to the intervention group (telephone contact within 2-4 days of release by continuity clinic coordinator), plus standard of care versus the control group, which received only standard of care. Rates of CCE within 6 weeks of jail release were assessed.
Results: There were 166 detainees enrolled, of which 56 were excluded due to being sent to prison (N = 49) or re-incarceration within 6 weeks (N = 7). The final cohort included 55 detainees in each of the groups. Baseline demographic and clinical characteristics of the two groups were similar, except for higher proportion of history of alcohol use in the control group (76% vs. 51%). The rate of CCE within 6 weeks after jail release was significantly higher in the intervention group compared to the control group (58% vs. 33%; P=0.007). By Kaplan-Meier survival analysis, the probability of failure to present for continuity care was significantly higher in the control group ($\chi 2$ = 7.44, P=0.006; Figure). In multivariable logistic regression analysis, being in the control group was the only factor associated with no CCE within 6 weeks (adjusted odds ratio 2.66; 95% confidence interval 1.18-6.00; P=0.02).



[Figure]

Conclusions: A simple contact intervention by telephone to schedule an appointment for HIV continuity care following release from jail, significantly improved CCE among HIV-infected jail detainees.

TUPED1306

Peers counseling at care entry point increase linkage to care among pre-ART HIV-infected patients: a case study

F. Epoupa[1], M.E. Ikechukwu[2], V. Enejoh[3]
[1]Center for Clinical Care and Clinical Research Nigeria, Technical Unit, Abakaliki, Nigeria, [2]Catholic Caritas Foundation, Nigeria, Technical Unit, Makurdi, Nigeria, [3]Centre for Clinical Care and Clinical Research Nigeria, Technical Unit, Abuja, Nigeria
Presenting author email: epoupafl@yahoo.com

Background: Mater Misericordiae Hospital is a faith-based institution offering comprehensive integrated HIV services for a decade through PEPFAR funding. As in other countries, linkage and retention in pre-ART care among newly diagnosed HIV infected clients was poor. To address this, the HCT counselor who is PLHIV was mentored in peer counseling, additionally the post-test counseling session for HIV infected clients was modified to include orientation of patients on clinic processes, obtain a commitment to seek care from patients, escorting clients to the next point of service and introducing patients to ART providers same day. Referral follow-up for those referred to other treatment centers was strengthened. This study seeks to evaluate the outcome of this intervention.
Methods: Baseline assessment of the linkage of clients who were identified at the HTC unit of MMH in 2013 was carried out; the intervention started in January 2014. The assessment was repeated end of 2014. All newly identified patients were included in the study. Referred-in clients were excluded from the study. Linkage was assessed using medical records. Complete linkage was defined as having ART number, completed adherence education, baseline laboratory results and WHO staging documented. For clients who were referred to other ART centers, the feedback referral form and the register documentation were the evidence of linkage. Identifiers of patients in HTC registers were traced in all other registers. Additionally, medical charts were reviewed for evidence of services provision.
Results: In 2013, 160 HIV infected clients were identified; 93(58%) were successfully linked to ART care at MMH, 40(25%) stopped during the Pre-ART period, 27(17%) never returned to the facility, totaling 42% lost to care. At the end of 2014, 127clients were identified, 98 agreed to receive ART at MMH, while 29 clients were referred to other centers. All 98(78%) remained in care at MMH and 22(17%) referred clients accessed care at other facilities yielding 95% linkage achievement.
Conclusions: Peer counseling at ART entry points, escort system and orientation of clients on clinic processes increased linkage to care at MMH. Unexpected outcome was improved referral process. Replication of this intervention in diverse settings may prove the strength of this intervention.

TUPED1307

Linkage-to-care among HIV-positive men who have sex with men (MSM) and transgender women (TW) diagnosed via venue-based testing in Lima, Peru

G.M. Calvo[1], E. Lugo[1], M.C. Herrera[2], S.K. Vargas[1], M.J. Bustamante[1], C.F. Caceres[1], J.D. Klausner[3,4], K.A. Konda[1,2]
[1]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Investigation in Sexuality, AIDS, and Society, Lima, Peru, [2]David Geffen School of Medicine, University of California Los Angeles, Medicine, Division of Infectious Diseases, Lima, Peru, [3]UCLA, Medicine, Division of Infectious Diseases, Los Angeles, United States, [4]Fielding School of Public Health, University of California, Los Angeles, United States
Presenting author email: kkonda@mednet.ucla.edu

Background: There is little information available on linkage-to-care processes among MSM and TW in Peru. Existing information is often restricted to individuals who do reach the HIV care facilities, though HIV testing primarily occurs elsewhere. We sought to monitor the linkage process among MSM and TW diagnosed during a venue-based HIV testing study.
Methods: We conducted venue-based HIV testing with 3rd and 4th generation rapid tests at bars, clubs, and sex work walks where MSM/TW congregate. Staff provided pre and posttest counseling and collected contact information. Then the study team maintained contact with the MSM/TW who tested positive to help with linkage-to-care at Peruvian Ministry of Health (MoH) or non-governmental organizations (NGOs) providing HIV care including antiretroviral therapy.
The study also provided funds for initial HIV program visits and testing required for program entry.
Results: Among the 300 MSM/TW tested, 67 (22%) were diagnosed with HIV. Among these 67, only 13 (19%) were able to successfully link to HIV care within 6 months of diagnosis, the number was lower among the HIV positive TW (10% TW vs. 19% MSM were enrolled) though this was not statistically significant. Their time to linkage-to-care was longer at the MoH (median 90 days) vs. NGOs (median 58 days). Another 15/67 (22%) began the linkage process, but remained unlinked 6-months post-diagnosis, most reported a lack of time to attend visits required for linkage or did not feel inclined to begin care yet.

Another 24/67 (36%) did not appear for follow-up HIV linkage visits, although they were contacted repeatedly by study staff. We were unable to contact the remaining group 15/67 (22%) after initial venue-based diagnosis due to non-working contact information.
Conclusions: Although venue-based testing works for case finding, additional interventions are needed to facilitate entry into care. Several individuals did not want to be contacted by the study post-diagnosis because they did not yet feel the need to link-to-care. HIV programs also need to improve understanding of current treatment and work to promote health care seeking. Peer navigator programs should be expanded and HIV care facilities should consider burden-of-care and public health when designing their protocols.

Enhancing referral to increase linkage to HIV care in rural South Africa: example from the ANRS 12249 TasP trial

M. Plazy[1,2], A. Diallo[1,2], C. Iwuji[3,4], J. Orne-Gliemann[1,2], N. Okesola[3], T. Hlabisa[3], D. Pillay[3,5], F. Dabis[1,2], J. Larmarange[6], for the ANRS 12249 TasP Study Group
[1]Univ. Bordeaux, INSERM, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [2]INSERM, ISPED, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [3]Africa Health Research Institute, Somkhele, South Africa, [4]Research Department of Infection and Population Health, University College London, London, United Kingdom, [5]University College London, Division of Infection and Immunity, London, United Kingdom, [6]Ceped UMR 196 (Paris Descartes IRD), SageSud ERL Inserm 1244, IRD, Paris, France
Presenting author email: melanie.plazy@isped.u-bordeaux2.fr

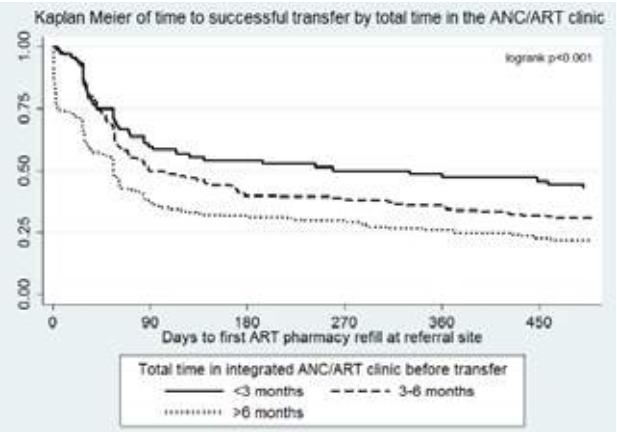
Background: Timely linkage to care following an HIV diagnosis is critical for people living with HIV to initiate antiretroviral treatment as early as possible and thus decrease the risks of HIV-related morbidity, mortality and HIV transmission. Linkage to HIV care is however often challenging and innovative strategies are required to help people accessing HIV care.
We aimed at evaluating the effect of phone calls and home visits following an initial referral on time to linkage to care in the context of a Universal HIV Testing and Treatment (UTT) trial in rural KwaZulu-Natal, South Africa.
Methods: The ANRS 12249 TasP trial was conducted from March 2012 to June 2016 with the aim to evaluate the effect of UTT on HIV incidence. Individuals ≥16 years were offered home-based HIV testing; those identified HIV-positive were referred to nearby TasP trial clinics to receive care and treatment. Starting April 2013, an enhancement strategy combining phone calls and home visits was implemented to re-refer people who did not link to care within three months of first referral. Effect of this strategy on time to linkage to care was studied as a time-varying variable among individuals not in care at first referral using a Cox regression model censored for death, migration and end of study observation.
Results: Among the 7,643 individuals identified HIV-positive at home and referred to TasP clinics, 2,254 (72% female) were not in care at referral and did not link to care within three months of first referral. Among them, 451 (20%) individuals were contacted through phone calls or home visits before migration or death. Probability of linkage to care was significantly higher among individuals re-referred to care compared to those not re-referred (Hazard Ratio 2.25; 95% Confidence Interval 1.83-2.78); significant positive effects were also observed for both genders and all age categories (< 30; 30-39; 40-49; ≥50 years old) after stratification.
Conclusions: Phone calls and home visits aiming at re-referring people to HIV care appear effective in improving linkage to care. Patient-centered strategies should be part of UTT programs in order to achieve the 90-90-90 UNAIDS targets.

TUPED1309

Postpartum transfer of HIV-infected women initiating antiretroviral therapy (ART) during pregnancy in an integrated antenatal care (ANC)/ART service in Cape Town, South Africa: a cohort study

T. Phillips[1,2], K. Brittain[1,2], A. Zerbe[3], J. McIntyre[1,4], G. Petro[5], E.J. Abrams[3,6], L. Myer[1,2], for the MCH-ART Study
[1]University of Cape Town, Division of Epidemiology and Biostatistics, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [3]Columbia University, ICAP, New York, United States, [4]Anova Health Institute, Johannesburg, South Africa, [5]University of Cape Town, Department of Obstetrics & Gynaecology, Cape Town, South Africa, [6]Columbia University, College of Physicians & Surgeons, New York, United States
Presenting author email: tk.phillips@uct.ac.za

Background: Integrated ANC/ART services are commonplace in high-burden settings and require transfer to general ART care postpartum. Given the challenges in engaging postpartum women on ART, we examined how postpartum transfer of ART services influenced engagement in general ART care.
Methods: Consecutive HIV+ pregnant women initiating ART in an integrated, public-sector ANC/ART service were followed from ART initiation through 20m postpartum in the MCH-ART study. Referral from ANC/ART services occurred 0-13m postpartum, with women referred to their nearest general ART clinic. Data on ART initiation and ANC/ART visits were abstracted from routine records, with time in ANC/ART clinic measured from ART start date to date of postpartum referral to general ART clinics. Electronic ART pharmacy refill (PR) was obtained through 20m postpartum from all ART services in the Western Cape Province. Analyses used product-limit methods and Poisson models to evaluate predictors of successful transfer to ART care (defined as PR ≤3m post-transfer).
Results: Among 486 women included, the median age was 28y and median time in the integrated ANC/ART clinic before transfer was 276d. Overall, 54% of women successfully transferred. Increased time in the integrated ANC/ART clinic was strongly associated with successful transfer (Figure, p< 0.001). After adjusting for age, gestation at ART initiation, relationship status, timing of HIV diagnosis and design effect, each additional month in the integrated ANC/ART clinic increased the likelihood of successful transfer by 7% (RR and 95%CI: 1.07 [1.04-1.10]). Women with >6m in the ANC/ART clinic were 1.52 and 1.28 times more likely to transfer successfully than women in the ANC/ART clinic < 3m and 3-6m (RR and 95%CI: 1.52 [1.07-2.16] and 1.28 [1.04-1.57], respectively).
Conclusions: While successful postpartum transfer appears low, raising concerns about disengagement from care after delivery, these data suggest that increasing total time in integrated ANC/ART services could be an important determinant of successful transfer.



[Kaplan Meier of time to successful transfer by total time in the ANC/ART clinic]

TUPED1310

Early diagnosis and the 2020 goals: the importance of a partnership between civil society orgaizations and the national health system

M. Serrado[1], P. Ferreira[2], J. Brito[3], E. Lima[2], J. Esteves[3], C. Gomes[1], J. Costeira[1], F. Caetano[2], D. Simões[3], A. Diniz[1,4]
[1]Centro Hospitalar Lisboa Norte - CHLN/HPV, Immunodeficiency Unit, Lisboa, Portugal, [2]Centro Hospitalar Lisboa Norte, Hospital de Dia de Doentes Imunocomprometidos (HDDI), Lisboa, Portugal, [3]GAT - CheckpointLX, Lisboa, Portugal, [4]Escola Nacional de Saúde Pública - UNL, Centro de Investigação em Saúde Pública (CISP), Lisboa, Portugal
Presenting author email: margaridaserrado@gmail.com

Background: According to the latest available data (2014), Portugal shows a proportion of late diagnosis similar to others EU countries, altough this value remains high, regarding the UNAIDS 90-90-90. So, we must evaluate new approaches of early diagnosis and linkage to care, namely those implemented in partnership with civil society organizations (SCO), looking at their potential benefits and replication in other contexts. The aim of the study is to compare, regarding the stage of infection, the MSM population with a new HIV diagnosis (a population growing up in Portugal) admitted in our hospital through an SCO referral (2014-16) with the total of new diagnosed cases in MSM and all the new diagnosed cases, in Portugal.
Methods: We study the MSM population admitted in our center (CHLN-HPV) by CheckpointLX referral (MSM LX) with a new HIV diagnosis between 2014 and 2016 (n=112). We analyze some demographics and HIV infection stage of disease (CD4 cell count, late diagnosis/advanced disease). We compare this results with the national data obtained in: a) new HIV MSM diagnosed cases; b) all new diagnosed cases. The statystical analysis was done using the $\chi 2$ and t-test.
Results: The results are sumarized in Table 1

	MSM LX 2014-2016	MSM PT 2014		Global PT 2014	
	n (%)	n (%)	*p**	n (%)	*p**
Age (mean)	30.4	34.0	***0.0011***	40.5	***<0.0001***
Migrant	31/112 (27.7)	67/389 (17.2)	***0.0033***	161/1101 (14.6)	***<0.0001***
CD4 (mean)	501.7 cells/mm3	427 cells/mm3	***0.0088***	378 cells/mm3	***<0.0001***
CD4 <350cells/mm3	29/110 (26.4)	119/299 (39.8)	***0.0040***	455/926 (49.1)	***<0.0001***
CD4 <200cells/mm3	11/110 (10.0)	61/299 (20.4)	***0.0068***	292/926 (31.5)	***<0.0001***

[Table 1]

* in relation to MSM LX
CD4 (MSM LX): n=110 (2 missed cases).
Conclusions:
1) The HIV positive MSM admitted through ChepointLX referral were significantly younger, had a higher proportion of migrants and less late diagnosis and advanced disease.
2) These data suggest that, at least in the MSM population, this methodology must be followed in other regions and/or other SCO in Portugal.
3) This methodology can contribute to reach the 2020 UNAIDS goals.

TUPED1311

Engagement in economic strengthening activities and retention in care among food insecure people living with HIV (PLHIV) in Ethiopia

T. Bezabih
World Food Programme, Programme/Nutrition and Education/ HIV/AIDS, Addis Ababa, Ethiopia
Presenting author email: tsegazeab.bezabih@gmail.com

Background: Retention in care, a critical factor for optimal clinical outcomes, is a particular challenge among food-insecure PLHIV in Ethiopia. It is hypothesized that Economic strengthening (ES) intervention designed to address poverty and food insecurity may also have an impact on retention in care positively. This study aims to assess the impact of ES interventions in Ethiopia on retention in care among PLHIV on ART or pre-ART.
Methods: Comparative Cross-sectional design was employed to compare food insecure PLHIV benefitting from the ES project of WFP Ethiopia to food insecure PLHIV not participating in ES. In this study, one is considered as non-retained if he/she misses at least one pre-ART or routine ART appointment in the last 12 months period. Logistic Regression model was employed to estimate the likelihood of missing a health facility appointment. Qualitative data were also collected to complement the quantitative data.
Results: After adjusting for important background characteristics including sex, place of residence, formal education attendance, marital status, numbers of daily ART pills, age and household size, non-participation in ES increases the odds of missing a clinic visit by a factor of 6.74, significant at 0.001 levels. The ES participants explained that the series of trainings, discussions at the saving and loaning association meetings, peer support mechanism and the boost in economic capacity created by the ES intervention have helped them rebuild their confidence, self-esteem, and self-worth which all are quoted as contributors for their consistent retention in care. On the contrary, for the comparison group, forgetfulness, internal stigma and lack of interest (depression) are cited as major constraints that discourage attendance to their appointments. This is reflected in the large difference in mental health scores noted between the ES and the comparison group in favor of the former (67.8 vs. 50.8).
Conclusions: The study suggest that participation in ES contributes to improve retention in care among food insecure PLHIV which may be explained by the effects of the intervention in improving mental health aspects of quality of life and economic well-being. Thus, ES can be taken as a strategy to improve retention in care among PLHIV in resource-limited settings.

TUPED1312

Evaluation of electronic medical records to track patients across health facilities in Malawi: case of women participating in Option B+ program at Bwaila District Hospital

B.C. Mthiko[1], M. Msukwa[2,3], A. Bengtson[4], M. John[1], M. Chagomerana[1], R. Mwanjomo[2], J. Phulusa[1], M. Chawani[2], R. Flick[1], A. Jumbe[1], C. Melhado[1], B. Harrington[1], M. Hosseinipour[1,4]
[1]University of North Carolina Project-Malawi, Research, Lilongwe, Malawi, [2]Baobab Health Trust, Medical Informatics, Lilongwe, Malawi, [3]University of Bern, Data, Lilongwe, Malawi, [4]University of North Carolina, Epidemiology, North Carolina, United States
Presenting author email: bmthiko@unclilongwe.org

Background: The introduction of Option B+ program in Malawi has resulted in a large number of women starting antiretroviral therapy (ART). However, it is not easy to accurately trace all lost to follow up (LTFU) and transferred out patients using conventional methods only. Currently, Malawi uses an Electronic Medical Record System (EMRS) developed and maintained by Baobab Health Trust at over 86 health facilities, including all large volume ART clinics. Approximately 40-45% of all ART patients receive care at facilities with EMRS. We evaluated the feasibility of EMRS as a tool for tracing LTFU and transferred out women participating in option B+ across health facilities in Malawi.
Methods: We conducted a retrospective cohort study of HIV-infected pregnant women who enrolled in Option B+ and were LTFU at Bwaila Hospital or were transferred out to EMRS facilities within central Malawi between January 2015 and June 2016. We assessed for matches across all 20 facilities with EMRS in central Malawi. Many-to-one probabilistic record linkage algorithm was employed to assess records for matches using last name, first name and date of birth.
Results: Of 385 women recorded as LTFU, 127(33.0%) records were found at other health facilities other than Bwaila, while 12(48.0 %) of the 25 women documented to have transferred out were found at other facilities within central Malawi. However, none were found at the facilities documented on the transfer. Median time between last visit and registration at the new health facility was 110 days (IQR=72-250) for LTFU and 199.5 days (IQR =179-270) for those transferred out. Sensitivity and specificity for both groups was 60.6% (95%CI: 51.6-69.8) and 88.0% (95%CI: 83.4-91.7) respectively.
Conclusions: Linkage across EMR modules and facilities can identify women who are LTFU, detect those at risk for lost to follow-up and confirm patient transfers. Continued expansion of electronic medical records may improve the ability to track patient outcomes.

TUPED1313

High linkage to ART and HIV RNA suppression among HIV-positive MSM and TG, along with high PrEP uptake among HIV-negative MSM and TG, through community-led health service model in Thailand

R. Vannakit[1], J. Jantarapakde[2], S. Pengnonyang[2], T. Pankam[2], D. Trachunthong[2], K. Pussadee[3], R. Reankhamfu[4], D. Linjongrat[5], S. Janyam[6], T. Nakpor[7], P. Leenasirimakul[8], T. Jadwattanakul[9], A. Nilmanat[10], S. Charoenying[11], S. Mills[11], P. Phanuphak[2], M. Cassell[1], A. Schubert[1], N. Phanuphak[2]
[1]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand, [2]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]HIV-NAT, Bangkok, Thailand, [4]Caremat Organisaiton, Chiang Mai, Thailand, [5]Rainbow Sky Association of Thailand, Bangkok, Thailand, [6]The Service Workers In Group Foundation, Bangkok, Thailand, [7]Sisters Foundation, Chonburi, Thailand, [8]Nakornping Hospital, Chiang Mai, Thailand, [9]Queen Savang Vadhana Memorial Hospital, Chonburi, Thailand, [10]Hat Yai Hospital, Songkhla, Thailand, [11]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand

Background: More than half of new HIV infections annually occur among men who have sex with men (MSM) and transgender women (TG) in Thailand. To more effectively and efficiently prevent and treat HIV in these populations, a community-led health service (CLHS) model was established in Bangkok, Chiang Mai, Pattaya and Songkhla to train and mentor peers to provide HIV clinical services as community health workers (CHW) at non-government organizations.
Methods: Thai MSM and TG aged ≥18 years were recruited through six community-based organizations from May 2015 - September 2016. Trained CHWs provided same-day result HIV testing and sexually transmitted infection (STI) screening at baseline. HIV-positive clients had point-of-care CD4 measurements, immediate offers of antiretroviral therapy (ART) and HIV RNA assessments at six-months. Pre-exposure prophylaxis (PrEP) was offered to a subset of HIV-negative clients. We evaluated risk characteristics, HIV diagnosis yield, ART uptake and virologic suppression rates among HIV-positive clients, PrEP uptake, and HIV incidence.
Results: Of 2,497 participants enrolled, HIV prevalence was 18.15% in MSM (n=1,763) and 8.99% in TG (n=734) and incidence was 5.86 (3.90-8.82) per 100 person-years among MSM and 2.48 (0.93-6.61) per 100 person-years among TG. Among 386 HIV-positive participants, median (IQR) CD4 count was 370 (267-504) cells/mm^3 at baseline and 82% initiated immediate ART with a median (IQR) time to ART initiation of 15 (8-22) days. HIV-positive participants were more likely to have: never had HIV testing (66% vs. 45%, p< 0.001), have STIs at baseline (58% vs. 29%, p< 0.001); reported unprotected sex (84% vs. 76%, p=0.002); receptive anal sex (83% vs. 71%, p< 0.001); use of amphetamine-type stimulants (9% vs. 6%, p=0.03) in the past 6 months; and, never heard of PrEP (32% vs. 23%, p< 0.001). Among 70% retained on ART at six months, 93% had HIV RNA <1,000 copies/mL. Of 409 HIV-negative participants offered PrEP, uptake was 40.1%.
Conclusions: The CLHS model is highly feasible and effective, enabling previously unreached high-risk populations to access HIV testing and treatment services early as demonstrated by high HIV yield, rapid linkage to ART, high retention rate, high virologic suppression rates, and high PrEP uptake in this cohort.

TUPED1314

Utility of SMS-based reporting for supply chain management and fast tracking PMTCT intervention: a pilot study in West Bengal

K. Sachdeva[1], S. Ganguly[2], P. Sarkar[3], A. Hegde[4], S. Swarankar[1]
[1]National AIDS Control Organisation, Basic Services, Delhi, India, [2]West Bengal AIDS Control Society, Basic Services, Kolkata, India, [3]Department of Health and Family Welfare, HIV, Kolkata, India, [4]National AIDS Control Organisation, Basic Services, Thane, India
Presenting author email: drsachdevak@gmail.com

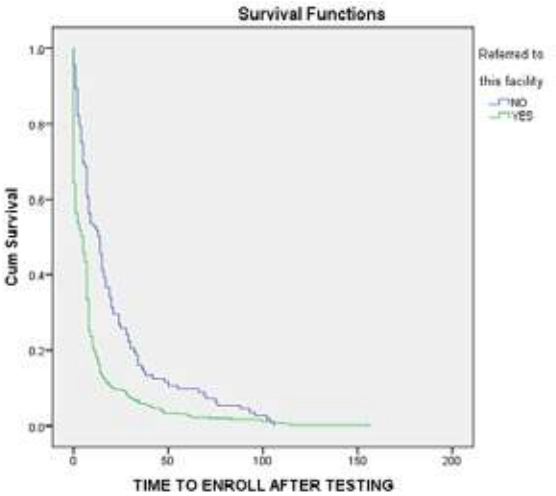
Background: Under National AIDS Control Program, commodities like testing kits and drugs are procured centrally and supplied to the States for further distribution to the facilities. Monitoring of drugs and testing kits placed at the facility and timely replenishment of stock to the facility is a real challenge to the State AIDS Control Society (SACS). Excel sheet was used to report the stock from the field level status on a weekly basis. In addition, for facilitating linkage of all HIV positive pregnant women to treatment and continuum of care services, real-time information of positive pregnant women detection was utmost required centrally, which could help to minimize linkage loss.
Methods: A mobile sms-based reporting system on stock management and linkage mechanism was developed by SACS in collaboration with State Information Technology cell. Mobile number of identified focal person at each facility was linked to the system and she/he need to send weekly stock report of seven main consumables in single sms syntax to a specified number at the end of every week. Similarly the details of HIV positive pregnant women are sent in specified syntax from mobile number of the focal person of the facility. Web based monitoring of stock and linkage to care services could be conducted by SACS.
Results: The number of facilities reporting stock out of commodities decreased from 10% to 2% and linkage of HIV positive pregnant women to treatment and care services increased from 80% to 95% , after the implementation of the weekly SMS reporting system.
Conclusions: This system being an offline reporting, is easy to implement in rural part of the State. Inbuilt central feedback mechanism ensures that the focal person at the facility upload correct data and in time. This system could be easily replicated across the country and is cost effective.

TUPED1315

Outcomes and predictors of linkage to care among newly diagnosed human immunodeficiency virus (HIV) infected patients in Central Kenya

J.K. Muthoka[1,2], R.K. Muinde[3], F.G. Njogu-Ndongwe[4], P. Wekesa[4]
[1]Center for Health Solutions, Programs, Nairobi, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology (JKUAT), Public Health, Nairobi, Kenya, [3]Centre for Health Solutions- Kenya, Program, Nairobi, Kenya, [4]Centre for Health Solutions-Kenya (CHS), Program, Nairobi, Kenya
Presenting author email: ken.muthoka@gmail.com

Background: There is substantial loss of HIV infected clients after diagnosis and before enrolment into HIV care in Kenya. The extent of the loss after HIV diagnosis and the reasons for the loss are not well documented in Kenya. This information will help programs to know the extent of the problem and areas to intervene. The aim was to determine the proportion who get linked to HIV care and the predictors of linkage to care among newly diagnosed HIV infected clients in Central Kenya.
Methods: This was a retrospective cohort with a sample of 634 newly diagnosed HIV patients from October 2015 to March 2016. The subjects were selected from Thika, Murang'a, Karatina and Nyahururu Hospitals. Each client was followed for up to three months to determine the outcome of the referral.
A data abstraction tool was used. Proportions were computed for patient characteristics and outcomes. Logistic regression was used to determine predictors of linkage. Kaplan Meier graph was done to show difference in time to enroll.
Results: Of 634 patients, 62.6% were females, 98.9% were referred to HIV care, 96.7% were documented in linkage register, 77% were linked to care, 53.8% were assessed for ART eligibility, 38.8% were eligible and 34.1% were started on ART. Patients diagnosed at inpatient had a 3.5 fold (p<0.05) higher odds of failure to be linked compared to those diagnosed at outpatient. Those diagnosed at HIV clinic were 2 times more likely to link (p<0.05) than those diagnosed at outpatient. Referral to a different facility (OR 2.3, p<0.05), non-documentation on linkage register (OR 2.3, p<0.05) and missing phone number information (OR 3.9, p<0.05) were associated with failed linkage.



[Figure 1. Time to enroll after HIV testing (p<0.05)]

Conclusions: The findings show certain predictors that can be addressed at program level to improve linkage to HIV care.

TUPED1316

Linkage of HIV-positive clients to antiretroviral care and treatment: an assessment of a finance-based linkage system in Nigeria

A.E. Ogundana[1], M. Sadiq[2]
[1]Diadem Consults Ltd, Abuja, Nigeria, [2]Diadem Consults Ltd, Utako, Nigeria

Background: Community-based HIV Testing and Counselling (conducted outside of a health facility) has the potential to identify asymptomatic HIV-positive individuals at high CD4 counts. However, linkage to care remains a challenge for those identified at these settings. We assessed the effect of a finance based linkage-to-care intervention in Nigeria.
Methods: A reimbursable coupon mechanism was implemented in Benue, Nasarrawa and the Federal Capital Territory, Abuja, Nigeria in 2016. HIV positive clients identified at outreaches were issued coupons and referred to ART clinics. Data from those who were enrolled into care were abstracted from facility record. Data from a period prior to commencement of the coupon system (pre-coupon phase) were collated for comparison. Descriptive statistics and Chi square tests of comparison for differences between categorical variables were conducted. Logistic regression was used to assess the effect of the coupon system on linkage and enrollment into HIV care and treatment.
Results: A total of 120 and 806 HIV positive clients were referred in the pre-coupon (October-December 2015) and coupon phase (January-March 2016) respectively. Majority of the clients were women (64%). Median age for females was 30 years (interquartile range {IQR}:26 - 35) and 37 years for men (IQR:31 - 40). Overall 87% of the clients received a coupon. Median time to linkage to care was 0 days (IQR: 0-7 days). Enrollment was higher in coupon phase compared to pre-coupon phase (90% vs. 17%; p<0.0001). Enrollment was similar for women (82%) and men (79%;p=0.297). Seventy-one percent compared to only 1% (p<0.0001) of clients provided invalid/wrong phone numbers in the pre-coupon and coupon phase respectively. When controlled for sex and if a client received coupon, logistic regression showed that those who received coupon were 38 times more likely to be linked and enrolled into care [OR: 38.2; 95% CI:22.7 - 64.2, p<0.0001).
Conclusions: The coupon system resulted in 90% of clients being linked and enrolled into care. The coupon has addressed a key barrier to linkage and its strong association to linkage is a promising strategy that must be scaled up. Reaching the UNAIDS 90:90:90 goal is achievable if evidence based and innovative strategies are implemented.

TUPED1317

Strategies for linking adolescents living with HIV (ALHIV) to HIV services: experience from Benue state, Nigeria

V. Isiramen[1], O. Akinleye[2], G. Wende[3], G. Dura[4], F. Agarau[5]
[1]UNICEF, Children and AIDS Section, Abuja, Nigeria, [2]UNICEF, Children and AIDS Section, Enugu, Nigeria, [3]Benue State Agency for the Control of AIDS, MOH, Markurdi, Nigeria, [4]Benue State Agency fOr the Control of AIDS, MOH, Markurdi, Nigeria, [5]Education as Vaccine, Abuja, Nigeria
Presenting author email: visiramen@unicef.org

Background: Much progress have been made in the HIV response, however ALHIV are left behind globally. While HIV related mortality has reduced by 25% in the general population, it has increased by 50% in adolescents. An HIV free generation is possible only when adolescents left behind are identified and placed on treatment especially in Nigeria where 10% of ALHIV reside.
Methods: A pilot project was conducted to evaluate approaches to the delivery of comprehensive HIV services for Adolescents and Young People (AYP) in Gboko and Makurdi Local Government Areas (LGA) in Benue state, Nigeria. The pilot had 3 components: intensive demand creation, facility and outreach based HIV testing and counselling (HTC), and referral of HIV positive clients to HIV treatment services. Two approaches were applied to test the most effective strategy for ensuring AYP testing positive were successfully referred to HIV treatment services. Under the same conditions, AYP testing positive during outreaches in Makurdi LGA were referred to HIV services by the use of peer escorts only; while those in Gboko LGA were referred using both peer escorts and SMS message reminders. Effectiveness was measured in terms of the number of HIV positive adolescents and young people who were successfully referred to HIV treatment services.
Results: Overall 401 (97.6%) AYP were successfully linked to HIV services. The use of peer escorts resulted in 208 (98.6%) AYP being successfully linked to HIV services in Markudi, while the use of peer escorts together with text message reminders resulted in the successful referral of 193 (96.5%) AYP in Gboko. (Table: 1). The addition of text messages did not result in a statistically significant rate of successful referral (P>0.05).

Access to follow-up services after HIV test and referral	Peer escort support only (Makurdi LGA)	Peer escort & text message (Gboko LGA)	Total
Yes	208 (98.6%)	193 (96.5%)* *p>0.05	401 (97.6%)
No	3 (1.4%)	7 (3.5%)	10 (2.4%)
Total	211	200	411

[Distribution of AYP Acessing Services]

Conclusions: This pilot highlights that interpersonal communication is an effective means of referral for adolescents and is not significantly augmented by the use of text messages.

TUPED1318

A comparative analysis of barriers and facilitators to HIV service utilization among three key populations in Zambia

N. Pilgrim[1], M. Musheke[2], H.F. Raymond[3], R. Keating[4], H. Witola[5], L. Banda[2], D. Mulenga[2], L. Phiri[2], S. Geibel[1], W. Tun[1]
[1]Population Council, HIV & AIDS Program, Washington, United States, [2]Population Council, HIV & AIDS Program, Lusaka, Zambia, [3]San Francisco Department of Health, San Francisco, United States, [4]University of California, San Francisco, United States, [5]National AIDS Council, Lusaka, Zambia
Presenting author email: npilgrim@popcouncil.org

Background: Female sex workers (FSWs), men who have sex with men (MSM), and people who use drugs (PWUD) are key populations (KPs) at high risk of HIV acquisition and transmission. In Zambia, their behaviors are illegal and little information exists about their HIV prevention, care and treatment needs. We compared barriers and facilitators to HIV service utilization among these populations.
Methods: Focus group discussions (FGDs) and in-depth interviews (IDIs) were conducted from July 2013 to September 2015 in nine districts in Zambia. 196 FSWs participated in 65 IDIs and 18 FGDs; 102 MSM in 38 IDIs and 10 FGDs; and 72 PWUD in 28 IDIs and 7 FGDs. Interview guides gathered information on knowledge, attitudes and experiences surrounding existing HIV/STIs service utilization. Thematic content and constant comparative analysis was used.
Results: Four domains emerged as facilitators and barriers to HIV service utilization differing by KP and health facility type- private, public, NGO, and traditional healers.
Interpersonal factors -
(a) need to protect privacy served as a barrier for all KPs;
(b) need to protect themselves and others from HIV was a facilitator among FSWs and MSM; and
(c) fear of HIV test results was a barrier among FSWs and PWUD.
Confidentiality and privacy -
(a) all KPs agreed it was lacking in public but present in private facilities; and
(b) fear of legal prosecution, believing public facilities reveal their behaviors to police, was a barrier for MSM and PWUD.
Patient-centered care -
(a) fear of and experienced stigma and discrimination and
(b) unwelcoming environments were barriers for all KPs in public facilities but not at other facility types.
Accessibility -
(a) available and free services at public facilities facilitated FSWs and PWUD access; high cost at private facilities hindered access by FSWs and MSM;
(b) long waiting times for FSW and PWUD and
(c) lack of support organizations for PWUD served as barriers.
Conclusions: There is need to improve HIV services, especially in public health facilities, for KPs. Furthermore, services must take into account the unique circumstances of each KP in order to adequately meet their HIV prevention, care and treatment needs.

TUPED1319

Reasons for switching from first-line to second-line ART regimen among patients recorded in the APMR database in Swaziland

N.H. Nxumalo[1], T. Motsa[2], F. Shabalala[3], M. Shongwe[3], A. Wagner[4], M. Malik[5], K. Matshotyana[1], K. Payne[5]
[1]Management Sciences for Health, Mbabane, Swaziland, [2]Ministry of Health, Strategic Information Department, Mbabane, Swaziland, [3]University of Swaziland, Faculty of Health Sciences, Mbabane, Swaziland, [4]Harvard Medical School, Harvard Pilgrim Health Care Institute, Boston, United States, [5]Management Sciences for Health, Arlington, United States

Background: In Swaziland, successful scale-up of antiretroviral therapy to near-universal access has led to a need to strengthen patient monitoring to achieve treatment outcomes. Management Sciences for Health (MSH) has supported the ministry of health (MOH) over the past eight years to improve HIV data management and use. This support included the development, implementation, and support of an electronic medical record database, the ART patient management system (APMR) at all HIV treatment sites. In an effort to demonstrate and build capacity of MOH on how routine data stored in the APMR can be used to inform HIV programming decisions, the systems for improved access to pharmaceuticals and services (SIAPS) project worked with MOH to conduct a study to identify reasons for switching from first to second line ART regimen. Knowing the reasons for switching to second line is critical for the ART programme to put in place interventions to prevent unnecessary switches while ensuring timely switching for those who are eligible.
Methods: This was a retrospective-descriptive study aimed at documenting the reasons for switching from first line to second line ART regimen as recorded in the APMR. Data used for analysis of this study was extracted from the national APMR database. Data was analysed using SPSS version 2.0; STATA-12, and presented as descriptive statistics.
Results: A total of 4266 ART patients identified as having switched from first to second line regimen between years 2010 to 2015 were studied. A large proportion of these patients were among the age range 25-44 years (32.6%). 67% of patients who switched had no recorded reasons for regimen switching. 15.3% (N=4266) registered treatment failure as the main reason for regimen switching. Toxicity was recorded in 8% of patients records, clinical reasons (2, 7%), and ‚other' reason were recorded in 5.5% of the patients records.
Conclusions: The findings of this study further support the need for routine viral load monitoring as part of HIV treatment standard of care.There is also a need to strengthen data collection into the APMR system to correctly inform analysis into the reasons for regimen switching.

TUPED1320

An evaluation of the Elizabeth Glaser Pediatric AIDS Foundation supported quality improvement program in Zimbabwe, 2016

B. Mutede[1], R. Chivanga[1,2], S. Balachandra[3], J. Mandisarisa[3], J. Murungu[4], A. Mahomva[1], T. Nyamundaya[5,6]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe, [2]Midlands State University, Applied Statistics, Gweru, Zimbabwe, [3]Centers for Disease Control Zimbabwe Mission, CDC/CGH/DGHT, Harare, Zimbabwe, [4]Ministry of Health and Child Care, AIDS and TB, Harare, Zimbabwe, [5]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Harare, Zimbabwe, [6]University of Zimbabwe College of Health Sciences, Community Medicine, Harare, Zimbabwe
Presenting author email: tnyamundaya@pedaids.org

Background: In 2013, the Zimbabwe Ministry of Health and Child Care developed the national HIV Quality Improvement (QI) Program in partnership with Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) and HEATLHQUAL International. The program seeks to improve uptake of HIV prevention, care and treatment services in 14 priority areas covering children, pregnant women and general OI/ART clients. From June 2015, EGPAF supported 310 health facilities in 63 districts to implement the HIV QI program. We evaluated the EGPAF supported QI program.
Methods: A one-group pre-test post-test quasi-experimental retrospective review was conducted on 310 health facility records to determine changes in service uptake during QI implementation. The mean differences between indicator performance at baseline (July to December 2015) and during the QI implementation period (January to June 2016) for 13 of the 14 service delivery areas for all the facilities were tested for significance through paired t-testing at a=5%. Data were analyzed using Stata 13. In each facility, the six-month implementation period comprised performance measurement, structured QI coaching by EGPAF staff, planning activities to improve service weaknesses discovered during data review and testing changes to improve uptake.
Results: Overall uptake in 9 out of the 13 reviewed service delivery areas had significantly improved following the QI intervention, p < 0.05. (Table1). These comprised 5 out of 7 adult OI/ART indicators and half of the pediatric HIV treatment and care indicators. These improvements were observed across the entire cascade.
Conclusions: Our findings show that tailored QI interventions can lead to significant improvements in HIV service delivery in a high-prevalence setting such as Zimbabwe. QI should be considered as an effective strategy to increase service uptake and adherence to standard guidelines on HIV management.

QI Indicator	Baseline	Endline	p-value
% HIV- pregnant women retested in 3rd trimester	36.1%	65.2%	<0.001
% HEI with DBS collected age <2 mos	71.2%	77.5%	0.0054
% HEI with DBS <2 mos & result c/in 1 mo	15.6%	26.9%	<0.001
% HIV+ pregnant women start same-day ART	60.4%	69.9%	0.0055
% retained on ART in the past 6 mos	87.2%	90.9%	0.0077
% children start ART <2yrs & retain at 6 mos	3.4%	44.3%	<0.001
% ART clients with adherence assess last visit	78.3%	89.2%	<0.001
% ART clients with routine CD4 monitoring	12.4%	15.8%	0.0084
% HEI initiated on cotrimoxazole prophylaxis	65.8%	74.2%	<0.001

TUPED1321

The standardized pediatric expedited encounters for ART drugs initiative: description and evaluation of an innovative pediatric ART health service delivery model in Tanzania

J. Bacha[1,2,3], L. Aririguzo[2], S. Wanless[1], K. Ngo[1,2], L. Campbell[1,2,3], G. Shutze[1,2]
[1]Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Pediatrics, Houston, United States, [3]Baylor College of Medicine Children's Foundation, Pediatrics, Mbeya, Tanzania, United Republic of
Presenting author email: bacha@bcm.edu

Background: As countries scale up antiretroviral therapy (ART) for children, innovative strategies to deliver quality services to children are needed. Differentiated ART delivery models have been successful in adults, but no such program has been described in children. We describe the Standardized Pediatric Expedited Encounters for ART Drugs Initiative (SPEEDI).
Methods: We conducted a retrospective cohort analysis for children and adolescents on ART at the Baylor Centre of Excellence (COE) in Mbeya, Tanzania between January 2013 and December 2015 comparing patients with at least one SPEEDI visit to those pre-SPEEDI implementation. Stable children and adolescents on ART for approximately 3 months or longer, no medical or social complications, good adherence to ART, and having a reliable caregiver were eligible for SPEEDI and seen every two-months alternating SPEEDI visits with standard visits. During a SPEEDI visit, patients were fast tracked in triage to collect medications directly. Baseline characteristics and outcomes of the two groups were compared and Kaplan-Meier survival curves and the hazard ratio were calculated in the survival analysis.
Results: 1164 patients utilized SPEEDI, totaling 3493 SPEEDI visits. SPEEDI reached 51.3% (1164/2269) of pediatric ART patients, accounting for 7.7% (3493/44489) of total patient encounters. SPEEDI patients were 52% (605/1164) female, median age of 11.7 years (range 1.2-25.5yr), median time on ART of 21 months (range 4-130 months) and 83.5% (964/1155) categorized as no or mild HIV-associated immunodeficiency. SPEEDI patients had significantly higher percentage of good outcomes (98.8% vs. 94.5%, p<0.001), lower LTFU (0.1% vs. 2.1% p<000.1) and lower mortality rates (0.61 deaths vs. 2.59 deaths per 100 patient-years) compared to pre-SPEEDI patients. There was a statistically significant difference in the survival curves favoring SPEEDI patients (Hazard ratio log rank statistic =1.786, 95% CI 1.271-2.508, p<0.001).
Conclusions: SPEEDI was an effective model for delivering ART to children and adolescents in our setting, leading to good clinical outcomes. The SPEEDI program safely and effectively expedited and spaced out ART visits for children and adolescents, and can serve as an adaptable ART delivery model for other resource limited settings.

TUPED1322

"If I'm not in the club, I have to move from one chair to another." A qualitative evaluation of patient experiences of adherence clubs in Khayelitsha and Gugulethu, South Africa

E. Venables[1,2], C. Towriss[3,4], Z. Rini[3], X. Nxiba[1], S. Solomon[1], T. Cassidy[1], A. Grimsrud[5], L. Myer[3,6], L. Wilkinson[1]
[1]Medecins Sans Frontieres, Cape Town, South Africa, [2]University of Cape Town, Division of Social and Behavioural Sciences, School of Public Health and Family Medicine, Cape Town, South Africa, [3]University of Cape Town, Centre for Infectious Disease Epidemiology Research, Faculty of Health Sciences, Cape Town, South Africa, [4]University of Cape Town, Centre for Actuarial Research, Faculty of Commerce, Cape Town, South Africa, [5]International AIDS Society, Cape Town, South Africa, [6]University of Cape Town, Division of Epidemiology and Biostatistics, School of Public Health & Family Medicine, Cape Town, South Africa

Background: Quantitative outcomes of adherence clubs (ACs), an ART delivery model differentiating care for stable adults, have been well described for pilot and scaled implementation in South Africa. ACs are comprised of 15-30 stable ART patients, meet five times per year at their clinic/community location and are facilitated by a lay health-care worker who distributes pre-packed ART. To date, there has been no qualitative evaluation of the ACs. We explored the experiences of AC members and non-members.
Methods: Eleven focus group discussions with 85 participants and 43 in-depth interviews were conducted in Khayelitsha and Gugulethu, Cape Town, South Africa. FGD participants were current AC members and interview participants were stable patients who had never joined an AC and AC members referred back to clinician-led facility-based ‚routine' care due to missed appointments or viral rebound. Both were conducted in isiXhosa, translated and transcribed into English, entered into NVivo, coded and thematically analysed.
Results: ACs saved patients time and money and created peer-support networks. Perceived benefits included fewer clinic visits, longer drug refills and allowing refill collection up to 5 days late or by a ‚buddy'. Perceived disadvantages included reduced regular access to a clinician. Patients talked about membership as an achievement and considered being returned to routine care a ‚failure'. AC removal for missed appointments or viral rebound were acceptable rules to those in ACs, but perceived as unfair by those referred-out. Patients viewed little value in increased clinical support provided after losing AC benefits. Moving between ACs and routine care created frustration and broke down trust in the health-care system and relationships with health-care providers, especially when referral criteria weren't fully understood. Stable patients not in ACs had heard of clubs, but did not feel sufficiently empowered to request enrolment if not directly offered by their clinician, or if offered, did not fully understand the enrolment process.
Conclusions: The AC model was considered acceptable by patients, with specific appreciation for refill collection flexibilities. Improved patient understanding of enrolment processes, eligibility and referral criteria and the role of clinical oversight is essential for building relationships with health-care workers and trust in the overall health-care system.

TUPED1323

The role of community drug distribution point of care model on retention of HIV-positive individuals from a pastoral community in Kigaju, Kalungu district

K. Musinguzi Rugamba, P. Gonza K., C. Senyimba, B. Mukasa
Mildmay Uganda, Kampala, Uganda
Presenting author email: kenneth.musinguzi@mildmay.or.ug

Background: Retention in care of HIV-positive individuals residing in pastoral communities is essential for successful HIV management. Mildmay Uganda (MUg) developed a partnership with Bukulala HC IV, Kalungu district to establish a community drug distribution point to facilitate persons living with HIV from a pastoral community at Kagaju to access HIV care and treatment. The purpose of this paper is to highlight lessons learnt from implementation of this care model.
Methods: Mildmay working with Bukulula HC IV, a community drug distribution point of care model was established at Kigaju pastoral village in October of 2011. The health workers at the health facility identified clients residing in a pastoral community. Training sessions on adherence to ART, retention in care, and aim of this care model were given to all clients. The clinical team packs ARV drugs and distributes them to clients on scheduled appointment dates every month. Clinical evaluations would be done by clinicians at Bukulala HC IV every after every 3 months and ART response monitoring using viral load was done every after 6 months.
Results: A total of 139 adult clients on ART were enrolled on this care model. Majority (63%) were female. Majority (81%) consistently kept their clinic appointments and were retained in care. 91% (102/112) reported good adherence on ART. 82 clients were had their viral load test done, and 98% (80/82) were virally suppressed (viral load < 1,000 copies/mL as per national guidelines). There were no new WHO clinical stage 3 or 4 events reported among these clients during the follow-up period.
Conclusions: Community drug distribution point of care model was successfully integrated into HIV program serving a pastoral community. The retention in care of 81% and viral suppression of 98% are encouraging.

TUPED1324

Community-based ART Initiation, delivery and monitoring in rural Southwest Uganda: participant experiences of a differentiated model of HIV care delivery

M.A. Wyatt[1,2], E.E. Pisarski[1], M.L. Krows[3], B. Turyamureeba[4], S. Asiimwe[4], C.L. Celum[5], R.V. Barnabas[6], N.C. Ware[1]
[1]Harvard Medical School, Global Health and Social Medicine, Boston, United States, [2]Harvard Global, Cambridge, United States, [3]University of Washington, International Clinical Research Center, Seattle, United States, [4]Integrated Community Based Initiatives, Kabwohe, Uganda, [5]University of Washington School of Medicine, Medicine and Global Health, Seattle, United States, [6]University of Washington, Global Health, Seattle, United States
Presenting author email: monique_wyatt@hms.harvard.edu

Background: In settings of high HIV prevalence and resource scarcity, differentiated models of HIV care refocus clinical resources on symptomatic patients, while providing stable clients with less intensive community-based services. By adapting services for particular patient groups, this client-centered approach can reduce burdens on health care systems. Individuals' experiences of differentiated care will inform how future services are utilized. Using qualitative data from a randomized trial of community-based ART initiation, delivery and monitoring, we describe participant experiences of a differentiated model of ART delivery.
Methods: The Delivery Optimization for Antiretroviral Therapy (DO ART) study is evaluating community-based ART initiation and follow-up compared to clinic-based care in rural southwest Uganda and Kwa-Zulu Natal, South Africa. Fifty DO ART study participants from the Uganda site were purposefully sampled for qualitative research. Sampling aimed to represent a range of experiences across three study arms at different stages of HIV follow-up care. Data collection included in-depth interviews eliciting participants' experiences of initiating ART and receiving follow up. Trained research assistants conducted interviews and transcribed the audio-recordings into English. For this analysis, transcripts were inductively content-analyzed to characterize interviewees' experiences of this differentiated model of care. Results are represented as descriptive categories.
Results: Overall, qualitative interview data reveal a favorable response to community-based care experiences. Compared to clinic-based care, perceived advantages of home ART initiation and community-based follow-up include:
(1) convenience: ART delivery in communities saves time and money otherwise spent on travel to clinics;
(2) personalized services: one-on-one interactions with health workers in communities allow time to address individual questions and concerns;
(3) increased privacy: receiving services at home or in communities (e.g. mobile vans) eliminates the possibility of being recognized at clinics, decreasing disclosure risk; and
(4) responsiveness: focused attention and flexible approaches to care outside clinic settings communicate caring, strengthening patients' commitment to treatment.
Conclusions: These data suggest community-based ART initiation and follow-up is an acceptable and effective approach to HIV service delivery in rural Uganda. Differentiated models of care are a promising strategy for eliminating longstanding access barriers and improving HIV service quality from the perspectives of HIV-infected persons living in rural sub-Saharan Africa.

TUPED1325

Retention and viral suppression outcomes of patients enrolled in family ART adherence clubs in Cape Town, South Africa

P. Tsondai[1], L. Wilkinson[1,2], R. Henwood[2], A. Ullauri[1], T. Cassidy[2], S. Tutu[3], M.-A. Davies[1]
[1]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [2]Medecins Sans Frontieres, Cape Town, South Africa, [3]Provincial Government of the Western Cape, Department of Health, Cape Town, South Africa
Presenting author email: lynne.susan.wilkinson@gmail.com

Background: Design and implementation of differentiated antiretroviral therapy (ART) delivery models are important for children as well as adults. Since 2011, HIV positive children (stable on ART) and their caregivers (stable or not on ART) were offered the option to enroll in family ART adherence clubs (FCs) - a healthcare worker managed group model of ART delivery for families with five visits per year.

Patients that require more frequent adherence or clinical follow-up are referred back to clinician-led individual care. We describe retention and viral suppression outcomes of patients enrolled in FCs.
Methods: We conducted a retrospective cohort analysis of children and caregivers on ART enrolled in FCs between March 2011 and December 2014. We linked patients to service access data to validate retention and virologic outcomes and using Kaplan-Meier methods estimated the outcomes: retention, loss to follow up (LTFU), transfers (TFO), mortality and viral load completion and suppression (≤400 copies/mL).
Results: 163 children and 84 caregivers on ART were included in this analysis, contributing 733 person-years of follow up (88% in FC, median 3.7 years). At enrolment, 45% of children were female, median age 8.7 (Interquartile range (IQR), 6.3-11.1) years; and 95% of caregivers were female, median age 37.7 (IQR, 33.5-41.8) years. Cumulatively retention remained high from 12 to 36 months among both children (94-86%) and caregivers (94-90%) (Table 1).

Duration of follow up	n (%)	Loss to follow up % (95% CI)	Transfers % (95% CI)	Retention % (95% CI)
Children	163			
12 months	148	2.5 (0.9 - 6.5)	3.8 (1.7 - 8.3)	93.7 (88.7 - 96.6)
24 months	139	4.5 (2.2 - 9.3)	3.8 (1.7 - 8.3)	91.8 (86.3 - 95.2)
36 months	112	9.0 (5.3 - 15.1)	5.3 (2.7 - 10.3)	86.1 (79.5 - 90.8)
Caregivers	84			
12 months	74	5.0 (1.9 - 12.7)	1.2 (0.2 - 8.2)	93.9 (85.9 - 97.4)
24 months	59	7.6 (3.5 - 16.2)	1.2 (0.2 - 8.2)	91.3 (82.6 - 95.8)
36 months	45	7.6 (3.5 - 16.2)	2.9 (0.7 - 11.3)	89.7 (80.4 - 94.8)

[Table 1: Kaplan-Meir estimates of outcomes]

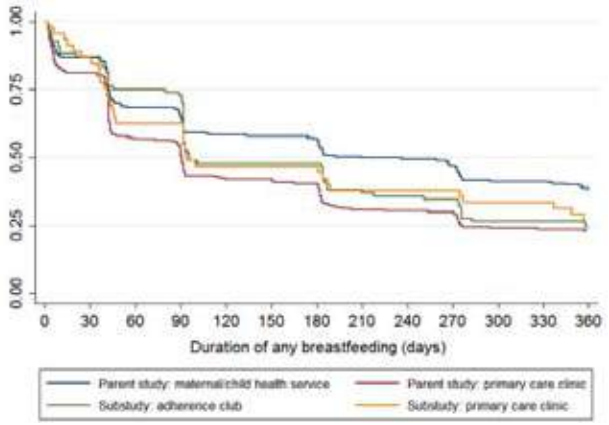
After 36 months, 86% (95% confidence interval (CI), 78-92) of children and 95% (95% CI, 83-99) of caregivers were virally suppressed, with viral load completion in 98% and 89% of patients respectively.
Conclusions: The FC model ensured simplified, family-centered HIV care and ART refill access for children and their caregivers, supporting high rates of retention and viral suppression. These findings provide evidence that differentiated ART delivery models can safely be provided to stable children and family-centered management is feasible within such group models.

TUPED1326

Breastfeeding practices and infant care engagement among HIV-infected postpartum women on antiretroviral therapy (ART) attending community-based adherence clubs (ACs) in Cape Town, South Africa

A. Zerbe[1], K. Brittain[2], T. Phillips[2], V.O. Iyun[2], E. Mukonda[2], E.J. Abrams[1], L. Myer[2], for the MCH-ART Study
[1]ICAP at Columbia University, New York, United States, [2]University of Cape Town, Division of Epidemiology & Biostatistics and Centre for Infectious Disease Epidemiology & Research, School of Public Health & Family Medicine, Cape Town, South Africa
Presenting author email: az2258@cumc.columbia.edu

Background: There is an urgent need for effective models to deliver postpartum care to women initiating ART in pregnancy and their infants. ACs have been proposed as one model of differentiated care but the ability of ACs to support newly postpartum women and maximize maternal and child health (MCH) is unclear.
Methods: As a substudy to the MCH-ART trial, we enrolled newly postpartum, breastfeeding women who initiated ART in pregnancy, and asked participants to choose between: (i) ACs or (ii) primary care clinics (PHCs) for postpartum ART care. Women were followed through 12m postpartum with breastfeeding reported at study visits separate from either ART service; evidence of PCR for early infant diagnosis (EID) and immunizations were abstracted from routinely-collected records. In analyses, outcomes were compared to that of a comparator cohort of women randomized in the parent study to either (i) an MCH-focused ART service or (ii) PHCs for postpartum care.
Results: From February-September 2015, 129 postpartum women were enrolled (mean age, 28y), with 65% choosing ACs and 35% choosing PHCs. Median duration of any breastfeeding was 3.2m in ACs and 3.1m in PHCs (p=0.861); the median duration of exclusive breastfeeding was 3.0m and 2.2m (p=0.568), respectively. Breastfeeding duration was similar across women attending ACs and those attending PHCs, but was significantly longer in women attending the MCH-focused service (Figure). Of women attending ACs, 96% had evidence of infant PCR testing < 12w postpartum, versus 93% of those attending PHCs. The proportion of infants with evidence of immunizations received through 10w postpartum was >90% in both services. Compared to comparator cohort, no differences were observed in EID or immunizations across any of the four ART services compared.
Conclusions: Effective strategies for delivering ART and related services during the postpartum period must account for MCH-specific service needs to ensure the health of women and their infants.



[Figure. Time to cessation of any breastfeeding, by postpartum ART service.]

TUPED1327

Service delivery costs for HIV treatment under differentiated models of care for stable patients in Malawi

K. Callahan[1], I. Nnakabonge[1], M. Prust[2], C. Banda[3], R. Nyirenda[4], F. Chimbwandira[4], T. Kalua[4], A. Jahn[5], M. Eliya[4], P. Ehrenkranz[6], M. Prescott[2], E. McCarthy[2], A. Gunda[3], E. Tagar[1]

Presenting author email: kcallahan@clintonhealthaccess.org

Background: Despite gains in improving the efficiency and coverage of antiretroviral therapy (ART), Malawi is expected to face an ART funding gap in coming years. Models of differentiated care may further improve efficiency by streamlining services for stable patients. An analysis was conducted to understand the costs associated with three models of differentiated care in Malawi: multi-month scripting (MMS), fast-track refills (FTRs), and community ART groups (CAGs). The models were compared against a hypothetical model of monthly clinic visits, which is used in many other national ART programs.
Methods: Data were collected in 30 purposefully selected sites that represented a range of facility types and sizes. All sites implemented MMS, while four sites also offered FTRs and eight sites offered CAGs. Patient visit frequency was measured through facility questionnaires and 1,473 observations of visit time and clinic flow. Cost modeling was performed in Excel to identify average unit costs of each model and the expected resources required for scale up.
Results: Annual per patient costs of MMS, FTRs and CAGs are similar and represent an estimated 10% reduction compared with a monthly clinical visit policy. These reductions are largely driven by decreased visit frequency and the delegation of some service delivery tasks to lower level cadres. Monthly clinic visits for all stable patients in Malawi would cost $63.8 million per year. However, $5.8 million per year has been saved with current implementation of differentiated care models. Expanding participation in the MMS model or coverage of the FTR model would lead to $745,000 and $67,000 in additional savings, respectively. Expansion of CAGs is not projected to lead to savings given some limited additional supervision costs required for implementation.
Conclusions: Malawi has already generated efficiencies in ART service delivery by introducing MMS for stable patients. Limited additional savings could be realized by improving MMS coverage and, to a lesser extent, by rolling out the FTR model nationwide. Since the variation in service delivery costs are largely driven by human resource costs, savings would likely be greater in countries where salary levels are higher and represent a greater proportion of overall ART costs.

TUPED1328

Patient and health worker perspectives on implementation of models of differentiated care for stable HIV patients in Malawi

C. Banda[1], M. Prust[2], R. Nyirenda[3], F. Chimbwandira[3], T. Kalua[3], A. Jahn[4], M. Eliya[3], K. Callahan[5], P. Ehrenkranz[6], M. Prescott[2], E. McCarthy[2], E. Tagar[5], A. Gunda[1]
[1]Cli, Lilongwe, Malawi, [2]Cli, Applied Analytics Team, Boston, United States, [3]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [4]Ministry of Health / I-TECH Department of Global Health, Department of HIV and AIDS, Lilongwe, Malawi, [5]Cli, HIV, TB and Health Financing Team, New York, United States, [6]Bill & Melinda Gates Foundation, Seattle, United States
Presenting author email: cbanda@clintonhealthaccess.org

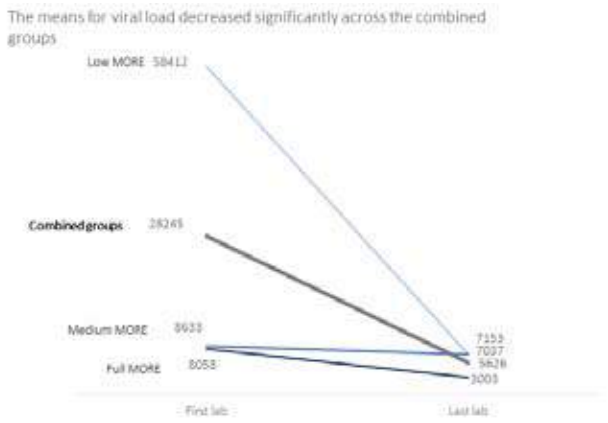
Background: In Malawi, various models of differentiated care have been launched for stable HIV patients on antiretroviral therapy (ART), including: multi-month scripting (MMS), fast-track drug refills (FTRs), and community ART groups (CAGs). These models introduce adjustments to service delivery standards to ensure that care is efficient and patient-centered. We aimed to understand the patient and health worker perspectives on the challenges and successes of implementing these models of care.
Methods: Qualitative data was collected in 30 purposefully selected ART facilities. All 30 sites offered MMS, and 8 and 4 sites offered CAGs and FTRs, respectively. Semi-structured interviews were held with 32 health workers that manage ART clinics, and 30 focus groups were held with 216 patients receiving the models of care. Interviews and focus groups were audio recorded, transcribed and coded thematically. Dedoose software was used to facilitate analysis.
Results: Patients and health workers reported that these models of differentiated care have yielded key benefits, including: reduced travel and visit times for patients, reduced health worker burden, decongestion of facilities, and enhanced social support. Both health workers and patients suggested that these benefits could lead to improved patient adherence and retention. At the same time, challenges were reported, such as inconsistent stocks of ART and other supplemental drugs like cotrimoxozole, which can restrict the provision of multi-month refills. For CAGs, the group-based nature of the model presented some unique problems, such as conflicts within groups or patient concerns about privacy. For all models, some health workers had concerns that patients would fail to seek care if they became ill between appointments, while patients reported having an understanding of the need to seek care if they felt ill before an appointment.
Conclusions: Overall, differentiated care is strongly supported by both patients and health workers and appears to have significant and immediate benefits. To maximize impact, however, challenges relating to supply availability, model logistics, and patient support should be addressed. Patients are likely to cycle in and out of differentiated care as their needs change and the ability of facility to provide these models may vary, so a one-size-fits-all approach to differentiated care is not realistic.

TUPED1329

Improvements in engagement, retention, and viral load suppression in a mobile outreach retention and engagement (MORE) project at a community health center in Washington DC

B. Walsh[1], M. Coleman[2], M. Dieterich[2], J. Du Mond[2], J. Jue[3], M. Sadler[4], S. Saperstein[4], C. Wickham[3], S. Henn[2]
[1]Whitman-Walker Health, Retention and Engagement, Washington, United States, [2]Whitman-Walker Health, Washington, United States, [3]Washington Aids Partnership, Washington, United States, [4]Shattuck and Associates, Washington, United States
Presenting author email: bwalsh@whitman-walker.org

Background: HIV+ individuals on antiretroviral therapy, engaged and retained in services, and who are virologicaly suppressed have improved health outcomes and are less likely to transmit HIV infection, providing the basis for the United Nations 90:90:90 target goals. MORE is a novel community health approach to increase patient engagement, retention, and virologic suppression at Whitman-Walker Health, Washington DC's largest HIV care provider. The MORE team (consisting of community health workers (CHW), care navigators (CN), and a nurse practitioner and physician assistant), offered supportive services and medical care inside and outside the clinic for high-risk HIV+ patients.
Methods: EMR review identified high risk HIV+ patients who were not retained in care (no medical visit in the last 6 months) and/or with a viral load >200 . 258 individuals were approached for MORE and 202 engaged.
Engagement levels were self-selected as:
Low - <3 month intervention with CHW and CN only;
Medium - declined home visits but received increased ongoing care navigation and access to CHW;
Full - medical home visits with coordinated care team in addition to uber travel support.
Results: Study uptake was 78% (202) (26% Full MORE, 18% Medium MORE, 34% Low MORE). Medium and Full MORE participants were more likely to have at least one viral load during follow up. (90% versus 76%). 80% of participants across groups either maintained or decreased their viral load. The mean decrease across groups was significant, with a reduction in community viral load from an average of 28245 copies to 5626 copies.
Conclusions: One year after the initiation of MORE, preliminary evaluation demonstrates increased patient engagement, retention, and decreased community viral load in a select population of high risk patients whom were previously failing to meet treatment targets. MORE is a potential effective intervention to reduce community disease burden and HIV transmission.



[Mean change in viral load]

Acceptability of interventions to improve retention in HIV care among pregnant women in Johannesburg, South Africa

K. Clouse[1,2,3], C. Mongwenyana[3], M. Musina[3], D. Bokaba[4], L. Long[3], M. Fox[3,5,6]
[1]Vanderbilt Institute for Global Health, Nashville, United States, [2]Vanderbilt University Department of Medicine, Division of Infectious Diseases, Nashville, United States, [3]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [4]Hikhensile Clinic, City of Johannesburg, Johannesburg, South Africa, [5]Boston University School of Public Health, Department of Global Health, Boston, United States, [6]Boston University School of Public Health, Department of Epidemiology, Boston, United States
Presenting author email: kate.clouse@vanderbilt.edu

Background: Women who initiate antiretroviral therapy during pregnancy in South Africa are at high risk of dropping out of routine HIV care after delivery. We conducted a pilot study of the feasibility of a financial incentive intervention—a one-time R50 (~USD4) supermarket voucher for completing one postpartum visit—to attempt to reduce postpartum losses. We here assess the acceptability of the intervention.
Methods: We interviewed 100 pregnant, HIV-positive women at enrollment. We assessed the acceptability of the intervention as well as respondents' attitudes towards other interventions to improve HIV retention for pregnant and postpartum women.
Results: Median (IQR) respondent age was 28 years (24-31), most (78%) had previously been pregnant, and 31% were employed. Three-fourths (76%) of respondents found the supermarket voucher incentive acceptable and 86% responded that the incentive would motivate them to return to the clinic, with responses such as, "If you know that you´ll get something you won´t miss your appointment" and "I´m not working. If the clinics could offer incentives like these they will help me and my kids so much." Among the 23% who found the intervention unacceptable, the most frequent reason was perceived personal responsibility for one's own health (21/23), with responses including, "People should attend their visits without getting anything" and "It´s like they bribe them for their health." Overall, when asked to rank preferred hypothetical incentive interventions, assistance with social services ranked first (29%), followed by provision of infant formula (22%) and cash (21%); assistance with social services was the top-ranked choice by both those who found the voucher incentive intervention acceptable and unacceptable. To encourage HIV-positive women to remain in care, respondents most frequently suggested health education (32%), counseling (25%), financial incentives (17%) and home visits (12%).
Conclusions: The problem of poor retention in postpartum HIV care is well documented, but few successful interventions have been found. Our results suggest a financial incentive intervention is acceptable, but women frequently expressed pref-

erence for integrated services and improved education and counseling to improve retention in care. Interventions exploring the feasibility and efficacy of education and counseling interventions to improve postpartum HIV care are warranted.

TUPED1331

Effect of incentivizing men for HIV testing on HIV testing behavior of women in rural Uganda

D.M. Emperador[1], A. Ndyabakira[2], E. Schaffer[3], D. Kwarisiima[4], C.S. Camlin[1], J.G. Kahn[1], M.R. Kamya[5], D.V. Havlir[1], H. Thirumurthy[3], G. Chamie[1]
[1]University of California, San Francisco, San Francisco, United States, [2]Makerere University-UCSF Research Collaboration, Mbarara, Uganda, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States, [4]Makerere University Joint AIDS Program, Kampala, Uganda, [5]Makerere University College of Health Sciences, Kampala, Uganda
Presenting author email: devy.emperador@ucsf.edu

Background: Despite expansion in HIV testing services, men test for HIV at lower rates than women in sub-Saharan Africa. In a recent randomized trial in rural Uganda, we found that men were more likely to test for HIV when offered a low-cost lottery incentive than a low-cost gain-framed incentive. The indirect (i.e. "spillover") effects of such incentives on close ties like family members are not well understood. We evaluated the impact of offering HIV testing incentives to men on HIV testing behavior of their spouses.
Methods: Following the IBIS-Health Trial (NCT02890459), we conducted a post-hoc analysis among wives of men enrolled and randomized to receive various incentives for HIV testing: low-cost ($1) gain-framed incentives (control), where men were told they would receive a small prize for HIV testing; or lottery incentives, where men who came for HIV testing had a chance to instantly win large prizes. Women were not incentivized to test for HIV. The primary outcome was HIV testing uptake of wives of male trial participants at community health campaigns held between June-July 2016.
Results: Overall, 397 households were included - 397 men and 401 women. Men had significantly higher HIV testing uptake than women (81% vs. 61%, p< 0.001). Although men randomized to lottery incentives were significantly more likely to test than those randomized to gain-framed incentives, there was no difference in testing uptake among their wives by incentive type (123/207 [62%] vs.121/194 [59%], p=0.545). In the lottery group, there was no difference in testing among wives whose husband was a lottery winner vs. non-winner (10/14 [71%] vs. 94/147 [64%], p=0.772).
Conclusions: The type of incentive to which men were randomized had no significant impact on HIV testing uptake among their wives, suggesting a lack of spillover effects. However, the overall lower testing uptake among women compared to men suggests negative spillover, which may be explained by factors such as community perception that the testing campaigns were for men. Clear communication is necessary when delivering incentives to specific population subgroups, and equitable implementation may be needed to avoid negative spillover effects on health behavior of others.

Behavioral economic incentives supported by SMS messaging to improve antiretroviral adherence among youth in Uganda

H. Huang[1], S. Linnemayr[2]
[1]Pardee RAND Graduate School of Policy Analysis, Santa Monica, United States, [2]RAND Corporation, Santa Monica, United States
Presenting author email: chuang1@rand.org

Background: Youth account for nearly half of all new HIV infections worldwide and face specific barriers to optimal ART adherence, yet few interventions target this population. Interventions using behavioral economic insights have proven effective in improving adherence among adults; in this study, we test the use of prize drawings supported by mobile health to improve ART adherence and viral suppression among HIV-positive youth.
Methods: Patients at an urban HIV clinic in Kampala, Uganda aged 17-24 years were randomly assigned in a 1:1:1 ratio to one of two incentive groups or a control group. In the first intervention group, clients were eligible to participate in prize drawings to win mobile airtime with expected value of 5,000 Ush (~$1.50USD) if their electronically measured adherence exceeded 90%. In the second group, drawing eligibility was based on a target of their own choosing (but exceeding 80%); we hypothesize that this novel approach leads to improved adherence through higher intrinsic motivation and identity congruence. All three study groups receive weekly SMS reminders conveying motivational messages aimed at adherence maintenance. Main outcomes are mean dose-taking adherence and viral suppression over the 9 month study period. This trial is registered with ClinicalTrials.gov, NCT02918838.
Results: 211 clients approached enrolled in the study, and only 4 people declined to participate. 2,766 messages were sent and 83.5 percent of these were successfully delivered to the participant's phone. Among the group setting their own adherence goal, fewer than one-third chose the lowest possible adherence target, and two thirds chose 90% or higher. As of January 2017, 94 participants in the intervention groups completed their first clinic visit and 60 percent of these were eligible to participate in a prize drawing.
Conclusions: Prize drawings coupled with SMS reminders are feasible to implement in a low-income setting. A novel finding is that those asked to choose their own adherence targets set high goals for themselves. Subsequent analysis of study data will show whether these findings translate to improved adherence and health outcomes among this vulnerable population.

A pilot randomized trial of conditional cash incentives to increase pediatric HIV testing

I. Njuguna[1], A. Wagner[2], J. Neary[2], R. Bosire[3], J. Babigumira[2], C. Levine[2], V. Ogweno[4], V. Anyango[4], E. Maleche-Obimbo[5], D. Wamalwa[5], G. John-Stewart[6], J. Slyker[7]
[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Kenya Pediatric Association, Nairobi, Kenya, [5]University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya, [6]University of Washington, Department of Epidemiology, Global Health, Medicine & Pediatrics, Seattle, United States, [7]University of Washington, Department of Epidemiology & Global Health, Seattle, United States
Presenting author email: anjuliwagner@gmail.com

Background: Pediatric HIV diagnosis is often delayed due to parental reluctance to test children. A systematic offer of pediatric testing to HIV-infected parents in Kenya resulted in 14% uptake, suggesting need for additional approaches. We conducted a pilot study to assess acceptability of incentives to increase pediatric testing.
Methods: Between October-December 2016, we recruited HIV-infected caregivers at Kisumu County Hospital, Kenya, with children of unknown status aged 0-12 years, and randomized them to receive $5, $10 or $15 conditional on child testing within 2 months. We compared proportion testing child(ren), preference for incentive type and impact on test timing.
Results: Of 2,196 recruited, 72(3%) were eligible, 60(83%) randomized; 20 to each arm. Forty three (72%) completed testing; 15(75%), 15(75%) and 13(65%) in the $5 $10, $15 arms, respectively. This uptake was significantly higher than in the recent cohort (72% vs. 14%, p< 0.001). Of 17 not tested, 13 failed to complete testing in 2 months and 4 are pending testing.
Of 54 children tested, median age was 9 years (IQR 5-11), 1 was HIV positive. Median days to testing were 17, 4, and 7 in the $5 $10, $15 arms, respectively. Caregivers reported preferring incentives provided as cash (37%), household goods (14%), agricultural goods (9%), health services or food vouchers (10%); 30% had no preference. Thirty-five (81%) said the incentive influenced testing, and 35(81%) motivated earlier testing. Thirteen (30%) perceived their children were HIV positive before testing but these tested negative. Eighteen (42%) caregivers previously had avoided health care during child illness for fear of HIV testing.

	n(%) or median (IQR) $5 arm	n(%) or median (IQR) $10 arm	n(%) or median (IQR) $15 arm
Completed testing of 1+ child	15 (75) 95%CI (51-91)	15 (75) 95%CI (51-91)	13(65) 95%CI (41-85)
Median (IQR) days to testing	17 (1-28)	4(1-6)	7(2-20)
Number of children tested	18	20	16
Median age of children tested	8.5(4,10)	8(5.5, 10.5)	10.5(7-11)
Preferred cash	7(47)	4(27)	5(38)
Household goods or agricultural items	6(40)	2(13)	2(15.5)
Health services or food voucher	0	2(13)	2(15.5)
No specific preference	2(13)	7(47)	4(31)
Previously avoided health care	8(53)	4(27)	6(46)

[Testing uptake and preference for incentive]

Conclusions: Cash incentives motivated pediatric HIV testing. Confirming HIV negative status may alleviate parental fears and increase uptake of other health services. An efficacy trial with incentive values of $0, $1.25, $2.50, $5, and $10 will begin January 2017.

TUPED1334

Conditional food or cash transfers do not increase purchase of temptation goods among adults living with HIV infection in Shinyanga, Tanzania

J.L. Kadota[1], S.I. McCoy[1], P.F. Njau[2], C. Fahey[1], N. Kapologwe[3], W.H. Dow[1], N.S. Padian[1]
[1]University of California, Berkeley, United States, [2]Ministry of Health and Social Welfare, Dar es Salaam, Tanzania, United Republic of, [3]Regional Medical Office, Shinyanga, Tanzania, United Republic of
Presenting author email: jill.kadota@berkeley.edu

Background: Conditional cash and in-kind incentives are increasingly recognized as effective tools for increasing demand for HIV care and treatment services. However, a common concern is that incentives may increase expenditures on ‚temptation goods' like alcohol and commercial sex. We evaluated this assertion among HIV-infected adults in Shinyanga, Tanzania who received short-term cash or food support.
Methods: We analyzed data from a study of 805 individuals randomized to one of three study arms: standard of care (SOC), short-term cash transfers or short-term food assistance. Eligible participants were:
1) ≥18 years old;
2) HIV-infected;
3) food insecure; and
4) initiated antiretroviral therapy (ART) ≤90 days before enrollment.
Food or cash transfers, valued at approximately $11 USD/month and conditional on attending HIV clinic visits, were provided for up to 6 months and accompanied by a message to use the transfer as needed to improve health. An in-person survey after the incentive period (median ~8 months after enrollment) assessed self-reported expenditures, consumption of alcohol, and purchase of sex.
Results: The study population included 509 (64%) females with a mean age of 37 years. Most incentive group participants reported using transfers for food: on average, household food expenditures among cash recipients increased by 1428 Tanzanian shillings (TSH) (p=0.60), and 96% of food assistance recipients reported consuming the food. Purchase of sex was not reported by any participant.
Median monthly alcohol expenditures did not significantly differ between the SOC and the cash (3000 TSH vs. 6000 TSH, respectively, p=0.94) or food group (3500 TSH, p=0.73). The proportion of participants who reported drinking alcohol in the past month was significantly lower in the cash transfer group (0.35%) compared to the food assistance group (4.2%, p=< 0.01). Alcohol consumption in the past month did not differ significantly between the food and SOC group (3.9%, p=0.90) or cash and SOC group (p=0.11).
Conclusions: In this population of food insecure HIV-infected adults, provision of short-term conditional cash transfers did not increase temptation good usage. Consistent with findings from cash transfer programs for social protection, concerns that incentive programs for people living with HIV infection may increase purchase of temptation goods may be unfounded.

TUPED1335

Social norms messaging to improve antiretroviral adherence among youth in Uganda

S. Linnemayr[1], C.I. Gutierrez[2], S. Okoboi[3], J. Birungi[3]
[1]RAND Corporation, Santa Monica, United States, [2]RAND Corporation, Pardee RAND Graduate School, Santa Monica, United States, [3]TASO, Kampala, Uganda
Presenting author email: slinnema@rand.org

Background: SMS messaging to improve medication adherence has a mixed record of success and has largely focused on adult populations. We report findings from one of the first studies to target youth, and the use of social norms messaging, an approach that to date has not been tested in this population. In one group, we send weekly messages informing participants of their electronically measured adherence to counter over-optimism about their ability to stick to their pill regimen. In the second group, we also send information about group level adherence, which we hypothesize, will create a social norm to which participants in this group will strive to adhere to or even surpass.
Methods: Patients at two HIV clinics in Kampala, Uganda aged 15-24 years (80% female and 20% male) were randomly assigned to one of two intervention groups or a control group. In the first intervention group, participants received a weekly motivational message with information about their adherence level in that week. In the second group, participants in addition received information about the performance of their peers in the intervention. The main outcome is electronically measured mean dose-taking adherence. This trial is registered with ClinicalTrials.gov, NCT02514356.
Results: 147 clients were recruited and attrition over the nine study months was relatively low (17%). While we do not find an overall effect of the intervention, we find important treatment heterogeneity: those with low pre-intervention adherence experience about a 10% increase in mean adherence. Those with already high adherence before the intervention, on the other hand, see their adherence decrease by about 14%. We do not find differential impacts by gender.
Conclusions: The findings in this study suggest that SMS messaging to address over-optimism and creating a social norm is feasible and acceptable for a group of youth in HIV care in Uganda. The impact heterogeneity suggests that participants with lower adherence than the peer norm likely benefit most from such an intervention, and that different messaging may have to be used for those with higher initial adherence. The preliminary results and potential heterogeneity should be confirmed in a larger follow-up study.

TUPED1336

Describing the price differential for condomless sex into HIV prevention programming for female sex workers in Senegal

F. Yang[1], B. Liestman[2], F.M. Dramé[3], A.K. Diop[4], C. Lyons[2], K. Coly[2], A. Diallo[3], K. Diop[3], A. Kane[3], N. Leye Diouf[5], C. Touré Kane[5], G. Turpin[2], S. Ketende[2], L. Jennings[6], S. Baral[2]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]Enda Santé, Dakar, Senegal, [4]Division de Lutte contre le Sida et les Infections Sexuellement Transmissibles, Dakar, Senegal, [5]CHU Aristide le Dantec, Laboratoire Bactégriologie Virology, Dakar, Senegal, [6]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States
Presenting author email: fan.yang@jhu.edu

Background: There has been significant study of the effectiveness of economic incentives as components of an effective HIV response. Studies to date have observed limited utility of these approaches for female sex workers(FSW). Concurrently, descriptive studies have examined the price differential, defined here as the price difference for condomless sex with FSW. Here, we explore the price differential as a guide for incentive programs aiming to support exclusive condom use during sex work in Senegal.
Methods: 194 FSW aged 18 and older reporting selling sex as their primary source of income for the last 12 months were enrolled into a prospective cohort in Dakar, Mbour, and Thies, Senegal. The cohort participants were originally recruited from a cross-sectional study of FSW recruited using Respondent-Driven Sampling and complete quarterly structured socio-behavioral questionnaires. This analysis presents the preliminary results of the price differential in relation to economic variables from month 6 and month 12 visits (Table 1).
Results: The prevalence of clients offering more money for condomless sex was 27.3%(57/194) and 44.9%(70/156) at months 6 and 12 respectively. The average price differentials at these times were 10,506 FCFA(17.21USD) at month 6 and 11,564 FCFA(18.95USD) at month 12 comparing condomless sex with condom-use sex. On average, client offered twice as much compensation for condomless sex as compared to sex with a condom, characterizing a strong financial incentive to engage in condomless sex and an elevated HIV risk for FSW.

	Month 6 (N= 194)	Month 12 (N= 156)
Individual characteristics		
Registered as FSW (n, %)	58(29.90%)	43(27.56%)
Experience stigma from low financial situation (n, %)	73(37.63%)	101(64.74%)
Compensating differential (XOF)		
Experience a client's offer (n, %)	53(27.32%)	70(44.87%)
Price per vaginal sex (Mean ± SD)		
With condom	7995(±6297)[a]	8663(±9086)
Without condom	17928(±17332)[a]	21628(±21290)[b]
Compensating differential	10506(±13777)[a]	11564(±24260)[b]
Reliance on sex work (XOF)		
Weekly income (Mean ± SD)		
from sex work	39672(±38879)	49404(±55970)
from other profession	8443(±13881)	6760(±13185)
from family/friends	3915(±11058)	5030(±14126)

[a]: number of participants who responded is 77.[b]: number of participants is 39.

[Table 1. Preliminary analysis of economic factors]

Conclusions: The data presented here reinforces the challenges in ensuring condom use during sex work for FSW in Senegal. In combination with condom negotiation difficulties, these data highlight the economic benefits to FSW with condomless sex. While these data suggest that economic empowerment-based HIV interventions should calibrate their effective dosage based on the price differential, they also highlight the importance of comprehensive approaches to addressing vulnerabilities during sex work.

TUPED1337

The use of a performance-based financing approach in the engagement of private health facilities for HIV testing services in Nigeria

T.T. Oladele[1], A. Ikpeazu[2]
[1]National Agency for the Control of AIDS, Programme Coordination, Abuja, Nigeria, [2]National Agency for the Control of AIDS, Abuja, Nigeria
Presenting author email: toladelet@gmail.com

Background: Engagement of the Private Health Sector (PHS) has been identified as one of the key strategies in bridging the huge gap in PMTCT service coverage in Nigeria. With forty three percent (43%) of facility-based deliveries occurring in this sector, there is a consensus among stakeholders that the sector offers an opportunity to expand access to HIV services. Also important is the need to ensure increased value for money and greater accountability in the health system in the face of dwindling resources. So far in Nigeria, d engagement of private health facilities have been limited and accountability in the health system inadequate.
Methods: The Nigerian National Agency for the Control of AIDS with support from the World Bank adopted a performance (PBF) based financing approach to motivate private healthcare providers to provide HIV testing services (HTS) for pregnant women. 390 facilities were to be engaged in the pilot project across 13 states (Lagos, Oyo, Kaduna, Sokoto, Akwa-Ibom, Rivers, Kano, Taraba, Cross-River, Imo, Nasarawa, Benue and the Federal Capital Territory (FCT). Facilities would be reimbursed N2, 750 for every pregnant woman tested. Women who test positive are referred to antiretroviral therapy (ART) centres to which they are linked. Using a developed eligibility criteria, thirty facilities were selected per state for the project. Personnel in selected facilities were trained on HTS provision, data collection and referral. Contracted independent verification agents (IVAs) verify services provided before providers are paid based on achievements.
Results: After four months of programme implementation, 293 facilities (81%) met the eligibility criteria and were engaged. 63,074 pregnant women were tested, 612 (0.97%) women were identified positive and 384 (62.7%) successfully referred for ART. Private health facilities were willing to participate in the scheme. The use of IVAs ensured the linkage of financing to result.
Conclusions: PBF can be used in engaging the private health sector to expand access to HIV services in Nigeria and by extension other similar health service packages in the country.

TUPED1338

Rapid test and early treatment of HIV infection in a community-based sexual health care system associating "the Checkpoint" and "The 190" dedicated to the MSM population in Paris, France

P. Gazalet[1], M. Ohayon[1], D. Gosset[1], M. Fremondiere[1], N. Day[2], N. Reydellet[3], F. Cazein[4], L. Wormser[1], T. L'yavanc[1], P. Bonhomme[1], N. Pierre[1], S. Lasry[1], E. Moreau[1], A. Zugmeyer[1], Y. Lavéant[1], A. Fior[1], D. Levasseur[1], J.-P. Viard[5], J. Ghosn[5], G. Pialloux[6], C. Rouzioux[7]
[1]'Le 190' Sexual Health Care Center Focused on LGBT Population, Paris, France, [2]Centre Biologique du Chemin Vert, Paris, France, [3]Checkpoint Paris-Le Kiosque Infos Sida-Groupe SOS, Paris, France, [4]Santé Publique France, Paris, France, [5]Hôpital Hôtel-Dieu, Université Paris Descartes, Paris, France, [6]Hôpital Tenon-APHP, Paris, France, [7]EA 7327 Université Paris Descartes, Virologie, APHP, Hôpital Necker, Paris, France
Presenting author email: philippe.gazalet@gmail.com

Background: In France, 40% of new HIV diagnoses occurs in the men who have sex with men (MSM) population and 40% of new diagnoses occur in Paris area. In this context, two community-based sexual health medical centers dedicated to the MSM population were created in 2010 and decided to combine their activities : „the Checkpoint" offering HIV rapid testing, and „The 190" proposing ARV treatment to positive patients. The aim of this study was to evaluate benefits of this coordinated system proposed to the highly exposed MSM in Paris.
Methods: In this retrospective observational study, data of sociodemographic characteristics, stage of HIV infection according to Fiebig classification, delay between the positive test and HAART initiation and efficacy of HAART were collected for patients diagnosed positive at the „Checkpoint" and then came to the „190" for care, between 02/01/2010 and 12/31/2014.
Results: 82 patients were included during the study period. Median age at diagnostic was 30,5 years and 19,5% of the patients were less than 25 years old. 24,4% (20/82) were born outside of France. Socioprofessional group was known for 61 patients: 28% were students and 43% belonged to highly-qualified working people. Interestingly, based on HIV-1 western blot results, 78% (64/82) had an incomplete HIV-1 Western blot and 28% (23/82) were diagnosed at the time of primary infection (Stage III to V Fiebig). Median time between positive test and the first medical consultation was 7 days for 79 patients who came to "the 190" for care. 61 patients (74,4%) had HAART initiation at "the 190" with a median time of 13 days. Among the 23 patients with primary infection, median time for HAART initiation was 8 days. Viral load was undetectable < 50 copies/ml after 6 months for 98,3% patients.
Conclusions: This model, sustaining a sort of rapid "Test and Treat" within a community has shown a strong attractivity for a fairly young MSM population who beneficiate to be diagnosed and treated at a very early stage of HIV infection. That kind of approach could participate to reduce the dramatic epidemic among young Parisian MSM.

Feasibility and acceptability of delivering prenatal test results at the point-of-delivery through a non-internet dependent mobile health platform

S. Gbadamosi[1], C. Eze[2], T. Bruno[1], J. Olawepo[3], D. Patel[1], R. Jadhav[1], W. Menson[1], J. Iwelunmor[4], D. Sarpong[5], J. Oko[3], C. Onoka[6], E. Ezeanolue[1]
[1]University of Nevada, School of Community Health Sciences, Las Vegas, United States, [2]SCRX LLC, Arlington, United States, [3]Caritas Foundation, Abuja, Nigeria, [4]University of Illinois, Urbana-Champaign, United States, [5]Xavier University, Louisiana, United States, [6]University of Nigeria, Nsukka, Nigeria
Presenting author email: semiu.gbadamosi@unlv.edu

Background: Community-based strategies for HIV testing have expanded opportunities to increase the proportion of pregnant women who are aware of their HIV diagnosis. In order to use this information to implement evidence-based interventions for the prevention of mother-to-child HIV transmission, these results have to be available to the clinician at the point-of-delivery. Most electronic health records are dependent on the availability of internet connectivity and thus, have limited use in rural and resource-limited settings. The purpose of our study was to (a) determine the feasibility of developing a non-internet dependent mobile health (mHealth) platform that made results from community-based screening programs available to clinicians at the point-of-delivery and (b) the acceptability of such platform by pregnant women.
Methods: We leveraged on existing technology to integrate a database, smartcard technology, and a cell phone-based application. We selected a convenience sample of 240 pregnant women from an ongoing NIH-funded study and obtained consent after explaining the purpose of the smartcards. Each participant who consented was offered a card with their encrypted test result. We used an investigator-administered survey to obtain information on the willingness of participants to allow clinicians to retrieve information from their card. Participants were eligible if they tested positive for at least one of three conditions: HIV, Hepatitis B virus (HBV) infection and sickle cell trait or disease (SCD).
Results: We successfully designed an integrated platform that stored test results on a database, securely encrypted the results on a smartcard and used a cell phone application to read the information on the smartcard, without the need for internet connectivity. Participants were mostly rural dwellers with low education (92%) and economic levels (96%); 23% were HIV-positive, 29% HBV-infected and 59% had SCD. A majority of participants (76%) self-reported access to a mobile phone. All participants (100%) accepted and indicated the willingness to use the smartcards for prenatal and delivery services.
Conclusions: Our findings indicate that it is feasible to develop a non-internet dependent mHealth platform that can make test results obtained through community-based strategies available at the point-of-delivery. This platform is well accepted when the potential benefit of early intervention is explained to participants.

Enhanced peer mobilization and use of a real-time HIV cascade performance system: on-going lessons in peer-driven interventions and improving HIV yield

M. Avery[1], M. Cassell[2], T. Sattayapanich[1], A. Arunmanakul[1], T. Nakpor[3], P. Chanlearn[4], R. Reankhomfu[5], S. Janyam[6], D. Linjongrat[7]
[1]FHI 360, USAID LINKAGES Project, Bangkok, Thailand, [2]U.S. Agency for International Development, Regional Development Mission Asia, Bangkok, Thailand, [3]Sisters Foundation, Pattaya, Thailand, [4]MPlus Foundation, Chiang Mai, Thailand, [5]Caremat, Chiang Mai, Thailand, [6]Service Workers in Group (SWING), Bangkok, Thailand, [7]Rainbow Sky Association of Thailand, Bangkok, Thailand
Presenting author email: mavery@fhi360.org

Background: Although HIV testing is the critical entry point for antiretroviral treatment and pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM), fewer than half of MSM in Asia know their HIV status, and outreach-based test promotion has achieved low testing uptake and yield.

We introduced an enhanced peer mobilizer (EPM) model, a peer-driven intervention, to increase rates of HIV testing and strengthen case finding.
Methods: EPM was implemented by community-based organizations in four cities in Thailand. Under EPM, a small team of trained outreach workers manage a wider, informal network of incentivized Peer Mobilizers (PMs) to recruit clients from their social networks. Data on client demographics, risk behaviors, and referrals are collected and shared via a real-time mobile data collection system (eCascade).
Results: From July 2015 to December 2016, 12,599 unique clients were registered under the EPM model, 61% of whom received an HIV test (n=7,717) with an 11% testing yield (n=848) and 285 of whom initiated ART at a collaborating site (34%). Most clients were MSM (64%) between the ages of 15-29 (74%). 86% of clients had not previously been reached with HIV prevention interventions and 56% had never previously been tested for HIV. Of program clients, 8,207 were recruited via contracted outreach workers, 3,281 via clinic walk-in, and 1,576 via peer-driven recruitment. Clients recruited by PMs were more likely to be tested than clients recruited by outreach workers (86% versus 44%), but testing yield varied by site. Peer-driven recruitment overall contributed only about 12% to total program coverage but this also varied by site and target population (in one site, it reached approximately 50%). Only 3% of clients became successful peer mobilizers and, of those, the majority only recruited one additional client. A small number of highly motivated "super mobilizers," using creative strategies within their own personal networks, contributed the majority of peer-driven recruitment.
Conclusions: EPM and the use of real-time HIV cascade performance monitoring offer opportunities to increase efficiencies in outreach, to increase HIV testing and yield, and to adjust strategies to reach higher-risk networks of key population, a common challenge of outreach programs.

TUPED1341

A primary care level algorithm increases yield of HIV-positive adolescents in a community intervention: HPTN071 (PopART) Study, Zambia

M.J. Chaila[1], D. Macleod[2], A. Schaap[1,2], S. Floyd[2], M.M. Thornicroft[1], G. Hoddinott[3], R. Hayes[2], S. Fidler[4], H. Ayles[1,2], K. Shanaube[1], HPTN 071 (PopART) Study Team
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa, [4]Imperial College, London, United Kingdom
Presenting author email: mwatejchaila@gmail.com

Background: The PopART for Youth (P-ART-Y) study aims to evaluate the acceptability and uptake of a community-level combination HIV prevention package among young people, including UTT. The study is nested within the HPTN071 (PopART) trial, a 3-arm randomized study in 21 communities in Zambia and South Africa. It's delivered through a door-to-door approach by Community HIV-care Providers (CHiPs). HIV prevalence is low among 10-14 year olds, hence to prioritise HCT, a screening tool was used to identify those at risk of being HIV-infected.
Methods: Adolescents contacted at home were offered participation in the PopART intervention. Data were recorded electronically by CHiPs during household visits. For the 10-14 year olds, a screening tool developed and validated elsewhere was used to identify those at risk of being HIV-infected. Screening questions were history of hospital admission; recurring skin problems; poor health in last 3 months; and death of one or both natural parents. A "yes" response to ≥1 question was considered as an HIV infection suspect ("at risk"). We present findings from Zambia for the period, October 2015-August 2016.

[Figure 1. HIV testing in adolescents aged 10-14 year old]

Results: A total of 32,220 adolescents aged 10-14 years were enumerated; 56.0% (n=18,040) participated in the intervention and had their health data recorded (Figure 1). 12.1% (n=2,181) were "at risk". In the at risk group, 4.4% (96/2,181) self-reported as HIV+ compared with 0.5% (74/15,859) in the not at risk group. Among those who did not self-report HIV+, uptake of testing was 69.5% (1,449/2,085) and 49.1% (7,755/15,785) in the "at risk" and "not at risk" groups respectively. HIV prevalence among those tested was 2.4% (35/2,085) in the at risk group, compared with 0.6% (44/7,755) in the not at risk group.
Conclusions: The screening tool identified adolescents in the general population who are at relatively high risk of being HIV-infected, this can be exploited to allow targeted offer of HCT in resource limited settings.

TUPED1342

The effect of community led vulnerability reduction intervention on risk reduction among MSM-TG population across 3 states in India

S. B Syam[1], P. Patel[1], E. Elijah Daniel[1], P. Mathew[2], A. Chaudhuri[1]

Background: The ever growing body of research shows that HIV epidemics are socially and culturally produced and multi-level processes determine an individual's ability to adopt safe sex practices. This has influenced HIV prevention approaches to be designed around structural and social factors that decide individual level risk behaviors and also target the vulnerabilities of communities that are marginalized and at higher risk. Avahan Phase-III program as part of BMGF supported AIDS India Initiative, examines the impact of combined vulnerability reduction intervention coverage (CVRICI) on risk behavior among MSM and TG.
Methods: A systematic process of Member Engagement and Communication was conducted by Field Workers in their respective intervention areas using existing lists available with community organizations (CO) and TI Programs wherever accessible during April - September 2015 covering 8594 MSMs and 2169 TGs across 11 COs from 3 states of Maharashtra, Karnataka and Tamil Nadu. Information was collected on CVRICI, bonding with the CO (COBI) and risk behaviors like condom use etc. The data collected was managed and required comprehensive analysis was conducted using SPSS V 22.0
Results: MSMs and TGs with higher CVRICI reported consistent condom use (CCU) with 1 or all type of sexual partners. [MSM-AOR 2.168, CI (1.908-2.464) and TG-AOR 1.390, CI (1.027-1.881)] The analysis also showed that having a better bonding with the CO (COBS) is also significantly associated with the consistent condom use. But it was seen that above the COBS, CVRICI was more important in showing significant behavior change.
Conclusions: The findings from the study shows that combined vulnerability reduction interventions which focus on crisis response system, social protection and financial security which are community led have significant effects, direct and indirect on sustaining safe sex practices. The findings from the study ascertains the importance of combined approach of vulnerability and risk reduction to bring sustainability in the existing HIV program.

The cost-effectiveness of HIV testing and treatment engagement initiatives in British Columbia, Canada: 2011-2013

B. Nosyk[1], J. Min[1], E. Krebs[1], X. Zang[1], M. Compton[2], R. Gustafson[2], R. Barrios[1], J. Montaner[1], STOP HIV/AIDS Study Group
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Vancouver Coastal Health Authority, Vancouver, Canada
Presenting author email: bnosyk@cfenet.ubc.ca

Background: Recognition of the secondary preventive benefits of antiretroviral therapy (ART) have mobilized global efforts to ‚seek, test, treat and retain' people living with HIV/AIDS (PLHIV) in HIV care. Our objective was to determine the cost-effectiveness of a set of HIV testing and treatment engagement interventions initiated in British Columbia (BC), Canada in 2011-2013.
Methods: Using a previously-validated dynamic, compartmental HIV transmission model, and linked individual-level health administrative data for PLHIV and aggregate-level HIV testing data, we estimated the cost-effectiveness of primary care testing (hospital, emergency department, outpatient), ART initiation and ART retention initiatives, versus a counterfactual scenario approximating the status quo. HIV incidence, mortality, costs (in 2016$CDN), quality-adjusted life years (QALYs), incremental cost-effectiveness ratios were all estimated. Analyses were executed over 5, 10 and 25-year time horizons, from a government-payer perspective.
Results: ED testing was the best value at $30,216 per QALY gained and had the greatest impact on incidence and mortality among PLHIV, while ART initiation provided the greatest QALY gains. Delivered in combination at the observed scale

and sustained throughout the study period, we estimated a 12.8% reduction in cumulative HIV incidence and a 4.7% reduction in deaths among PLHIV at an incremental cost of $55,258 per QALY gained. Results were most sensitive to uncertainty in the number of undiagnosed PLHIV.
Conclusions: HIV testing and ART initiation interventions were cost-effective, while the ART retention intervention was not. Reducing uncertainty in the size of the undiagnosed population and developing strategies to re-engage PLHIV lost to care are priorities moving forward.

Clients' experiences utilizing a safer conception service: results from a process evaluation assessing knowledge, self-efficacy and perceived value of services among clients accessing care

S. Schwartz[1,2], N. Davies[2], N. Naidoo[2], D. Pillay[2], N. Sikhosana[2], S. Mullick[2]
[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa
Presenting author email: sschwartz@jhu.edu

Background: Data from safer conception services (SCS) for HIV-affected couples trying to conceive are limited. Experiences from clients utilizing SCS are needed to identify persistent gaps in patient knowledge and self-efficacy in order to optimize service delivery packages.
Methods: A sub-sample of clients attending SCS at Hillbrow Community Health Centre in Johannesburg, South Africa were invited to participate in a process evaluation; stratified sampling was used to ensure clients were sampled across different visits. Clients were asked to rate their perceived knowledge of and self-efficacy to use safer conception methods, such as PrEP, timed condomless sex and self-insemination using visual analog scales ranking success from 0-100. Results are described and trends across visits assessed using linear regression.
Results: Of 556 individuals enrolled into SCS, 117 (21%) were sampled for the evaluation between April 2016-January 2017, including 74 women and 43 men. Participants completed a median of three SCS visits (IQR 2-4) prior to the survey. On a scale of 0-100 (no valueàhigh value), clients strongly valued continuing SCS attendance until pregnancy is achieved (mean score 96% [95%CI 94-98]); results were independent of the number of completed visits. Clients' perceived knowledge and self-efficacy to use safer conception methods are illustrated in Figure 1. For every additional visit completed, knowledge of the fertile window increased by 4 points (sd: 2, p=0.047); no other significant trends in knowledge or self-efficacy were observed over time.

[Clients safer conception knowledge & self-efficacy]

Conclusions: Clients' perceived value of SCS and confidence to reduce conception-related transmission risks were high, and understanding of peak fertile days improved over time. However, understanding of PrEP, identifying peak fertile days and knowledge about preconception STI management could be improved, emphasizing the need for multiple SCS visits rather than a once-off counseling approach. Follow-up counseling should focus on building self-efficacy to apply HIV prevention strategies, including self-insemination for male negative serodiscordant couples.

Impaired Nef's ability to counteract SERINC5 is associated with decreased plasma viremia

M. Toyoda[1], D. Kamori[1], J. Carlson[2], H. Gatanaga[3], A. Kawana-Tachikawa[4], S. Oka[3], M. Pizzato[5], T. Ueno[1]
[1]*Kumamoto University, Center for AIDS Research, Kumamoto, Japan,* [2]*Microsoft Research, Los Angeles, United States,* [3]*National Center for Global Health and Medicine, Tokyo, Japan,* [4]*University of Tokyo, Tokyo, Japan,* [5]*University of Trento, Trento, Italy*
Presenting author email: uenotaka@kumamoto-u.ac.jp

Background: It is recently revealed that an HIV-1 accessory protein Nef plays an essential role in virion infectivity by antagonizing a host restriction molecule SERINC5. However, it remains elusive whether Nef's ability to counteract SERINC5 influences viral fitness in vivo. Because Nef is a highly polymorphic protein due to the selective forces by host cellular immunity, we hypothesized that certain immune-escape polymorphisms might affect the Nef function and thereby plasma viremia.
Methods: We collected plasma viral RNA from HLA-typed, treatment-naïve, chronically HIV-1-infected subjects (n=375) and analyzed DNA sequences of Nef-encoding region. Immune-associated Nef polymorphisms were analyzed by a phylogenetic network model. We also introduced several mutations to a control strain and patient-derived Nef clones and tested various Nef functions in vitro, including downregulation of CD4 and HLA class I as well as enhancement of virion infectivity and counteraction of SERINC5.
Results: We identified 112 Nef polymorphisms that were overrepresented within patients sharing the same HLA genotypes. Specifically, two mutations, Tyr-120 to Phe and Gln-125 to His were overrepresented in patients carrying HLA-B*51:01 and HLA-C*14:03 and the number of the two mutations correlated inversely with plasma viral load (p=0.004). Nef functional assays demonstrated that the double mutant Nef impaired in SERINC5 counteraction and enhancement virion infectivity whereas other Nef functions such as CD4 and HLA class I downregulation remained unchanged. Jurkat cells lacking SERINC5 expression lost such functional difference between the parental and mutant Nef clones.
Conclusions: Taken together, these results suggest that naturally occurring immune-associated mutations impair Nef's ability to counteract SERINC5 and enhance virion infectivity, associating with reduced plasma viral load in vivo.

HIV-1 concentrates and shelters cell-associated infectivity a "viral biofilm"

C. Inizan[1], A. Derames[1], M. Caillet[1], A. David[1], P. Versmisse[1], A. Saez-Cirion[1], M. Mesel-Lemoine[1], A. Mallet[1], M. Sachse[1], H. Mouquet[1], F. Boufassa[2], O. Lambotte[3], K. Bourdic[3], M.-I. Thoulouze[1]

Presenting author email: thoulouz@pasteur.fr

Background: Highly Active Antiretroviral Therapy (HAART) does not allow the complete clearance of the virus since it does not target viral reservoirs nor efficiently block HIV-1 cell-to cell transmission in vivo. HIV-1 cell-to-cell spread is thousands fold more efficient than cell-free infection; yet how virions are transferred via cell contacts remains unknown.
Methods: Using a panel of cutting-edge imaging techniques (Cryo-TEM, CL/SEM, CL/FIB and super resolution imaging) to functional assays, we investigated and characterized viral structures involved HIV-1 cell-associated infectivity. We analyzed a range of infected T cells cultures (chronically infected T cell lines, primary CD4+ T cells infected in vitro with virus primary isolates, and CD4+ T lymphocytes from untreated HIV-1 infected patients with a detectable viremia).
Results: We show here that HIV-1 cell-associated infectivity mostly resides at the surface of CD4+ T lymphocytes in a viral biofilm, formed by viral particles aggregated within a scaffold of extracellular matrix (ECM) components. Our set of data demonstrates that (i) biofilm-associated viral particles are more efficient in establishing infection than free viral particles and (ii) they confer HIV with important properties characterizing cell-to-cell spread. This includes the decreased sensitivity to HAART and to the broad neutralizing antibody 3BNC117. HIV-1 regulates biofilm matrix composition that controls both viral particles organization at the cell surface and the resulting cell associated infectivity. The organized clustering of viral particles along an ECM framework locally concentrate virions, favors their collective transfer to target cells and limits their exposure to nAbs. Finally, CD4+ T cells from HIV-1 infected patients produce and transmit viral biofilms, supporting that they may also be involved in vivo.
Conclusions: Thisstudy thus unveils HIV biofilm as a new highly infectious extracellular entity that concentrates, stores, disseminates and shelters HIV-1 infectivity. This may have implications for HIV-1 spread and persistence in host, including for maintaining HIV-1 sanctuaries in treated patients. Our results unveil a new role for the ECM in clustering and protecting HIV-1 at the plasma membrane, and in their collective transfer through virological synapses. Targeting biofilm ECM components could represent a promising approach to favor HIV-1 clearance or to potentiate the effect of available anti-viral therapies.

WEAA0103

Coordinated mTOR-mediated rewiring of nucleotide anabolism regulates HIV-1 infection of CD4 T lymphocytes

H.E. Taylor[1], I. Clerc[1], N. Calantone[1], G.E. Simmons[2], R.T. D'Aquila[1]
[1]*Northwestern Feinberg School of Medicine, Division of Infectious Diseases, Department of Medicine and Northwestern Medicine HIV Translational Research Center, Chicago, United States,* [2]*UT Southwestern, Dallas, United States*
Presenting author email: harryetaylor@yahoo.com

Background: HIV-1 replication is restricted in resting CD4 T lymphocytes. Stimulation of these cells via either the T cell receptor (TCR) or gamma-cytokine receptors up-regulates HIV provirus formation at levels of reverse transcription (RT) and nuclear import. However, the enhancements of both RT and nuclear import are not fully explained by activation-induced changes in known restriction factors. Here, we study a "master regulator" activated by both TCR and gamma-cytokine signaling: the mechanistic target of rapamycin (mTOR) kinase.
Methods: Resting CD4 T cells purified from blood donor PBMCs using immunomagnetic cell separation were stimulated with anti-CD3/anti-CD28 beads, PHA/IL2, or IL7/15. Inhibitors were used before activation to study the role of mTOR. qPCR quantified HIV-1 RT products and 2-long terminal repeat (2-LTR) circles. Flow cytometry after infection with a single-round HIV-1-GFP reporter virus monitored productive infection. Quantitation of dNTPs used ultra-sensitive LC-MS/MS detection. Flow cytometry and immunoblotting assessed effects of treatments on mTOR activity.
Results: mTOR activity induced by engagement of either T cell or gamma-cytokine receptors coordinates expression of transporters for glucose (GLUT1), glutamine (ASCT2), and transferrin (CD71), as well as rate-limiting enzymes for pyrimidine (CAD), purine (IMPDH2), and deoxyribonucleotide (dNTP) synthesis (RRM1). mTOR has been previously reported to govern the expression of nutrient transporters and pyrimidine biosynthetic genes, but this is the first demonstration of this global mTOR-dependent program in activated CD4 T lymphocytes. Pharmacological ablation of mTOR activity suppressed dNTP pool expansion after activation. Multiple chemically distinct catalytic inhibitors of mTOR were found to reduce HIV-1 RT products after TCR-stimulation. Moreover, both TCR and gamma-cytokine-activation induced mTOR inhibitor-sensitive accumulation of 2-LTR circular forms of HIV-1 DNA, indicating that mTOR activity also regulates active, energy (GTP/ATP)-dependent) HIV-1 nuclear import.
Conclusions: CD4 T lymphocyte activation-induced mTOR "metabolic reprogramming" drives increased susceptibility to HIV-1 by expanding key nucleotide substrate and energy pools necessary for both reverse transcription and nuclear import. This adds mechanistic understanding, confirms earlier reports that catalytic inhibitors of mTOR hold promise for improving HIV-1 chemo-therapy and prevention, and suggests continued investigation of mTOR's role in establishment as well as reactivation of HIV-1 infection.

WEAA0104

Membrane-associated RING-CH (MARCH) 1 and 2 are other members of MARCH proteins that inhibit HIV-1 infection

W. Yao[1,2], T. Tada[1], Y. Zhang[1,2], H. Fujita[3], S. Yamaoka[2], K. Tokunaga[1]
[1]*National Institute of Infectious Diseases, Department of Pathology, Tokyo, Japan,* [2]*Tokyo Medical and Dental University, Department of Molecular Virology, Tokyo, Japan,* [3]*Nagasaki International University, Faculty of Pharmaceutical Sciences, Nagasaki, Japan*
Presenting author email: tokunaga@nih.go.jp

Background: Membrane-associated RING-CH 8 (MARCH8), which is one of 11 members of MARCH family, downregulates several host membrane proteins (MHC-II, CD86, transferrin receptor, etc.). We have recently reported that this

protein also targets HIV-1 envelope glycoproteins and acts as an antiviral factor (Nat. Med. 21:1502-1507, 2015). It remains unclear whether other family members might have similar antiviral functions to those seen in MARCH8. Here, we show that MARCH1 and MARCH2, are such MARCH family members that reduces virion incorporation of envelope glycoproteins.
Methods: Plasmids expressing family members of MARCH (MARCH1, MARCH2, MARCH3, MARCH5, MARCH6, and MARCH7) were created by RT-PCR-amplifying their mRNAs. The HIV-1 proviral luciferase indicator plasmid was cotransfected with plasmids expressing either HIV-1 Env, or VSV-G, and those expressing MARCH family members including MARCH8, into 293T cells. Supernatants were subjected to assays for infectivity, viral entry, or virion incorporation, and producer cells were used for flow cytometry. Real-time RT-PCR was performed to determine endogenous levels of MARCH1 and MARCH2 expression.
Results: Infectivity assays showed that, two other members of MARCH family, MARCH1 and MARCH2 had the antiviral activity in a dose-dependent manner. The expression of these proteins in virus-producer cells decreased the efficiency of viral entry and indeed downregulated HIV-1 envelope glycoproteins from the cell surface, resulting in reduced incorporation of envelope glycoproteins into virions, exactly as observed in MARCH8 expression. Endogenous expression of MARCH1 and MARCH2 were enhanced in monocyte-derived macrophages by treatment with type I interferon.
Conclusions: As the antiviral MARCH family members, MARCH1 and MARCH2 join a growing list of host factors that inhibit HIV-1 infection.

WEAA0105

Bicaudal D2 facilitates the cytoplasmic trafficking and nuclear import of HIV-1 genomes during infection

A. Dharan[1], S. Opp[2], F. Diaz-Griffero[2], E. Campbell[1]
[1]Loyola University Chicago, Microbiology and Immunology, Maywood, United States, [2]Albert Einstein School of Medicine, Microbiology and Immunology, Bronx, United States
Presenting author email: ecampbell@luc.edu

Background: Numerous viruses, including HIV-1, exploit the microtubule network to traffic towards the nucleus during infection. Although numerous studies have observed a role for the plus end microtubule motor dynein in HIV-1 infection, the mechanism by which the viral core containing the viral genome associates with dynein and induce their perinuclear trafficking has remained unclear.
Methods: We utilized CRISPR mediated depletion of the dynein adapter protein Bicaudal D2 (BICD) and monitored the stages of viral replication by qPCR, measured viral trafficking using live cell imaging, and the induction of antiviral gene expression by RT-PCR.
Results: We observe that BICD2 depletion inhibits infection, preventing the nuclear entry of the viral genome, while fusion and reverse transcription are unimpaired. Using live cell imaging, we show that viral trafficking is altered in BICD2 depleted cells, and show that NC-CA tubes bind cellular BiCD2. Finally, we observe that disruption of the CA-BiCD2 interaction in the monocytic cell line THP-1 results in the accumulation of viral genomes in the cytoplasm and the induction of interferon stimulated genes in these cells.
Conclusions: These studies demonstrate that BICD2 is required for efficient HIV-1 infection and reveal the BICD2/CA interaction as a novel target for possible therapeutic interventions designed to increase innate immune activation in response to HIV-1 infection.

WEAA02 Catch Me If You Can: Reservoir Intervention

WEAA0201

Investigating the SHIV reservoir in a non-human primate model following allogeneic bone marrow transplantation

L. Colonna[1,2], J.B. Schell[2], C.W. Peterson[3], J. Carlson[2], M. Brown[2], V. Tkachev[2], A. Taraseviciute[1], S.N. Furlan[1], H. Zheng[1], D.J. Hunt[2], A. Yu[2], J. Lane[1], C.R. Moats[1], K. Vogel[1], C.E. Hotchkiss[1], R.D. Murnane[1], A. Baldessari[1], C. English[1], M. Hoffman[2], K. Zeleski[2], J. Olvera[2], C.A. Astley[1], S. Wangari[1], B. Agricola[1], J. Ahrens[1], N. Iwayama[1], P. Polacino[1], H.M. Mack[1], S.-L. Hu[1], L. Stensland[1], M.-L.W. Huang[1], H.P. Kiem[3], L.S. Kean[1,2,3]
[1]University of Washington, Seattle, United States, [2]Seattle Children's Research Institute, Ben Towne Center for Childhood Cancer Research, Seattle, United States, [3]Fred Hutchinson Cancer Research Center, Seattle, United States
Presenting author email: lcolonna@uw.edu

Background: Three components are thought to have contributed to the Berlin patient's cure following BMT: myeloablative conditioning, graft-versus-viral reservoir (GVVR), and HIV resistance of the donor CCR5D32 cells, yet the contributions of each to reservoir clearance is unknown. Moreover, while the Boston patients' viral rebound suggests HIV-resistance will be key, this has not yet been rigorously determined. To dissect the role of myeloablative conditioning, GVVR and viral resistance on the SHIV reservoir, we have developed the first NHP model for allogeneic BMT in SHIV-infected, cART-treated rhesus macaques.
Methods: We intravenously infected 6 animals with SHIV-1157ipd3N4 and left them untreated for six months, followed by six months of cART (Raltegravir, PMPA and FTC). 3 animals remained untransplanted, and 3 animals received myeloablative total body irradiation (1020 Gy) followed by haplo-identical BMT without ART discontinuation. Donor chimerism was monitored, and viral DNA and RNA were measured by qPCR in ~35 tissues following necropsy.
Results: All animals showed peak viral titers in the range of ~10^7 copies/ml ~2 weeks post-infection, which subsequently reached steady-state. 1 animal controlled viremia before ART initiation (day 184). In the other animals, plasma viral RNA became undetectable 2-3 weeks post cART initiation. The 3 transplanted animals were euthanized at day 47, 29, and 9 post-transplant, due to infection, acute graft-versus-host disease, and renal complications, respectively. Analysis of whole blood and sorted CD4+ T cells showed rapid acquisition of 100% donor blood chimerism, with lower chimerism in multiple tissues. Despite undetectable viremia post-transplant, viral DNA quantification in 35 tissues, including hematopoietic and major organs, CNS, and reproductive organs revealed an increased reservoir in transplanted non-controllers versus untransplanted controls.
Conclusions: Our results indicate that the DNA reservoir significantly increases early after transplant, despite control of peripheral viremia. This suggests that transplant represents a significant initial ‚shock' with loss of anti-HIV immunity contributing to reservoir enlargement, potentially explaining the rebound observed in the Boston patients. We believe that full recovery of anti-HIV immune control may be restored if additional HIV resistance factors and/or anti-HIV strategies are incorporated post-transplant to enhance the targeted killing of infected cells.

WEAA0202

Investigating clinical therapeutics to target infected cells and promote HIV clearance

P. Arandjelovic[1,2], C. Allison[1,2], S. Preston[1,2], J. Cooney[1,2], M. Pellegrini[1,2]
[1]The Walter and Eliza Hall Institute of Medical Research, Infection and Immunity, Melbourne, Australia, [2]The University of Melbourne, Department of Medical Biology, Melbourne, Australia
Presenting author email: arandjelovic.p@wehi.edu.au

Background: Efforts to eliminate the latent HIV reservoir highlight the need for alternative strategies geared towards killing latently infected cells. HIV manipulates host apoptotic pathways in order to sustain the infection cycle and evade immune surveillance. BH3-mimetic inhibitors antagonise pro-survival proteins and promote intrinsic apoptosis.
Here, we employ a novel humanized mouse model of latent HIV infection, together with in vitro cell survival assays, to investigate the usefulness of BH3-mimetics in clearing the latent reservoir and achieving a functional cure.
Methods: Primary human $CD4^+$ T lymphocytes were isolated from healthy donors, activated and infected with HIV-GFP. Infected primary $CD4^+$ T cells were treated with BH3-mimetics and assessed for death of GFP-positive, HIV infected cells.
Briefly, humanized mice were generated as follows: NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/Sz (NSG) neonates were sub-lethally irradiated in order to achieve myeloablation, followed by injection of human $CD34^+$ cord blood haematopoietic stem cells into the

orbital vein. Mice were assessed for degree and quality of reconstitution at 16 weeks of age before infection with HIV. Virological suppression was recapitulated using a clinically-relevant ART regimen before testing novel interventions.
Results: We first sought to investigate the in vitro sensitivity of actively infected cells to pro-apoptotic interventions. Treatment with the pre-clinical BH3-mimetic ABT-737, which targets pro-survival proteins Bcl-2, Bcl-xL and Bcl-w, resulted in preferential killing of HIV-infected cells in a concentration-dependent manner. A similar outcome was observed using the FDA-approved, clinical-stage Bcl-2 inhibitor Venetoclax.
Our humanized mouse model successfully recapitulates key stages of human disease, including chronic infection, viral suppression, as well as subsequent rebound following treatment interruption. Suppressed mice were administered Venetoclax over three treatment cycles before therapy was interrupted to assess for viral rebound. Humanized mice treated with Venetoclax experienced a substantial delay in rebound up to one week longer than vehicle-treated controls.
Conclusions: These results pave the way for further in vivo studies using a humanized mouse model of HIV latency. Efforts are underway to optimise treatment regimens as well as to investigate the combination of BH3-mimetics with traditional latency-reversing agents. Overall, these findings represent a novel approach to killing latently infected cells and purging the proviral reservoir.

WEAA0203

Inhibiting memory CD4+ T-cell self-renewal to reduce HIV persistence

M. Mavigner[1], M. Zanoni[2], J. Habib[1], C. Mattingly[2], J. Demarest[3], H. Kouji[4], B. Lawson[2], T. Vanderford[2], G. Tharp[2], S. Bosinger[2], G. Silvestri[2], A. Chahroudi[1]
[1]Emory University School of Medicine, Pediatrics, Atlanta, United States, [2]Emory University, Yerkes National Primate Research Center, Atlanta, United States, [3]ViiV Healthcare, Durham, United States, [4]Prism Biolab, Kanagawa, Japan
Presenting author email: maud.mavigner@emory.edu

Background: Long-lived memory CD4+ T-cells with high self-renewal capacity such as central memory (T_{CM}) T-cells and T memory stem cells (T_{SCM}) are major contributors to the viral reservoir in HIV-infected individuals on antiretroviral therapy (ART). The Wnt/beta-catenin signaling pathway primarily regulates the balance between self-renewal and differentiation of T_{SCM}/T_{CM} and pharmacological manipulation of this pathway offers an opportunity to reduce persistence of latently-infected cells.
Methods: To block self-renewal and promote T_{SCM}/T_{CM} differentiation, we used an inhibitor targeting the Wnt/beta-catenin pathway initially developed to target cancer stem cells (called PRI-724). We evaluated the safety of PRI-724 with a dose escalation study in healthy rhesus macaques (RM). We then conducted an efficacy study in twelve SIV_{mac251}-infected RM treated with ART. After suppression of viremia, 8/12 RM received PRI-724 at 10 or 20 mg/kg/day while 4/12 RM were maintained on ART only. The gene profile of CD4+ memory T-cell subsets was assessed longitudinally by RNAseq analyses. RM were sacrificed on ART following twelve weeks of PRI-724 treatment for assessment of SIV reservoirs.
Results: PRI-724 was well tolerated in both healthy and ART-treated SIV-infected RM, with blood counts, liver function, and renal function within normal limits. No alteration of tri-lineage hematopoiesis was observed in bone marrow. The transcriptomic profiling of genes associated with T-cell differentiation showed an increased expression of the EOMES transcription factor in the CD4+ T_{SCM} of PRI-treated animals as compared to controls. Moreover, Gene Set Enrichment Analyses showed that gene sets distinguishing effector versus memory were significantly enriched in the CD4+ T_{SCM} as compared to the naïve T-cells. Interestingly, this CD4+ T_{SCM} enrichment in effector-like genes was significantly higher in the PRI-treated than in the control RM. These results suggest an effect of PRI-724 on CD4+ T_{SCM} differentiation. PCR analyses in the sorted subsets of memory CD4+ T-cells showed no significant difference in cell-associated SIV DNA levels between PRI-724 treated and untreated RM.
Conclusions: This work provides novel support for the strategy of promoting CD4+ T_{SCM} differentiation by pharmacological modulation of the Wnt/beta-catenin pathway. However, combination strategies targeting stem cell pathways and/or additional anti-reservoir strategies are likely necessary to reduce SIV/HIV persistence.

WEAA0204

PBMCs from patients with chronic myeloid leukemia treated with different tyrosine kinase inhibitors show variable susceptibility to HIV-1 infection: searching for the best therapeutic approach

M. Bermejo[1], J. Ambrosioni[2], G. Bautista[3], N. Climent[2], E. Mateos[1], C. Rovira[2], R. Duarte[3], F. Cervantes[2], M. Plana[2], J.M. Miro[2], J. Alcami[1], M. Coiras[1]
[1]National Center of Microbiology, Instituto de Salud Carlos III, Madrid, Spain, [2]Hospital Clinic, Barcelona, Spain, [3]Hospital Puerta de Hierro, Madrid, Spain
Presenting author email: mcoiras@isciii.es

Background: Tyrosine kinase inhibitors (TKIs) such as imatinib, nilotinib, dasatinib, bosutinib and ponatinib are currently used for treating chronic myeloid leukemia (CML). Imatinib was the first TKI introduced in clinical practice and is very selective of the chimeric fusion protein BCR-ABL responsible for causing CML. Second generation TKIs nilotinib, dasatinib and bosutinib are 20-, 300- and 200-fold more potent than imatinib against BCR-ABL, respectively. Third generation Ponatinib has been approved for patients resistant to other TKIs. Our group demonstrated that Dasatinib interferes with SAMHD1 phosphorylation, preserving its antiviral activity and avoiding HIV-1 retrotranscription and proviral integration. Therefore, using dasatinib as adjuvant of antiretroviral therapy in HIV-infected patients could reduce the formation of the viral reservoir. In this work, we evaluated which TKI would be the best choice for treating HIV-infected patients.
Methods: PBMCs isolated from 42 CML patients on treatment with imatinib, nilotinib, dasatinib, bosutinib or ponatinib and 44 healthy controls. All patients were treated for >2 years with normal TKI dose; they showed no HIV-1 infection, normal lymphocyte count and general good health.
Results: 1) IC_{50} for inhibiting HIV-1 replication was calculated in vitro for each TKI: imatinib IC_{50}=10μM; nilotinib IC_{50}=10μM; dasatinib IC_{50}=37.5nM; bosutinib IC_{50}=0.5μM; ponatinib IC_{50}=150nM. 2) Ex vivo infection of PBMCs from CML patients showed that imatinib, dasatinib and bosutinib effectively inhibited both early and late reverse transcription ($p< 0.001$). Ponatinib was also very effective but we only recruited one patient. 3) PBMCs from CML patients showed lower SAMHD1 phosphorylation after PHA/IL-2 treatment for 5 days ($p<0.0001$ for dasatinib; $p<0.01$ for bosutinib). 4) Proviral integration was inhibited after treatment with all TKIs, being dasatinib the most significant ($p<0.01$). 5) Synthesis of viral proteins was mostly significantly interfered by dasatinib ($p<0.0001$).
Conclusions: PBMCs from CML patients on chronic treatment with TKIs showed resistance to SAMHD1 phosphorylation after activation with PHA/IL-2. HIV-1 reverse transcription and proviral integration was reduced in these cells. Dasatinib was the most potent against HIV-1 replication, closely followed by ponatinib. Consequently, preserving SAMHD1 antiviral function with TKIs such as Dasatinib could reduce the reservoir size during HIV-1 acute infection.

Background: HIV persists in latently infected CD4+T cells in infected individuals even after prolonged periods on suppressive antiretroviral therapy (ART). Transcriptional reactivation from latency is not inhibited by current ART, highlighting the need for novel approaches.
The HIV-1 Tat protein exponentially activates viral transcription, and limited Tat-transactivation correlates with HIV-1 latency establishment. We identified didehydro-cortistatin A (dCA) as a potent Tat inhibitor. Over time, treatment of infected cells with dCA drives HIV-1 gene expression into an induced state of persistent latency, refractory to viral reactivation by a standard panel of latency reversing agents (LRAs), suggesting the HIV promoter is epigenetically repressed. We postulated a strategy for a functional cure, dubbed "block-and-lock", where a specific HIV-1 transcriptional inhibitor would promote a durable state of latency, reduce ongoing viral replication during ART, and inhibit spontaneous reactivation during ART or when ART is discontinued.
Methods: We will present our long-term studies of the activity of dCA in primary human CD4+T cells isolated from aviremic infected individuals, using an optimized approach that maintains cell cultures up to 10 weeks. To explore the in vivo efficacy of dCA we used the bone marrow-liver-thymus (BLT) humanized mouse model of HIV-1 latency.

We will also discuss epigenetic mechanisms regulating dCA induced deep latency in CD4+T memory T cells, as well as mechanisms of viral evasion to dCA.
Results: We demonstrate in CD4+T cells from five suppressed infected individuals that not only combining dCA with ART promotes faster HIV-1 suppression, but more importantly that prior treatment with dCA significantly reduces viral rebound up to 25 days of treatment interruption, even when viral reactivation is stimulated by LRAs.
In the BLT mouse model of latency, we demonstrate that adding dCA to ART suppressed mice, for a period of 14 days, results in a significant 1.5 to 10.5 fold reduction in viral RNA production in all tissues. Experiments assessing the ability of dCA to inhibit viral rebound upon treatment interruption are ongoing and will be presented.
Conclusions: In combination with ART, dCA abrogates residual HIV production from cellular reservoirs, blocks viral reactivation, and may ultimately reduce reservoir replenishment and latent reservoir size.

Background: Over 10 years ago, hematopoietic stem cell transplant (HSCT) with infection-resistant CCR5Δ32 cells led to cure/remission of HIV infection and leukemia in the Berlin patient. HIV cure was likely a combined result of the conditioning regimen, an allogeneic „graft versus reservoir" effect, and the CCR5Δ32 donor cells. We studied the impact of conditioning and CCR5-edited cells in simian-human immunodeficiency virus (SHIV)-infected macaques suppressed by combination antiretroviral therapy (cART). The goal of this study was to identify the mechanisms by which each facet impacted the latent viral reservoir.
Methods: Pigtailed macaques were challenged with CCR5-tropic, HIV enveloped SHIV, and suppressed by cART following viral set point. In one cohort, autologous HSCT was performed with unmodified stem cells. In a second cohort, animals received CCR5-edited stem cells. Control animals were infected and suppressed, but did not undergo transplantation. Flow cytometry and ELISA were used to monitor changes in immune homeostasis, and quantitative PCR and viral reservoir assays were used to identify virologic changes between experimental and control animals.
Results: The conditioning regimen resulted in a dramatic, but incomplete depletion of CD4+, CD8+ T-cells and B-cells, disrupted T-cell homeostasis, elevated markers of microbial translocation, a significant loss of SHIV-specific antibodies, and increased viral rebound, relative to untransplanted controls. Although CCR5 editing did not reach threshold levels for post-cART control of viremia, correlates of protection were observed: quantitative viral outgrowth, Tat/Rev-induced limiting dilution, and tissue viremia assays showed that the size of SHIV reservoirs was impacted.
Conclusions: Our data identify perturbations of the immune system as a mechanism for the failure of autologous transplantation (without gene-protected cells) to eradicate HIV, highlighting the importance of an intact immune system for viral control after cART withdrawal. We conclude that reduced-intensity conditioning, which is safer and less toxic, should be a focus for transplant-based approaches. Analogous to cutting-edge therapies for cancer patients, next generation HIV cure strategies should balance killing of virus-infected target cells with retention of greater immune function, e.g. with immune modulators. High efficiency gene therapy/gene editing to protect transplanted cells and actively target the viral reservoir during ongoing cART will be essential.

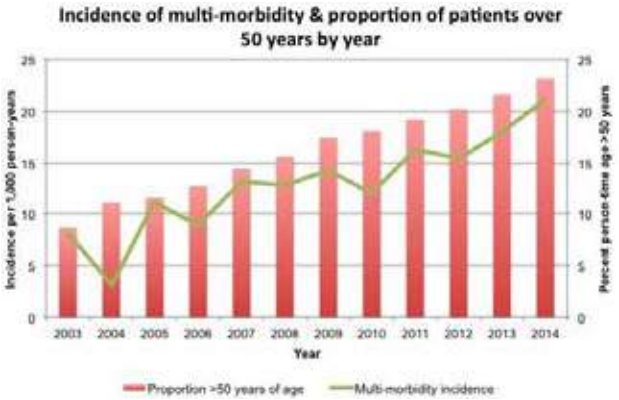
Presenting author email: jessica.castilho@vanderbilt.edu

Background: HIV-infected adults on ART experience high rates of non-communicable diseases (NCDs). These co-morbidities can accumulate and older HIV-infected adults often suffer from multi-morbidity. Little is known of the burden of multi-morbidity in HIV-infected adults in low- and middle-income countries.
Methods: HIV-Brazil Cohort is an observational, multi-site study of HIV-infected adults initiating ART between 2003-2014. We studied NCDs and multi-morbidity in patients from seven clinical sites in six Brazilian cities. NCDs included coronary artery disease, cerebrovascular disease, high-grade hyperlipidemia (HLD), diabetes, chronic kidney disease, cirrhosis, osteoporosis, osteonecrosis, venous thromboembolism (VTE), and non-AIDS-defining cancers. Multi-morbidity was defined as the incident accumulation of two or more unique NCDs. We examined incidence trends using Poisson regression and predictors of multi-morbidity using competing risk and Cox regression models.
Results: Of the 5,786 adults included, 388 (7%) developed multi-morbidity during the study period. From 2003 to 2014, parallel to the rise of patients over the age of 50 in the cohort, the incidence of multi-morbidity rose to 21 patients per 1,000 person-years (Figure). HLD and VTE incidence decreased while diabetes and osteoporosis rates significantly increased from 2003-2014. In adjusted Cox models, female sex, age, and low CD4 nadir at baseline were significantly associated with risk of multi-morbidity (Table, also adjusting for education, race, year, hepatitis C). Among all patients with multi-morbidity, the most common NCDs were HLD (87%) and diabetes (59%); however, women with multi-morbidity were more likely to have osteoporosis than men (15.4 vs. 6.8%).



[Figure. Incidence of multi-morbidity & proportion of patients over 50 years by year]

	Adjusted Hazard Ratio [95% CI]	P value
Female sex (ref: male sex)	1.35 [1.06-1.70	0.014
CD4 cell count nadir at baseline (µ/L)		
>200	(ref)	
100-199	1.59 [1.18-2.13]	0.002
<100	1.77 [1.35-2.32]	<0.001

[Multivarbiable Cox proportional hazard model]

Conclusions: Multi-morbidity of NCDs increased from 2003-2014. Females were more likely to develop multi-morbidity in adjusted analyses. Further studies examining sex-specific screening, prevention and management of NCD co-morbidities in HIV-infected adults are needed.

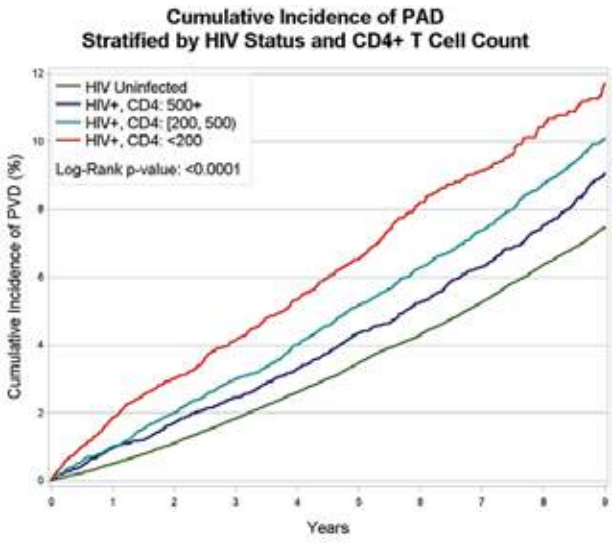
HIV infection and the risk of peripheral arterial disease

M. Freiberg[1,2], M. Duncan[3], A. Justice[4,5], J. Beckman[3], Veterans Aging Cohort Study
[1]Vanderbilt University Medical Center, Medicine, Nashville, United States, [2]Tennessee Valley Veterans Affairs Medical Center, Nashville, United States, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Yale University School of Medicine, New Haven, United States, [5]West Haven Veterans Affairs Medical Center, West Haven, United States
Presenting author email: matthew.s.freiberg@vanderbilt.edu

Background: Peripheral arterial disease (PAD) affects ~8 to 10 million U.S. adults annually and is the second most common clinical manifestation of atherosclerosis after acute myocardial infarction (AMI). While the increased risk of AMI and ischemic stroke among HIV infected (HIV+) compared to uninfected people is well documented, data linking HIV to incident PAD events are sparse. We, therefore, compared PAD risk among HIV+ and uninfected veterans.
Methods: We analyzed data on 91,457 veterans (33% HIV+) without prevalent cardiovascular disease from the Veterans Aging Cohort Study (VACS). VACS is an observational, longitudinal cohort of HIV+ veterans matched 1:2 with uninfected veterans on age, gender, race/ethnicity, and clinical site. Participants were followed from their first clinical encounter on or after 4/1/2003 until a PAD event, death, their last follow-up date, or 9/30/2012. We used ICD-9 and CPT codes to identify participants with incident PAD. Cox proportional hazard regression models were utilized to assess the association between HIV, CD4+ T cell count, and PAD adjusting for atherosclerotic risk factors (Table). Finally, we constructed cumulative incidence curves to examine PAD risk stratified by HIV status and CD4 + T cell count.
Results: During a median follow-up of 7 years, there were 5091 PAD events. See Table and Figure for rates and risk of PAD stratified by HIV status and CD4+ T cell count.

Group	N	PAD Events	Rate/1000PY 95% CI]	Unadjusted PAD Risk [HR 95% CI]	Adjusted PAD Risk [HR 95% CI]a
HIV Uninfected	61,498	3103	8 [7.8, 8.4]	1.00	1.00
HIV+, CD4: 500+	10,682	663	10 [9.4, 11.0]	1.23 [1.13, 1.34]	1.31 [1.20, 1.43]
HIV+, CD4: [200, 500)	12,368	835	11 [10.6, 12.1]	1.41 [1.31, 1.52]	1.46 [1.35, 1.59]
HIV+, CD4: <200	6909	490	14 [12.8, 15.3]	1.77 [1.60, 1.95]	1.62 [1.45, 1.80]
a adjusted for age, sex, race/ethnicity, hypertension, diabetes, LDL and HDL cholesterol, triglycerides, HCV infection, smoking status, renal disease, BMI, anemia, cocaine dependence or abuse, alcohol dependence or abuse, and COPD.					

[Rates and risk of PAD by HIV status and CD4+ T cel]



[Figure. Cumulative incidence of PAD stratified by HIV status and CD4+ T cell count]

Conclusions: Conclusions and Relevance: HIV+ veterans have a significantly higher risk of PAD than uninfected veterans.

WEAB0103

Impact of exposure to each antiretroviral treatment (ARV) on the risk of fracture in HIV-1-infected individuals: an analysis from FHDH ANRS CO4

D. Costagliola[1], V. Potard[1,2], S. Lang[1,2], S. Abgrall[1,3], C. Duvivier[4,5], H. Fischer[6], V. Joly[7], J.-M. Lacombe[1,2], M.-A. Valantin[1,8], M. Mary-Krause[1], S. Rozenberg[9], on behalf of the FHDH ANRS CO4

Background: HIV-infected patients have a lower bone mineral density (BMD) and a higher incidence of fractures compared to the general population of same age and sex. To assess the impact of exposure to each ARV on the risk of osteoporotic fractures, we conducted a nested case-control study.
Methods: Cases were individuals enrolled while ART-naïve, with a first prospectively reported fracture between 01/2000 and 12/2010. Controls were randomly selected after matching on sex, age (±3 years), diagnosis period (< 1997/≥1997) and clinical centre. The risk of fracture was analysed using conditional logistic regression models. Exposure to each ARV was measured either by cumulative duration of exposure (model1), or by exposure yes/no (model2). In a 3rd model, the exposure variable was chosen for each ARV according to the lowest Akaike criterion value. All exposure variables and potential confounders were included in the multivariable models.
Results: Among the 861 reviewed fractures, 261 were osteoporotic fractures, and 254 were matched to at least one control (376 controls). The median year of fracture diagnosis was 2007(IQR 2004-2009), 67% of cases were men, 71% diagnosed with HIV-infection before 1997, median age was 49 years, CD4 436[293-592], nadir CD4 196[82-287], 31% at AIDS-stage, 65% with VL< 50cp/mL, and 49% exposed to tenofovir, 82% to PIs and 37% to efavirenz.
After accounting for transmission group, AIDS-stage, geographic origin, BMI, current smoking, alcohol consumption, exposure to systemic glucocorticoids, and period of enrolment, no association was found between the risk of fracture and exposure to tenofovir (OR for cumulative exposure: 1.03[0.86-1.24], similar results for exposure yes/no), or to NRTIs, or to PIs (exposure to PI overall: OR 1.01[0.92-1.11] or to each PI). Cumulative exposure to efavirenz was associated with a lower risk of fracture in models 1 and 3 (respective OR 0.81[0.69-0.95] and 0.82[0.70-0.96] per year of exposure), while exposure to efavirenz (yes/no) was not (OR 0.84[0.51-1.40]). Sensitivity analyses do not favour the causal nature of the association with exposure to efavirenz.
Conclusions: There was no evidence of excess risk of fracture following exposure to tenofovir or to PIs. This is an important result in the debate about TAF versus generic tenofovir.

WEAB0104

Being HIV-1-infected is independently associated with decreased erectile function among older men who have sex with men

M. Dijkstra[1], R.H.W. van Lunsen[2], K.W. Kooij[3], U. Davidovich[1], R.A. van Zoest[3], F.W.M.N. Wit[3], M. Prins[1], P. Reiss[3], M.F. Schim van der Loeff[1], AGEhIV Cohort Study Group
[1]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [2]Academic Medical Center, Department of Sexology and Psychosomatic Gynaecology, Amsterdam, Netherlands, [3]Academic Medical Center, Department of Global Health and Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands
Presenting author email: mdijkstra@ggd.amsterdam.nl

Background: Several studies have reported that HIV-1-infected men who have sex with men (MSM) more often experience sexual dysfunction compared to HIV-1-uninfected MSM. HIV-1-infected individuals have a higher prevalence of non-communicable comorbidities, which may affect sexual health, compared to HIV-1-uninfected individuals. We assessed whether HIV-1 infection is independently associated with decreased sexual functioning among MSM aged 45 years and older.
Methods: Data from HIV-1-infected and HIV-1-uninfected MSM aged ≥45 years at the time of enrolment into the on-going AGE$_h$IV Cohort Study were used. The questionnaire included 3 questions (representing 3 sexual domains) on sexual functioning from the International Index of Erectile Function (IIEF), addressing erectile

function, sexual desire, and sexual satisfaction (scale 1-5, higher score represents better function). The 3 separate questions were dichotomised using a cut-off of ≤2. Three multivariable logistic regression models were constructed to investigate the association between HIV-1 infection and the 3 domains. Variables associated with both HIV-1 infection and one of the outcomes (at p<0.20) were included in all 3 multivariable models. We explored HIV-1- and ART-related variables in the established multivariable models including only HIV-1-infected individuals.
Results: In total, 399 HIV-1-infected and 366 HIV-1-uninfected MSM were included in the analyses. Decreased erectile function (13.0% vs. 3.4%, p<0.001), decreased sexual desire (7.0% vs. 3.6% p=0.033), and decreased sexual satisfaction (17.8% vs. 11.8%, p=0.019) were more prevalent among HIV-1-infected MSM compared to HIV-1-uninfected MSM. In multivariable logistic regression models including age, ethnicity, waist-to-hip ratio, noncommunicable comorbidities, depression, frailty, use of antidepressants, and antihypertensive medication, HIV-1 infection was independently associated with decreased erectile function (adjusted odds ratio (aOR) 2.53, 95%CI 1.23-5.21), but not with decreased sexual desire (aOR 1.78, 95%CI 0.81-3.92), and decreased sexual satisfaction (aOR 1.35, 95%CI 0.84-2.17). Among HIV-1-infected participants, previous (aOR 3.20, 95%CI 1.52-6.75) and current (aOR 4.71, 95%CI 1.90-11.71) use of lopinavir were independently associated with decreased erectile function.
Conclusions: Among MSM aged ≥45 years, being HIV-1-infected was independently associated with decreased erectile function. Exposure to lopinavir appeared to be an independent risk factor for decreased erectile function. No independent association between HIV-1 infection and decreased sexual desire or decreased sexual satisfaction was observed.

WEAB0105

SHIV infection and drug transporters influence brain tissue concentrations of efavirenz

N. Srinivas[1], J. Fallon[1], C. Sykes[1], N. White[1], A. Schauer[1], L. Adamson[2], M. Matthews[1], P. Luciw[2], P. Smith[1], A. Kashuba[1]
[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]University of California, Davis, Davis, United States
Presenting author email: nithyas@email.unc.edu

Background: Despite antiretroviral (ARV) therapy, there is a high prevalence of HIV-associated neurocognitive disorder (HAND) in HIV-infected individuals. Using CSF data, it has been theorized that inadequate ARV concentrations may contribute. However, information on brain tissue concentrations is sparse. This study compared the concentration of ARVs in four regions of brain tissue with CSF in uninfected and SHIV-infected rhesus macaques.
Methods: In 12 male macaques (6 uninfected; 6 SHIV-infected) dosed to steady-state condition, concentrations of 6 ARVs - tenofovir (TFV), emtricitabine (FTC), efavirenz (EFV), raltegravir (RAL), maraviroc (MVC) and atazanavir (ATZ) were measured by LC-MS/MS in the CSF (LLOQ=0.5 ng/mL) and cerebrum, cerebellum, basal ganglia and parietal cortex regions of the brain (LLOQ of homogenate ranged from 0.002-0.01 ng/mL). Tissue concentrations were converted to ng/g using density of 1.06. To assess the influence of drug transporters on ARV concentration, brain tissue was analyzed for Pgp and BCRP efflux transporter proteins by LC-MS proteomics (LLOQ=0.1 pMol/mg protein). Data are presented as median (range); statistical analysis was by Kruskal-Wallis test.
Results:

	CSF concentration (ng/ml)		Brain tissue concentration (ng/g)	
	Uninfected	Infected	Uninfected	Infected
TFV	0.8 (0.0, 4.6)	2.2 (1.5, 3.0)	55.0 (47.1, 392.1)	34.9 (22.7, 65.1)
FTC	2.1 (0.0, 11.7)	5.7 (3.9, 7.3)	29.9 (19.5, 85.8)	28.4 (14.8, 33.6)
EFV	2.1 (1.4, 3.4)	0.5 (0.5, 1.4)	1615.2 (965.2, 1983.0)	391.6 (239.8, 792.3)
RAL	1.2 (0.6, 1.3)	0.5 (0.5, 0.5)	27.7 (15.8, 78.3)	14.7 (9.7, 21.8)
MVC	2.9 (0.5, 11.1)	0.0 (0.0, 0.0)	57.5 (21.9, 193.0)	48.7 (34.8, 104.8)
ATZ	0.5 (0.0, 40.5)	0.5 (0.5, 0.5)	84.1 (49.7, 554.1)	133.1 (59.4, 138.0)

[Concentration of ARVs in brain and CSF]

CSF concentrations did not differ by infection status (p>0.1). Since there was no difference in ARV concentration in the various regions of the brain (p>0.1), these data were combined. Concentrations in brain tissue were significantly greater than CSF for TFV, FTC and EFV: ranging from 5-times (FTC) to 769-times (EFV) higher. Brain tissue concentration of EFV was 4.1 times higher in uninfected animals. BCRP concentration was 1.7 times higher in infected animals (p=0.02); Pgp concentration did not differ with infection status (p=0.06).
Conclusions: In this study, brain tissue concentration of EFV was 4-fold lower in infected macaques and this may be due to increased BCRP concentrations. Further, we have shown that ARV CSF concentrations may need cautious interpretation when used as surrogate for brain tissue exposure. Based on these data, further investigations are needed to determine how ARV brain tissue concentrations influence HAND prevalence.

Barriers to uptake of pre-exposure prophylaxis among respondents to the Flash! PrEP in Europe survey

A. Bernier[1], R.M. Delabre[2], V. Schlegel[2], A. Vilotitch[3,4], S. Duken[5], R. Stranz[6], D. Rojas Castro[2,7,8], K. Jonas[9]
[1]Coalition Internationale Sida, Community-based Research Department, Pantin, France, [2]AIDES, Community-based Research Department, Pantin, France, [3]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, INSERM U912, Marseille, France, [4]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [5]University of Amsterdam, Psychology Department, Amsterdam, Netherlands, [6]AIDES, Advocacy Department, Pantin, France, [7]University of Lyon 2, Social Psychology Research Group (GRePS), Lyon, France, [8]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [9]Maastricht University, Work and Social Psychology Department, Maastricht, Netherlands
Presenting author email: abernier@coalitionplus.org

Background: Pre-exposure prophylaxis (PrEP) has been shown to effectively reduce HIV infection risk and is recommended by the World Health Organisation (2015) and the European AIDS Clinical Society (2015). As of January 2017, only two European countries, France and Norway, have authorized prescription and reimbursement of PrEP. In this analysis we identify potential barriers to PrEP uptake across Europe.
Methods: The Flash! PrEP in Europe (FPIE) online survey was a community-based research study aiming to assess interest in and barriers to PrEP uptake amongst respondents from 11 European countries. Data was collected from June to July 2016. Respondents were ≥18 years old and self-reported HIV-negative or unaware of their serological status. A 5-point Likert scale was used to assess potential PrEP uptake barriers, responses were dichotomized (Yes, probably/ Yes, definitely vs Maybe/ No, probably/ No, definitely). To assess barriers amongst different groups, and due to high response rate from Germany, four groups were analyzed separately: German men (GM), other European men (OEM), women and transgender men and women (TMW).
Results: Of 15 461 respondents, there were 10 288 GM, 4201 OEM, 690 women, 245 TMW and 37 did not provide gender information. Among the 10 833 (72.7%) respondents potentially interested in PrEP, the greatest potential barriers were fear of side effects (GM: 53.6%, OEM: 39.0%, women: 55.8%, TMW: 40.0%) and necessary hospital visits for PrEP (GM: 49.1%, OEM: 27.3%, women: 33.0%, TMW: 35.7%). Among respondents not interested in PrEP, a majority (>64% in each group) did not want to take PrEP daily, feared side effects or did not feel the need to change their protection strategy. Fear of getting other sexually transmitted infections (STI) was also predominant particularly among GM (72.8%).
Conclusions: FPIE results highlight high interest but widespread knowledge gaps in relation to PrEP use among potential users. Improved communication on PrEP, including regular STI testing, follow-up for side effects, possibility of event-driven regimen and facilitating PrEP access, may help address some barriers. Better understanding of PrEP uptake barriers may help inform public health policies which meet the needs of at-risk populations.

Preferences regarding emerging HIV prevention technologies among Toronto men who have sex with men

D.H.S. Tan[1,2,3], J. Rana[4], S. Fowler[5], T.A. Hart[4,6], J. Wilton[7], A. Bayoumi[2,3,8]
[1]St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, [2]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada, [3]St. Michael's Hospital, Centre for Urban Health Solutions, Toronto, Canada, [4]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [5]Hassle Free Clinic, Toronto, Canada, [6]Ryerson University, Department of Psychology, Toronto, Canada, [7]Ontario HIV Treatment Network, Toronto, Canada, [8]St. Michael's Hospital, Department of Medicine, Toronto, Canada
Presenting author email: darrell.tan@gmail.com

Background: New HIV prevention technologies (NPTs) currently in development include long-acting injectables and topical microbicides, and have unique attributes that may appeal differently to different users. We used a discrete choice experiment (DCE), in which participants' choices between hypothetical alternatives are used to infer preferences for attributes, to characterize NPT preferences among men who have sex with men (MSM) in Toronto, Canada.
Methods: MSM undergoing anonymous HIV testing completed a DCE with 12 ‚choice sets' by selecting their preferred option within each set. Each set included "usual methods to prevent HIV infection" (excluding pre-exposure prophylaxis) as

one option and two hypothetical NPT options which differed according to HIV prevention efficacy (50%, 65%, 80% or 99% risk reduction), route of administration, side effects (none or mild), and risk of drug resistance (none, low, or moderate). We used mixed logistic regression to infer relative preferences for NPT attributes and latent class analysis to determine patterns of responses.
Results: Of 306 participants, 54% were White and median (IQR) age was 30 (25, 38). Participants reported 6 (3, 10) partners and 0 (0, 2) condomless receptive anal sex-acts in the preceding six months. Most had heard of post-exposure prophylaxis (80%) and pre-exposure prophylaxis (91%), but only 11% and 5% respectively had used them. We excluded 40 participants who had all missing data or gave invariant responses. An on-demand pill was the most preferred NPT, followed by a daily pill, monthly injection and on-demand rectal gel. Resistance was an important determinant of NPT preference if the risk was moderate, but not if low. The minimum NPT efficacy required for an on-demand pill to be preferred over usual methods was 52.8% (95%CI=46.9-58.7); for a daily pill, injections, and rectal gel, estimates were 60.1% (95%CI=53.8-66.5), 67.0% (95%CI=61.0-73.0), and 78.3% (95%CI=70.9-85.7), respectively. Latent class analysis identified one subset of participants clearly favouring on-demand PrEP (40.5%), and three others preferring usual methods but with an aversion to injections (20.7%), aversion to rectal gels (21.9%), or relative indifference to NPTs (16.9%).
Conclusions: Attitudes towards NPTs among MSM are heterogeneous. Understanding these preferences and aversions may help predict NPT uptake.

WEAC0103

"Early adopters" of PrEP in SEARCH study in rural Kenya and Uganda

J. Ayieko[1], C. Koss[2], A. Owaraganise[3], F. Mwangwa[3], D. Kwarisiima[3], D. Black[2], T. Clark[2], M. Kaur[2], J. Wallenta[2], E. Charlebois[2], C. Cohen[4], E.A. Bukusi[1], M. Kamya[3], M. Petersen[5], D. Havlir[2]
[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]University of California, San Francisco, Division of HIV, Infectious Diseases & Global Medicine, San Francisco, United States, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]University of California, San Francisco, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [5]University of California, Berkeley, Berkeley School of Public Health, Berkeley, United States
Presenting author email: jimayieko@gmail.com

Background: PrEP is now recommended for high-risk persons in Africa. There are limited data on PrEP uptake in Africa outside of clinical efficacy trials. "Early adopters" can provide insights for program strengthening. We report on early PrEP adopters in SEARCH (NCT01864603), an ongoing population-based combination prevention study of 320,000 persons in rural Uganda and Kenya.
Methods: Following mobilization and community education, 2 groups were offered PrEP: i)HIV-uninfected adults at high risk (R) based an HIV risk score that maximized observed seroconversion coverage under a minimized number of persons needed to treat and ii)those who perceived themselves at risk (S) including being in serodiscordant relationship. "Early adopters" were defined as those who started PrEP within 30 days of being offered. To estimate predictor coefficients for early PrEP uptake, we used generalized linear models with binomial distribution.
Results: Of 24,709 HIV-uninfected individuals in six communities, 4622 were identified for PrEP; 2995 based on risk score(Rs) and 1627 as self-referrals(Ss). 2374(51%) scheduled an appointment with 946(20%) initiating PrEP; 916(97%) of these were "early adopters" with a vast majority 712(78%) starting PrEP on the same day. "Early adopters" tended to be Ss (64%), women (52%) and married (68%). Youth accounted for only 29% of "early adopters." Predictors of PrEP uptake among Rs were older age (ref: 18-25, age 36-45 OR 1.6, 95% CI 1.0-2.5, age 46-55 OR 2.1,95%CI 1.2-3.9), polygamy (OR 1.9,95%CI 1.3-2.7), serodiscordant spouse (OR 4.3,95%CI 1.6-11.5), no history of recent migration (ref: 0 months, 1-6 months OR 0.6, 95% CI 0.4-1.0 >6months OR 0.3, 95%CI 0.2-0.7), perceived current risk of HIV (OR 2.2, 95%CI 1.8-2.8). Among Ss, predictors were gender (male vs female OR 0.7,95%CI 0.6-0.9), age >=26(ref: 18-25, age 26-35 OR 1.4,95%CI 1.1-1.9, age 36-45 OR 1.8,95%CI 1.4-2.5, age 46-55 OR 2.4,95%CI 1.7-3.4, age>55 OR 2.0 95%CI 1.3-3.2) and a serodiscordant spouse (OR 2.5, 95%CI 1.0-6.1).
Conclusions: Among the 916 PrEP "early adopters", most started the same day as offered, two-thirds were married and perceived themselves as high-risk. Low participation among certain crucial groups such as youth (18-25 years) emphasizes the need for more effective mobilization.

WEAC0104

Health systems and study design features permitting rapid enrolment of individuals at high-risk of HIV acquisition into a pre-exposure prophylaxis study in Melbourne, Victoria, Australia

Presenting author email: edwina.wright@monash.edu

Background: Australia's Medicare system provides clinicians fee-for-service and residents receive free or low-cost health care. Australia's Pharmaceutical Benefits Scheme (PBS) subsidises medication costs. Tenofovir/Emtricitabine (TDF/FTC) is registered in Australia for HIV pre-exposure prophylaxis (PrEP) but is not PBS subsidised, hence individuals must import generic TDF/FTC or pay A$800 monthly. In 2016 we implemented a 2,600-person PrEP demonstration study in Victoria, hypothesising a resultant 33% decline in new HIV infections in men who have sex with men (MSM). We describe the health systems and processes that facilitated rapid study enrolment and concomitant increases in HIV and sexually transmitted infection (STI) testing.
Methods: Victoria's population is approximately 6 million, including an estimated 37,000 HIV negative, sexually active MSM. From January 2016, individuals registered study interest online and nominated which of seven study clinics in Melbourne they would attend, whether they already attended that clinic and whether they were currently using PrEP. At study commencement, on July 26, 2016, 2,198 individuals had registered interest. Key community stakeholders, study clinics, and retail pharmacies were engaged in the study design and service system planning. Clinics were incentivised with A$100/participant, or a study nurse. Australian PrEP guidelines' specified eligible individuals at high risk. Participants were enrolled electronically. HIV/STI test results were extracted automatically using a sentinel surveillance system (ACCESS), extant in five clinics. We report HIV and syphilis testing rates in three of seven clinics across five-month pre-intervention (26/07/2015-26/12/2015) and PrEP-intervention (26/07/2016-26/12/2016) periods.
Results: 1,000 participants were enrolled within 21 days of the study commencing, and one in three participants were using PrEP; 2,350 participants were enrolled in six months. Six clinics chose the A$100 payment per patient. HIV tests increased from 3,009 to 4,952 and syphilis tests increased from 2,926 to 4,704 compared to the same five-month period in 2015, respectively.
Conclusions: In a free healthcare system that provides clinicians fee-for-service, rapid enrolment into PrEP programs appears feasible. A detailed registry of interest, prior use of PrEP, clinic remuneration, electronic enrolment and data extraction and collaborative planning were features of the study's rapid enrolment rate. A substantial rise in HIV and syphilis testing accompanied the study rollout.

WEAC0105

Self-report and medication possession ratio are accurate measures of HIV pre-exposure prophylaxis use in a real-world clinical setting

R. Patel[1], L. Harrison[1], A. Liu[2], P. Chan[3], R. Presti[1], P. Anderson[4], K. Mayer[5], J. Liu[6], W. Powderly[1], K.R. Amico[7]
[1]Washington University in St. Louis, Infectious Diseases, St. Louis, United States, [2]San Francisco Department of Health, San Francisco, United States, [3]Brown University, Infectious Diseases, Providence, United States, [4]University of Colorado Anschutz Medical Campus, Pharmaceutical Sciences, Aurora, United States, [5]The Fenway Institute, Boston, United States, [6]Washington University in St. Louis, Public Health Sciences, St. Louis, United States, [7]University of Michigan, Health Behavior and Health Education, Ann Arbor, United States
Presenting author email: rupapatel@email.wustl.edu

Background: Oral, daily pre-exposure prophylaxis (PrEP) prevents HIV acquisition in optimally adherent men who have sex with men (MSM). Given the importance of adherence in PrEP-related outcomes, accurately and affordably monitoring adherence is a priority during implementation. We evaluated two low-burden measurements, self-report (SR) and medication possession ratio (MPR), for concordance with the well-established method of determining tenofovir diphosphate (TFV-DP) levels in dried blood spot (DBS).
Methods:
We reviewed behavioral and DBS data on patients presenting to the Washington University in St. Louis (USA) PrEP Clinic between November 2015 and August 2016. Optimal adherence was defined as TFV-DP ≥700 fmol/punch and was compared to patient 7-day SR and 3-month MPR using pharmacy refill data. Sensitivity, specificity, and negative and positive predictive value (NPV, PPV) for SR and MPR in relation to DBS were calculated.
Results: From 88 MSM, 137 DBS TFV-DP levels were analyzed. Their median age was 27 years; 58% were White, 30% Black, 6% Latino; 69% graduated college; and 71% reported condomless receptive anal sex in the last 3 months. Ten patients had a DBS < 700 fmol/punch. Drug concentration was not related to demography and did not significantly decline over time. By SR, 5 patients took < 4 doses/week, 4 of whom had sub-optimal DBS (NPV 80%), and of the 83 reporting ≥4 doses/week, 77 had optimal DBS (PPV 93%), resulting in 99% sensitivity and 40% specificity. For MPR, 3 patients had a MPR < 0.60 (indicating < 4 doses/week), all of whom had sub-optimal DBS (NPV 100%), and of the 84 with MPR ≥0.60, 77 had optimal DBS (PPV 92%), resulting in 100% sensitivity and 30% specificity. MPR and SR correlated with DBS TFV-DP levels (r=0.55, P< 0.001; r=0.48, P< 0.001). More stringent cut-offs to the strategies produced higher specificity- 60% for SR ≥6 doses/week and 70% for MPR at 0.70.
Conclusions: In a real-world clinical setting, SR and MPR correlated with optimal DBS concentrations despite different measurement windows (past 7, 30, 90 days). Specificity in this sample was improved when more stringent SR and MPR cut-offs were used. Results provide evidence for using low-burden measurements for PrEP adherence monitoring.

WEAC02 PMTCT: We Must Do Better

Raltegravir vs Lopinavir/r for late-presenters pregnant women

C. Brites[1,2], I. Nobrega[3], A.G. Travassos[3], E. Luz[2], C. Stelitano[2], S. Fernandes[3], C. Figueredo[3], C. Lorenzo[3], E. Martins Netto[1,2]
[1]Universidade Federal da Bahia, Medicine, Salvador, Brazil, [2]Fundação Bahiana de Infectologia, Clinical Research, Salvador, Brazil, [3]Centro Especializado em Diagnóstico Assistência e Pesquisa, Salvador, Brazil
Presenting author email: crbritesl@gmail.com

Background: Late-presenters pregnant women need aggressive antiretroviral therapy to reach a plasma viral load (PVL) <50 copies/ml before delivering. We compared the safety and efficacy of LPV/r and Raltegravir (RAL) in decreasing PVL in late-presenters pregnant women in Salvador, Brazil.
Methods: in this open-label, pilot trial (N=40), we included drug-naïve pregnant women who started antiretroviral therapy (ART) at a gestational age ≥ 28 weeks. They were randomly assigned to receive AZT+3TC+LPV/r or AZT+3TC+RAL. We measured time to reach undetectable PVL, and compared the proportion of women with PVL< 50 copies/ml at delivery, in each group. PVL was measured weekly by Real Time PCR, up to delivery. Frequency of side effects and MTCT rate were assessed. Babies were tested for HIV-1 plasma RNA at 4 weeks of age.
Results: we already enrolled 28 women (14/arm). Groups were comparable for age, education, smoking/alcohol use, number of previous gestations/miscarriages. Most (73%) were black/racially mixed, and single (82%). Twenty-five women already completed the trial. Median baseline PVL was similar for LPV/r (4.26 log_{10}, IQR: 4.02-4.04) and RAL (4.05 log_{10}, IQR: 3.55-4.31) groups, as well as mean gestational age (32.8 ± 11.4 vs 32.9 ± 10.4 weeks, respectively). At delivery, only 1/11 (9%; 95%CI:0.5-37%) women in group LPV/r had PVL< 40 cps/ml, compared with 9/14 (62%; 95%CI:38-86%) in RAL group (p=0.01). The median time to reach undetectable PVL was significantly shorter for RAL (44 days) in comparison with LPV/r arm (69 days, p=0.009). In RAL arm, 2 (14%) patients reached PVL <50 cps/ml at week 1, and 3 (21%) at week 2 of ART. In contrast, in LPV/r arm the first PVL< 50 copies/ml was reached only after 6 weeks of therapy. More gastrointestinal adverse events were observed in LPV/r arm (5/11) than in RAL one (1/14). No case of MTCT was detected.
Conclusions: use of RAL was associated with significantly higher rate of undetectable PVL at delivery and lower incidence of adverse events, in comparison with LPV/r. Time to reach undetectable PVL was significantly shorter in RAL group. RAL should be the preferential option to treat late-presenters pregnant women, to minimize the risk of HIV-1 MTCT.

WEAC0202

Intensification of antiretroviral treatment with raltegravir for late-presenting HIV-infected pregnant women

N. Thepnarong[1], T. Puthanakit[1], S. Chaithongwongwatthana[2], S. Anugulruengkitt[1], O. Anunsittichai[3], T. Theerawit[3], C. Pancharoen[1], P. Phanuphak[4]
[1]Research Unit in Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [2]Research Unit in Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Chulalongkorn University, Department of Obstetrics and Gynecology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Research Unit in Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [4]Thai Red Cross AIDS Research Centre, Bangkok, Thailand
Presenting author email: j_nattawan@hotmail.com

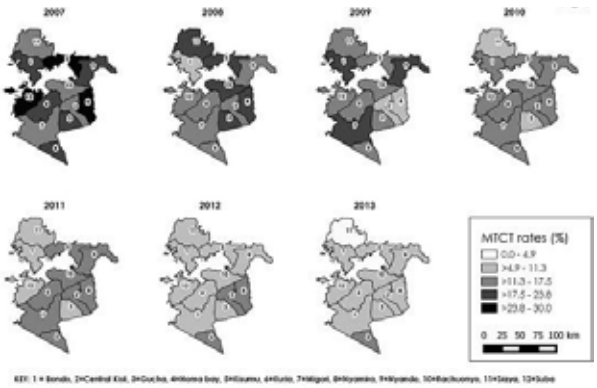
Background: The risk of HIV perinatal transmission in HIV-infected pregnant women who are started late on antiretroviral therapy during the third trimester is estimated to be up to 6-10%. Raltegravir, HIV integrase inhibitor, has rapid viral reduction and is recommended by the British HIV Association (BHIVA) guideline for late-presenting HIV-positive pregnant women. This study aims to describe HIV perinatal transmission from high-risk HIV-positive pregnant women who have received raltegravir intensification antiretroviral treatment.
Methods: A prospective cohort study was conducted at the Thai Red Cross AIDS Research Centre. Inclusion criteria were HIV-positive pregnant women with high-risk of HIV vertical transmission defined as (1) Having been started on antiretroviral therapy (ART) at gestational age (GA) ≥32 weeks or (2) Having received ART but having HIV-RNA >1,000 copies/ml at GA 32-38 weeks. Pregnant women received standard 3-drug ART regimen plus raltegravir 400 mg twice daily until delivery and then were continued on 3-drug ART after delivery. Plasma HIV-RNA was performed before adding raltegravir and at time of delivery. The HIV status of infant was determined by HIV-DNA PCR at birth, 1, 2 and 4 months.
Results: From January to December 2016, 57 pregnant women were enrolled. Median CD4 count was 307 cell/mm^3(IQR 155-507). Median plasma HIV-RNA before initiation of raltegravir was 3.6 log_{10}copies/ml (IQR 2.9-4.3). Median GA at time of starting raltegravir was 35 weeks (IQR 33-37). Combinations of ART were 32 EFV-based (56%), 21 LPV/r-based (37%), and 4 others (7%). Median duration of raltegravir was 18 days (IQR 7-28). The proportion of pregnant women who had plasma HIV-RNA < 50 and < 1,000 copies/ml at time of delivery were 47% and 81%, respectively. To date 50 infants were born, 40% by cesarean section and 8% preterm (GA < 37 weeks). HIV perinatal transmission rate was 0% (95%CI 0-6.3). No rash, hepatitis and jaundice in mothers or infants has been reported.
Conclusions: No HIV vertical transmission occurred among high-risk HIV pregnant women who received raltegravir intensification ART. This strategy is feasible and effective, supporting elimination of HIV mother to child transmission.

WEAC0203

Spatial-temporal trend of mother to child HIV transmission in western Kenya, 2007-2013

A. Waruru[1], T. Achia[1], H. Muttai[1], L. Ng'ang'a[1], E. Zielinski-Gutierrez[1], B. Ochanda[1], A. Katana[1], P. Young[1], J. Tobias[2], T. Tylleskär[3]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB (DGHT), Nairobi, Kenya, [2]Centers for Disease Control and Prevention, Division of Global HIV and TB (DGHT), Atlanta, United States, [3]University of Bergen, Bergen, Norway
Presenting author email: awaruru@cdc.gov

Background: Using spatial-temporal analyses to understand coverage and trends in elimination of mother to child transmission of HIV (e-MTCT) may be helpful in understanding effectiveness of interventions while refocusing e-MTCT programs efforts to the right places to achieve epidemic control. We measured MTCT rates using early infant diagnosis (EID) program data collected from January 2007 to November 2013 in Western Kenya; and assessed associated HIV transmission risk factors within a spatial context irrespective of treatment guideline changes.
Methods: We performed trend analysis for 102,116 HIV-exposed infants (HEIs) using extended Cochran-Mantel-Haenszel stratified test and logistic regression models to determine associations of infant HIV status with maternal and infant characteristics recorded on EID laboratory test request forms. We fitted spatial and spatial-temporal semi-parametric Poisson regression models with infant and maternal covariates to explain MTCT rates. We used R-Integrated Nested Laplace Approximation (INLA) package and Quantum GIS to map raw and fitted estimates.
Results: Median age of HEIs was 2 months, interquartile range (IQR) 1.5 to 6 months. Pooled positivity was 11.8% in the 7-year period, which significantly, spatial-temporarily declined from 17.9% in 2007 to 8.4% in 2013, p< 0.001(Figure 1). Uptake of polymerase chain reaction (PCR) HIV testing ≤8 weeks after birth was under 40% in 2007 and increased to 60% by 2013. A spatial-temporal model with covariates was better in explaining geographical variation in MTCT (deviance information criterion (DIC 296)) than either a non-temporal spatial model (DIC 326) or temporal model without covariates
(DIC 311).
Conclusions: Improved EID uptake and reduced MTCT rates are indicators of success of the e-MTCT program in this low-resource setting. Adding both time and covariates in spatial-temporal analysis provides a robust approach for explaining programmatic impact over time. Geographical disparities in program achievements may signify gaps in spatial distribution of e-MTCT efforts, and indicate areas needing further resources and intervention.



[Fig 1: Spatial-temporal trend of fitted MTCT (%)]

WEAC0204

Cost and cost-effectiveness analysis of a randomized controlled trial evaluating perinatal home visiting among South African mothers/infants

A. Wynn[1], M. Tomlinson[2], M.J. Rotheram[1], I. Le Roux[3]
[1]University of California, Los Angeles, Psychiatry, Los Angeles, United States, [2]Stellenbosch University, Psychology, Stellenbosch, South Africa, [3]Philani Nutrition Centers, Cape Town, South Africa
Presenting author email: adriane.wynn@g.ucla.edu

Background: South Africa faces a high antenatal HIV prevalence and infant mortality rate. Community-based programs involving home visits contribute to reductions in neonatal mortality. However, most low and middle-income countries lack the budget to deliver such preventive interventions by nurses. Therefore, paraprofessional interventionists may be an innovative alternative strategy to healthcare workers. This study assesses the costs and benefits of implementing a home visiting program utilizing community health workers (CHW).
Methods: We conducted an economic evaluation alongside a cluster RCT in Cape Town, South Africa, called Philani+. The trial assessed the impacts of training CHWs to deliver antenatal and postnatal home visits to address maternal and child health risks. Financial costs were collected from the perspective of the health system. We calculated ICERs by dividing the costs of the intervention by the number of low birth weight newborns and cases of infant undernutrition averted among intervention participants compared with controls. These measures are strong indicators of maternal and newborn health. Numbers of averted cases were modelled as the product of intervention subjects and differences in the rates of adverse outcomes between intervention and control groups.
Results: The total cost of the intervention over 24 months was estimated at US$91,574. The average cost of supporting 12 CHWs was $7,631 per CHW and the cost per mother was US$142. The intervention group had higher HIV treatment adherence and longer breastfeeding duration. The intervention was associated with averting an estimated 55 (90% CI: 41-74) cases of low birth weight and 59 (90% CI: 42-83) cases of undernutrition. The estimated cost per low birth weight averted was $1,664 and the estimated cost of averting an undernourished child was US$1,552.
Conclusions: Philani+ was innovative because it integrated HIV care and prevention with activities to improve maternal and child health. The employment of CHWs provides cost savings compared to use of nurses; and builds capacity in a country with a high unemployment rate and shortage of healthcare workers. Finally, Philani+ was able to improve child health at a relatively low cost considering the costs to the health system caused by low birth weight and undernutrition.

A community-based, household survey to determine mother to child HIV transmission rates and HIV-free survival in Swaziland

C. Chouraya[1], R. Machekano[2], S. Mthethwa[3], L. Krysia[4], M. Mirira[5], K. Kudiabor[1], M. Gill[2], G. Maphalala[6], G. Woelk[2], L. Guay[2]
[1]Elizabeth Glaser Paediatric AIDS Foundation, Mbabane, Swaziland, [2]Elizabeth Glaser Paediatric AIDS Foundation, Washington, United States, [3]Ministry of Health, Sexual Reporductive Health Unit, Mbabane, Swaziland, [4]University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [5]United States Agency for International Development, Mbabane, Swaziland, [6]Ministry of Health, Health Laboratory Services, Mbabane, Swaziland
Presenting author email: cchouraya@pedaids.org

Background: The Joint United Nations Programme on HIV/AIDS (UNAIDS) renewed efforts to virtually eliminate mother-to-child HIV transmission (MTCT) with a target of reducing the mother-to-child transmission rate to 5% or less among breastfeeding populations by breastfeeding cessation, and to 2% or less among non-breastfeeding populations. In Swaziland, although data are available on MTCT rates at six weeks, no study has been performed to determine MTCT and HIV-free survival through the end of breastfeeding.
Methods: The Elizabeth Glaser Pediatric AIDS Foundation performed a national, cross-sectional study of children born 18-24 months prior to the study launch among HIV-infected mothers to determine MTCT rates and HIV-free survival through a community survey in randomly selected constituencies in all four regions of Swaziland. At the time of this cohort's birth, Swaziland had been implementing World Health Organization Option A for prevention of MTCT (PMTCT). We also evaluated the relationship between both maternal and child characteristics and child infection or death.
Results: Most HIV-positive mothers (91.8%) received antiretroviral prophylaxis for PMTCT or antiretroviral treatment during pregnancy. Among 724 known HIV-exposed children between 18 and 24 months, 26 children were HIV-positive and 694 were HIV-negative and alive. Four (all with unknown HIV status at time of death) HIV-exposed children died by 24 months of birth. The overall 18-24-month HIV-free survival among this cohort was 95.9% [95% CI: 94.1-97.2]. At 18-24 months, the estimated proportion of HIV-positive children among known HIV-exposed children was 3.6% [95% CI: 2.4-5.2]. Older maternal age, delivering in a health facility, high maternal CD4 count and receiving antenatal antiretroviral drugs were associated with reduced risk of child infection or death. Child hospitalization was associated with higher rates of child HIV infection or death.
Conclusions: The Swaziland PMTCT program under Option A was largely effective with a high HIV-free survival of 95.9% and low MTCT at 18-24 months of 3.6%. This would be expected to improve further under current Option B+ (universal maternal antiretroviral therapy).

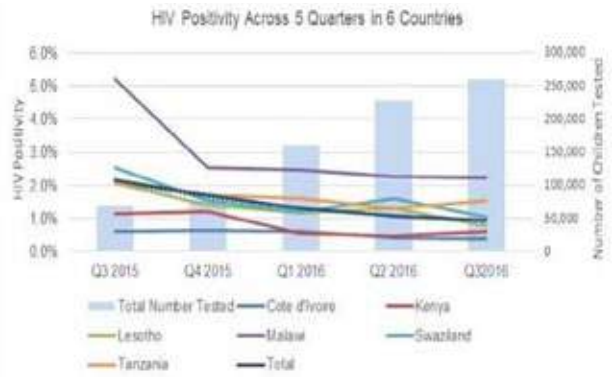
WEAD01 Care for Kids

WEAD0101

Trends in pediatric HIV testing across six African countries

T. Wolters, E. Okoth, A. Ahimbisibwe, G. Antelman, D. Brou Charles-Joseph, M. Dlamini, N. Nguessan Jean-Paul Kouadio, K. Moyo, E. Tumbare, R. Van de Ven
Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States
Presenting author email: twolters@pedaids.org

Background: Improving the identification of HIV-positive children is integral to increasing the number of HIV-positive children on lifesaving treatment; however, there is limited current data on the yield of intensified pediatric HIV case finding approaches. Between July 2015 and September 2016, the Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) scaled-up intensified pediatric HIV case finding in facility and community-based service delivery points (SDP) in six countries (Cote d'Ivoire, Kenya, Lesotho, Malawi, Swaziland, Tanzania). Through this initiative, 791,851 children, aged 0-14, were tested.
Methods: We conducted a descriptive analysis of aggregate pediatric HIV testing data from the six countries to identify cross-country trends in HIV-positivity, including data disaggregated by age group and SDPs, where available.
Results: From July 2015 to September 2016, the number of children tested for HIV and identified as HIV-positive increased by 275% and 60%, respectively. Total HIV-positivity decreased from 2.2% in Q3/2015 to 0.9% in Q3/2016. In Kenya, where SDP disaggregated data is available, outpatient departments (OPDs) represented 63% of children tested and 62% of HIV-positive children identified (0.8% positivity). TB clinics, malnutrition wards, and MNCH services had higher positivity (10.2%, 1.9% and 1.4% respectively). The proportion of HIV-positive children identified in those services was lower than OPD (3%, 2%, and 10%, respectively).



[Pediatric HIV Positivity in 6 Countries]

Conclusions: The rate of HIV-positivity in most countries remained relatively stable, although there was large decrease between Q3 2015 and Q4 2015 in Malawi. Intensified pediatric HIV testing dramatically increased the numbers tested and identified 9,688 HIV-positive children. Overall HIV positivity was relatively low, likely due to effective PMTCT programs in these countries combined with mortality among undiagnosed older children. Testing of higher-risk children (e.g., TB clinics, malnutrition wards, risk-screening in OPDs) as opposed to broad testing, may be a more effective way to identify HIV-positive children in an era of maternal treatment.

Evaluation of the impact of the accelerating children's HIV/AIDS treatment (ACT) initiative on pediatric and adolescent HIV testing and yield in Western Kenya

N.A. Okoko[1], A.R. Mocello[2], J. Kadima[1], J.L. Kulzer[2], G. Nyanaro[1], C. Blat[2], M. Guze[2], E. Bukusi[1], C.R. Cohen[2], L. Abuogi[3], S. Shade[2]
[1]Kenya Medical Research Institute (KEMRI), Family AIDS Care and Education Services (FACES), Center for Microbiology Research (CMR), Kisumu, Kenya, [2]University of California, San Francisco, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [3]University of Colorado, Department of Pediatrics, Aurora, United States
Presenting author email: awuornicollate@gmail.com

Background: Despite declining new infections, pediatric HIV remains significant, with 150,000 new infections annually and 1.8 million children (< 15 years old) living with HIV globally. We examined whether activities under the Accelerating Children's HIV/AIDS Treatment (ACT) initiative increased testing and identification of children with HIV.
Methods: Family AIDS Care and Education Services (FACES) implemented activities under the ACT initiative in 144 health facilities in western Kenya between October 2015 and September 2016. Interventions targeting pediatric testing included: provision of HIV-testing counselors; renovation/allocation of space for HIV testing and counseling (HTC space); use of a Family Information Table (FIT) and FIT chart audits; community outreach testing; and text message reminders for HIV-exposed infants. We compared the number of children tested monthly and the number of HIV-positive children between intervention and control sites using negative binomial generalized estimating equations. Analyses adjusted for repeated measures, geographic location, health facility tier, and test kit stock-outs.
Results: Mean number of children tested monthly increased across all age groups: From 2.8 to 7.2 ($p<0.0001$) in infants <18 months; from 44.8 to 142.0 ($p<0.0001$) in children 18 months to 9 years; and from 30.1 to 123.3 ($p<0.0001$) in adolescents 10-14 years. Identification of HIV-positive children increased: 0.06 to 0.37 (per month per facility; $p<0.0001$) in infants;0.34 to 0.62 ($p=.002$) in children; and 0.17 to 0.26 ($p=.03$) in adolescents.Use of the FIT was significantly associated with increased HIV testing in infants, incidence rate ratio (IRR)=2.89 (95% confidence interval [CI]=1.53,5.49; $p\leq0.001$) and identification of HIV-positive infants, IRR=8.71 (95% CI=1.45,52.4; $p\leq0.02$). Among children, FIT chart audits were significantly associated with increased testing, IRR=2.15 (95% CI=1.36,3.40; $p\leq0.001$). Among adolescents, HTC space was significantly associated with increased HIV testing, IRR=1.45 (95% CI=1.09,1.93; $p\leq0.01$).
Conclusions: Targeted testing of family members of HIV-positive adults increased both testing and identification of HIV-positive children. Our findings suggest that the one-time investment in improving HTC space may be an effective approach for increasing HIV-testing among adolescents in this context. Significant increases in number of children tested resulted in only a modest number of new children identified with HIV, highlighting the need for multiple testing approaches.

Disclosure of HIV status to children living with HIV in Malawi: needs assessment and formative evaluation of an intervention intended to help with the disclosure process

F. Kalembo[1,2], G.E. Kendall[2], M. Ali[2]
[1]Mzuzu University, Mzuzu, Malawi, [2]Curtin University, Nursing and Midwifery, Perth, Australia
Presenting author email: kalembofatch@yahoo.com

Background: Approximately 10% of people living with HIV in Malawi are children under the age of 15 years. While the World Health Organisation recommends that disclosure of HIV status should take place between the ages of 6 to 12 years, very little is known about the practice of HIV disclosure in Malawi. This study aimed to evaluate the current practice of HIV disclosure to Malawian children and to assess the acceptability of a series of age-appropriate, culturally acceptable story books intended to help with the disclosure process
Methods: Questionnaires, interviews, and focus group discussions were used to collect data from caregivers, healthcare workers, school teachers, adolescents living with HIV, and community leaders across the three administrative regions of Malawi. Data on disclosure of HIV to the child, reasons for non-disclosure, the need and acceptability of the proposed series of story books, the child's mental health, and the family psychosocial characteristics were collected using reliable instruments. Data were analysed using chi-square test, multiple logistic regression, and thematic analysis.
Results: The response rate was 99 per cent: 600 questionnaires, 19 interviews, and 12 focus groups were completed. The prevalence of non-disclosure was 64 per cent. Non-disclosure of HIV status was more likely for younger children (aOR 3.8; 95% CI: 2.1-6.8), those in a farming family (aOR 3.495% CI: 1.2-9.3), and those whose healthcare workers lacked training about disclosure (aOR 7.7; 95% CI: 3.4-11.6). The lack of disclosure guidelines and materials (33%), the child's capacity to cope with the diagnosis (29%), and a lack of confidence to disclose appropriately (19%) were cited as the main reasons for non-disclosure. Ninety-eight per cent of participants supported the idea of developing the proposed series of story books. More than three-quarters of the participants emphasized the need for all stakeholders involved in caring for children living with HIV to work together towards promoting effective HIV disclosure.
Conclusions: The rate of non-disclosure in Malawi is high. The results of this study support the need for the development and rigorous evaluation of disclosure materials and the involvement of all stakeholders to promote effective disclosure and meet the evolving needs of children.

An assessment of the effectiveness of reaching undiagnosed HIV+ children through community-based testing in Lesotho

K. Sindelar[1], J. Joseph[2]
[1]Clinton Health Access Initiative, Lesotho - Pediatric HIV, Maseru, Lesotho, [2]Clinton Health Access Initiative, Applied Analytics, Denver, United States
Presenting author email: ksindelar@clintonhealthaccess.org

Background: All health facilities in Lesotho offer free, provider-initiated HIV testing and counseling (PITC) and treatment, and the country adopted the WHO-recommended "Treat All" policy in 2016. However, the antiretroviral treatment coverage for children, 0-14 years, is less than 60%, suggesting many children are not regularly accessing services at facilities. Recognizing that testing is the critical first step in initiating HIV+ children to lifesaving treatment, community-based PITC strategies were piloted to understand the effectiveness of identifying undiagnosed children in Lesotho beyond the facility.
Methods: From December 2015 - December 2016, four community-based strategies were utilized: 1) mobile outreach clinics; 2) door-to-door testing; 3) household-based index patient testing; 4) targeted testing events conducted at venues thought to have high-risk children. A mobile application was designed for use by healthcare workers for real-time data collection at point-of-care to capture data on newly identified HIV+ children; this included residence, gender, and age, as well as HIV testing history and health facility attendance history.
Results: Out of 36,121 children tested, 161 were HIV+ (0.44% positivity yield), and 123 were enrolled in the program with a 1:1.2 male-to-female ratio. Only 23.5% of all enrolled patients were known to be previously tested. Overall, 12% were 0-2 years, 25% were 2-5 years, and 63% were 5-14 years. Of the 52% of patients with known facility attendance history, 20% had not been in over one year, 17% had attended within 4 months to 1 year, and 15% had visited a facility within the previous 3 months.
Conclusions: The majority of children testing HIV+ through community-based PITC were 5-14 years, nearly half had unknown facility attendance history, and 9.5% who had been to a facility in the previous year did not receive an HIV test. This establishes the need for investigation into causes of Lesotho's shortcomings in offering facility-based PITC. Additionally, it proves that community-based PITC is a necessary tool in closing the access gap by bringing these lifesaving services to children in need, particularly older children. National scale-up is essential in reaching UNAIDS' first 90 target and is recommended for other countries struggling to achieve widespread coverage for children through facility-based testing.

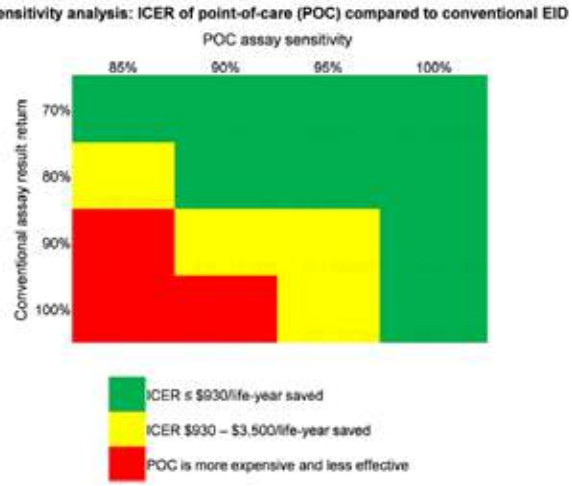
The clinical impact and cost-effectiveness of incorporating point-of-care (POC) assays into early infant HIV diagnosis (EID) programs at 6 weeks of age in Zimbabwe: a model-based analysis

S.C. Frank[1,2], J. Cohn[3,4], L. Dunning[5], E. Sacks[6], R.P. Walensky[1,2,7], S. Mukherjee[6], E. Turunga[3], K.A. Freedberg[1,2,7], A.L. Ciaranello[1,2]
[1]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States, [2]Massachusetts General Hospital, Division of General Medicine, Boston, United States, [3]Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland, [4]University of Pennsylvania, Division of Infectious Disease, Philadelphia, United States, [5]University of Cape Town, Division of Epidemiology and Biostatistics, School of Public Health & Family Medicine, Cape Town, South Africa, [6]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States, [7]Massachusetts General Hospital, Division of Infectious Disease, Boston, United States
Presenting author email: scfrank@mgh.harvard.edu

Background: Many EID programs use laboratory-based total nucleic acid (conventional) assays. New POC EID assays are costlier, but may increase access to testing and shorten time to result-return and ART initiation.
Methods: We used the CEPAC-Pediatric model to examine the clinical benefits, costs, and cost-effectiveness of using POC EID assays at 6 weeks of age in Zimbabwe. We simulated two EID strategies: conventional and POC. Positive results led to ART initiation; ART was stopped if a confirmatory assay of the same type and a third conventional assay (all sent pre-ART) were negative. Modeled assays differed in sensitivity (conventional: 100%; POC: 96.9%), specificity (conventional: 98.8%; POC: 100%), time and probability of result-return (conventional: 1-month delay, 71%; POC: immediate, 97%), and cost (conventional: $15; POC: $21). Model outcomes included early survival, life expectancy (LE), and average lifetime per-person cost for HIV-infected infants and all HIV-exposed infants. We calculated incremental cost-effectiveness ratios (ICERs) using discounted (3%/year) costs and LE for all HIV-exposed infants, defining ICERs ≤$930/life-year saved (Zimbabwe per-capita GDP) as cost-effective.
Results: With conventional EID, projected undiscounted LE was 24.95y (HIV-infected infants) and 60.16y (all HIV-exposed infants), at $1,050/HIV-exposed infant (Table). POC EID improved projected undiscounted LE (HIV-infected: 26.58y, HIV-exposed: 60.27y) at $1,120/infant, and increased survival by 4.5% in months 1-2 of life. The ICER of POC vs. conventional was $730/life-year saved (LYS). This ICER remained < $930/LYS if POC specificity was >95% or POC sensitivity was >85%. Large improvements in conventional assay result-return were needed to offset slightly lower POC assay sensitivity (Figure).

Strategy for EID testing at 6 weeks of age in Zimbabwe	Outcomes for HIV-infected infants	Outcomes for all HIV-exposed infants (including HIV-infected and HIV-uninfected infants)				
	LE (years, undiscounted)	LE (years, undiscounted)	LE (years, discounted)	Lifetime per-person costs (USD, undiscounted)	Lifetime per-person costs (USD, discounted)	Incremental cost-effectiveness ratio ($/life-year saved)
Conventional	24.95	60.16	24.84	$1,050	$570	Comparator
POC	26.58	60.27	24.91	$1,120	$620	$730

[POC and conventional EID: modeled outcomes]



[Figure: Sensitivity Analysis]

Conclusions: POC assays for HIV-exposed infants improve survival and life expectancy and are cost-effective compared to conventional assays. EID programs in Zimbabwe should replace conventional testing with POC assays.

When donor funding leaves: the immediate impact on resources of USAID's withdrawal of support for direct HIV care and treatment at a public health facility in South Africa

N. Lince-Deroche, R. Mohamed, S. Kgowedi, L. Long
Health Economics and Epidemiology Research Office, Johannesburg, South Africa
Presenting author email: nlince-deroche@heroza.org

Background: From 2008-2014, USAID-funded organizations were responsible for directly delivering HIV care and treatment via "Comprehensive Care, Management and Treatment" facilities" (CCMTs) in South Africa. Despite USAID having communicated its plans to phase out funding for direct service delivery (DSD) and instead focus primarily on technical assistance, there has been a sense that public clinics were not adequately prepared for the transition.
The aim of this study was to examine the impact on financial and human resources and workloads immediately after the withdrawal of funds for a CCMT at a clinic in Johannesburg.
Methods: In late 2016, we conducted a natural experiment in which trends in budgets and expenditure, clinical staff complements, patient loads, and services rendered were compared at the study clinic before (2007-2012), during (2012-2014), and after (2014-2016) the withdrawal of the clinic's USAID-supported CCMT site. Data were drawn from the country's District Health Information System, local budget and expenditure reports, and staff records supplied by the city. Analysis was conducted in Excel (2013).

Results: Phasing out of the CCMT occurred between July 2012 and June 2015. Reductions in clinic staff occurred in parallel, first by 33% in 2012-2013 and then by a further 29% in 2014-2015. The reduction in staff drastically raised the workload per staff member (i.e. patient-to- staff headcount ratio) in 2013 and 2015.
The withdrawal of the CCMT was not accompanied by an increase in real expenditure. Real expenditure per capita was on average lower after 2012 (ZAR 77) than it had been between 2008 and 2012 (ZAR 85) when the CCMT was providing HIV treatment to patients.
Despite increased workload, service volumes for primary healthcare services at the clinic (HIV counselling and testing, tuberculosis testing, and family planning) did not decrease after the departure of the CCMT.
Conclusions: The phasing out of funding for DSD by USAID at a clinic in Johannesburg negatively impacted on human resources and staff workload while decreasing per capita expenditure. The volume of primary healthcare services delivered at the clinic did not decline; however, the impact on service quality is unknown.

WEAD0202

How changes in United States funding policies could impact the HIV epidemic in sub-Saharan Africa

J. McGillen[1], A. Sharp[2], B. Honermann[2], G. Millett[2], C. Collins[3], T. Hallett[1]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]amfAR, The Foundation for AIDS Research, Washington DC, United States, [3]Friends of the Global Fight Against AIDS, Tuberculosis, and Malaria, Washington DC, United States
Presenting author email: j.mcgillen@imperial.ac.uk

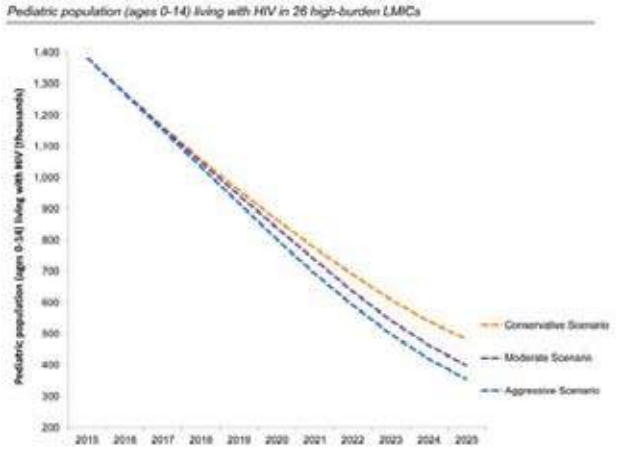
Background: The United States is a giant in the global fight against HIV/AIDS. The bipartisan foundation of PEPFAR in 2003 transformed the world´s approach to anti-retroviral therapy in developing countries, and the US is the largest contributor to the Global Fund. However, the isolationism of the Trump Administration may soon place these activities under threat.
Methods: To test the potential impact of changes in American HIV/AIDS funding policies, we employed a mathematical model of the HIV epidemic and response across 18 countries in sub-Saharan Africa. We used financing data from PEPFAR, the Global Fund, and the IMF to estimate the US share of the total HIV/AIDS response historically and in future. We then removed this US share from the total funding available, or changed the way it could be allocated to future prevention efforts, to explore a series of alternative policy strategies that the administration might adopt.
Results: The model finds that US participation in the AIDS response is likely to have averted 2.5 million AIDS deaths and 21 million HIV infections in sub-Saharan Africa between the start of the epidemic and the end of 2016. Looking forward, sustained US funding could avert 300,000 AIDS deaths and 8.4 million HIV infections on the subcontinent between now and 2030. If the US instead withdraws from the funding landscape, for example by defunding PEPFAR in 2017 and breaking its pledge to the Global Fund, the cost could reach 298,000 AIDS deaths and 7.9 million HIV infections by 2030. How funds are disbursed also matters. If the new administration continues to fund PEPFAR but turns a moralistic blind eye to sex workers and gay men, an avoidable 239,000 AIDS deaths and 5.4 million HIV infections could occur.
Conclusions: Our work suggests that the choice before the US government is stark: it can shirk the mantle of global leadership in the AIDS response and thereby reverse the past decade of progress against the epidemic, or it can continue to fund PEPFAR and the Global Fund and potentially save 8.4 million people across sub-Saharan Africa from infection with HIV.

WEAD0203

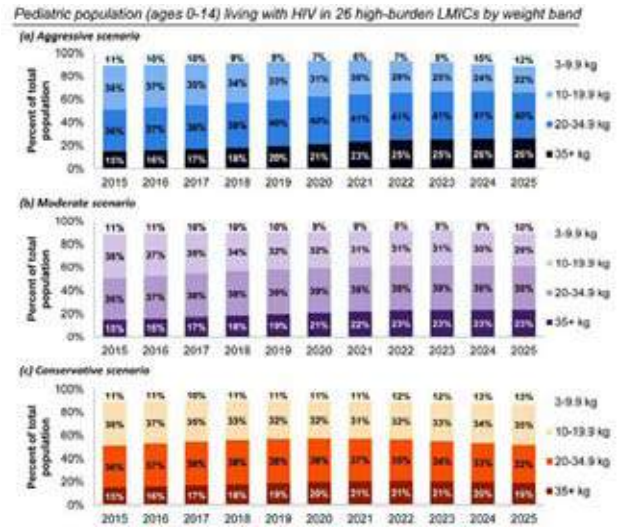
Estimating the size of the pediatric antiretroviral (ARV) market in 26 low- and middle-income countries (LMICs) through 2025 as prevention of mother to child transmission (PMTCT) initiatives continue to succeed

V.R. Prabhu[1], S. McGovern[1], P. Domanico[2]
[1]Clinton Health Access Initiative, HIV Access Program, Boston, United States, [2]Clinton Health Access Initiative (CHAI), Boston, United States
Presenting author email: vprabhu@clintonhealthaccess.org

Background: PMTCT initiatives have significantly reduced HIV infections in children, a trend expected to accelerate with the "Start Free, Stay Free, AIDS Free" initiative. Its "Super Fast-Track" targets aim, by 2020, to reduce new perinatal infections to <20,000 annually and achieve universal pediatric ART coverage. Population projections are needed to help optimize supply of pediatric ARVs, especially new formulations.
Methods: Provisional single age band estimates for HIV-infected children (ages 0-14) for 26 high-burden LMICs, provided by UNAIDS, representing ~77% of the global pediatric HIV burden in 2015, were used. For each forecast year, age cohorts were moved from one age bracket to the next, new perinatal HIV infections were added to the age 0 cohort, and the age 14 cohort "aged out" of the market. Annual decreases in AIDS-related deaths were assumed to be similar to 2011-2015, and evenly distributed across age groups.
Three scenarios of the "Super Fast-Track" targets for new infections were modeled: "Aggressive" (targets met), "Moderate" (2 year delay), and "Conservative" (similar decrease as 2011-2015). Resulting cohorts were converted to weight bands using published tables.
Results: The number of HIV-infected children will continue to rise until 2019 before decreasing. By 2025, there could be between 350,000 and 500,000 children living with HIV, needing ART, across the 26 high volume countries. The more aggressive scenarios suggest an increasing proportion of >20kg children.



[Figure 1. Total Ped. PLWHA]



[Figure 2. Weight Distribution]

Conclusions: As pediatric ART coverage increases, more children will need second- or third-line treatment. These population estimates can inform discussions on the development of new pediatric ARV formulations.

WEAD0204

Can differentiated care models solve the crisis in treatment financing? Analysis of prospects for 38 high-burden countries in sub-Saharan Africa

C. Barker, A. Dutta, K. Klein
Palladium, Washington, United States
Presenting author email: arin.dutta@thepalladiumgroup.com

Background: Rapid scale-up of antiretroviral therapy (ART) in the context of financial and health system constraints has resulted in calls to maximize efficiency in ART service delivery. Adopting differentiated care models (DCMs) for ART

could potentially be more cost-efficient and improve outcomes. However, no study comprehensively projects the cost savings across countries. We model the potential reduction in facility-level costs and number of health workers needed when implementing two types of DCMs while attempting to reach 90-90-90 targets in 38 sub-Saharan African countries from 2016 to 2020.
Methods: We estimated the costs of three service delivery models:
1) undifferentiated care,
2) differentiated care by patient age and stability, and;
3) differentiated care by patient age, stability, key versus general population status, and urban versus rural location.
Frequency of facility visits, type and frequency of laboratory testing, and coverage of community ART support varied by patient subgroup. For each model, we estimated the total costs of antiretroviral drugs, laboratory commodities, and facility-level personnel and overhead. Community-based ART costs were included in the DCMs. We took into account underlying uncertainty in the projected numbers on ART and unit costs.
Results: Total five-year facility-based ART costs for undifferentiated care are estimated to be US$23.33 billion (95% confidence interval [CI] $23.3-$23.5 billion). An estimated 17.5% (95% CI 17.4%-17.7%) and 16.8% (95% CI 16.7%-17.0%) could be saved from 2016 to 2020 from implementing the age and stability DCM and four-criteria DCM, respectively, with annual cost savings increasing over time. DCMs decrease the full-time equivalent (FTE) health workforce requirements for ART. An estimated 46.4% (95% CI 46.1%-46.7%) fewer FTE health workers are needed in 2020 for the age and stability DCM compared with undifferentiated care.
Conclusions: Adopting DCMs can result in significant efficiency gains in terms of reduced costs and health workforce needs, even with the costs of scaling up community-based ART support under DCMs. Efficiency gains remained relatively unchanged with increased differentiation due to some groups requiring more intensive inputs. More evidence is needed on how to translate analyzed efficiency gains into implemented cost reductions at the facility level.

Characterizing the South African private sector ART market

H. Awsumb, K. Little, P. Aylward, N. Hasen
Population Services International, Washington, United States
Presenting author email: hawsumb@psi.org

Background: South Africa has the largest public sector HIV treatment program in the world, with >3 million clients on ART. It also has one of the most robust and diverse private health care sectors in Africa. We hypothesized that a substantial segment of South African PLHIV are accessing ART through the private sector, especially for 2nd line (2L) treatment regimens. We characterized the private sector ART market indirectly by comparing public and private sector drug procurement data from 2012-2015.
Methods: For the private sector we analyzed IMS Health data from pharmaceutical wholesalers and distributors in South Africa. For the public sector we analyzed data from the Global Price Reporting Mechanism. To avoid double counting, we used regimens with Efavirenz or Nevirapine as a proxy for 1st line (1L) regimens and regimens with Atazanavir or Lopinavir/Rotanivir as a proxy for 2L regimens.
Results: The total patient years of treatment (PYTs) for 1L and 2L regimens in the private sector ART market peaked at 244,760 in 2014 and then decreased to 231,938 PYTs in 2015. Total public sector PYTs for 1L and 2L regimens in South Africa increased more than seven-fold during 2012-2015, from 544k to 4.3 million PYTs.
Rapid growth in public sector ARV procurement, did not appear to significantly displace ARV purchasing in the private sector. Growth in the private sector 1L treatment decreased only 4.2% on average from 2013-2015 while the number of PYTs for 2L treatment in the private sector increased 3.9% on average for the same time period.
Conclusions: Our analysis found a substantial private sector market for ART in South Africa. By 2015 PYTs, the private sector ART market in South Africa would have been the 14th largest treatment program in the world, and the 10th largest in Africa. As public sector treatment budgets reach capacity, there may be opportunities to leverage domestic financing through private sector channels in South Africa. Better landscaping of the private sector ART market is needed to guide future interventions and investments.

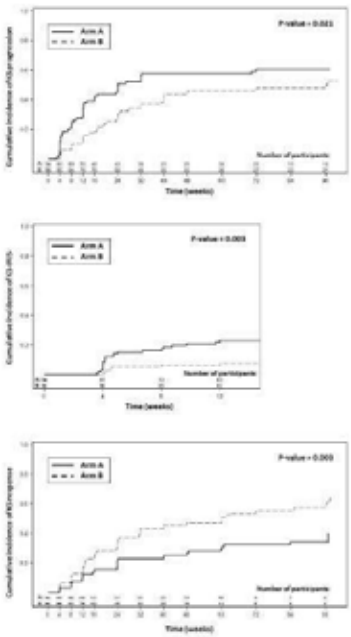
Presenting author email: minach@med.unc.edu

Background: Limited-stage KS often responds to ART alone; the role for adjuvant chemotherapy is unclear. We assessed the impact of immediate vs. delayed oral etoposide (ET) among HIV-infected individuals with limited-stage KS initiating ART.
Methods: ART-naïve, HIV-1-infected adults with limited-stage KS (stage T0 and T1 [minimal oral KS and/or asymptomatic edema]) were randomized to ART (TDF/FTC/EFV) alone (Arm A) vs ART plus up to 8 cycles of oral ET (Arm B) and followed for 96 weeks. Participants with KS progression on ART alone received ET as part of Arm A strategy. Participants who received non-study chemotherapy after ET continued follow-up. Primary outcome was categorical (van Elteren test stratified by CD4): Failure (composite of KS progression, initiation of non-study chemotherapy, lost-to-follow-up, death), Stable, and Response (Partial or Complete) at 48 weeks compared to baseline. Sensitivity analysis excluded receipt of non-study chemotherapy in Failure. Secondary outcomes included times to initial KS progression, suspected KS-IRIS, and KS response (Gray's tests).



[Figure 1. Time to Event Analysis]

Results: Study terminated early for futility after DSMB interim review. Of 190 participants (A=94, B=96); male: 71%; African: 93%; mean age: 35 years; T1:61%. Failure (53.8% vs 56.6%), Stable (16.3% vs 10.8%) and Response (30% vs 32.5%) did not differ between arms (A vs B) among those with Week 48 data potential (N=163, p=0.91). Failure (48.8% vs 38.6%), Stable (16.3% vs 16.9%) and Response (35.0% vs 44.6%) were also not different in sensitivity analysis (p=0.17). Times to KS progression (p=0.021), KS-IRIS (p=0.003), and KS response (p=0.003) favored Arm B (Figure 1). Mortality and adverse events were similar.
Conclusions: Immediate ET showed no benefit compared to delayed ET by the primary endpoint. Pre-specified secondary analyses showed shortened time to KS response, reduced KS-IRIS incidence, and increased time to KS progression with immediate ET, but no effect on mortality or need for additional, non-ET chemotherapy.

Implementing CRAG screening in HIV patients initiating ART in rural HIV clinics with regular absence of CD4 testing services in rural Tanzania

G. Mbwanji, Diana Faini1*, A. Nyuri1, Andrew Katende1, Aneth Kalinjuma1, Maja Weisser1,3, David Boulware2,4, Emili Letang1,3,5
Ifakara Health Institute, HIV/AIDS, Morogoro, Tanzania, United Republic of
Presenting author email: gmbwanji@ihi.or.tz

Background: The World Health Organization (WHO) recommends screening for cryptococcal antigen (CRAG) in blood of HIV-infected antiretroviral therapy (ART)-naïve patients with CD4 < 100 cells/μL. CRAG+ persons who receive ART but not antifungal therapy are at a high risk of death. However, absence of reliable or prompt CD4 testing services in rural clinics jeopardizes implementation of CRAG screening.
Methods: We implemented CRAG screening in all primary health HIV clinics in the Kilombero district, southern Tanzania. Point-of-care CRAG lateral flow assay testing was recommended for all ART-naïve HIV-infected persons with criteria for ART initiation or with headache for >5 days. All CRAG+ persons were transported to the Referral Hospital in Ifakara for a meningitis diagnostic workup and antifungal therapy. Patient transport costs, antifungals, and incentives to clinicians were provided.
Results: From November 2015 to November 2016, 723 ART-naïve patients were tested for CRAG in 8 HIV clinics. Of these, 45 (6.2%) were CRAG+, and 26 (58%) were diagnosed at peripheral clinics and referred to Referral Hospital for evaluation. The median age of the CRAG+ patients was 35 years (interquartile range [IQR], 21-55), and 60% (27/45) were women. Lumbar punctures were performed in 41 consenting (91%) patients, and 51% (21/41) of patients were CRAG+ in cerebrospinal fluid (CSF). Among these 21 CSF CRAG+ persons, 3 were asymptomatic (7% of overall CRAG+ persons).
Conclusions: Our CRAG screening algorithm tailored for rural HIV clinics was effective in maximizing cryptococcal detection in advanced HIV patients at a district level in the absence of regular CD4 testing. The high CRAG prevalence found highlights the importance in the absence of CD4 testing of extending CRAG screening to all HIV-infected persons enrolling in care in order to reduce early mortality.

Background: Mortality from HIV-associated cryptococcal meningitis (CM) remains unacceptably high in low-income countries, where applicable and effective antifungal strategies are needed. In a context where Amphotericine B (AmB) is unavailable, in hospitals lacking intensive care units, we evaluated prospectively the safety and efficacy of an oral combination of fluconazole 1600 mg and flucytosine associated with serial lumbar punctures (SLP) in HIV- associated CM.
Methods: Eligible HIV-infected patients presenting a first episode of CM were enrolled in a one-arm open-label clinical trial in Burundi and Ivory Coast from 2012 to 2015. After inclusion, patients received fluconazole 1600 mg per day in combination with flucytosine 100 mg/kg per day for 2 weeks, followed by fluconazole alone, 800 mg per day for 8 weeks and then 200 mg until the end of follow-up (24 weeks). Intracranial pressure was treated with SLP, according to IDSA recommendations. The primary endpoint was 10-week mortality, expected at 35% +/-15% precision. Secondary endpoints were 2-week and 24-week mortality, early fungicidal activity (EFA) determined by serial quantitative cerebrospinal fluid (CSF) cultures, and safety.
Results: Forty-one (22F/19M) patients were included, 59% being antiretroviral therapy (ART)-naive; 14 (34%) had reduced level of consciousness and 24 (59%) had elevated intracranial pressure at presentation. Overall 10-week mortality was 48.8% (95% CI = 32.9-64.9); 2-week and 24-week mortality were 26.8% (14.2-42.9) and 58.5% (42.1-73.7), respectively. Mean EFA was -0.27 +/- 0.20 log CFU/ml per day, and 16 patients had sterile CSF after two weeks of treatment. The treatment appeared to be well tolerated with no study drug discontinuation. For naive patients, ART was started at a median of 28 days, with no cryptococcal immune reconstitution inflammatory syndrome observed.
Conclusions: Mortality with high dose oral fluconazole and flucytosine associated with SLP was at the upper range of expected values. Oral treatment seems to be less effective than AmB-based combinations, probably due to lower fungicidal activity. Nevertheless, in low-income countries where AmB is not available, this combination appears to be a well tolerated therapeutic option.

Presenting author email: laurence.weiss@aphp.fr

Background: There is no international consensus on anal cancer screening strategy. Guidelines range from digital anorectal examination (DARE) including standard anoscopy (SA) alone (France) to DARE combined with anal cytology (Pap) (IDSA) +/- HPV genotyping in HIV-positive men who have sex with men (HIV+ MSM), to detect high grade intraepithelial neoplasia (HGAIN).
This study aimed at comparing various HGAIN screening strategies yields based on Pap, SA and HPV genotyping alone or in combination in HIV+ MSM.
Methods: Pap, SA and HPV genotyping were performed systematically on consecutive HIV+ MSM attending for the first time a cancer screening consultation between January 2012 and August 2016 in a French hospital. High-resolution anoscopy (HRA) was performed in case of HPV16 positivity or abnormal cytology (ASCUS, LSIL, HSIL). Targeted biopsies were performed when dysplasia was suspected. Screening yield was defined as the number of patients with HGAIN relative to the total number of patients screened. Each strategy was compared with the complete strategy.
Results: 212 patients (median age 51 [IQR:45-57], HIV-RNA< 20 in 84% of patients, median CD4: 682/mm^3 [IQR:491-890]) were screened. The most frequent HPV genotypes were high risk HPV: HPV52 (24.5%), HPV16 (18.9%), HPV53 (18.4%), HPV31 (15.6%) and HPV68 (15.6%). 86/212 (40.6%) patients had at least one positive screening test (Pap+: 62/212(29.2%), HPV16+: 40/212 (18.9%), SA=dysplasia: 19/212 (9.0%)). Screening strategies yields to detect HGAIN compared with the complete strategy and Pap alone are presented above.

Anal cancer screening strategy (N=212)	Number of HRA performed	Number of Biopsies performed	HGAIN at histology: N(%)	Strategy vs Complete strategy: P(Fisher)	Strategy vs Pap alone: P(Fisher)
SA	0	19	7 (3.3%)	<0.001	0.02
HPV16 genotyping	39	26	14 (6.6%)	<0.05	0.47
Pap	59	40	19 (9.0%)	0.27	
SA + HPV16 genotyping	33	40	19 (9.0%)	0.27	1.00
Pap + HPV16 genotyping	75	48	23(10.8%)	0.65	0.63
SA + Pap	51	52	24 (11.3%)	0.77	0.52
SA + Pap + HPV16 genotyping	67	59	27 (12.7%)		0.27

[Table 1]

Conclusions: Pap alone or combinations of two screening tests yielded to similar rates of HGAIN detection than the complete strategy. Compared to Pap alone, Pap + HPV16 slightly improved the number of HGAIN detected but not significantly. Given the limited number of clinicians trained in HRA and the perspective of self-sampling, Pap +/- HPV16 screening might be the best strategy to increase screening acceptance and to identify HGAIN in HIV+ MSM.

Background: Rates of Human Papillomavirus (HPV) infections and cervical lesions are both increased in HIV-infected women. The objectives of the study were to estimate the prevalence and factors associated with Human Papillomavirus (HPV) infection, HPV genotypes and cytological/histological high-grade (HSIL+/CIN2+) lesions in HIV-1 infected women receiving combination antiretroviral therapy (cART).
Methods: We conducted a cross-sectional study (PapilloV study, NCT01792973) within a prospective cohort (the PHPT cohort) of HIV-infected women on cART in 24 hospitals accross Thailand. Cervical specimens were collected for cytology and HPV genotyping (Papillocheck®). Any women with High-Risk-HPV (HR-HPV), and/or potentially HR-HPV (pHR-HPV) and/or ASC-US or higher (ASC-US+) lesions were referred for colposcopy. Factors associated with HR-HPV infection and with HSIL+/CIN2+ lesions were investigated using mixed effects logistic regression models.

Results: 829 women were enrolled: median age 40.4 years, on cART (613 on NNRTI-based regimen and 213 on PI-based regimen) for a median of 6.9 years, median CD4 cell-count 536 cells/mm3, and 788 (96%) with HIV-viral load <50copies/mL, 196 (24%) were CDC-stage C and 125 (18%) had history of virologic failure. Of 214 (26%) infected with HPV: 159 (19%) had ≥1 HR-HPV, of whom 38 (5%) HPV52, 22 (3%) HPV16, 9 (1%) HPV18; 21 (3%) had pHR-HPV, 34 (4%) low risk-HPV infection, and 56 (26%) had multiple genotypes. Younger age, low CD4 cell-counts and low education were independently associated with HR-HPV infection. 72 women (9%) had ASCUS+ and 28 (3%) HSIL+/CIN2+ lesions. HR-HPV infection was independently associated with HSIL+/CIN2+ lesions.
Conclusions: The prevalence of HPV infection and of cervical lesions was low. CD4 cell count was inversely associated with the presence of HR-HPV infection, indicating the need for closer gynecological follow-up in case of immunological failure.

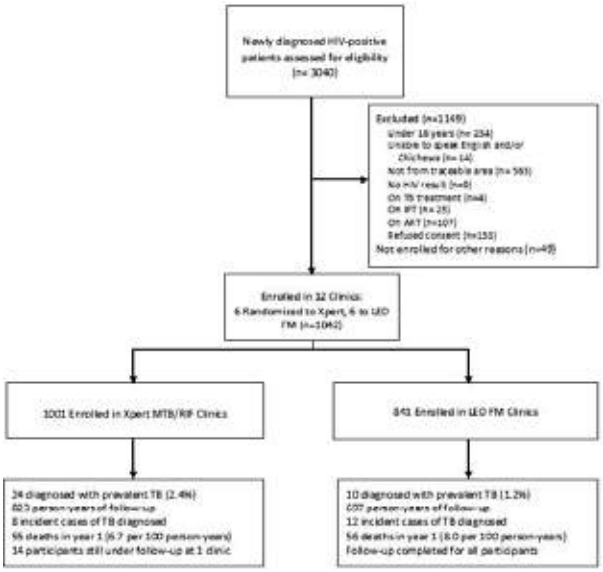
Screening for tuberculosis with Xpert MTB/RIF versus fluorescent microscopy among people newly diagnosed with HIV in rural Malawi: a cluster-randomized trial

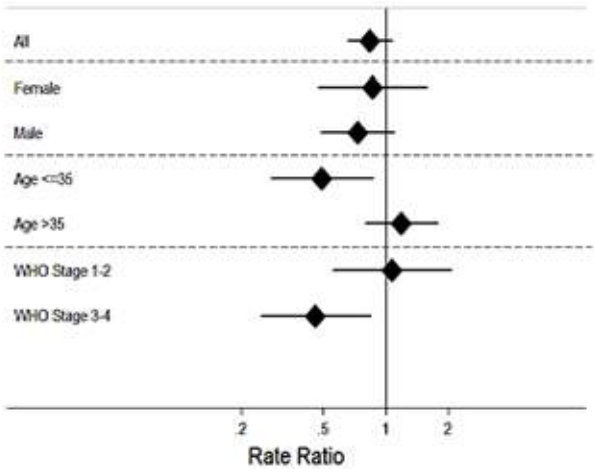
L.G. Ngwira[1], M. Khundi[2], G.L. Barnes[3], A. Nkhoma[2], M. Murowa[4], S. Cohn[3], L. Moulton[3,5], R.E. Chaisson[5,6,7], E.L. Corbett[8,9], D.W. Dowdy[5,6,7], CHEPETSA Study Group
[1]Malawi Liverpool Wellcome Trust, Clinical Research Department, Blantyre, Malawi, [2]Malawi Liverpool Wellcome Trust, Clinical Research, Blantyre, Malawi, [3]Johns Hopkins School of Medicine, Center for TB Research, Baltimore, United States, [4]Malawi Ministry of Health, Thyolo, Malawi, [5]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [6]Center for TB Research, Johns Hopkins School of Medicine, Baltimore, United States, [7]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [8]Malawi Liverpool Wellcome Trust, Clinical Research Programme, Blantyre, Malawi, [9]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom

Background: Tuberculosis (TB) is the leading cause of HIV-associated death. Xpert MTB/RIF (Xpert) has greater diagnostic sensitivity than microscopy but also higher costs and infrastructural requirements. Sensitive TB screening following HIV diagnosis could potentially reduce mortality.
Methods: Cluster-randomized trial of point-of-care TB screening using Xpert versus LED fluorescent smear microscopy (LED FM) across 12 primary care clinics in Thyolo District, Malawi (ClinicalTrials.gov NCT01450085). Randomization was constrained (1:1), with a primary outcome of 12-month all-cause mortality. Participants newly diagnosed with HIV underwent TB symptom screening followed by Xpert or LED FM if symptomatic and isoniazid preventive therapy if asymptomatic. Analyses used t-tests of log-transformed cluster-level rates, and Poisson regression.



[Fig 1. Study profile]

Results: Of 1,842 participants recruited (Figure 1), 24/1,001 (2.4%) participants in the Xpert arm and 10/841 (1.2%) in the LED FM arm had TB diagnosed at entry. The primary outcome was similar across arms (overall mortality 6.45 per 100 person-years with Xpert vs 7.80 with LED FM, rate ratio 0.83, 95%CI: 0.63-1.09; p=0.14; see Figure 2). However, a pre-specified secondary analysis among people with WHO stage 3 or 4 disease (n=463) showed significantly lower mortality in the Xpert arm (15.9 versus 34.8 per 100 person-years, rate ratio 0.46, 95%CI: 0.22-0.93; p=0.03). Unadjusted` and adjusted results were similar.



[Fig 2.RR (Xpert v LED FM) for all-cause mortality]

Conclusions: Screening rural adult Malawians recently diagnosed with HIV for tuberculosis using point-of-care Xpert MTB/RIF increased baseline diagnoses of TB and halved mortality among individuals with stage 3 or 4 disease but did not significantly affect all-cause mortality overall.

WEPDC01 It's Time to Focus on STIs

WEPDC0101

STI co-infections at HIV diagnosis in France

F. Lot, J. Pillonel, F. Cazein
Santé Publique France, Saint-Maurice, France
Presenting author email: florence.lot@santepubliquefrance.fr

Background: Sexual risk behaviours expose people to HIV infection but also to other sexually transmitted infections (STI). In the context of an increase of STI in France, the aim of our work was to analyse the frequency of STI in people newly diagnosed for HIV between 2012 and 2015.
Methods: Since 2012, mandatory HIV surveillance system in France has collected information on bacterial STI (syphilis, gonorrhea, chlamydia trachomatis infection or lymphogranuloma venereum-LGV). These infections had to be reported if they were concurrently diagnosed at the time of HIV diagnosis or diagnosed in the last 12 months before HIV diagnosis (STI/HIV co-infections).
Results: Information on STI infection was available for 9.207 HIV diagnoses in adults during the period 2012-2015 (52% of all diagnoses). STI/HIV co-infection was globally 14.2% (1.310/9.207), but was more frequent in men having sex with men (MSM) (25.4%) than in heterosexuals born in France (9.0%: 11.1% in men and 6.0% in women) or abroad (3.4%: 5.0% in men and 2.3% in women) and in injecting drug users (6.7%). STI/HIV co-infection was more frequent when HIV infection was diagnosed during acute illness.
STI/HIV co-infection has increased overtime (from 12.9% in 2012 to 16.9% in 2015), but this increase was observed only in MSM (from 22.0% to 30.0%).
Among STI, the frequency of syphilis, gonorrhea, chlamydia and LGV were respectively 74.3%, 15.8%, 15.0% and 1.7%. Chlamydia was the only STI more frequent in heterosexuals compared to MSM.
Conclusions: STI/HIV co-infections affect almost one third of MSM newly diagnosed with HIV in 2015, and most commonly syphilis/HIV. These results highlight the importance to combine HIV testing to other STI, and to offer an HIV test to patients presenting with a STI.

WEPDC0102

Acquisition of sexually transmitted infections among women using a variety of contraceptive options: a prospective study among high-risk African women

F.K. Matovu[1,2], E. Brown[3], A. Mishra[4], G. Nair[5], T. Palanee-Phillips[6], N. Mgodi[7], C. Nakabiito[8], N. Chakhtoura[9], S. Hillier[10], J. Baeten[4]
[1]Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, [2]Makere University School of Public Health, Kampala, Uganda, [3]SCHARP-FHCRC, Seattle, United States, [4]University of Washington, Seattle, United States, [5]Emavundleni Research Centre, Cape Town, South Africa, [6]Wits RHI, Johannesburg, South Africa, [7]UZ-UCSF, Harare, Zimbabwe, [8]MUJHU Research Collaboration, Kampala, Uganda, [9]NICHD/ NIH, Bethesda, Uganda, [10]Magee-Womens Research Institute, Pittsburgh, United States
Presenting author email: fmatovu@mujhu.org

Background: In many African settings, women concurrently face high risk of HIV-1, STIs, and unintended pregnancies. Few studies have evaluated STI risk among users of hormonal implants and intrauterine devices (IUDs) although these long-acting reversible methods are being promoted widely because of their contraceptive benefits. Within a prospective study of women at risk for HIV, we compared the risk of STI acquisition among women using different contraceptive methods.
Methods: MTN-020/ASPIRE was a randomized trial of the dapivirine vaginal ring for HIV-1 prevention that enrolled 2629 women from Malawi, South Africa, Uganda, and Zimbabwe; all were required to use contraception at study entry. Analysis was restricted to 2264 women (50.2% from South Africa) who used DMPA (n=1147), implants (n=692), NET-EN (n=438) or IUD (n=541) at any point during follow-up. Screening and treatment for Chlamydia trachomatis, Neisseria gonorrhoeae, and Trichomonas vaginalis occurred at baseline, semi-annually, and when clinically indicated.
Results: Over 3,440 person-years of follow-up, 408 cases of C.trachomatis (incidence 11.86/100 person-years), 196 of N.gonorrhoeae (5.70/100 person-years), and 213 cases of T.vaginalis (6.19/100 person-years) were detected. The incidence of C.trachomatis and N.gonorrhoeae were not significantly different across contraceptive methods (Table), although DMPA and implant users had lower incidence than IUD users. The incidence of T.vaginalis was significantly lower for DMPA, implant, and NET-EN users, compared with IUD users. Findings were consistent across South Africa and non-South Africa sites.

Method	*Chlamydia trachomatis*			*Neisseria gonorrhoeae*			*Trichomonas vaginalis*		
	incidence	aHR*	95% CI	incidence	aHR*	95% CI	incidence	aHR*	95% CI
IUD (copper)	12.92	1	-	6.77	1	-	9.07	1	-
Implant	9.19	0.69	(0.47,1.01)	5.92	0.97	(0.60,1.57)	6.01	0.58	(0.39,0.87)
DMPA	12.44	0.86	(0.65,1.16)	5.13	0.74	(0.48,1.14)	4.75	0.37	(0.24,0.59)
NET-EN*	17.35	1.45	(0.94,2.23)	6.55	0.86	(0.48,1.57)	5.84	0.40	(0.20,0.81)

* NET-EN only South African women; hazard ratios adjusted for randomization arm, age, sexual behavior, baseline STIs

[Incidence of STIs by contraceptive method]

Conclusions: Among African women at high risk for HIV-1, we found that risk of cervical infections (N.gonorrhoeae and C.trachomatis) did not differ across contraceptive methods. Significantly lower rates of T.vaginalis among progestin based methods compared to IUD users was seen, likely due to hypoestrogenic states which may not be conducive for persistence of T.vaginalis. Results are reassuring and lend support to current WHO guidance that women should have a wide range of contraceptive options.

WEPDC0103

Differences in biological and behavioral HIV risk before, during and after PrEP use among a national sample of gay and bisexual men in the United States

J. Parsons[1], H.J. Rendina[1], T. Whitfield[1], C. Grov[2]
[1]Hunter College-CUNY, Psychology, New York, United States, [2]CUNY School of Public Health, New York, United States
Presenting author email: jeffrey.parsons@hunter.cuny.edu

Background: Some have expressed concern that gay and bisexual men (GBM) who use pre-exposure prophylaxis (PrEP) will engage in more condomless anal sex (CAS) and acquire/transmit STIs more frequently while on PrEP. Others, however, argue that increases in STIs among men on PrEP result from required STI screening and testing. There has been little longitudinal data to support either conclusion.
Methods: Data were collected from One Thousand Strong, a longitudinal study of 1,071 HIV-negative GBM from across the U.S. Participants were tested for urethral and rectal gonorrhea and chlamydia and asked to report on their PrEP use every 12 months.
Results: In cross-sectional between-group analyses, the 823 PrEP-naïve men had a significantly lower STI infection rate (4.2%) than the 77 men currently (10.4%) or 17 men formerly (11.8%) on PrEP, $X^2(2) = 7.72$, p = 0.02; men currently on PrEP also reported significantly more acts of CAS, H(2) = 37.73, p <0.001. Within-person longitudinal analyses of the 181 men who reported PrEP use indicated slight but non-significant increases in the odds of an STI diagnosis while on PrEP (OR = 1.25, p = 0.55) and after discontinuing PrEP (OR = 1.43, p = 0.53) in comparison to pre-uptake of PrEP. We also saw no significant changes in CAS while on PrEP (OR = 1.09, p = 0.76) or after PrEP discontinuation (OR = 0.48, p = 0.10) compared to pre-uptake levels.
Conclusions: Our findings failed to support the notion that GBM experience an increase in CAS and STIs while on PrEP. Although PrEP-naïve GBM have fewer STIs and report less CAS than current and former PrEP users, these data provide support for the notion that the highest risk GBM are the ones who initiate PrEP use, and their risk behaviors do not change substantially as a result. It is worth noting that most of the men on PrEP in this sample are early adopters, and further research is needed to determine whether behavioral differences may emerge in larger samples of men who may engaging in lower levels of HIV risk behavior at the time of PrEP initiation.

WEPDC0104

Partner notification of sexually transmitted infections among MSM on PrEP: a sub-study of the ANRS-IPERGAY trial

M. Suzan-Monti[1,2,3], L. Cotte[4], L. Fressard[1,2,3], E. Cua[5], C. Capitant[6], L. Meyer[6], J.-M. Molina[7], B. Spire[1,2,3]
[1]INSERM UMR912 - SESSTIM, Marseille, France, [2]Aix Marseille Université, UMR_S 912, IRD, Marseille, France, [3]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [4]Hôpital de la Croix Rousse, Centre Hospitalier et Universitaire de Lyon, Lyon, France, [5]Hôpital de l'Archet, Centre Hospitalier de Nice, Département de Maladies Infectieuses, Nice, France, [6]INSERM SC10, Villejuif, France, [7]Hôpital Saint Louis AP-HP, Service de Maladies Infectieuses, Paris, France
Presenting author email: marie.suzan@inserm.fr

Background: Sexual partners of people with HIV or other sexually transmitted infections (STI) are at high risk of infection. Partner notification (PN) is a useful public health approach to enhance both targeted testing of those at very high risk, and linkage to care for undiagnosed HIV+ /STI+ individuals. Despite WHO recommendations, PN is implemented differently worldwide. In France, there are no specific guidelines, and information about PN practices is scarce. We used the ANRS-IPERGAY PrEP prevention trial to investigate PN in HIV-negative men who have sex with men (MSM), who reported STI.
Methods: The present sub-study was conducted among 275 participants who completed a specific online PN questionnaire, during the open-label extension study of the ANRS-IPERGAY trial, between April and June 2016. Socio-demographic data were collected at inclusion. Data about their most recent sexual encounter and about preventive behaviours were collected at the follow-up visit prior to filling out the PN questionnaire to define variables to be used as proxies of at-risk practices. Chi-2 or exact Fisher tests were used to select variables eligible for multiple logistic regression analysis.
Results: Among the 275 participants, 250 reported at least one previous STI. Among the latter, 172 (68.8%) had informed their partner(s) of their most recent STI. Of these, 138 (80.2%) had notified their occasional partners and 83 (48.3%) their main partner. There was no significant socio-demographic difference between MSM who notified their partner(s) and those who did not. Multiple logistic regression showed that MSM were less likely to notify their main partner when their most recent sexual encounter was through unprotected anal sex with an occasional partner (aOR[95%CI] 0.31[0.14;0.68], p=0.03). Older MSM were less likely to inform occasional partners (aOR[95%CI] 0.44[0.21;0.94], p=0.03), while those participating in chemsex at their most recent sexual encounter were more likely to inform their occasional partners (aOR[95%CI] 2.56[1.07;6.09] p=0.03).
Conclusions: Unprotected sexual relationships with people other than main partners, and recreational drug use were identified, respectively, as a socio-behavioural barrier to and motivator of PN among a sample of high-risk MSM. These results provide a first insight into the process of PN and might fuel reflection about PN in France.

WEPDC0105

Predictors of genital ulcerations in HIV-serodiscordant couples, Lusaka, Zambia

K. Wall[1], W. Kilembe[2], B. Vwalika[2], L. Haddad[3], S. Lakhi[2], R. Chavuma[2], K. Naw Htee[3], I. Brill[4], C. Vwalika[2], L. Mwananyanda[2], E. Chomba[2], J. Mulenga[2], A. Tichacek[3], S. Allen[3]
[1]Emory University, Epidemiology, Atlanta, United States, [2]Rwanda Zambia HIV Research Group, Lusaka, Zambia, [3]Rwanda Zambia Emory HIV Research Group, Atlanta, United States, [4]University of Alabama at Birmingham, Department of Medicine, Birmingham, United States
Presenting author email: kristin.wall@gmail.com

Background: Genital ulcers are known risk factors for HIV transmission, and reduction of genital ulcers could reduce HIV incidence. However, little is known about risk factors for ulcers, limiting their early identification and treatment.
Methods: HIV-serodiscordant heterosexual couples (M+F-, M-F+) were followed with censoring at antiretroviral treatment uptake or HIV transmission (1994-2012). Exposures (demographic, clinical, laboratory) were measured every 3 months. Anderson-Gill survival models evaluated associations between exposures measured during the visit prior to the time-to-undiagnosed genital ulcer outcome (defined as incident syphilis diagnosis via rapid plasma regain test or active ulcer on genital exam).
Results: We followed 1393 M+F- couples for 2756 couple-years and 1656 M-F+ couples for 3216 couple-years. The proportion of intervals positive for ulcers were 13.7% for HIV+ men, 5.6% for HIV- men, 8.5% for HIV+ women, and 4.4% for HIV- women. Risk for genital ulcer for HIV- women was associated (p< 0.05) with bilateral inguinal adenopathy (BIA) (adjusted hazard ratio, aHR=1.9), genital inflammation (GI) (aHR=1.5-1.9), man´s non-STI GI (aHR=2.9), and increasing number of previous pregnancies (aHR=1.1). Risk for genital ulcer for HIV+ women was associated with BIA (aHR=1.5), GI (aHR-1.5-2.0), man´s non-STI GI (aHR=2.0), HIV stage III-IV versus I (aHR=1.5), and being pregnant (aHR=0.7). Risk for genital ulcer for HIV- men was associated with man´s BIA (aHR=1.8) and STI GI (aHR=2.9), woman´s ulcer (aHR=1.7) and non-STI GI aHR=1.4), and being uncircumcised (aHR=1.7); being uncircumcised with foreskin smegma was independently predictive (aHR=3.2). Risk for genital ulcer for HIV+ men was associated with man´s STI GI (aHR = 2.8), HSV-2-positivity (aHR=2.5), and HIV stage III-IV versus I (aHR=1.7); being uncircumcised with foreskin smegma was independently predictive (aHR=2.4).
Conclusions: BIA and GI may be early indicators or risk factors for genital ulceration; importantly, partners' non-STI GI is also a strong risk factor, and screening of both partners for BIA and GI is indicated. Uncircumcised men with foreskin smegma were at increased risk for genital ulceration. Interestingly, HSV-2-positivity was only predictive of genital ulcer for HIV+ men. Targeted screening among HIV+ individuals with more advanced stage of disease may be worthwhile.

Community-based testing strategies among sex workers in the transport corridor in Mozambique

E. Simons[1], T. Ellman[2], R. Giuliani[3], C. Bimansha[1], L. O'Connell[1], E. Venables[2], H. Jassitene[1], C. das Dores T.P. Mosse Lázaro[4], M. Jose Simango[4]
[1]Medecins Sans Frontieres, Tete, Mozambique, [2]Medecins Sans Frontieres, Southern Africa Medical Unit, Cape Town, South Africa, [3]Medecins Sans Frontieres, Maputo, Mozambique, [4]Ministry of Health, Tete, Mozambique
Presenting author email: tom.ellman@joburg.msf.org

Background: The MSF Corridor project aims to implement a comprehensive intervention for sex workers (SW) along the transport corridor in Mozambique and Malawi. The community-based model incorporates outreach services, HIV testing and counseling, condom distribution, retesting for HIV-negative SWs, and access to STI and HIV care. Sex worker peer educators (SWPE) play an important role in supporting outreach activities, health education and linkage to care. This analysis describes testing, retesting and seroconversion among SWs in Tete and Sofala, Mozambique and explores SWPE perspectives on their role.
Methods: Retrospective analysis of routinely collected data included SWs enrolled in the outreach program between January 2014 and June 2015. The proportion HIV-positive among SWs who initially tested between January 2014 and June 2015 and the proportion of those initially negative who retested within 6 months were assessed. Seroconversion was determined among those who retested within 6 months. Participant and non-participant observations were conducted during SWPE outreach activities in four project sites, along with nine in-depth interviews and two focus group discussions.
Results: 1810 female SWs enrolled, with a median age at first contact of 28 years [23-32]. Among 1207 SWs tested, HIV positivity at initial test was 44%. Overall HIV positivity rate, including 371 additional SWs who self-reported positive, was 57%; 32%, 42%, 61% & 78% among SWs <18, 18-24, 25-34 and ≥35 years, respectively. 42% of SWs initially HIV-negative retested within 6 months and 14 (5%) seroconverted (median time: 114 days). SWPEs described their ability to reach out to their peers, to engage new and 'informal' SWs with health-care services, including HIV testing. Challenges included experiencing prejudice and undervaluation by non-SW colleagues.
Conclusions: Despite stigma and mobility challenges, most SWs contacted agreed to test. Among those negative, almost half retested within 6 months. However retention for retesting remains a major challenge. HIV prevalence and apparent incidence demonstrate the extreme risk among this group and importance of community strategies to access testing, treatment and prevention, including PrEP. SWPEs have a key role in developing trust among their peers and supported uptake of testing and re-testing. Greater efforts are needed to develop their role in SW programs.

WEPDD0102

Views on HIV self-test kit distribution strategies targeting female sex workers: qualitative findings from Zimbabwe

M. Tumushime[1], N. Ruhode[1], E.L. Sibanda[1], M. Mutseta[2], C. Watadzaushe[1], S. Gudukeya[2], M. Mapingure[2], K.E. Hatzold[2], M. Taegtmeyer[3], E. Corbett[4], F.M. Cowan[1,3], S. Napierala Mavedzenge[5]
[1]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [2]Population Services International (PSI) Zimbabwe, Harare, Zimbabwe, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]RTI International, San Francisco, United States
Presenting author email: mary@ceshhar.co.zw

Background: HIV self-testing (HIVST) may be a suitable strategy to increase HIV testing uptake and frequency among female sex workers (FSW). Optimal ways of distributing test kits to FSW are unclear. We qualitatively explored views on HIVST and distribution methods, amongst FSW and potential self-test kit distributors.
Methods: Focus group discussions (FGD) were held among FSW and peer educators (PE), condom-promoting hairdressers and community female condom sales agents ("Care Promoters"), ≥18 years. Discussions were transcribed and analysed thematically.
Results: From September 2016 to January 2017, 15 FGD were conducted across Zimbabwe with 7-10 participants each: 6 each among FSW (n=54) and PE (n=55); 2 among hairdressers (n=16); and 1 among Care Promoters (n=7).
Though knowledge of HIVST was limited, FSW felt it provides increased privacy and convenience. Most were against PE and hairdressers distributing kits, preferring healthcare workers from dedicated FSW clinics to do so and provide HIVST information. Preference for on-site self-testing at these clinics was expressed. Provision of HIVST vouchers for distribution to other FSW was suggested; some PE agreed, proposing they do pre-test HIV counselling alongside.
PE reported HIVST may empower FSW and provide opportunities to test clients/partners. Most were interested in distributing self-test kits if trained, though some preferred clinic distribution. Like FSW, they felt hairdressers should not be distributors.
Hairdressers showed willingness to distribute kits to FSW even at their households; conversely, FSW and PE views were mixed regarding door-to-door distribution, partly due to low prospects of linkage to post-test services. Some thought Care Promoters were better positioned as they already distribute condoms to FSW. Hairdressers expressed a need to be incentivized, seeing self-test kit distribution as an opportunity for additional income.
Care Promoters felt HIVST may increase testing among FSW. They expressed willingness to distribute kits, and like FSW, proposed a voucher system, redeemable at clinics.
Conclusions: Though all potential distributors demonstrated willingness, FSW and PE preferred HIVST distribution through FSW clinics where support and post-test services are easily accessible. Distribution of HIVST vouchers also emerged as a potential strategy. These findings will inform scale-up of HIVST distribution targeting FSWs in Zimbabwe.

Feasibility and acceptability of home-based HIV testing among refugees: a pilot study in Nakivale Refugee Settlement in southwestern Uganda

K. O'Laughlin[1,2,3], W. He[4], K. Greenwald[3], J. Kasozi[5], Y. Chang[3,4], E. Mulogo[6], Z. Faustin[7], P. Njogu[8], R. Walensky[2,3,9], I. Bassett[2,3,9]
[1]Brigham and Women's Hospital, Department of Emergency Medicine, Boston, United States, [2]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States, [3]Harvard Medical School, Boston, United States, [4]Massachusetts General Hospital, Division of General Medicine, Boston, United States, [5]United Nations High Commissioner for Refugees, Kampala, Uganda, [6]Mbarara University of Science and Technology, Mbarara, Uganda, [7]Bugema University, Kampala, Uganda, [8]United Nations High Commissioner for Refugees, Nairobi, Kenya, [9]Harvard University Center for AIDS Research, Boston, United States
Presenting author email: kolaughlin@bwh.harvard.edu

Background: Home-based HIV testing may help reach refugees who face obstacles accessing testing in sub-Saharan Africa. We conducted a pilot study to determine the acceptability and feasibility of home-based HIV screening in Nakivale Refugee Settlement.
Methods: From February-March 2014, we visited homes up to 3 times in 3 geographic zones within Nakivale. We enrolled adults ³18 years who spoke English, Kinyarwanda, Runyankore, or Kiswahili and surveyed them about their country of origin, years in the settlement, and reasons for testing acceptance/refusal. We used the proportion of eligible participants present to demonstrate feasibility. The primary outcome was participation in HIV testing and receipt of result. We used logistic regression models with the generalized estimating equation to correlate willingness to test with gender and number of eligible individuals present in the household at time of consent, while taking into account clustering within households.
Results: Of 319 homes visited with 566 eligible individuals reported living in these homes, 292 homes (92%) had 507 (90%) individuals present; 353 (70%) present at visit one, 127 (25%) additional people at visit two, and 27 (5%) additional people at visit three. Home-based HIV testing participants totaled 378 (75%); all received their results and 7 (1.9%) had new HIV diagnoses. Of participants, 134 (35%) were from the Democratic Republic of the Congo, 129 (34%) from Rwanda, 91 (24%) from Burundi, and 23 (6%) from Uganda. Participants were predominantly refugees (93%) and female (56%), with a median age of 30 (IQR 24-40) and a median time of 6 years (IQR 3-8) in Nakivale. Willingness to participate was positively associated with the number of participants at home at time of consent (OR 1.59 [1.17-2.14], p=0.003). Testing was not associated with gender (OR=1.00 [0.71-1.41], p=0.99). The most common reason for testing was: "to know if I am HIV-infected" (91%).
Conclusions: In this home-based HIV testing pilot study, the majority of eligible individuals (75%) participated in HIV testing and received their results. Most participants were reached by the second visit and were more likely to participate when others were present at the time of consent. Home-based HIV testing is feasible and acceptable in a refugee setting.

WEPDD0104

Sex, test and treat: implementing an incentivized community-driven intervention to promote the uptake of HIV testing services among clients of sex workers

T.N. Flavien[1], F. Ghislaine[1], N. Denise[2], G. Honorat[1], S. Billong[3], J.B. Elat M.[3], D. Levitt[4], S. Baral[5]
[1]CARE, CHAMP, Yaounde, Cameroon, [2]Horizons Femmes, Yaounde, Cameroon, [3]National Aids Control Committee, Yaounde, Cameroon, [4]CARE International, Washington, United States, [5]Center for Public Health & Human Rights, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States
Presenting author email: flavienndonko@gmail.com

Background: Female sex workers (FSW) and their clients face elevated risks of acquisition and transmission of HIV and other sexually-transmitted infections globally. In Cameroon, HIV prevalence among FSWs is estimated at 36%, and HIV testing uptake among clients of FSW is suboptimal. To increase uptake of HIV testing services (HTS) among FSW clients, the USAID-funded Continuum of HIV/AIDS prevention, care and treatment for Most-at-risk Populations (CHAMP) program developed a community-led referral recruitment approach. FSWs were provided a small incentive to promote HTS to their clients, who could access the services directly at, or near sex work hotspots.
Methods: FSW at high-volume hotspots were given coupons with unique identifier codes (UICs) and basic training to refer clients to an HTS counselor (and lab technician) located in a room nearby. FSW received USD$1 for each client who agreed to take a test. Each client who accessed HTS was assigned a UIC. Quantitative client data were collected via the CommCare digital platform and analyzed for the period September 2015 through December 2016. In addition, the team collected qualitative data via in-depth interviews with 30 clients who attended HTS.
Results: Prior to the implementation of this innovation, HTS uptake averaged less than 100 FSW clients per month. Recruitment and referral through FSW increased HTS uptake among clients dramatically (1,071 clients of FSW were tested in just one month, with a yield of 4.8% living with HIV). Most clients who agreed to be tested noted the discrete environment and time saved as reasons for testing, as compared to mass screening campaigns. FSW expressed satisfaction and pride serving as community mobilizers.

[Clients of FSW - HTC uptake]

Conclusions: Incentivized, FSW community-led referral recruitment approaches may have strong potential to identify clients more likely to be living with HIV, effectively recruit them into the services network, and concurrently engender building of social capital among FSW.

WEPDD0105

Implementing test & start program in a rural conflict affected area of south Sudan: the experience of Médecins Sans Frontières

M.C. Ferreyra Arellano[1], B. Oulo[2], E. Grandio[2], V. Achut[3]
[1]Medecins Sans Frontieres, Medical Department, Barcelona, Spain, [2]Medecins Sans Frontieres, Juba, South Sudan, [3]Ministry of health South Sudan, HIV/AIDS/STI, Juba, South Sudan
Presenting author email: cecilia.ferreyra@barcelona.msf.org

Background: Community-based HIV counselling and testing (CB-HCT) and early initiation of antiretroviral therapy (ART) reduce HIV transmission and mortality. Access to HIV care in settings with low ART coverage and/or affected by conflict is low; innovative strategies are needed to increase HIV care and ensure continuation of ART in case of instability. A pilot test and start project was implemented in rural areas of Yambio South Sudan, a chronically conflict-affected area aiming to determine feasibility and acceptability of this intervention.
Methods: Data from July 2015 to December 2016 was analysed. The project involved five mobile teams offering HCT and same day ART initiation at community level. Contingency plan included delivery of key messages on "what to do in case of conflict" during counselling sessions and coordination with community health workers (CHWs) to distribute "run-away bags" with 3 months of ART. Several episodes of acute instability occurred during this period which needed to activate the plan to ensure that patients would not interrupt their treatment.
Results: During this period 13,872 people were tested; 442 (3.2%) was found to be HIV positive and 344 (77.8%) started on ART. 224 (54.4%) where women with a mean age of 33 years, 207 (60.2%) had CD4 count below 500cells/µl. By December 2016, 67 (19.5%) patients were loss of follow up, 8 (2.3 %) died. Retention in care at 6 and 12 months of follow up was respectively 291(84%) and 277(81%) patients. 114 patients with available viral load results (85.7%) had VL less than 1000 copies/ml after 6 months of ART. At 17 months 251 (73%) patients are still under follow up and on ART.
Conclusions: Our program shows a high level of acceptance to HCT and early ART initiation despite rural context and security situation. Early results shows retention in care and virological suppression outcomes comparable with HIV programs at clinic level and without security issues. We believe this strategy could be extrapolated to other contexts with low access to ART and instability.

WEPDX01 Phylodynamics: Tracking Molecules in Populations

Phylogenetic, epidemiological and virological insights on the rise of large cluster outbreaks fueling the HIV-1 epidemic among men having sex with men within Quebec

B. Brenner[1], R.-I. Ibanescu[2], M. Roger[3], M. Oliveira[4], I. Hardy[3], M. Wainberg[5], Montreal PHI and SPOT cohort study groups
[1]McGill University, Medicine & McGill AIDS Centre, Montreal, Canada, [2]Lady Davis Instutute, Montreal, Canada, [3]Universite de Montreal, Montreal, Canada, [4]Lady Davis Institue, Montreal, Canada, [5]McGill University, Montreal, Canada
Presenting author email: bluma.brenner@mcgill.ca

Background: HIV-1 epidemics remain uncontrolled among Men having Sex with Men (MSM) within Quebec in the era of treatment-as-prevention. Phylogenetics infer two patterns of HIV-1 spread among MSM, each contributing to half of the epidemic. While the majority (95%) of HIV-1 strains lead to self-limiting clusters (size 1-4), thirty-two viruses contributed to micro-epidemics (cluster size 20-140) disproportionately rising from 13%, 25%, and 42% of diagnoses in 2004-2007, 2008-2011, and 2012-2015, respectively. Here, phylogenetic, epidemiological and virological data deduced factors favoring the selective advantage of large cluster variants.
Methods: Population-level phylogenetics across the RT/protease domain deduced temporal dynamics of HIV-1 clustering. Phylogenetics across the viral integrase and V3 loop was performed on representative clusters. Epidemiological data from the SPOT rapid testing site and Montreal primary HIV cohort deduced epidemiological and behavioral risk effects implicated in clustering. Primary HIV-1 strains from MSM associated with large 20+ clusters or singleton/small clusters (cluster size 1-4) were grown in cell culture under dolutegravir (DTG), elvitegravir (EVG) and/or lamivudine (3TC) pressures. Sanger and deep sequencing assessed HIV-1 genotypic changes under drug pressure.
Results: Phylodynamics charted the introduction and spread of 32 large clusters (median cluster size 20-140), over median two year periods. Clusters were concentrated in Montreal with several clusters in Quebec City and Sherbrooke. Three large clusters (cluster size 38, 43, 45), with median transmission dates of 06/2010, 02/2012 and 10/2013, shared a common integrase. Large cluster strains (n=11) were resilient showing accelerated acquisition of resistance within 5-8 weeks to DTG, EVG, and 3TC compared to small cluster strains where resistance arose after 20 weeks. Several large clusters displayed dual X4/R5 tropism. Large clusters were arising in younger persons with 29%, 35% and 41% under 30 years of age over the 2004-2007, 2008-2011 and 2012-2015 periods. Only 48% of infections within large clusters were first genotyped in primary/recent infection. HIV-1 testing habits remain poor and significantly better for persons reporting multiple anonymous partnerships than those reporting low risk behavior.
Conclusions: HIV-1 continues to spread among MSM with an alarming shift towards large cluster outbreaks, emphasizing the need for improved prevention paradigms.

WEPDX0102

Transmission cluster-specific pattern of adaptive evolution of the HIV-1 envelope gp120 protein sequence in a Japanese MSM population

T. Shiino[1], M. Matsuda[2], A. Hachiya[2], W. Sugiura[3], Y. Yokomaku[2], Y. Iwatani[2], K. Yoshimura[4], The Japanese Drug Resistance HIV-1 Surveillance Network
[1]National Institute of Infectious Diseases, Infectious Disease Surveillance Center, Shinjuku-ku, Japan, [2]Nagoya Medical Center, Clinical Research Center, Nagoya, Japan, [3]Gla, Shinjuku-ku, Japan, [4]National Institute of Infectious Diseases, AIDS Research Center, Shinjuku-ku, Japan
Presenting author email: tshiino@nih.go.jp

Background: HIV-1 envelope protein (Env) is the target of neutralizing antibodies (NAbs), which show a potential in the treatment and prevention of HIV infection. To combat against the rapid evolution of the Env gene during the HIV transmission chain, development of various broad NAbs corresponding to the genetic diversity is required. Recently, we've identified unique transmission clusters (TCs) of subtype B circulating in Japan based on their protease-RT gene sequences. In this study, we analyzed adaptive evolution of the Env sequences in the TCs to further characterize the immune escape of the Env gene within a TC.
Methods: We determined 2,673 C2-V5 sequences of Env gp120 from 712 individuals who underwent tropism testing between 2011 and 2015 at Nagoya Medical Center, the second largest medical facility participating in the Japanese Drug Resistance HIV-1 Surveillance Network. The TC of each sequence was identified by searching our TC database, and was confirmed by inferring the phylogenies of gp120 sequences. Neutral evolution of each region within each TC was tested by Kumar's Z-test for the null hypothesis of strict neutrality. Codon-by-codon neutral selection was analyzed by maximum-likelihood computations of synonymous and nonsynonymous substitutions per site using the HyPhy software package.
Results: We identified 89 TCs, 77 of which belong to subtype B associated with the MSM population. The nucleotide diversity of the C3 region was greater than that of the V3 region and was similar to that of the V4 region. Regions with greater diversity exhibited significantly positive selection during the evolution of subtypes, whereas the directions of selection during the evolution of TCs were much more variable. Furthermore, different amino acid sites in the C3 region were under positive selection during the evolution of each TC. Viruses circulating in each TC of gp120 have a distinct substitution pattern to confer escape from NAbs.
Conclusions: Our study indicates that a prevention program targeting a key population using an effective broad NAb may not work efficiently for another patient group. Identification and characterization of the HIV transmission network is thus crucial to choose the most appropriate NAb for an antibody-mediated prevention strategy targeting a local key population.

WEPDX0103

Analysis of U.S. HIV sequence data indicates that recent and rapid HIV transmission is focused among young Hispanic/Latino men who have sex with men

A.M. Oster[1], A.M. France[1], N. Panneer[1], J.O. Wertheim[2], M.C. Ocfemia[1], S. Dasgupta[1], A.L. Hernandez[1]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]University of California, San Diego, Department of Medicine, San Diego, United States
Presenting author email: aoster@cdc.gov

Background: Although the estimated rate of HIV transmission in the United States is approximately 4 transmission events per 100 person-years, the rate of transmission in some risk networks is likely much higher. Identifying these networks can provide critical data for focusing efforts on populations in need of the most intensive prevention interventions. To describe the leading edge of HIV transmission, we identified molecular clusters with recent and rapid growth, determined the transmission rate for these clusters, and described the persons involved in rapid transmission.
Methods: We analyzed baseline partial HIV-1 polymerase sequences reported to the National HIV Surveillance System through December 2015 by 27 participating jurisdictions for persons with HIV diagnosed during 2013-2015. We calculated genetic distance for each pair of sequences. Using a pairwise threshold of 0.005 substitutions/site, we inferred clusters and identified rapidly growing clusters (those with ≥5 diagnoses during 2015). We used node ages determined through molecular clock phylogenetic analysis to calculate HIV transmission rates for these rapidly growing clusters and compared persons in these clusters to other persons with sequences included in the analysis, accounting for correlation between cases in the same cluster.
Results: Sequences were analyzed for 30,323 persons; 13 rapidly growing clusters were identified. These clusters had a transmission rate of 34/100 person-years. Compared with the 30,127 persons not in these clusters, the 196 persons in these 13 clusters were disproportionately men who have sex with men (MSM) (94% vs. 62%, P< 0.0001), aged <30 years (68% vs. 41%, P< 0.0001), Hispanic/Latino (49% vs. 28%, P<0.0001), and, specifically, young Hispanic/Latino MSM (32% vs. 9%, P<0.0001). The clusters included high levels of transmitted drug resistance (43% vs. 20%, p=0.0006).
Conclusions: This approach identified a small number of clusters with a transmission rate more than 8 times that of previous national estimates. These findings highlight the extent of rapid transmission among young Hispanic/Latino MSM, suggesting the need for prevention efforts that focus on this population. Identifying clusters of active transmission can help programs effectively direct limited public health resources.

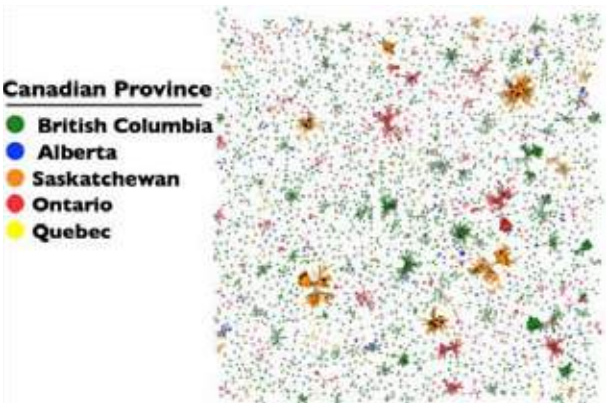
Presenting author email: jjoy@cfenet.ubc.ca

Background: Despite the importance of HIV, the early history, geographic dissemination, and dynamics of the virus within populations across Canada remain unclear. Epidemiological processes stamp measurable signatures on HIV genomes sampled at different places and times. Using statistical phylodynamic approaches applied to HIV sequences sampled from across Canada we test hypotheses concerning past and present HIV epidemic dynamics.
Methods: We compiled 51,493 doubly-anonymized HIV pol sequences from 20,000+ patients annotated with clinical and socio-demographic parameters. Data were available from 5 Canadian provinces: British Columbia, Alberta, Saskatchewan, Ontario, and Quebec. Analyses were restricted to the first sample collected from each patient and drug resistance codons were censored from the alignment. Phylogenetic trees were inferred using FastTree2. Phylogenetic clusters of five or more participants were identified using a tip-to-tip distance cutoff < 0.02 substitutions per site. Diversification rate and phylogeographic analyses were conducted in R and BEAST respectively.
Results: We observed variation among provinces in the proportion of non-subtype B infections, with the Prairies displaying significantly greater numbers of non-B infections ($p < 0.05$). We recovered 285 clusters of size ≥ 5 (Fig.1). Cluster size was associated with proportion of people who inject drugs ($p < 0.004$). Most provinces contain large, primarily province specific, clusters dominated by transmission through injection drug use. Some between-province clustering is observed (n=55 clusters including 3 or more provinces). Association of clusters with more than one province was associated with proportion MSM risk factor ($P < 0.05$). Consistent with other evidence, the Prairies had the highest rates of HIV diversification.
Conclusions: Secondary analysis of genotypic resistance data provides useful epidemiological inferences on a national scale. Different circumstances permitted establishment, dissemination, and growth of the HIV epidemic in Canada at different times within component subpopulations. Our results emphasize the varied challenges facing different regions of Canada in controlling the HIV epidemic in the future.



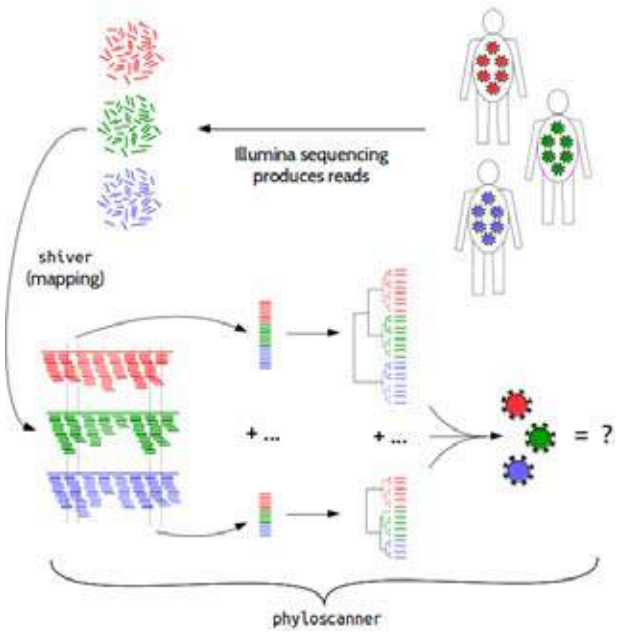
[Figure 1. Phylogenetic clusters of HIV in Canada.]

WEPDX0105

Phylogenetics between and within hosts along the genome reveals transmission, dual infections, recombination and contamination

C.M. Wymant[1,2], M. Hall[1,2], F. Blanquart[2], O. Ratmann[2], C. Fraser[1,2]
[1]University of Oxford, Big Data Institute, Nuffield Department of Medicine, Oxford, United Kingdom, [2]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom

Background: Next-generation sequencing (NGS) has transformed genomics for many pathogens, increasing the availability of sequence data for studying evolution, epidemiology, vaccines and therapeutic design. However on the comprehensive Los Alamos National Laboratory database, more than 90% of HIV sequences were generated with the older method of Sanger sequencing. Widespread adoption of NGS may have been hindered by the technical difficulty of reconstructing and interpreting quasispecies data from reads (short fragments of DNA), given the high diversity of HIV between and within hosts.
Methods: Our public computer program ´shiver´ reconstructs whole HIV genomes using two commands, by mapping (aligning) reads to a reference genome constructed specifically for each sample to maximise accuracy, then finding the consensus of the reads. Our program ´phyloscanner´ interprets mapped reads with a single command. This extracts all patients´ reads in a sliding window of the genome, processes and aligns them, constructs a phylogeny with RAxML, analyses the diversity within and between hosts, performs ancestral host-state reconstruction, and produces a per-patient summary. Contamination is detected by comparing reads between patients and by finding phylogenetic outliers. We used these two programs on new whole-genome NGS data for 24 seroconverters from European and African cohorts: 5 each from subtypes A1, B, C and D, and 1 each from 01_AE, 01_AG, F1 and G.



[Understanding NGS data for HIV]

Results: In our data we found donor-recipient pairs with the direction of transmission suggested by the host-state reconstruction, identifying ancestry between quasispecies. (Unsampled intermediate patients are always possible.) Variability across the genome highlighted the importance of whole genomes and many genomic windows for detecting transmission from sequence data. Dually infected individuals had two distinct phylogenetic clusters of reads. Phylogenetic intermediates showed where these two strains recombined in the host.
Conclusions: Raw NGS data for HIV can be analysed easily and powerfully with our public tools phyloscanner and shiver.

Background: Many studies have shown clustering in recently HIV-1 infected Men having Sex with Men (MSM) but few data are available on the link with transmitted drug resistance (TDR). Moreover, the added value of Ultra Deep Sequencing (UDS) over Sanger sequencing (SS) for phylogenetic HIV transmission studies needs to be determined. We explored the epidemiological linkage between HIV infected MSM using both sequencing approaches, and evaluated its impact on TDR detection.
Methods: Reverse transcriptase, protease and integrase sequences were obtained by SS and UDS from 70 HIV-1 infected, treatment-naïve MSM diagnosed between January 2012 and July 2013 in Paris. Maximum likelihood phylogenies were estimated using FastTree and RAxML, with SH-like tests and 1000 bootstrap replicates, respectively with both datasets. Transmission events were identified as clades with branch support ≥70% and intra-clade genetic difference < 2.5%. TDR mutations were recognised from the consensus list of TDR surveillance.
Results: Median time between the HIV-1 diagnosis and date of the sample used for genotypic analysis was 12 days; 5 diagnosis occurred during the acute infection stage.
SS and UDS data concurred in the identification of 7 transmission pairs and 1 cluster of 3 patients. With UDS, direct linkage and direction of transmission was unambiguously inferred in 3/8 and 1/8 clusters, respectively. Sequences from the putative recipient were polyphyletic for 4/8 clusters, suggesting multiple founder viruses and excluding unobserved, intermediary links. By SS, the prevalence of TDR mutations was 5.7% in the unlinked patients and 0.0% in the linked patients (13.2% and 35.3% by UDS, respectively). Minority resistant variants were not shared among the transmissions chains.
Conclusions: While SS and UDS identified the same transmission chains, UDS provided extra information on founder viruses, linkage and levels of TDR. No mutation within the clusters were associated with reduced efficiency of PrEP, even by UDS. Moreover, no sharing of minority resistant variants was observed among the chains of transmission. These results highlight the benefits of UDS data in the phylogenetic identification of transmission chains, allowing the inference of direct linkage and multiplicity of founder viruses in the recipients, and potentially of direction of transmission.

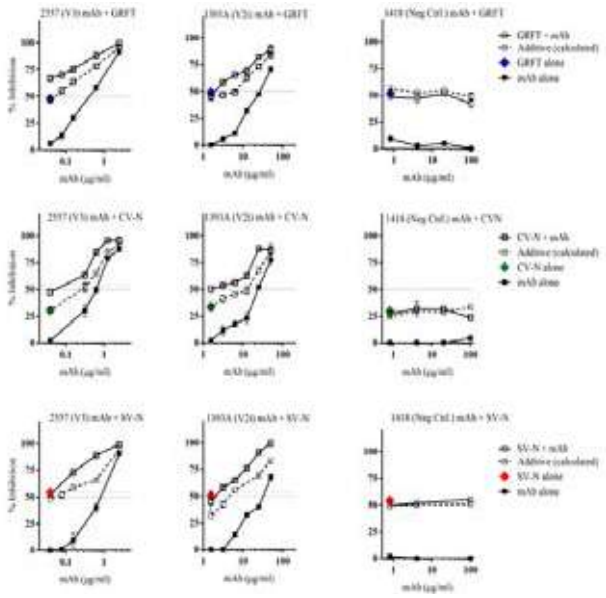
Interventions to Fight HIV

WEPEA0165

Activity of mannose-binding lectins to enhance virus neutralization by antibodies to V1V2 and V3 loops of HIV-1 envelope

M. Jan[1], C. Upadhyay[2], A. Sharma[3], C.E. Hioe[2], S.K. Arora[1]
[1]*Postgraduate Institute of Medical Education and Research, Department of Immunopathology, Chandigarh, India,* [2]*Icahn School of Medicine at Mount Sinai, Department of Infectious Disease, New York, United States,* [3]*Postgraduate Institute of Medical Education and Research, Deaprtment of Internal Medicine, Chandigarh, India*
Presenting author email: muzijan@gmail.com

Background: The apex of HIV-1 envelope (Env) trimers, comprising the V1V2 and V3 regions in the Env gp120, contains neutralizing antibody epitopes. However, it is extensively shrouded by N-linked glycans that hinder antibody recognition. The predominant N-linked glycans are of high-mannose ($Man_{5-9}GlcNAc_2$) type and Manα1-2Man terminating glycans are 3-fold more abundant among high-mannose glycans. In this study, we sought to evaluate whether the addition of lectins targeting Manα1-2Man terminating N-linked glycans would affect the virus neutralization activity of antibodies against V1V2 and V3 conformational epitopes.
Methods: HIV-1 pseudoviruses with tier 1 Env of BaL.01, BaL.ec1, and SF162.LS were treated with Manα1-2Man-binding lectins (GRFT, CV-N, and SV-N), monoclonal antibodies (mAbs) to V1V2 (1393A) or V3 crown (2557), or combinations of lectin and mAb, and incubated with TZM-bl target cells. To test the lectin and mAb combination, reagents were added sequentially; one was serially diluted, while the other was kept at a constant IC_{50} concentration. After 48 h, virus infectivity was measured using a β-galactosidase-based assay.
Results: Each of the 3 viruses tested was sensitive to mAbs 1393A and 2557, with median IC_{50} (μg/mL) of 24.86 and 1.25, respectively. The viruses were also inhibited by each of the 3 lectins, with median IC_{50} (μg/mL) of 0.003 for GRFT, 0.15 for CV-N, and 4.07 for SV-N. These IC_{50} values correlate with lectin avidity. Virus neutralization by mAbs was enhanced by the addition of lectins, with GRFT being the most potent, followed by CV-N and SV-N. Neutralization levels were significantly higher than the calculated additive value (Fig 1), indicating synergism. This activity was seen when lectins were added before, but not after, mAbs.
Conclusions: The Manα1-2Man specific lectins potently synergize with poorly neutralizing antibodies. The enhancement in neutralization potency resulted due to stabilization of glycans by Manα1-2Man binding lectins with concomitant enhanced access of antibodies to epitopes.



[Enhancement in the neutralization potency of mAbs]

Background: Induction of a sustained and broad antibody (Ab) response is a major goal in developing a protective HIV vaccine. DNA is an attractive priming strategy when combined with protein or viral vector boosting; however, DNA priming alone fails to induce a substantial Ab response, limiting its potential as a stand-alone immunogen.
Methods: Using the VC10014 DNA/protein vaccine consisting of gp160 plasmids and gp140 proteins derived from an HIV clade B infected subject who developed broadly neutralizing serum Abs, and which has been previously shown to induce Tier 2 heterologous neutralizing Abs in rhesus macaques, we screened a panel of factors in C57BL/6 mice for their ability to enhance the Env-specific Ab response.
Results: IL-33, an alarmin, emerged as the lead candidate. The addition of recombinant IL-33 during the gp160 DNA priming phase dramatically changed the kinetics of the Ab response, inducing serum gp120-specific IgG (>1:12,500 titer) after a single DNA immunization, which was not detectable in mice that did not receive IL-33 ($p<0.0001$). Then following boosting with DNA/protein co-immunization in Alum, gp120-specific IgG levels were extraordinarily durable, remaining stable even at 6 weeks after final immunization compared to mice not receiving IL-33 ($p<0.0001$), in which they rapidly declined. IL-33 also increased the cross-clade breadth and avidity of the serum gp120-specific IgG response.
Conclusions: Analysis of the Env-specific B cell immunoglobulin repertoire and the IL-33 mechanism of action is ongoing. These results demonstrate the profound effect that priming conditions can have on the quality of the Env-specific antibody response.

Background: Due to the enormous diversity of HIV-1 and other virus escape mechanisms, the development of an effective vaccine has proven to be challenging. Case-control studies of RV144 identified an inverse correlation of HIV-1 infection risk with antibodies (Abs) to the V1V2 region of gp120 with high Ab dependent cellular toxicity (ADCC) activity. Using primary effector and target cells and virus isolates grown on primary PBMCs (peripheral blood mononuclear cells), we studied the inhibitory profile of monoclonal Abs (mAbs) targeting the V1V2 loop, designated V2i mAbs, that were previously isolated from HIV-1 infected patients and display numerous immunologic similarities to the Abs elicited in RV144.
Methods: PBMCs were isolated from donor blood and separated into CD4+ lymphocytes and NK cells using an autoMACSpro. CD4+ cells, infected with primary HIV-1 virus isolates, were incubated with autologous NK cells at a 1:1 ration in the presence or absence of mAbs. Intracellular p24 was measured after 4hrs by flow cytometry. Fc-receptor mediated inhibition of Abs was analyzed on monocyte-derived macrophages, which were infected in the presence of Abs and the percentage of infected cells measured after a single round of infection.
Results: Studying the ADCC profile of several mAbs, we found that the V2i mAbs induce strong NK cell mediated lysis of HIV-1 infected CD4+ cells in our physiologically relevant ADCC model. We also discovered that some non-neutralizing mAbs directed against V2 reached higher levels of ADCC (up to 60%) than some well-known broadly neutralizing Abs such as 3BNC117, 10-1074, and 10E8 (ADCC levels of 23%, 14%, and 10%, respectively).
We also studied the Fc-receptor mediated inhibition of V2i mAbs on macrophages, infected with primary HIV-1 isolates. Several of the V2i mAbs efficiently reduced the infection rate by up to 90% and the addition of anti-Fcγ receptor blocking antibodies partly reversed this inhibition. Thus, V2i mAbs display Fc-receptor mediated inhibition of infection on macrophages.
Conclusions: Our data suggest that in addition to neutralization other inhibitory functions can effectively participate in HIV protection. V2i mAbs display functions that inhibit virus infection and kill HIV-1 infected cells, highlighting the interest in inducing such Abs in future HIV-1 vaccine research.

Antibody dependent cell-mediated phagocytic activity is increased in the genital tract mucosae of HIV-infected women with prior tenofovir gel exposure

K. Fisher[1,2], J. Mabuka[3], C. Baxter[1,2], R. Cromarty[1,2], L. Mansoor[1,2], Q. Abdool Karim[1,2,4], S. Abdool Karim[1,2,4], N. Garrett[1,2], N. Yende[1,2], L. Morris[5,6], J.-A. Passmore[1,7,8], D. Archary[1,2]
[1]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [2]University of KwaZulu-Natal, Durban, South Africa, [3]Africa Health Research Institute, Durban, South Africa, [4]Mailman School of Public Health, Columbia University, Clinical Epidemiology, New York, United States, [5]National Institute for Communicable Diseases, Division of the National Health Laboratory Service, Johannesburg, South Africa, [6]Centre for the AIDS Programme of Research In South Africa, Durban, South Africa, [7]Institute of Infectious Disease and Molecular Medicine, Department of Clinical Laboratory Sciences, Cape Town, South Africa, [8]University of Cape Town, Division of Medical Virology, Cape Town, South Africa

Background: Pre-exposure prophylaxis (PrEP) can alter antibody kinetics resulting in delayed antibody binding avidity and reduced titers during the breakthrough and early post-HIV infection periods. However, the effect of prior PrEP on subsequent antibody function remains poorly described.
Methods: Using an in vitro neutrophil-based functional assay, the antibody dependent cell-mediated phagocytic function (ADCP) to p66, p24, gp41 and gp120 were investigated in the blood and genital tracts of women who seroconverted from the CAPRISA 004 1% tenofovir microbicide gel trial at 3; 6 and 12 months post-infection in the tenofovir arm (n=24) and placebo arm (n=24).
Results: Detection of HIV-specific antibody mediated phagocytic responses (phagocytic scores above background) at 3 months post-infection, were higher in the genital tract compared to the blood with a mean of 92% detectability versus 89%, in both arms. In the blood, evolving and significantly increased phagocytic activity mediated through antibodies specific to p66 and gp120 ($p<0.05$) were found from 3 to 12 months post-infection in both arms. However, there were no differences in the magnitude of ADCP activity between the arms. In contrast, the magnitude of mucosal ADCP activity was higher in the tenofovir arm than in the placebo arm over 12 months for p24 ($p= 0.006$) and gp41 ($p=0.01$) specific antibodies. Specifically, at 6 months, mucosal ADCP activity in the tenofovir arm was significantly higher for p24 ($p=0.003$) and gp41 ($p=0.005$) compared to the placebo arm. ADCP activity did not correlate between the blood and genital tracts for either arm, despite the strongly significant inter-compartmental correlations for the profile of HIV-specific antibodies. Irrespective of arm, the genital tract had early and detectable ADCP activity albeit at lower magnitude compared to the blood ADCP activity.
Conclusions: Prior topical tenofovir gel did not diminish antibody-mediated effector ADCP function, as evidenced by the higher mucosal specific ADCP activity in the tenofovir arm relative to the placebo arm. Together, these data inform combination prevention strategies, that parallel PrEP usage can influence humoral immunity, and may even enhance both the ensuing antibody profiles and perhaps diverse antibody-mediated effector functions post HIV vaccination, at the site of vulnerability, the genital tract.

Background: In the absence of antiretroviral therapy (ART), elite controllers (EC) naturally control HIV infection maintaining low to undetectable viral loads. Immune responses, in particular cytotoxic T cell responses, participate in the control of HIV. Increasing evidences suggest that the B cell antibody (Ab) responses might also play a role. Understanding the mechanisms implicated in natural control of HIV infection will help in developing efficient HIV vaccines. In EC, we aimed at characterizing memory B cell compartments and determining the frequency, the specificity and the isotype of HIV-specific memory B cell responses. We asked whether the preservations of HIV-specific B cells could be associated with the capacity to neutralize HIV viruses.
Methods: In EC expressing or not the protective HLA-B*57 allele, patients under ART and HIV-negative individuals, we characterized memory B cell compartments and HIV-specific memory B cells responses using flow cytometry and B cell-ELISPOT. We analyzed the capacity of sera from EC to neutralize a panel of 10 HIV strains including mostly transmitted/founder (T/F) viruses.
Results: EC preserve memory B cell compartments and in contrast to treated patients, maintain HIV-specific responses. HIV-specific B cells mainly express IgG1+ Abs. Importantly, 25% of EC neutralized at least 40% of viral strains tested. Moreover, in HLA-B*57+ EC, effective cross-neutralization was associated with high HIV-specific B cell frequencies.
Conclusions: Preservation of HIV-specific B cells and its association with cross-neutralizing capacities in HLA-B*57+ EC suggest that efficient memory B cell responses could contribute to the natural control of HIV infection.

WEPEA0170

Early recovery of antibody-mediated neutralization and ADCC responses in HIV-positive individuals under dolutegravir-based antiretroviral therapy

J. Liang[1], A. Hassan[1], B. Brenner[1], J.-P. Routy[2], T. Mesplède[1], M.A. Wainberg[1]
*[1]McGill AIDS Centre-Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, Canada, [2]Montreal PHI Cohort Study Group, McGill University, Department of Medicine, Montreal, Canada
Presenting author email: tibo_mes@hotmail.com*

Background: Dolutegravir (DTG) is the newest and most potent member of the integrase inhibitor drug family. No reports of drug resistance have been reported in patients receiving first-line DTG treatment since its FDA approval in 2013. It has been shown that resistance mutations associated with first-line treatment contribute to functionally impaired viruses without compensatory mutations. The impact of DTG-treatment on viral evolution in patients is not clear, but characterization of host immune responses against HIV-1 will shed light on the status of viral infection during suppression achieved by antiretroviral (ARV) therapy.
Methods: Our study is a longitudinal observational study. Sequential serum samples were obtained from patients suppressed with DTG-based or Elvitegravir (EVG)-based therapy (n=8 and n=5, respectively) at one month (T1), two months (T2), and five to six months (T3) after treatment initiation. The antibody-dependent cellular cytotoxicity (ADCC)-mediating potency and virus neutralization titers of the serum samples were measured.
Results: T2 and T3 sera from four individuals treated with DTG- or EVG-based ART (two in each group) were tested for their ability to mediate ADCC activity. The serum dilutions at which 50% of the infected target cells were killed were 48-fold higher at T2 and 11-fold higher at T3 for DTG-treated individuals when compared to EVG-treated individuals. The 50% neutralization titers of the sera were 1:227 at T1, 1:640 at T2, and 1:647 at T3 for DTG-treated individuals and 1:247 at T1, 1:225 at T2, and 1:633 at T3 for EVG-treated individuals.
Conclusions: Patients treated with DTG compared to EVG had more robust levels ADCC responses ($p < 0.01$) and earlier recovery of neutralization titre overtime. These data are consistent with reports of a reduced likelihood of HIV Env evolution following exposure to DTG compared to other drugs.

WEPEA0171

Post-translational processing influences antibody reactivity against the gp120 V2 domain on infected CD4+ T cell

J. Yolitz, D. Wei, D. Van Ryk, C. Cicala, J. Arthos, A.S. Fauci
*National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States
Presenting author email: jason.yolitz@nih.gov*

Background: Following the RV144 vaccine trial, interest in non-neutralizing antibody responses directed against the V2 domain of gp120 has increased. Such responses may contribute to ADCC and other effector mediated anti-viral activities. The V2 domain of gp120 can adopt distinct conformations that influence antibody reactivity. The structure of the V2 domain is strongly influenced by post-translational processing (PTP), including glycosylation. In this study we investigated the influence of PTP on V2 conformation and the reactivity of V2-specific monoclonal antibodies (mAbs).

Methods: To manipulate Env PTP, we cultured HIV infected CD4+ T cells in the presence of Brefeldin A (BreA), an inhibitor of transport between the endoplasmic reticulum and Golgi. BreA treatment of infected cells should increase the proportion of Env expressed on the surface of the cell that is processed in a Golgi-independent manner. Env processed in this way is incorporated into infectious virions, but has no demonstrable function. We then probed the surface of these cells with a panel of V2 mAbs that recognize distinct conformations that differ with respect to neutralization sensitivity.
Results: In the absence of BreA, several mAbs specific for alternative conformations recognize significant fractions of Env on the surface of infected CD4+ T cells. This indicates that alternative conformations are present on the surface of infected cells. Interestingly, for CH58, a non-neutralizing V2 mAb derived from an RV144 vaccine recipient, reactivity was largely unaffected by BreA treatment of infected cells. In contrast, for PG9, a broadly neutralizing mAb that recognizes an alternative glycan-dependent conformation of V2, reactivity was almost completely absent when cells were cultured in the presence of BreA.
Conclusions: Our results indicate that the mAb CH58 recognizes a conformation of V2 that can be processed in a Golgi-independent manner and that this epitope is retained on the surface of infected primary CD4+ T cells. This finding raises the possibility that certain antibodies targeting alternatively processed forms of HIV Env may have added value and contributed to the mechanisms underlying reduced risk of acquisition in the RV144 trial. These findings may have implications for the design of protective HIV vaccine immunogens.

WEPEA0172

A unique N332 supersite directed bnAb from a slow progressor shares characteristics with both CD4bs and V3-glycan bnAbs

H. Ebner[1], M. Schanz[1], P. Rusert[1], M. Huber[1], C. Kadelka[1], T. Liechti[1], H. Kuster[2], J. Weber[1], T. Uhr[1], O. Zagordi[1], D. Braun[2], H.F. Guenthard[1,2], A. Trkola[1]
[1]University of Zurich, Institute of Medical Virology, Zurich, Switzerland, [2]University Hospital Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland
Presenting author email: ebner.hanna@virology.uzh.ch

Background: Broadly neutralizing antibodies (bnAbs) can protect from HIV-1 acquisition but it is still poorly understood which factors drive bnAb development in natural infection. Here we report on the development of a potent bnAb response in a slow progressing, subtype B infected individual, Z91, enrolled in the Zurich Primary HIV Infection (ZPHI) study, who controlled viremia at low level (range: 750-40 000 HIV-1 RNA copies/ml) for 9 years before initiation of therapy.
Methods: A potent bnAb, ZPHI-12, was isolated from PBMC of patient Z91. The evolution of the bnAb was studied longitudinally by deep sequencing. Env genes were cloned from plasma viruses at multiple time points and analyzed for sensitivity to autologous plasma and ZPHI-12. Breadth was determined against a 38 multiclade virus panel in the TZM-bl assay. Comprehensive neutralization, binding and competition analyses were performed to map the epitope of bnAb ZPHI-12.
Results: Plasma neutralization breadth in patient Z91 increased from 13% at week 46 to 78% after 7 years of infection. BnAb ZPHI-12, isolated at 5.4 years post infection neutralizes 58% of probed viruses. ZPHI-12 has a 21 amino acid long CDRH3 containing an unusual stretch of 7 tyrosines. Autologous virus quasispecies showed variable resistance and sensitivity to ZPHI-12 during the 8 year observation period. Autologous viral resistance at different time points was differentially influenced by N332 glycosylation and accompanied by mutations in the V3-"GDIR" motif. ZPHI-12 binds both gp120 monomer and trimer and competes with PGT128 and VRC01 bnAbs for binding. Interestingly, ZPHI-12 shows differential binding to the Env core probe RSC3/RSC3d371I similar to CD4-bs directed bnAbs.
Conclusions: bnAb ZPHI-12 shows characteristics of both, CD4bs and V3-glycan site bnAbs. Mutations of the V3-GDIR motif and its surrounding glycans suggest that the bnAb response kept continuous pressure on that target region. While dependent on the N332 in the context of some virus strains, the autologous virus found ways to escape ZPHI-12 while maintaining the N332 glycosylation site.

WEPEA0173

Antibody dependent cellular cytotoxicity and neutralization antibody responses in HIV-1-infected elite controllers

S. Dispinseri[1], M. Tolazzi[1], G. Tambussi[2], S. Nozza[2], A. Riva[3], M. Malnati[1], G. Scarlatti[1]
[1]San Raffaele Scientific Institute, Division of Immunology, Tranplantation and Infecyious Diseases, Milan, Italy, [2]San Raffaele Scientific Insistute, Department of Infectious and Tropical Diseases, Milan, Italy, [3]L. Sacco University Hospital, Department of Infectious, Milan, Italy
Presenting author email: dispinseri.stefania@hsr.it

Background: A small percentage of HIV-1 positive individuals (1%), the "elite controllers" (EC), spontaneously control viremia in the absence of therapy for one year or more. The ability to suppress viral load below the limit of detection by standard assays was associated with more favorable clinical outcomes compared with viremic patients.
Methods: Here, we analyzed the neutralization capability (Nabs) and the antibody dependent cellular cytotoxicity (ADCC) of the plasma of 13 EC. The 13 patients, all immunologically healthy, were therapy naïve with a viral load below the detection limit of standard assay (< 50 cp/ml). The time from diagnosis of HIV-1 infection varied from 1 to 25 years.
Nabs were tested against laboratory (n=2) and primary (n=2) heterologous isolates in a PBMC-based assay. ADCC was performed by Grantoxilux assay using $gp120_{BAL}$-coated target cells and purified NK cells as effector.
Results: Seventy-nine percent of plasma were able to neutralize at least one virus and 30% neutralized at least 2 viruses. In general neutralization titers were low or medium level (1/20-200). Interestingly, five of 13 patients did not neutralize the highly neutralization-sensitive SF162. All plasma samples showed ADCC activity independently from neutralization capacity. Titers of ADCC ranged from 1/1100 to 1/156250 with maximum granzyme B activity varying between 30-88%.
Conclusions: Our results show that plasma neutralizing capacity is frequent but generally of low titer in EC. Interestingly, ADCC is present in all EC tested, suggesting that non neutralizing response could play a role in controlling viremia.

WEPEA0174

Identification and characterization of broadly neutralizing antibodies against founder viruses

N. Gonzalez[1], R. Klitting[1], F. Garcia[2,3], V. Sanchez-Merino[3,4], E. Yuste[1,3,4], J. Mascola[5], J. Alcami[1]
[1]Instituto de Salud Carlos III, AIDS Immunopathology Unit, Majadahonda, Spain, [2]Hospital Clinic, Infectious Diseases Service, Barcelona, Spain, [3]HIVACAT, Barcelona, Spain, [4]AIDS Research Unit, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [5]National Institute of Allergy and Infectious Diseases (NIH), Vaccine Research Center, Bethesda, United States
Presenting author email: ppalcami@isciii.es

Background: In most cases HIV-1 infection results from the transmission of a limited number of viral variants termed transmitted/founder (T/F) viruses. We propose that the antibodies generated by a preventive vaccine should be able to neutralize preferably the transmitted variants that establish the infection. The objective of this study is the identification and characterization of antibodies capable of neutralizing T/F viruses in a cohort of patients with chronic infection.
Methods: 190 serum samples from a cohort of chronically infected individuals (Hospital Clinic, Barcelona) were analyzed. The neutralization capacity of these sera was determined by neutralization assays against two different panels: a mini-panel of 6 recombinant viruses with envelopes of T/F viruses (Fiebig stages I to IV, subtypes B and C) and a mini-panel of 5 recombinant viruses from chronic infection of several subtypes. The specificities of the neutralizing antibodies were studied using the following techniques: ELISA using mutated gp120 that abrogates antibody binding, neutralization assays with viruses mutated in the antibody binding regions and peptide competition neutralization assays.
Results: We have identified 12 serum samples with broadly neutralizing antibodies against founder viruses, 3 of which are also capable of neutralizing chronic viruses. The remaining 9 sera neutralized only founder viruses and 3 sera neutralized only chronic viruses. In patients displaying broad neutralizing activity, epitope mapping showed that the percentage of sera targeting the CD4 binding site and the V1/V2 domain was higher against the panel of founder viruses than in those with neutralizing responses to chronic viruses. These differences did not reach statistical significance probably due to the small population size.
Conclusions: We have identified a group of neutralizer patients against founder viruses and observed differences in the susceptibility to neutralization between chronic and founder viruses included in the neutralization panels of this study. These results could suggest that there are structural differences between T/F and chronic HIV-1 envelopes and that an effective preventive vaccine should induce antibodies able to neutralize these early viral envelopes.

WEPEA0175

The impact of HIV-genetics on imprinting HIV-1 neutralization and binding responses

R. Kouyos, P. Rusert, C. Kadelka, A. Marzel, T. Liechti, M. Schanz, H. Ebner, H. Günthard, A. Trkola, Swiss HIV Cohort Study
University of Zurich, Zurich, Switzerland
Presenting author email: roger.kouyos@uzh.ch

Background: A key question on the way towards an HIV-1 vaccine is the impact of viral genetics on the neutralization response: Will a given HIV-1 envelope immunogen induce the same antibody specificities across vaccinees? Here we addressed this by studying the influence of virus genetics in potential transmission pairs identified within a recently conducted systematic screen of HIV-1 neutralization in 4,484 individuals (Swiss 4.5K Screen; Rusert, Kouyos Nat Med 2016).
Methods: Potential transmission pairs were defined based on HIV-1 pol gene phylogenies and plasma neutralization activity against a 14 multi-clade pseudovirus panel and IgG binding activity to 13 HIV-1 Gag and Env antigens was determined. Neutralization and binding similarity within pairs was determined by Spearman correlation and a range of shuffling tests and similarity measures.
Results: We identified 336 potential transmission pairs within the Swiss 4.5K Screen. For 7/14 pseudoviruses, we observed a significant ($p<0.05$) positive within-pair correlation of neutralization. The average Spearman correlation coefficient across all 14 viruses was weakly ($\rho=0.10$) but significantly ($p_{shuf}<0.001$) positive, even after controlling for viral subtype, infection-length and ethnicity ($p_{shuf}<0.001$). Similarly, binding to different HIV-1 antigens was significantly correlated within pairs (average $\rho_{spear}=0.12$, $p_{shuffling}<0.001$). This similarity was stronger for IgG1-responses (average $\rho_{spear}=0.18$, $p_{shuffling}<0.001$) than for IgG2 (average $\rho_{spear}=0.08$, $p_{shuffling}=0.01$) and IgG3 (average $\rho_{spear}=0.08$, $p_{shuffling}=0.01$). Notably, we found that two elite neutralizers (top 1% of neutralizers) formed a transmission pair and exhibited highly similar neutralization ($\rho_{spear}=0.73$) fingerprints. To generalize this finding, we present a novel systematic approach which could identify pairs with similar neutralization and binding responses.
Conclusions: Our results indicate that viral genetic factors significantly affect the breadth and specificity of the antibody responses to HIV-1. A large proportion of this effect is likely due to the env gene. Not all bnAb Envs may carry the capacity to imprint identical Ab specificity, thus utilizing Envs from bnAb inducers with proven transferability of antibody reactivities as identified here may be the ultimate immunogen candidates to base vaccine design on.

Neutralizing antibodies efficiently inhibit HIV transmission from infected T cells to heterologous DC and T cells

C. Ducloy[1,2], B. Su[3], J. Klingler[1,2], L. Mayr[1], T. Decoville[1], S. Schmidt[1], G. Laumond[1], C. Moog[1,2]
[1]INSERM U1109, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Strasbourg, France, [2]VRI : Vaccine Research Institute, Créteil, France, [3]Beijing Key Laboratory for HIV/AIDS Research, You'an Hospital, Capital Medical University, Beijing, China
Presenting author email: camille.ducloy@etu.unistra.fr

Background: In the semen, both free viruses and infected cells are able to transmit HIV during sexual intercourse. An efficient vaccine should therefore inhibit both infection states. The aim of this study is to analyze the capacity of antibodies (Abs) to inhibit HIV transmission from infected cells.
Methods: We developed an in vitro model aiming to mimic mucosal HIV transmission via infected cells. Briefly, PHA-activated CD4(+) T cells labeled with PKH26 from donor A were infected with HIV-1_{Bal}, HIV-1_{Bx08} or a transmitted/founder virus HIV-$1_{pREJO.}$ As at the mucosal site both CD4(+) T cells and dendritic cells (DCs) have been described to be the first HIV targets, we further co-cultured the infected cells with CD4(+) T cells and DCs from another donor (donor B) in the presence or absence of Abs. The different infected cell populations were identified by PKH26 labelling, membrane marker phenotyping and p24 staining by FACS. Statistic analysis was performed using Mann-Whitney test or one-way ANOVA (Kruskal Wallis test), where $p< 0.05$ was considered significant.
Results: In this DC/T cell co-culture model, we found a significantly increased infection rate ($p< 0.05$) in DCs compared to CD4(+) T cells from donor B after 1 day of co-culture with infected CD4(+) T cells from donor A. In the presence of broadly neutralizing Ab 10-1074, a dose dependent decrease of infected cells was observed at a similar level for both cell types of donor B. Analysis of the inhibitory potential of other HIV-specific Abs is currently in progress.
Conclusions: Overall, our results indicate that DCs are strategic cells efficiently infected in addition to CD4(+) T cells in this heterologous co-culture transmission model. Neutralizing antibodies are potent inhibitors of both infected target cells. Future HIV prophylactic vaccine design should develop immune strategies able to prevent infection of DCs, in addition to the prevention of infection of CD4(+) T cells.

WEPEA0177

Suppression of SAMHD1 in dendritic cells improves antigen presentation and HIV-specific cytolytic T cell response *in vitro*

S. Kurle, J. Dhande, M. Thakar, R. Paranjape
National AIDS Research Institute, Immunology, Pune, India
Presenting author email: skurle@nariindia.org

Background: Sterile Alfa Motif domain and HD domain-containing protein 1 (SAMHD1) is one of the human host proteins known to block HIV replication in dendritic cells (DCs). Suppression of SAMHD-1 may lead to infection of DCs and efficient antigen processing leading to induction of effective adaptive immune response.
We studied the effect of HIV-2 Vpx induced down regulation of SAMHD-1 in human monocytes derived dendritic cells (MDDCs) on HIV-specific cytolytic T cell response.
Methods: MDDCs generated in vitro from blood monocytes from healthy donors (N=6) were nucleofected using plasmid containing Vpx from HIV-2 ROD9 (for Vpx expression) to suppress SAMHD-1 and subsequently infected with primary HIV-1 isolate (0.01 MOI). These HIV-1 infected MDDCs ($MDDC_{HIV+Vpx+}$) were mixed with autologous T cells (1:10) and cultured for 10 days. HIV-specific cytolytic $CD4^+$ and $CD8^+$ T cell response was assessed by determining the expression of CD107a (a degranulation marker) against HIV-1 gag and env peptide pools using multicolour flowcytometry. $MDDC_{HIV-Vpx-}$ and $MDDC_{HIV+Vpx-}$ were used as the assay controls. Wilcoxon matched paired test was used to check the statistical significance in the comparative analysis.
Results: HIV-specific CTL response generated using $MDDC_{HIV+Vpx+}$ was found to be significantly higher as compared to T cells mixed with $MDDC_{HIV+Vpx-}$. A significantly higher response of CD107a+ expression by CD8+ T cells was seen when stimulated with $MDDC_{HIV+Vpx+}$ (Mean: 4.62%; Range: 0%-23.7%) as compared to CD8+T cells mixed with $MDDC_{HIV+Vpx-}$-(Mean: 0.23%; Range: 0%-0.95%) (p=0.001).
Similarly, CD4+CD107a+ T cells when stimulated using $MDDC_{HIV^+Vpx^+}$ were found to be significantly higher (Mean: 2.0%; range: 0.02%-11.8%) as compared to when stimulated with $MDDC_{HIV^+Vpx^-}$ (Mean: 0.2%; range: 0.01%-0.77%) (P=0.0068).
Conclusions: Vpx mediated downregulation of SAMHD-1 resulted in more efficient antigen presentation and induction of CD4+ and CD8+ CTL responses by MDDCs. This finding may provide a new target for immunological intervention for control of HIV infection, especially during early stage of infection.

WEPEA0178

Impact of a single escape mutation selected by HLA-A*24:02-restricted $CD8^+$ T cells on HIV-1 control by HLA-B*35:01-restricted ones and T cell adaptation

H. Murakoshi[1], T. Akahoshi[1], M. Koyanagi[1], T. Chikata[1], K. James[2], Y. Tamura[1], N. Kuse[1], X. Sun[1], H. Gatanaga[1,3], S.L. Rowland-Jones[2], S. Oka[1,3], M. Takiguchi[1,2]

Presenting author email: tlmura@kumamoto-u.ac.jp

Background: It is well known that HLA-B*35 is an HLA allele associated with rapid progression to AIDS. Recent studies demonstrated that most prevalent subtype HLA-B*35:01 is a detrimental allele in HIV-1 clade B-infected individuals. However, the mechanisms underlying the detrimental impact of this allele on the clinical outcome of HIV-1 clade B-infected individuals remain unclear. To clarify this mechanism, we sought to identify HLA-B*35:01-restricted epitope-specific $CD8^+$ T cells controlling HIV-1 in HIV-1 clade B-infected Japanese individuals and further analyzed the effect of mutations within the epitopes on the T cell responses and clinical outcome.
Methods: We analyzed 15 HLA-B*35:01-restricted epitope-specific $CD8^+$ T cells in 63 HIV-1 clade B-infected Japanese individuals carrying HLA-B*35:01 using ELISPOT assay. To clarify effects of mutations on the epitope-specific $CD8^+$ T cell responses, we next analyzed HLA-associated mutations within the HLA-B*35:01-restricted epitopes in the Japanese cohort.
Results: The T cell responses to only 4 HLA-B*35:01 epitopes (GagNY9, PolVY10, NefRY11, and NefYF9) were significantly associated with low plasma viral load. However, the control of HIV-1 by YF9-specific T cells are impaired by a single NefY135F mutation selected by RF10-specific CTLs restricted by HLA-A*24:02 which is found in 70% of Japanese individuals. The longitudinal analysis of the YF9-specific T cells showed that the emergence of the virus having this mutation led to the induction of the mutant epitope-specific T cells having entirely different TCR clonotypes from those of the wild type-specific T cells. The ability of mutant-specific T cells to suppress the mutant virus was significantly weaker than that of wild type-specific ones to suppress wild type virus in vitro, suggesting

that the mutant-specific T cells fail to control HIV-1 replication in vivo. Thus, the HLA-B*35:01-restricted T cells adapt to the mutation virus selected by the HLA-A*24:02-restricted ones.
Conclusions: The accumulation of NefY135F mutation selected by the HLA-A*24:02-restricted CTLs and the adaptation of YF9-specific T cells to the mutant virus are key factors in the impairing control of HIV-1 in Japanese individuals having a detrimental allele HLA-B*35:01.

WEPEA0179

Control of HIV-1 by HLA-B*52:01-restricted or C*12:02-restricted cytotoxic T lymphocytes specific for 6 epitopes in an HIV-1-infected Japanese cohort, in which HLA-B*57 and HLA-B*27 are very rare

T. Chikata[1], H. Murakoshi[1], M. Koyanagi[1], K. Honda[1], H. Gatanaga[1,2], S. Oka[1,2], M. Takiguchi[1,3]
[1]Kumamoto University, Center for AIDS Research, Kumamoto, Japan, [2]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [3]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom
Presenting author email: tchikata@kumamoto-u.ac.jp

Background: Our previous study showed that the HLA-B*52:01-C*12:02 haplotype, which is the most prevalent haplotype in Japan (approximately 20%), was significantly associated with both low plasma viral load (pVL) and high CD4 counts in treatment-naïve Japanese individuals chronically infected with HIV-1, suggesting that these alleles are protective ones in Japan and implying that HLA-B*52:01-restricted or C*12:02-restricted cytotoxic T lymphocytes (CTLs) may control HIV-1 replication. The following study demonstrated the control of HIV-1 replication by 4 HLA-B*52:01-restricted CTLs in the Japanese cohort. However, it is still unclear whether HLA-C*12:02-restricted CTLs control HIV-1.
Methods: We first identified novel HLA-C*12:02-restricted CTL epitopes by IFN-g ELISpot assay using a set of HIV-1 overlapping peptides spanning Gag, Pol, and Nef regions and intracellular cytokine staining assay. We next statistically analyzed correlations between these epitope-specific CTL responses and pVL or CD4 counts in 80 HIV-1-infected HLA-B*52:01$^+$HLA-C*12:02$^+$ Japanese individuals using two-tailed Mann-Whitney test.
Results: We identified 4 novel HLA-C*12:02-restricted epitopes, Gag TH9, Pol KY9, Pol IY11, and Nef MY9. The frequencies of the responders to Pol IY11 or Nef MY9 were over 20% whereas those to Gag TH9 and Pol KY9 were less than 3%. The T cell responses to Pol IY11 or Nef MY9 were significantly associated with both low pVL and high CD4 counts in the Japanese cohort, suggesting that these epitopes were immunodominant ones. The breath of the T cell responses to these 2 HLA-C*12:02-restricted and 4 previously identified HLA-B*52:01-restricted epitopes (Gag MI8, Gag RI8, Gag WV8 and Pol SI8) revealed a significant inverse correlation with pVL and a positive correlation with CD4 counts, indicating that the CTLs specific for these 6 epitope synergistically control HIV-1 replication in Japanese individuals.
Conclusions: The present study highlighted the CTLs specific for 6 epitopes restricted by HLA-B*52:01 or HLA-C*12:02 play an important role on control of HIV-1 in Japanese individuals. These results strongly support our previous finding that the HLA-B*52:01-C*12:02 haplotype had the protective effect on clinical outcomes in Japan.

WEPEA0180

Follicular cytotoxic T cells specifically control the infection in follicular helper T cells

D. Yu
Australian National University, Immunology and Infectious Diseases, Acton, Australia
Presenting author email: di.yu@anu.edu.au

Background: Follicular helper T (T_{FH}) cells are a specialized subset of CD4$^+$ T cells that reside in B-cell follicles to support humoral immune response. Recently, T_{FH} cells were identified as a major cellular reservoir of HIV-1 in individuals under combination anti-retroviral therapy (cART) and may represent a major obstacle for a functional cure for HIV-1 infection. Cytotoxic CD8$^+$ T cells play a central role in the elimination of virus-infected cells. However, it remains unclear whether a specific subset of CD8$^+$ cytotoxic T cells controls the infection of T_{FH} cells.
Methods: The presence, phenotype and function of CD8$^+$ T cells in B-cell follicles were characterized in human HIV-1-infected human samples and a mouse model of infection with lymphocytic choriomeningitis virus (LCMV).
Results: We identified a specialized group of cytotoxic T cells that expressed the chemokine receptor CXCR5, selectively entered B cell follicles and eradicated infected T_{FH} cells. The differentiation of these cells, termed ‚follicular cytotoxic T cells' (T_{FC} cells), required the transcription factors Bcl6, E2A and TCF-1 but was inhibited by the transcriptional regulators Blimp1, Id2 and Id3. Blimp1 and E2A directly regulated Cxcr5 expression and, together with Bcl6 and TCF-1, formed a transcriptional circuit that guided T_{FC} cell development. We also found the differentiation of T_{FC} cells is regulated by certain cytokines including IL-2.
Conclusions: T_{FC} cells specifically control the infection in T_{FH} cells. The identification of T_{FC} cells has far-reaching implications for the development of strategies to eliminated persistent infection in T_{FH} cells for a functional cure of HIV-1 infection.

Presenting author email: brigitte.autran@aphp.fr

Background: The immunogenicity of the live attenuated Yellow fever vaccine (YFV) in HIV-infected patients even with high CD4 counts has been questioned. We previously reported the good YFV safety in HIV-infected adults with high CD4 cell counts from the NOVAA-AnrsEP46 study and the induction of similar levels of protective specific antibodies compared to uninfected vaccinated. Here we report the T cell immunogenicity of the YFV in this study.
Methods: The prospective NOVAA T cell sub-study included 36 YFV-naïve HIV-infected adults under antiretroviral therapy (ART) with CD4 counts >350/mm^3 and plasma HIV-RNA < 50 cp/ml for at least 6 months, and 16 HIV-negative healthy adults. Patients' characteristics were similar to the whole study. All received one YFV-17D injection. T cell responses were assessed ex vivo at D0, D28, D91 and D364 using an IFN-gamma ELISpot assay and a series of 15-mer peptides from the YF non-structural (NS) NS1, NS2, NS3, NS4, NS5, envelope and core proteins.
Results: YFV-specific T-cells were detected at D28 after vaccination in 21.4% HIV+ and 50% HIV- individuals, (p=0.082) with median cell frequencies of 57.5 [50-2,335] and 125 [50-1,645] SFC/10^{6}PBMC. At D91, YFV-specific T-cells persisted in 14.7% HIV+ compared to 50% HIV- individuals (p=0.01) with similar cell frequencies (65 [50-725] and 107.5 [55-605] SFC/10^{6}PBMC), and decreased at D364 down to 10% in HIV+ and 15.4% in HIV- individuals respectively (p=0.63). The YFV-specific T-cells from both groups recognized a median of one protein [1-3] per individual. NS1 was the most immunogenic protein, recognized in 22.5% cases, followed by NS2 in 10.2%, NS4: 7.8%, Env: 6% and NS3: 4% cases, respectively. Overall during the one year follow-up a specific YFV-T-cell response was detected at least once against at least one YFV protein in 27.8% HIV+ patients compared to 62.5% HIV- individuals (p=0.03).
Conclusions: The T cell immunogenicity of the live attenuated YFV vaccine was significantly lower in ART-treated HIV infected patients than in healthy uninfected subjects, despite high CD4 cell counts and suppressed viral replication, contrasting with similar antibody responses. Such a lower T cell immunogenicity might influence the limited duration of protective antibodies to YFV reported in HIV-infected patients.

WEPEA0182

Heterogeneity of circulating follicular helper T cells during hyperacute HIV-1 subtype C infection impact neutralizing antibody responses

O. Baiyegunhi[1], J. Mabuka[2], N. Ismail[1], A. Moodley[2], K. Dong[2], T. Ndung'u[1,2], Z. Ndhlovu[1,2]
[1]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [2]Ragon Institute of MGH, MIT and Harvard, Massachusetts General Hospital and Harvard Medical School, Boston, United States
Presenting author email: aral200@yahoo.com

Background: Seminal studies have described the characteristics of broadly neutralizing antibodies developed during HIV-1 infection, however, the immunological mechanisms responsible for their development is not well understood. Follicular helper T cells (Tfh) are a subset of CD4 T helper cells that support the development of high affinity and long-term B cell antibody responses, but their influence on the initial development of antibody breadth is not well characterized. Here we investigate how hyperacute HIV-1 infection modulates the Tfh phenotype and determined the relationship between Tfh phenotype subsets and neutralization breadth.

Methods: Two groups (HIV negative, n=10 and acute HIV, n=11) were drawn from a cohort of high risk females from Kwazulu-Natal, South Africa and were sampled longitudinally during the first year post infection. Tfh was phenotypically and functionally characterized from PBMCs using multicolor flow cytometry. Furthermore, the HIV-neutralizing ability of the serum was measured at one-year post infection using TZM-bl assay.
Results: An emergence of Tfh (CD45RA- CXCR5+ PD1+ CD4 T cells) was observed within the first week of infection, it peaked by the third month and subsequently declined. Interestingly, when we examined the Tfh subsets, we observed a significant increase in the frequencies of CXCR3+Tfh and a significant decrease of CXCR3-Tfh during hyperacute HIV. Four individuals developed cross reactive antibodies after one year of infection. Furthermore, we observed a trend of higher CXCR3+Tfh frequencies during hyperacute HIV infection among the neutralizers compared to non-neutralizers.
Conclusions: Our results indicate that hyperacute HIV infection alters Tfh subset composition. We also showed an association between higher frequencies of CXCR3+Tfh and the subsequent development of cross reactive anti HIV-1 antibodies. These data are relevant for HIV-1 vaccine strategies seeking to induce broadly neutralizing antibody responses.

WEPEA0183

CD8+ T-cell suppressive capacity directly correlates with peak viral load in a cohort of virally suppressed HIV+ patients on combination antiretroviral therapy

P. Pannus[1,2], E. Willems[1], L. Heyndrickx[1], M. Van Frankenhuijsen[3], E. Florence[3], K. Vervisch[2], M. Kiselinova[2], S. Rutsaert[2], W. Despiegelaere[2], L. Vandekerckhove[2], G. Vanham[1]
[1]Institute of Tropical Medicine, Biomedical Sciences, Antwerpen, Belgium, [2]University of Ghent, Internal Medicine, Ghent, Belgium, [3]Instituut voor Tropische Geneeskunde, Clinical Sciences, Antwerpen, Belgium
Presenting author email: ppannus@itg.be

Background: The combination of potent HIV-specific immune responses and a small latent viral reservoir is likely required to achieve post-treatment control of HIV infection. In this study we investigated correlations between CD8+ T-cell suppressive capacity, HIV reservoir and clinical parameters.
Methods: Fifty-three patients on cART with suppressed viremia (< 55 copies/mL) were recruited. Total HIV DNA and unspliced mRNA were quantified in PBMCs using digital droplet PCR. In a sub-group of patients infected with HIV subtype B, viral transcriptional activity was quantified with the ‚tat/rev induced limiting dilution assay' (TILDA) (N=21) and CD8+ T-cell suppressive capacity was measured against HIV-1 III_B superinfected autologous CD4+ T-cells before and after HIV consensus B Gag peptide stimulation (N=16). The latter assay was also done on six negative donors. Linear regression and student t-test were used for correlation analyses.
Results: Patients had a median: age 45.7 years, time on cART 70 months [IQR: 41 - 130], nadir CD4 count 283 cells/µL [IQR: 191 - 390]. 83% were male. Total HIV DNA was detected in all patients, ranging from 15 to 859 copies per million PBMCs (median: 196). Unspliced HIV RNA was detected in 42/53 patients (79%) ranging from 0.0 to 39.1 copies per million PBMCs (median: 2.8). TILDA values ranged from 0 to 313 cells [IQR: 1.4 - 55.8] with detectable HIV RNA transcripts per million CD4+ T cells after stimulation. Whereas CD8+ T-cell suppressive capacity without peptide stimulation was only observed in one patient, eight of 16 showed suppression with peptide stimulation. Suppression in the negative donors was used to determine the background threshold.
Total HIV DNA correlated directly with usRNA levels ($p< 0.05$). TILDA values tended to be higher for patients with residual versus undetectable viremia ($p=0.071$). Interestingly, a positive correlation between viral suppressive capacity and peak viral load was observed ($p< 0.05$).
Conclusions: In this group of virally suppressed patients, heterogeneity in terms of immune responses and reservoir size was observed, as expected. The remarkable correlation between peak viral load and CD8+ T-cell suppressive capacity after peptide stimulation might reflect the build-up of memory responses as a result of high antigen exposure before treatment initiation.

Early antiretroviral therapy intervention in HIV infection can rescue metabolic profiles of *ex vivo* CD8+ T cells

N. Rahman[1], J. Liu[1], S. Mujib[2], L. Wybenga-Groot[3], M. Ostrowski[1]
[1]University of Toronto, Department of Medicine, Toronto, Canada, [2]University of Toronto, Institute of Medical Science, Toronto, Canada, [3]The Hospital for Sick Kids, SPARC BioCentre, Toronto, Canada
Presenting author email: nur.rahman@gmail.com

Background: The molecular and cellular pathways that lead from HIV infection to AIDS are complex, multifactorial and not understood. One immunological phenomenon in HIV infected individuals that has been suggested as a factor for progression towards AIDS is chronic immune activation (CIA). The underlying causative mechanism(s) of CIA in HIV infected individuals are not well understood. The immune dysfunction and dysregulation upon HIV infection, which is characterized by the depletion of CD4+ T cells coupled with the expansion of non functional exhausted CD8+ T cells, confound the search for an underlying factor(s) for CIA. Recent work has established that metabolic programming itself influences T cell differentiation, effector function, persistence and survival into memory. We hypothesize that the chronic nature of HIV infection along with the associated CIA alter the metabolic profiles of effector CD8+ T cells to drive and to maintain their exhausted status.
Methods: Herein we generated metabolic profiles of isolated ex vivo CD8+ T cells from HIV uninfected, HIV Early infected treatment naïve and on treatment, HIV Chronic infected treatment naïve and on treatment, and viral controllers (VCs), who are able to control the HIV viral replication without treatment, by subjected them to Seahorse XF^{e}96 metabolic analyzer.
Results: We show that the baseline oxygen consumption rate (OCR), a readout of oxidative phosphorylation, of CD8+ T cells is enhanced in all the different HIV clinical stages, except HIV Early infected treatment naïve and on treatment, compared with HIV uninfected. The ATP linked and reserve capacity OCRs are also increased in all the different HIV clinical stages other than HIV Early infected on treatment. The overall metabolic profiles of CD8+ T cells from HIV Early infected on treatment is similar to that of HIV uninfected. Surprisingly, the baseline glycolysis rate is enhanced during HIV Early infected treatment naïve and VCs
Conclusions: Thus, the metabolic profile of ex vivo CD8+ T cells from chronic HIV infection was altered compared to HIV uninfected. This alteration can be rescued with early anti-retroviral therapy intervention. Further studies to understand the possible mechanism of the altered metabolic states of CD8+ T cells during HIV infection are currently underway.

WEPEA0185

Unilateral selection of viral mutations for escape from CD8+ T-cell recognition in SIV infection

H. Ishii[1], M. Jomori[1,2], S. Seki[1], S. Matsuoka[1], T. Matano[1,2]
[1]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [2]University of Tokyo, Institute of Medical Science, Tokyo, Japan
Presenting author email: hishii@niid.go.jp

Background: CD8+ T-cell responses exert strong suppressive pressure on HIV replication and frequently select for viral escape mutations. Some of these mutations result in loss of epitope-MHC-I interaction, whereas others do not inhibit epitope presentation but disturb CD8+ T-cell recognition. Selection of the latter mutations may induce CD8+ T-cell responses targeting the mutated epitope. In the present study, to investigate these virus-host CD8+ T-cell interaction, we analyzed CD8+ T-cell responses targeting Mamu-A1*065:01-restricted $Gag_{241-249}$ (SSVDEQIQW) epitope and viral genome sequences encoding this epitope in a macaque AIDS model of SIV infection. In our previous study, most Mamu-A1*065:01-positive macaques have been shown to select a mutation resulting in a D-to-E change at the 244th residue in Gag, which does not inhibit epitope presentation but $Gag_{241-249}$-specific CD8+ T-cell recognition.
Methods: We examined viral genome sequences encoding the $Gag_{241-249}$ epitope in Mamu-A1*065:01-positive rhesus macaques infected with wild-type SIVmac239 having Gag244D (n = 9) or mutant SIVmac239 having Gag244E (n = 5). We then investigated CD8+ T cells targeting $Gag_{241-249}$.244D dominantly ($Gag_{241-249}$.244D-specific), $Gag_{241-249}$.244E dominantly ($Gag_{241-249}$.244E-specific), or both equivalently by using wild-type ($Gag_{241-249}$.244D) and mutant ($Gag_{241-249}$.244E) epitope-Mamu-A1*065:01 tetramers.
Results: Wild-type SIV-infected macaques dominantly elicited $Gag_{241-249}$.244D-specific CD8+ T-cell responses in the early phase of infection. These animals showed selection of the 244D-to-244E mutation within a year post-infection and concomitant increases in the frequency of $Gag_{241-249}$.244E-specific CD8+ T cells. In contrast, mutant SIV-infected macaques elicited $Gag_{241-249}$.244E-specific CD8+ T-cell responses in the early phase. Interestingly, however, none of the mutant-infected showed the reverse 244E-to-244D change, although SIV with 244D

has higher in vitro replicative capacity than SIV with 244E. Induction of $Gag_{241-249}$:244D-specific $CD8^+$ T cells was inefficient in these animals.
Conclusions: Selection of escape mutations can result in induction of $CD8^+$ T cells targeting the mutated epitope. However, these $CD8^+$ T cells targeting the mutated epitope do not have the potential to induce the reverse mutation into the wild type. Varieties of epitope peptides may efficiently bind to MHC-I molecules, but this study suggests that only limited numbers of them can form optimal epitope-MHC-I complexes that could be efficiently targeted by potent $CD8^+$ T cells.

WEPEA0186

HLA-C is downregulated by most primary clones of HIV-1, and variation between these viruses is more pronounced for downregulation of HLA-C than HLA-A/B

R. Apps[1], G. Del Prete[2], P. Chatterjee[3], Z. Brumme[4], M. Brockman[4], S. Neil[5], S. Pickering[5], R. Thomas[6], G. Shaw[7], B. Hahn[7], B. Keele[2], J. Lifson[2], M. Carrington[3,8]

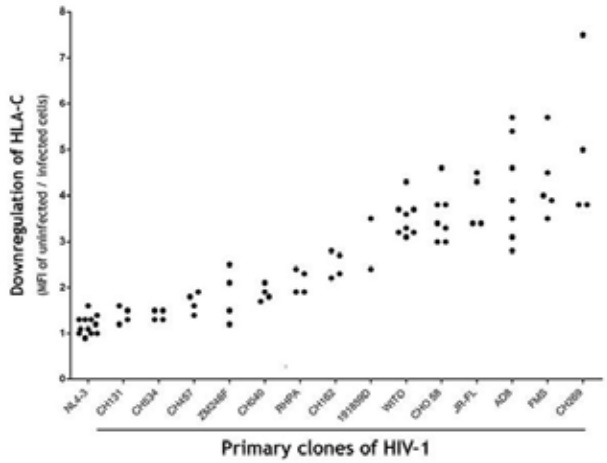
Presenting author email: rapps@gwu.edu

Background: Many pathogens evade CTL by downregulating HLA molecules on infected cells, but the loss of HLA can trigger NK cell-mediated lysis. HIV-1 has been thought to subvert CTLs and preserve NK cell inhibition by downregulation of specifically HLA-A/B but not HLA-C molecules, via the viral Nef protein. However analysis of HLA protein modulation by complete viruses has been largely restricted to the lab-adapted viral isolate NL4-3, and rarely been studied in primary cells.
Methods: Cell surface protein expression levels of each HLA class-I locus were characterized by flow cytometry, on primary CD4+ cells infected in vitro with molecular clones of primary HIV-1. This was enabled by recent advances in the characterization of HLA monoclonal antibody specificity, and in the cloning of primary viruses.
Results: In contrast to the laboratory-adapted NL4-3 virus, which downregulates specifically HLA-A/B, the transmitted founder primary HIV-1 clone WITO also downregulated HLA-C. Chimeric and mutated viruses show HLA-C reduction is mediated by the viral Vpu protein, and confirm Vpu does not contribute to downregulation of HLA-A/B. A screen of primary HIV-1 clones finds that most downregulate HLA-C to some extent (Fig. 1). The primary HIV clones vary in their ability to downregulate HLA-C, with a linear distribution, and show much more frequently significant differences between viruses in magnitude of downregulation of HLA-C than is observed for downregulation of HLA-A/B. This variation is investigated further by characterization of HLA-C downregulation by viruses and Vpu clones from different patients.



[Figure 1]

Conclusions: Downregulation of HLA-C on HIV-infected cells is distinct from the viral modulation of HLA-A/B, as the effects are mediated by different viral proteins and the magnitude of HLA-C reduction varies much more between viruses. Identification of the immune pressure selecting for HLA-C downregulation could represent a target for immune-mediated therapies, particularly as natural variation in HLA-C expression associates with patient viral loads.

WEPEA0187

HIV-1 accessory proteins hijack membrane trafficking to downregulate CD28

J. Dikeakos[1], E.N. Pawlak[2]
[1]University of Western Ontario, Microbiology and Immunology, London, Canada, [2]University of Western Ontario, London, Canada
Presenting author email: jimmy.dikeakos@uwo.ca

Background: HIV-1 Nef and Vpu lack enzymatic and structural functions, but improve the ability of the virus to replicate and persist within the host by binding to host cellular proteins. One way in which Nef and Vpu increase success of the virus is by downregulating cell surface receptors, such as the key immune cell activator cluster of differentiation 28 (CD28). However, the mechanisms utilized by these viral proteins to downregulate CD28 remains unknown. HIV-1 Nef and Vpu co-opt host cellular membrane trafficking proteins to alter the subcellular localization or levels of various host cellular receptors. We therefore hypothesized that Nef and Vpu subvert membrane trafficking pathways to downregulate CD28.
Methods: We infected CD4+ T cells with pseudotyped HIV-1 viruses expressing Nef, Vpu, or mutated forms of these viral proteins. A combination of flow cytometry and immunoblotting was utilized to determine the fate of endogenous CD28 in the presence of these HIV-1 accessory proteins.
Results: We observed a decrease in both cell surface and total CD28 protein levels, which could be attributed to both Nef and Vpu. Furthermore, impaired CD28 downregulation occurred upon introduction of mutations that impair the ability of Nef to bind to the vacuolar ATPase, an enzyme essential for acidification of the lysosome. This suggested that Nef may facilitate the transport of CD28 to a degradative compartment and was supported by an increase in total CD28 observed upon ammonium chloride treatment, which blocks lysosomal acidification. Additionally, mutation of a motif in Nef known to facilitate interactions with the membrane trafficking protein adaptor protein 2 (AP-2), decreased downregulation of cell surface CD28, implicating AP-2 in the transport of CD28 away from the cell surface. Vpu mutations known to inhibit interactions with specific host cell membrane trafficking proteins were tested for their effect on CD28 downregulation. We demonstrate that, similar to Nef-mediated downregulation, the ability of Vpu to interact with AP-2 is important for CD28 downregulation.
Conclusions: HIV-1 has evolved evolved multiple means to eliminate the immune cell activating receptor CD28 within infected cells. Our data suggest that Nef and Vpu hijack membrane trafficking, specifically AP-2, to reduce CD28 in HIV-1 infected cells.

Hide and seek with HIV-1 Nef: gaining super-resolution insights to immune evasion

J.D. Dikeakos, E.N. Pawlak, B.S. Dirk
University of Western Ontario, London, Canada
Presenting author email: jimmy.dikeakos@uwo.ca

Background: A major factor preventing the elimination of HIV-1 lies within the ability of the virus to hide from the immune system. This inherent ability of HIV-1 to confuse the immune system is accomplished by the small accessory protein Nef. Specifically, MHC-I downregulation by the HIV-1 Nef prevents infected cells from cytotoxic T-cell mediated killing. Nef downregulates MHC-I by modulating the host membrane trafficking machinery, resulting in the endocytosis and eventual sequestration of MHC-I within the cell. However, the precise cellular locations and the host proteins mediating these events remain unknown.
Methods: Our study utilized the intracellular protein-protein interaction reporter system, bimolecular fluorescence complementation (BiFC), in combination with super-resolution microscopy to uncover the membrane trafficking route undertaken by Nef and MHC-I. Our analysis describes protein-protein interactions in HIV infected cells in addition to ternary complexes formed by Nef in order to evade the immune surveillance response.
Results: We demonstrate that the Nef-MHC-I interaction occurs upon Nef binding the MHC-I cytoplasmic tail early during endocytosis in Rab5-positive endosomes. Disruption of early endosome regulation inhibited Nef-dependent MHC-I downregulation, demonstrating that Nef hijacks the early endosome to sequester MHC-I within the cell. Super-resolution imaging identified that the Nef:MHC-I BiFC complex transits through both early and late endosomes before ultimately residing at the trans-Golgi network. The membrane trafficking protein PACS-1 was essential to maintain the Nef:MHC-I complex and enhanced the formation of

a ternary complex within vesicles that were positive for adaptor protein-1 (AP-1). Indeed, disruption of the PACS-1 binding site on Nef inhibited Nef:MHC-I complex formation and thereby disrupted Nef's ability to evade immune surveillance.
Conclusions: Together we demonstrate the importance of the early stages of the endocytic network in the removal of MHC-I from the cell surface and its re-localization within the cell and define PACS-1's role and location as a key membrane trafficking regulator allowing HIV-1 to optimally evade host immune responses. Understanding these complex molecular pathways will aid in the development of new inhibitors targeted at crippling HIV-1's ability to evade our own immune surveillance system.

Deep sequencing analyses of emergence and maintenance of mutations in CTL epitopes of HIV-controllers with differential control of Viremia

D.G. Caetano[1], F.H. Côrtes[1], G. Bello[1], B. Hoagland[2], B. Grinsztejn[2], V.G. Veloso[2], M.L. Guimarães[1], M.G. Morgado[1]
[1]Oswaldo Cruz Institute - FIOCRUZ, Laboratory of AIDS and Molecular Immunology, Rio de Janeiro, Brazil, [2]National Institute of Infectology - FIOCRUZ, STD and AIDS Clinical Research Laboratory, Rio de Janeiro, Brazil
Presenting author email: diogo.caetano91@gmail.com

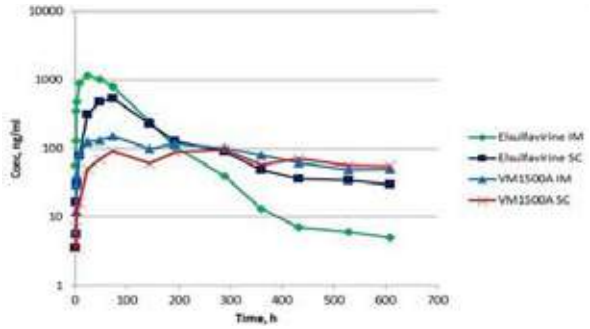
Background: HIV-Controllers are individuals able to control the viral replication to very low levels. Besides that, lower viral evolution and viral mutations related to escape of CTL response have been observed in HIV plasma sequences from those individuals. The dynamic of emergence and fixation of those mutants in reservoirs could be of great importance to comprehend spontaneous control of infection in HIV-Controllers.
Methods: In order to analyze the mutational profile of HIV and the dynamic of escape mutants we selected 11 HIV-controllers with more than 8 years of infection classified as Elite controllers, with (EEC-n=3) and without (EC-n=3) occasional viral blips, and Viremic controllers (VC-n=5), with persistent low viremia. Proviral DNA from PBMCs related to the earliest (V1) and latter visits (VX) available (mean interval of 50 months) were used to sequence gag and nef genes by using Illumina HiSeq. Reads obtained allowed to map the whole nef gene and the first 1000bps of gag (Medium coverage>200.000X). Consensus of each mapping, or previous sequences for 2 cases with unavailable NGS, were used to assess V1-VX divergence and Geneious Variant-call tool was used to identify variants (Frequency>0,5%).
Results: Deep sequencing analyses of VC showed higher divergence for nef comparing to gag (p< 0,02) and to both genes of EC (p< 0,04 for gag). Both genes showed low and similar divergence in ECs. Quantitatively, SNP analysis showed higher number of variants and variable positions in both genes of VC in comparison to EC and EEC. Analyses limited to CTL-restricted epitopes showed that non-synonymous mutations arose between V1 and VX in most individuals. All VCs had high number of mutations, with major frequency change between V1 and VX, that could be related to escape of immune response. All EC also presented non-synonymous mutation in CTL epitopes, in general, with frequencies lower than 1%.
Conclusions: The genetic conservation of gag and nef of EC indicates that the better viremia control restricts the evolution of both genes. All HIV-Controllers showed mutations on CTL epitopes. However, lower frequencies were observed for EC indicating that potential escape variations arise over time, but most do not fix in their reservoirs.

WEPEA0190

Pre-clinical pharmacokinetics of elsulfavirine/VM1500A long acting injectable formulations

V. Bichko[1], B. Rogovoy[1], A. Koryakova[2], R. Karapetian[2], I. Nikoulin[3], G. Yakatan[3], N. Savchuk[1], K. Klumpp[4], R. Murphy[5]
[1]Viriom Inc., San Diego, United States, [2]ChemDiv, Inc., San Diego, United States, [3]IriSys LLC, San Diego, United States, [4]Riboscience LLC, Sunnyvale, United States, [5]Northwestern University, Chicago, United States
Presenting author email: vbichko@viriom.com

Background: New options for the prevention and treatment of HIV infection that allow infrequent dosing will facilitate adherence and likely improve long-term outcomes. Elsulfavirine (Elpida®, VM1500) is the prodrug of VM1500A, a new, potent non-nucleoside reverse transcriptase inhibitor (NNRTI), currently under review for registration as an oral QD regimen for HIV/AIDS treatment. Unique pharmacokinetic properties ($T_{1/2}$ is ~8 days) of VM1500A suggest a possibility for long-acting formulation development.
Methods: Aqueous nanosuspensions of Elsulfavirine or VM1500A (particle size between 200 and 900 nm) were prepared by wet milling. Different surfactants and drug to surfactant ratios were used. Formulation safety and pharmacokinetics (PK) were studied in beagle dogs, following single (5, 10 or 20 mg/kg) dose administration by intramuscular (IM) or subcutaneous (SC) injection. Three animals were studied per dose and route of administration. Blood samples were collected frequently up to 72 h after administration and every week up to 3 months. Elsulfavirine and VM1500A plasma concentrations were measured using LC-MS/MS.
Results: All studied formulations were well-tolerated at all doses, no adverse reactions were observed, including at the injection site. The PK analysis showed that dosing with VM1500A provided more stable drug plasma concentrations than dosing with the prodrug Elsulfavirine from these administration routes. Following a single 10 mg/kg dose of VM1500A (either IM or SC), its plasma levels were maintained above 50 ng/ml for at least 4 weeks (the latest data point collected at the time of this abstract submission). These levels exceeded the clinically-efficacious VM1500A plasma concentrations. The graph plots VM1500A plasma concentrations over time after single IM or SC injections of 10 mg/kg Elsulfavirine or VM1500A.



[Fig. 1. Dog plasma VM1500A concentrations.]

Conclusions: This study provides proof-of-concept that VM1500A nanosuspensions could be developed into long-acting injectable formulations to enable infrequent dosing. Further pre-clinical development of these formulations is warranted.

WEPEA0191

Generation of phage recombinant single chain variable fragment (scFv) library from pooled PBMCs of HIV-1-infected humans and identification of cross-neutralizing anti-CD4 binding site and N332 glycan dependent scFvs

Gaitonde Centre for AIDS Research and Education (YRG CARE), Chennai, India, [5]Nat, Manesar, Gurgaon, India
Presenting author email: khanlubina@gmail.com

Background: More than 50% of HIV-1 infection globally is caused by subtype_C viruses. Majority of the broadly neutralizing antibodies (bnAbs) targeting HIV-1 have been isolated from non-subtype_C infected donors. A recent phase I clinical trial showed for the first time, that passive infusion of a single CD4 binding site directed bnAbs (3BNC117 and VRC01) and also V3 glycan supersite specific bnAb (10-1074) in humans reduced the viraemia in HIV-1 infected donors efficiently. Thus bnAbs against HIV-1 are potential candidates for a safe and effective eradication strategy, by way of prevention, immunotherapy and cure.
Methods: Recombinant antibody technology enables generation of a large repertoire of monoclonals with diverse specificities. It has been proven by studies that engineered antibody fragments can be more effective and can neutralize even resistant HIV-1 strains as they are smaller than full length IgGs. Hence, we constructed a phage recombinant single chain variable fragment (scFv) library, using a novel strategy of pooling peripheral blood mononuclear cells (PBMCs) of six select HIV-1 chronically infected Indian donors whose plasma antibodies exhibited potent cross neutralization efficiency. The library was panned and screened by phage ELISA using two different trimeric recombinant proteins (h-CMP-V1cyc1 gp120 protein and BG505:SOSIP.664 gp140) that mimic the native form of HIV-1 envelope, to identify viral envelope specific scFv clones.
Results: We constructed a phage recombinant single chain variable fragment (scFv) library with a diversity of 7.8×10^8 scFv clones. After bio-panning and screening, three scFv monoclonals D11, C11 and 1F6 were selected from the library. These scFvs cross neutralized subtypes A, B and C viruses at concentrations ranging from 0.09µg/mL to 100µg/mL. All the three scFvs showed distinct sequences and gene usage. The D11 and 1F6 scFvs competed with mAbs b12 and VRC01 demonstrating CD4bs specificity, while C11 demonstrated N332 specificity.

Conclusions: This is the first study to identify cross neutralizing scFv monoclonals with CD4bs and N332 glycan specificities from India. Employing antibody engineering strategies, it is feasible to generate bispecific and chemically-modified antibody reagents that can simultaneously target multiple HIV-1 epitopes with high avidity and can be potential candidates for passive immunotherapy, thereby prevent viral escape.

WEPEA0192

Complete protection of HIV-1 infection by a tandem BiIA in humanized mice and rhesus macaques

Z. Chen[1,2], X. Wu[1], J. Guo[1], M. An[1], L. Liu[1], H. Wang[2], X. Jin[3], P. Zhou[3]

Presenting author email: zchenai@hku.hk

Background: Viral genetic diversity is one of the major obstacles to prevention and immunotherapy against HIV/AIDS. Because none of native broadly neutralizing antibodies (bnAbs) inhibits all HIV-1 strains of genetically divergent subtypes, we aimed to engineer a bi-specific immunoadhesin (BiIA) with improved breadth and efficacy.
Methods: By testing six pairs of HIV-1-specific IAs in combination, we chose the synergistic pair of PGT-128 and Hu5A8 for BiIA construction. We generated two BiIAs, BiIA-DG by "knobs-in-holes" and BiIA-SG by tandem recombination. Their anti-HIV activities were extensively evaluated in vitro, and in humanized mice and rhesus macaques.
Results: In comparison to a panel of bnAbs, we show that BiIA-SG has the most broadly neutralizing activity against all HIV-1 strains tested, including multiple co-circulating subtypes/recombinant forms, transmitted/founder viruses and viral strains naturally resistant to parental IAs. Moreover, BiIA-SG confers complete protection not only against diverse live pathogenic HIV-1 challenges in a humanized mouse model but also against the R5-tropic $SHIV_{162P3}$ in rhesus macaques. Importantly, in vivo delivery of the BiIA-SG gene generates sufficient amount of BiIA-SG that eliminates productively and latently infected CD4 T cells in humanized mice as indicated by adoptive transfer of total splenocytes. In contrast, antiretroviral treated mice display rapid viral rebound after drug termination.
Conclusions: Our findings demonstrate that BiIA-SG is a promising biomedical product for HIV-1 immunoprophylaxis and immunotherapy, which warrants clinical development to control the expanding epidemic with diverse HIV-1 subtypes.

WEPEA0193

Ranpirnase exhibits dose-dependent inhibition of rectal explant HIV infection and inflammatory changes

R.M. Brand[1], A. Myerski[2], A. Siegel[2], E.J. Metter[3], J. Engstrom[2], R.E. Brand[1], L. Squiquera[4], T. Hodge[4], J. Sulley[4], R.D. Cranston[1], I. McGowan[1]
[1]University of Pittsburgh, Pittsburgh, United States, [2]Magee-Womens Research Institute, Pittsburgh, United States, [3]University of Tennessee Health Science Center, Memphis, United States, [4]Tamir Biotechnology, San Diego, United States
Presenting author email: rmb91@pitt.edu

Background: Ranpirnase (RNP) is a safe, low molecular weight type III endoribonuclease, isolated from frog oocytes, which demonstrates broad antiviral and antitumor properties. A phase I/II clinical study has just been completed examining the effectiveness of RNP in HPV infections. RNP is stable under harsh conditions and is not a substrate for RNAse inhibitors. We sought to characterize RNP HIV antiviral activity in the in vitro rectal explant challenge model.
Methods: Colorectal tissue biopsies were obtained from healthy, HIV uninfected volunteers (N=6). To determine the potential effectiveness of RNP on tissue based HIV infection, we incubated triplicate colorectal biopsies for 2 hours with $HIV\text{-}1_{Bal}$ in the presence of increasing concentrations of RNP (0-60 µg/mL). After washing, explants remained in culture for 14 days and cumulative p24 levels released into the supernatant were determined by Elisa (AlphaLisa, Perkin Elmer, Waltham MA). Supernatants from explants taken three days after HIV infection were assayed for biomarkers using the Meso Scale Discovery 30-Plex assay (Rockville, MD) for chemokines, cytokines, and proinflammatory agents.
Results: RNP inhibits p24 release in a dose dependent manner, with statistical significance occurring at 6 µg/mL ($p<0.05$) and 60 µg/mL ($p<0.01$). Of the 30 biomarkers measured, 14 demonstrated an RNP dose-dependent decrease vs infection alone, with dose-dependent defined as two or more consecutive doses demonstrating statistical significance ($p<0.05$). Affected biomarkers include the following members of the chemokine panel: IP-10, MDC, MIP-1β, IL-8 and TARC, the cytokine panel: IL-1α, IL12-p40, IL-7, IL-15 and IL-17, and the proinflammatory panel: IFNγ, IL-4, IL-13 and IL-1β.
Conclusions: RNP demonstrates dose-dependent efficacy in mitigating ex vivo HIV infection of colorectal explants, while remaining non-toxic to the tissues at the doses tested. In addition to treating HIV infection, RNP mitigates inflammatory changes associated with HIV infection. Further experiments are needed to determine whether RNP acts only directly on HIV or in addition through its immunomodulatory activity.

WEPEA0194

A comparison study of tenofovir alafenamide (TAF) plus emtricitabine (FTC) in solution and as nanoparticles (NPs) for pre-exposure prophylaxis (PrEP) in humanized BLT (hu-BLT) mice

S. Mandal[1], G. Kang[2], P. Prathipati[1], Z. Yuan[2], Y. Zhou[2], W. Fan[2], Q. Li[2], C. Destache[1]
[1]Creighton University, Pharmacy Practice, Omaha, United States, [2]University of Nebraska-Lincoln, Center for Virology, Lincoln, United States
Presenting author email: destache@creighton.edu

Background: The use of oral TAF+FTC has shown positive results for PrEP in a macaque model. However, when TAF+FTC was administered to uninfected women, tenofovir (TFV) + FTC drug levels were low or non-detectable in vaginal tissues. To resolve this issue, we encapsulated TAF+FTC into polymeric NPs and report here improved efficacy in hu-BLT mouse model of HIV-1 PrEP.
Methods: TAF+FTC powders were fabricated into a nanoformulation using an oil-in-water emulsion methodology. NPs were characterized for drug entrapment efficiency and size. Humanized bone marrow, liver, thymus (hu-BLT) mice with >50% human engraftment of peripheral blood by flow cytometry was randomized into control, solution (Sol), or NP dosing (n=5/group). Control animals received saline. TAF+FTC dosage (100 mg/kg) was administered SubQ and mice were vaginally challenged with two strains of HIV-1 (2.5×10^5 $TCID_{50}$). Challenge with HIV-1 occurred on day 4, 7, or 14 after NP administration and on day 4 for Sol and control groups. Plasma for viral load (pVL) was obtained every week starting 2 weeks post-challenge (PC) and determined by real-time PCR for 4 subsequent weeks. Euthanized mice will have organs harvested for in situ hybridization with p24 ribosomes. In parallel, humanized mice ($NSG\text{-}CD34^+$, n=3/time point) received 100 mg/kg NP formulation plasma and organs were harvested at 1, 2, 4, 7, 10, and 14 days post-NP administration for TFV drug levels using liquid chromatography-tandem mass spectrometry (LC-MS/MS).
Results: TAF+FTC NPs were 233 ±12.8 nm in diameter (n=5) and drug entrapment efficiency averaged 38% and 35%, respectively. Controls all became HIV-infected 14 days PC. Sol group became HIV-infected 21 days PC. TAF+FTC NP groups challenged at Days 4, 7, and 14 after SubQ NP administration became HIV-infected at rates of 40%, 60%, and 100%, respectively by day 42 PC ($p< 0.05$, Mantel-Cox test). Mean TNF vaginal tissue levels at 4, 7, and 14 days after NP injection was 140, 35, and 10 ng/mL, respectively.
Conclusions: TAF+FTC at 100 mg/kg as NP formulation produced significantly long-acting protection from HIV-1 compared to Sol. Higher doses of TAF+FTC NP may produce greater PrEP protection.

WEPEA0195

Bevirimat-like compounds overcome HIV resistance and target different infection steps

L.M. Bedoya del Olmo[1,2], H.E. De la Torre Tarazona[2], M. Beltrán[2], J. García-Pérez[2], O. Callies[3], I. López Bazzocchi[3], J. Alcamí[2]
[1]Universidad Complutense de Madrid, Pharmacology, Madrid, Spain, [2]INS, Centro Nacional de Microbiología. AIDS Immunopathology, Majadahonda, Spain, [3]Universidad de La Laguna, Instituto Universitario de Bio-Orgánica Antonio González, La Laguna, Spain
Presenting author email: erickdlt@isciii.es

Background: Antiretroviral therapy (ART) against HIV-1 encompasses at least two drugs with different targets on the viral replication cycle. ART intensification has been proposed as a strategy to eliminate infection but current antiretrovirals seems to be ineffective, and thus, new drugs should be developed. Bevirimat (BVM) was a first in class maturation inhibitor that failed to enter the market due to the presence of natural resistances.
In this work we study the antiviral effect of selected BVM-like compounds that have been developed with the aim of avoiding viral resistance.
Methods: Anti-HIV-1 activity was evaluated in vitro using a recombinant virus assay. Viral entry was assessed by infections with VSV pseudotyped HIV. Real time PCR was used for the quantification of total and integrated viral DNA. Cell transfection was used to evaluate transcriptional activity. Gag p24 viral protein was measured after transfection to evaluate the effect on HIV protease. Infectivity of new

virions was assessed by a maturation assay. Finally, inhibition of protease inhibitors and BVM resistant virus was evaluated.
Results: Compounds inhibited HIV infection with IC_{50}s values between 1 and 30 µM. Their effect was independent of viral entry since VSV pseudotyped HIV was inhibited with similar IC_{50}s. Compounds diminished the amount of viral DNA, suggesting the inhibition of viral reverse transcriptase but only one, lup-20(29)-en-28-ol-3-one, inhibited significantly proviral DNA integration. All of them inhibited viral transcription and p24 production after viral transfection. Compounds inhibited viral maturation even of BVM resistant viruses and they were active against BVM and protease inhibitors resistant viruses with similar IC_{50}s as wild-type strains.
Conclusions: BVM-like compounds were found to inhibit viral maturation also in BVM resistant viruses. Surprisingly, these compounds showed promiscuity of targets since they inhibited retrotranscription, integration, transcription and/or maturation. This behavior as multitarget drugs have been demonstrated to be effective in reducing the likelihood of drug resistance, drug-drug interactions and toxicities, as well as improving patient compliance. Therefore, this approach could help developing a new generation of anti-HIV agents.

WEPEA0196

Synthesis and properties of novel soluble bifunctional CD4-mimetic small molecules containing pyridine moiety

S. Harada[1], K. Konno[2], Y. Hikichi[1], S. Matsuoka[1], T. Matano[1,3], H. Tamamura[2], K. Yoshimura[1,3]
[1]National Institute of Infectious Diseases, AIDS Research Center, Shinjuku, Japan, [2]Tokyo Medical and Dental University, Institute of Biomaterials and Bioengineering, Bunkyo, Japan, [3]Kumamoto University, Center for AIDS Research, Kumamoto, Japan

Background: CD4 mimic small compounds (CD4MCs), NBD-556 and its analogues bind to the Phe43 cavity of gp120 and inhibit the gp120-CD4 interaction. CD4MCs can also induce conformational changes in the gp120 architecture thereby exposing masked epitopes of neutralizing antibodies (NAbs) on the Env protein and sensitizing infected cells to antibody-dependent cell-mediated cytotoxicity (ADCC) killing. In this study, we reported on the design, synthesis, and screening of a series of pyridine derivatives as potential novel soluble bifunctional CD4MCs, KKN series.
Methods: Twenty KKN compounds were designed and synthesized to improve water solubility and bioavailability using our previously reported method. A chimeric clone containing the primary KP-5mvcR virus isolate (subtype B, R5) gp160 within a pNL4-3 backbone was constructed. The susceptibility of the infectious clone to entry inhibition and neutralization sensitivity to the anti-cryptic V3 NAb KD-247, in the presence of the KKN compounds, was determined using the TZM-bl assay. The results were compared to those of the NBD-556 compound.
Results: We synthesized and tested 20 KKN compounds and found novel CD4MCs KKN-104, KKN-118, and KKN-134, which could inhibit the KP-5mvcR infection in IC_{50} values of 2.3, 3.0, and 2.1 µM, respectively. These compounds exhibited much higher solubility and markedly less cytotoxic than that of NBD-556. To investigate synergistic effect of these compounds and anti-cryptic V3 NAb KD-247, we calculated Combination Indexes (CIs) using the Chow and Talalay method. Combinations of KD-247 with NBD-556, KKN-104, KKN-118, or KKN-134 were highly synergistic, with CI values of 0.66, 0.87, 0.72, or 0.37, respectively. These results suggest that the KKN compounds render the primary HIV-1 sensitive to neutralization by NAbs directed against the V3 region involved in co-receptor binding, similar to the potent NBD-556.
Conclusions: In the present work, we designed, synthesized, and evaluated a series of novel soluble bifunctional CD4MCs containing pyridine moiety. Three compounds, KKN-104, KKN-118, or KKN-134 were strongly synergistic when combined with anti-cryptic V3 NAb KD-247. These findings indicate that KKN compounds might be useful in inhibiting HIV-1 infection not only by directly obstructing viral entry, but also enhancing sensitivity to NAbs.

Presenting author email: mirhaddad@gmail.com

Background: Apoptosis has been proposed as a key mechanism responsible for CD4 T cell depletion and immune dysfunction during HIV infection and associated with Aids pathogenesis. We demonstrated that a caspase inhibitor, inhibits spontaneous and activation-induced cell apoptosis of T cells from SIV-infected rhesus macaques (RMs).
Methods: Based on the pharmaco-toxicity and -kinetics of this compound in non-human primate, we performed an in vivo assay by administrating five injections of this drug during acute phase of infection. The therapeutic assay consisted of 20 infected monkeys, 10 of whom received the treatment.
Results: When administered during the acute phase of infection, this compound is associated with
(i) reduced levels of T cell apoptosis,
(ii) preservation of CD4/CD8 T cell ratio in lymphoid organs and in the gut,
(iii) maintenance of memory CD4 T cells, and
(iv) increased specific CD4 T cell response.
Although therapy was limited to the acute phase of infection, RMs showed lower levels of both plasma viremia and cell-associated SIV-DNA as compared to control SIV-infected RMs throughout the chronic phase of infection, and delayed the development of AIDS.
Conclusions: Overall our data demonstrate that injection of this compound in SIV-infected RMs may represent a novel adjunctive therapeutic agent to control HIV infection and delaying disease progression to AIDS.

WEPEA0198

Novel selection approaches to identify broadly neutralizing DARPins targeting the HIV-1 envelope protein

M. Gloegl[1], N. Friedrich[1], E. Stiegeler[1], T. Reinberg[2], J. Schäfer[2], A. Plückthun[2], A. Trkola[1]
[1]University of Zurich, Institute of Medical Virology, Zurich, Switzerland, [2]University of Zurich, Institute of Biochemistry, Zurich, Switzerland
Presenting author email: gloegl.matthias@virology.uzh.ch

Background: Broadly neutralizing antibodies (bnAbs) only evolve in a fraction of HIV-1 infected individuals. They have a unique potential to suppress viremia and inhibiting HIV-1 infection and are hence considered as blueprints for vaccine and therapeutics design. bnAbs recognize the HIV-1 Envelope (Env) proteins gp120 or gp41 within the context of the HIV-1 Env trimer rendering the trimer as major interest for HIV-1 vaccine research as target immunogen. Using the Designed Ankyrin Repeat Protein (DARPin) technology we recently generated broad and potent DARPins capable of targeting the membrane external proximal region (MPER) within gp41 and the variable loop 3 (V3) within gp120. The ~10-18kD sized DARPins binding to antigens of interest can be selected from high diversity (~10^{12}) libraries by ribosome display. The HIV-1 Env specific DARPins we isolated have exceptional breadth inhibiting up to 100% of tested HIV-1 strains and exceeding the breadth of bnAbs targeting the same epitopes. Differential recognition of the Env epitopes compared to the related bnAbs and an in part structure dependent binding mode make the Env DARPins highly interesting tools for immunogen characterization besides a use as antivirals.
Methods: To expand the DARPin toolbox we aimed in the current study to select DARPins targeting additional Env domains such as the variable regions 1 and 2 (V1V2). Using a range of stabilized, soluble Env trimers and Env derivatives including scaffold and chimeric envelope constructs presenting diverse V1V2 loops, we sought to yield DARPins targeting quaternary epitopes and/or the V1V2 loop.
Results: In total six different trimer-directed and eight V1V2 focused DARPin selections were conducted. From each obtained sub-library 200 clones were analyzed for specific Env binding and neutralization potential using a 5-virus panel. The screened libraries contained more than 90% Env binders and numerous novel broad and potently neutralizing DARPins that are currently characterized for epitope specificity.
Conclusions: Besides their potential as therapeutic agents by increasing the panel of broadly neutralizing DARPins we have gathered a valuable tool box for the characterization of neutralization sensitive epitopes that may aid in unraveling novel sites of vulnerability.

Background: It is known that triterpene derivatives such as IC9564 can inhibit human immunodeficiency virus type 1 (HIV-1) entry into the cells. Recently, by screening synthesized triterpene derivatives, we obtained a potent and low toxic, novel triterpene derivative OKS3-019. In the present study, to investigate the mechanisms for viral resistance to triterpene derivatives, we analyzed how HIV-1 can change to resist to previously-obtained IC9564 and newly-obtained OKS3-019, respectively.
Methods: Resistant variants were induced by culture of HIV-1 89.6-infected PM1 cells in the presence of triterpene derivative IC9564 or OKS3-019. We then constructed infectious 89.6 clones carrying mutations selected in the resistant variants. The susceptibility of the infectious clones to the two triterpene derivatives and anti-V3 neutralizing antibodies (NAbs) 447-52D and KD-247 was tested by TZM-bl assay.
Results: In the presence of IC9564, one mutation resulting in F522V substitution was first selected, followed by selection of H72Y mutation. In the presence of OKS3-019, one mutation resulting in R588K was first selected, followed by selection of V68I mutation. Both F522V and R588K are in the N-terminus of Env gp41, while both H72Y and V68I are in the C1 region of Env gp120. HIV-1 carrying both H72Y and F522V was highly resistant to the triterpenes, but single F522V or R588K mutation conferred only moderate resistance on viruses.
Unexpectedly, these triterpene derivative-resistant env variants exhibited higher sensitivity to anti-V3 NAbs 447-52D and KD-247 compared with the wild-type HIV-1 89.6.
Conclusions: In the present study of in vitro induction of triterpene-resistant variants, we found mutations in the region encoding the N-terminal gp41 that contribute to the resistance to triterpene derivatives. It can be speculated that gp41 modification by these mutations may induce structural rearrangements resulting in formation of the CD4-bound like conformation, thereby changing the accessibility of these compounds to the Env. These results provide valuable information for designing novel triterpene analogues inhibitory for HIV-1 infection.

New formulation of injectable and removable long-acting dolutegravir is effective in prevention of HIV transmission with high dose vaginal HIV challenges

M. Kovarova, S.R. Benhabbour, C. Sykes, A. Kashuba, J.V. Garcia-Martinez
University of North Carolina, Chapel Hill, United States
Presenting author email: kovarovm@med.unc.edu

Background: Oral pre-exposure prophylaxis (PrEP) is an effective prevention strategy for HIV transmission. Poor adherence decreases PrEP effectiveness. Injectable long-acting (LA) formulations of antiretrovirals (ARVs) represent a viable alternative. Currently available LA formulations cannot be removed. Here we describe a novel injectable in-situ forming implant (ISFI) formulation of dolutegravir (DTG) that:
1) Delivers drug for up to one year,
2) Can be safely removed and;
3) Efficiently prevents vaginal HIV transmission.
Methods: NSG mice (n=20) were used to assess the pharmacokinetic profile of DTG-ISFI in plasma using a validated LC/MS-MS method with a lower limit of quantification of 1 ng/mL. Highly relevant early passage and transmitted/founder viruses ($HIV_{JRC-SF, CH040, THRO}$) were used to 1) evaluate HIV suppression after acute infection, 2) the development of viral resistant mutations and 3) to evaluate protection against high dose repeated vaginal challenges using BLT mice. Statistical analysis was performed using Prism Software.
Results: With the objective of obtaining >30 day sustained release, an ISFI containing 6.5 micro grams of DTG was administered subcutaneously to NSG mice. Remarkably, this ISFI formulation resulted in sustained release of DTG for over 350 days. Importantly, removal of the DTG-ISFI resulted in fast clearance of the drug from plasma. Administration of the DTG-ISFI to accutely infected BLT mice resulted in a transient but statistically significant (1.5 log) reduction in plasma viral RNA levels. Viral rebound was associated with appearance of several amino acid substitution including the well characterized INSTI resistance R263K mutation. In the context of HIV prevention, administration of a single dose of DTG-ISFI resulted in significant protection from high dose vaginal challenges 1 and 7 weeks post ISFI administration (p=0.0128).
Conclusions: Subcutaneously administered DTG-ISFI in BLT mice resulted in sustained levels of DTG in plasma that are dramatically reduced after ISFI removal. The plasma concentration of DTG achieved (>4X IC50) were sufficient to effectively inhibit HIV replication and to prevent vaginal transmission after two high dose HIV challenges.

A novel NRTI, EFdA, effectively penetrates and suppresses HIV infection in all individual compartments of male genital tract

M. Kovarova, A. Wahl, S. Anderson, J.V. Garcia-Martinez
University of North Carolina, Chapel Hill, United States
Presenting author email: kovarovm@med.unc.edu

Background: Unprotected intercourse is the most common route of HIV transmission. Despite the success of antiretroviral therapy in suppressing plasma viremia to undetectable levels, HIV sheding persists in the semen from a subset of individuals. Thus, it is imperative to find more effective antiretroviral treatments that effectively suppress HIV in male genital tract (MGT) and prevent seminal HIV shedding. Here we evaluated a novel NRTI 4-ethynyl-2-fluoro-2-deoxyadenosine (EFdA) for suppression of HIV in MGT using a state-of-the-art animal model.
Methods: Reconstitution of MGT compartments of BLT mice including testes, epididymis, seminal vehicles, prostate and penis with human hematopoietic cells (CD4 and CD8 T cells, B cells and macrophages) was assessed by flow cytometry. To evaluate efficacy of EFdA at suppressing HIV infection in the MGT, infected BLT mice were treated orally once daily for 4 weeks. Levels of cell-associated HIV-RNA in the MGT compartments from suppressed BLT mice were analyzed by quantitative PCR and compared to animals not receiving treatment.
Results: All MGT compartments of BLT mice analyzed were reconstituted with human hematopoietic (CD45+) cells and CD4 and CD8 T cells as well as macrophages were readily and reproducibly detected. Cell-associated HIV-RNA was found in all MGT compartments of untreated BLT mice. Four-weeks treatment with EFdA resulted in dramatic reductions in the levels of cell-associated HIV-RNA in all MGT compartments.
Conclusions: BLT humanized mice are an excellent model for assessing HIV infection in all different compartments of the MGT. EFdA can effectively penetrate and suppress HIV replication in all MGT compartments. In current studies we are evaluating the pharmacokinetics of EFdA penetration and HIV suppression in the MGT.

Preclinical characterization of a potent D-peptide inhibitor of HIV entry: cholesterol-conjugated PIE12-trimer (CPT31)

J.N. Francis[1], Y. Nishimura[2], A. Smith[3], B. Welch[1], M. Martin[2], M. Kay[3]
[1]*Nav, Salt Lake City, United States,* [2]*NIAID, NIH, Bethesda, United States,* [3]*University of Utah, Salt Lake City, United States*
Presenting author email: bwelch@nvgn.com

Background: There remains an urgent need for new HIV entry inhibitors given the limited currently approved options. Mirror-image D-peptide inhibitors are protease-resistant and therefore have longer half-lives compared to natural L-peptides (e.g., Fuzeon). Our previously reported D-peptide HIV entry inhibitor, cholesterol-conjugated PIE12-trimer (CPT31) has exceptional potency due to its localization at membrane sites of viral fusion.
Methods: We characterized CPT31's pharmacokinetic properties in rats and NHPs using a sensitive and quantitative LC-MS bioanalytical assay on purified plasma samples. We characterized CPT31's inhibitory activity using TZM-BL reporter cells and an international panel of diverse primary isolates.
We used in vitro passaging studies coupled with deep sequencing to characterize the evolution of drug resistance.
Finally, the rhesus macaque model was used with SHIV-AD8 in prevention (single high-dose rectal challenge) and treatment protocols.
Results: CPT31 has potent and broad-spectrum inhibitory activity (IC_{50} < 1 nM in >90% of primary strains tested). CPT31 drug resistance is slow to develop during in vitro passaging studies and is mediated by mutations in the gp41 pocket residue Q577. Such mutations in isolation significantly hamper viral fitness. Subcutaneously administered CPT31 has a long terminal half-life in rats and NHPs (5.4 and 18 h, respectively). In a PrEP efficacy study, CPT31 dosed at 3.0 and 0.5 mg/kg/day fully protected 4 macaques, while 0.125 mg/kg/day was partially protective. As a therapy in animals with uncontrolled viremia, CPT31 rapidly induced a ~2-log drop in viral load. Virus rebound was also observed and attributed to resistance caused by Q577 mutations. In animals pre-treated with cART to achieve undetectable viremia, CPT31 monotherapy maintains viral suppression for >8 weeks.

Conclusions: CPT31's potent inhibition of diverse strains, strong resistance profile, and efficacy in NHP prevention and treatment models make it a promising preclinical HIV entry inhibitor candidate. Its long half-life and in vivo stability are ideal for sustained-release formulation (e.g., monthly or quarterly depot).

RNA-induced epigenetic silencing of HIV-1 involves actin regulators, Arp2 and Formin-like 1 protein

C. Ahlenstiel, J. Mitchell, V. Klemm, A.D. Kelleher
Kirby Institute, University of New South Wales, Sydney, Australia
Presenting author email: cahlenstiel@kirby.unsw.edu.au

Background: Antiretroviral therapy (ART) has revolutionized the treatment of HIV-1, however it does not cure the latent reservoir, which is a major barrier to eradication. An alternative to an eradication cure is a functional cure approach, whereby the virus reservoir is locked in latency through RNA-induced epigenetic silencing. We have previously reported the short-interfering RNA (siRNA), designated siPromA, which targets the HIV-1 5' long terminal repeat region, induces potent transcriptional gene silencing (TGS). The RNA interference (RNAi) machinery involved in this process is the RNA-induced Transcriptional Silencing (RITS) complex, comprising siRNA and Argonaute 1 (Ago1) protein. Our previous fixed cell microscopy studies identified filamentous actin (F-actin) as being associated with Ago1 in the RITS complex during TGS of HIV-1, however whether F-actin is directly linked to the trafficking of RITS remains unknown. This project aims to characterize the intracellular trafficking mechanism of RITS complex components in real time during TGS in HIV-1 infected cells and specifically the involvement of F-actin.
Methods: We employed advanced live cell imaging every 90 sec for 12 hr to capture HIV-1 infected HeLa T4+ cells, stably transduced with Ago1-GFP and mCherry-labelled F-actin-LifeAct, and transfected with AlexaFluor647-labelled siRNA, then screened several actin inhibitors for any effect on this process.
Results: Analysis of imaging data using arbitrary line intensity profiles and Pearson's correlation coefficient demonstrated significant nuclear co-localization and correlation of siPromA:Ago1-GFP (PCC=0.85±0.15; p=< 0.0001), compared to cytoplasmic co-localization of a scrambled siRNA control (PCC=0.31±0.3). Relative enrichment over time reported siPromA:Ago1-GFP signal intensity increased to a maximal level upon nuclear translocation compared to the siScrambled control, which showed a consistent signal intensity. Drug inhibition screens and subsequent knockdown studies of actin and actin-related proteins (Arps) revealed the actin nucleation and branching pathway to be essential for RITS complex nuclear translocation.
Conclusions: This study has identified the first known actin regulators, Arp2 and FMNL1 (formin-like 1), to be involved in RNA-induced TGS of HIV and may represent a conserved biological process.

WEPEA0205

Characterization of novel and potent U1 interference RNAs targeting the Gag open reading frame of HIV-1

O. Del Corpo[1,2], R. Scarborough[3], R. Goguen[3], A. Daher[1], A. Gatignol[1,2,3]

Presenting author email: olivier.delcorpo@mail.mcgill.ca

Background: HIV-1 replication is critically dependent upon a complex RNA splicing process, whereby over 40 different viral mRNA species are produced by alternative splicing. Assembly of the spliceosome begins with the recognition of splice donor sites by the complementary 5'-end of cellular U1 small nuclear RNAs (U1 RNAs). Recently, modified U1 RNAs, termed U1 interference RNAs (U1i RNAs), have been exploited to suppress HIV-1 production. Modifications of the 5'-end of U1 RNAs can redirect the molecule to specific target sites in HIV-1 RNA, where it can inhibit polyadenylation or induce excessive splicing of HIV-1 RNA transcripts. Our lab has identified novel and potent U1i RNAs targeting a conserved region in the Gag coding sequence of HIV-1 RNA.
Methods: We evaluated the therapeutic potential of our U1i RNAs and those previously designed targeting HIV, by measuring the production of HIV-1 in the culture supernatant of HEK293T cells co-transfected with an HIV-1 molecular clone (pNL4-3) and U1i RNAs. To identify the mechanisms of U1i RNAs targeting Gag, we compared their effects on HIV-1 RNA levels using Northern blots and on Gag processing by Western blots against HIV-1 capsid protein.
Results: U1i RNAs targeting Gag and those that induce excessive splicing were found to be the most potent, with half maximal effective concentrations (EC50s) ranging from 1 to 5 ng/ml, compared to those that inhibit polyadenylation, with EC50s of 50 ng/ml or greater. Like U1i RNAs that inhibit polyadenylation, U1i RNAs targeting Gag reduced RNA levels evenly, suggesting a global RNA inhibition. U1i RNAs targeting Gag were also found to inhibit processing of Gag, like U1i RNAs that induce excessive splicing. Our results suggest that U1i RNAs targeting Gag are acting through different mechanisms compared to previously described candidates and work is in progress to characterize their mechanism(s). We also found that U1i RNAs acting through any mechanism are more potent compared to ribozyme or decoy candidates and are comparable to short hairpin RNA candidates in development.
Conclusions: Overall, our results suggest that U1i RNAs are potent RNA interfering molecules that have the potential to be used in a gene therapy approach to cure HIV-1 infection.

A new highly sensitive retinoic acid-based viral outgrowth assay to detect replication-competent HIV reservoir

Y. Zhang[1,2], V. Wacleche[1,2], H. Chen[1,2], D. Planas[1,2], A. Gosselin[1,2], J.-P. Routy[3], P. Ancuta[1,2]
[1]Université de Montréal, Microbiology, Infectiology, and Immunology, Montreal, Canada, [2]CHUM-Research Centre, Montreal, Canada, [3]McGill University Health Centre-Glen Site, Montreal, Canada
Presenting author email: zhangyw927@gmail.com

Background: Current antiviral therapies (ART) successfully control viral replication in HIV infected subjects; however, the persistence of viral reservoir represents a major barrier for the cure. The development of HIV eradication strategies represents a major research priority. Sensitive assays are needed to assess the efficiency of such strategies.
Here we describe a modified viral out growth assay (VOA) that measures replication-competent viral reservoirs in low numbers of CD4+ T-cells.
Methods: CD4+ T-cells were isolated from PBMCs of HIV-infected individuals with undetectable plasma viral load under ART (HIV+ART). Quantification of integrated HIV-DNA was performed by ultrasensitive PCR. For the VOA, T-cells were stimulated with CD3/CD28 Abs for three days. To ensure optimal cell viability and viral cell-to-cell transmission, cells were split every three days. All-trans retinoic acid (ATRA) was added to facilitate viral reactivation and/or transmission. HIV reactivation was quantified by HIV-p24 ELISA in cell culture supernatants collected every three days and by flow cytometry analysis of intracellular HIV-p24 expression at day 12 post-culture.
Results: In the absence of ATRA, HIV reactivation was detected in CD4+ T-cells isolated from 8 out of 10 HIV+ART individuals. Levels of viral replication varied in different donors and did not correlate with integrated HIV-DNA levels ex vivo. This assay was highly reproducible and results from independent experiments were significantly correlated (r=0.96, p< 0.0001). Of particular importance, ATRA greatly increased and accelerated HIV reactivation efficacy in all donors tested, including those with undetectable HIV reactivation upon TCR triggering alone. The cost of this assay is estimated at 200$ per donor.
Conclusions: We described an easy, sensitive, and highly reproducible VOA that measures replication-competent HIV reservoirs in CD4+ T-cells of ART-treated individuals. This assay may be used to assess the efficiency of HIV eradication strategies and evaluate the risk of viral rebound upon treatment interruption.

WEPEA0207

The PPARγ antagonism inhibits HIV replication while restoring effector functions in Th17 cells

Y. Zhang[1,2], H. Chen[1,2], D. Planas[1,2], A. Gosselin[1,2], J.-P. Routy[3], P. Ancuta[1,2]
[1]Université de Montréal, Microbiology, Infectiology, and Immunology, Montreal, Canada, [2]CHUM-Research Centre, Montreal, Canada, [3]McGill University Health Centre-Glen Site, Montreal, Canada
Presenting author email: zhangyw927@gmail.com

Background: Mucosal Th17-polarized CD4+ T-cells are the first targets of HIV/SIV infection, with viral reservoirs persisting in long-lived Th17 cells during antiretroviral therapy (ART). Novel therapeutic strategies are needed for the normalisation of Th17 frequency/function toward mucosal immunity restoration in ART-treated individuals. PPARγ controls RORγt-mediated functions and HIV replication in Th17 cells. Here, we investigated the potential use of PPARγ agonism/antagonism for viral eradication and Th17 restoration during HIV infection.
Methods: Peripheral blood memory CD4+ T cells were isolated from HIV- and HIV+ on ART individuals using magnetic beads and stimulated with CD3/CD28 Abs. HIV- T-cells exposed to replication-competent or VSVG-pseudotyped HIV in vitro, as well as T-cells isolated from HIV+ on ART individuals, were cultured in the presence or absence of the PPARγ agonist Rosiglitazone (RGZ) or antagonist T0070907 for 12 days. HIV-p24 and IL-17A levels were quantified by ELISA and

FACS. HIV-DNA integration was quantified by real-time PCR. Gene expression was quantified by real time RT-PCR. The expression of HIV co-receptors CD4, CCR5 and CXCR4 was measured by FACS.
Results: RGZ decreased both HIV replication and IL-17A production. As predicted, T0070907 increased IL-17A production. Surprisingly, T0070907 also strongly inhibited HIV replication. T0070907 regulated HIV replication at multiple levels by reduction of CCR5 expression and HIV transcription, and alteration of lipid metabolism. The T0070907-mediated effects coincided with the induction of cholesterol-25-hydroxylase, an enzyme converting cholesterol into 25-hydroxycholesterol. Of note, 25-hydroxycholesterol is a broad inhibitor of viral infection and was recently identified as an intrinsic agonist of the Th17 master regulator RORγt. Finally, T0070907 inhibited HIV reactivation in a viral outgrowth assay and increased IL-17A production in CD4+ T cells from HIV+ on ART individuals.
Conclusions: We demonstrate that PPARγ antagonism reduces HIV replication in vitro as well as viral reactivation in CD4+ T-cell of HIV+ on ART individuals, while boosting the Th17 effector functions. These effects are mediated in part via the synthesis of 25-hydroxycholesterol. These findings open the path for future studies in animal models and human clinical trials to determine whether PPARγ is an appropriate target for viral eradication and Th17-mediated mucosal immunity restoration in HIV-infected individuals.

HIV-1-specific ADCC following anti-latency therapy and analytical treatment interruption

W.S. Lee[1], A.B. Kristensen[1], T.A. Rasmussen[2], M. Tolstrup[2], L. Østergaard[2], O.S. Søgaard[2], B.D. Wines[3], P.M. Hogarth[3], A. Reynaldi[4], M. Davenport[4], S. Emery[4], J. Amin[4], D. Cooper[4], V. Kan[5], J. Fox[6], H. Grüll[7], M.S. Parsons[1], S.J. Kent[1]
[1]The Peter Doherty Institute for Infection and Immunity, University of Melbourne, Microbiology and Immunology, Melbourne, Australia, [2]Aarhus University Hospital, Department of Infectious Diseases, Aarhus, Denmark, [3]Burnet Institute, Melbourne, Australia, [4]The Kirby Institute, University of New South Wales, Sydney, Australia, [5]Veterans Affairs Medical Center, Washington, United States, [6]St Thomas' Hospital, London, United Kingdom, [7]Center for Molecular Medicine Cologne, Cologne, Germany
Presenting author email: leews@student.unimelb.edu.au

Background: There is growing interest in utilising antibody-dependent cellular cytotoxicity (ADCC) to eliminate infected cells following latency reversal. A potential barrier is that HIV-1-specific ADCC antibodies decline in patients on long-term antiretroviral therapy (ART). It is unknown whether reactivation from latency with current anti-latency regimens could provide sufficient stimulus to boost HIV-1-specific ADCC. If current strategies are insufficient, we hypothesise that the recrudescence of virus after analytical treatment interruption (ATI) could provide larger antigenic stimulus to boost HIV-1-specific ADCC.
Methods: We analysed plasma samples from 14 subjects of the panobinostat trial, obtained pre- and post-panobinostat and after a short ATI (median 21 days). We also studied plasma from the SMART trial, from 30 subjects who underwent ATI for 12 months and 30 subjects who remained on ART. ADCC activity was measured in two ways:
(i) the binding of recombinant dimerised Fc gamma receptor (FcγRIIIa) to gp120-specific antibodies was used as a surrogate measure of Fc effector function,
(ii) infected cell elimination assays were performed to directly measure ADCC.
Results: Panobinostat or a short 21-day ATI did not increase HIV-specific ADCC, with no changes in FcγRIIIa-binding or ADCC killing. However, for the SMART trial subjects, there was a marked increase in FcγRIIIa-binding antibodies after 12 months of ATI [OD_{450}, baseline 0.331 (0.130-0.470) vs 12 months 0.908 (0.716-1.046), p< 0.0001] and a decrease in subjects who remained on ART [0.490 (0.181-0.750) vs 0.252 (0.097-0.740), p=0.04]. These findings were confirmed with significantly higher ADCC after 12 months of ATI [baseline, 14.4% (5.9-23.2%) vs 12 months 21% (17.5-26.9%), p=0.0002], as compared to the subjects who remained on ART [13.3% (11.8-16.5%) vs 15.7% (12.2-17.7%), p=ns]. Time course analyses showed that 90% of the subjects had increased ADCC antibodies by 2 months of ATI [OD_{450}, 0.331 (0.130-0.470) vs 0.678 (0.429-0.868), p=0.0014].
Conclusions: Our results show that low level viremia after panobinostat does not stimulate ADCC and there is a lag of several weeks between viral recrudescence and the stimulation of ADCC immunity after ATI. These data have implications for the antigenic stimulus required for anti-latency strategies or therapeutic vaccines to induce ADCC and assist in reducing the latent reservoir.

WEPEA0209

Sphingosine-1-phosphate receptor 1 agonists as HIV-1 latency reversing agents

S. Gimenez[1], B. Viala[1], C. Boulouis[1], A. Guigues[1], P. Corbeau[1,2], V. François[1]
[1]Institute of Human Genetics, CNRS, Montpellier University, UMR 9002, Montpellier, France, [2]University Hospital, Immunology Department, Nîmes, France
Presenting author email: pierre.corbeau@igh.cnrs.fr

Background: Various drugs are being tested to reactivate replication-competent HIV-1 in reservoir cells. Yet, many of these HIV-1 latency reversing agents (LRA) are toxic and/or poorly efficient in vivo. We have recently shown that S1P1, a receptor for sphingosine-1-phosphate (S1P), is a G-protein coupled receptor (GPCR) highly expressed in CD4+ T cells and able to dimerize with CCR5. Of note, we observed that S1P1 expression increased HIV-1 replication. Here we analyzed the mechanism responsible for this effect and tested S1P1 agonists as LRA.
Methods: Hela cells were transduced using HIV-1-derived vectors. HIV production was monitored by measuring gag p24 concentration in the culture supernatant. p65 NFkB nuclear translocation was monitored by immunofluorescence. Luciferase activity was quantified using a commercial kit.
Results: In Hela cells stably transfected with a luciferase gene driven by HIV-1 LTR, S1P1 but not LacZ transduction induced luciferase production. This effect was further increased in the presence of the S1P1 agonist SEW2871, indicating that S1P1 signaling results in LTR activation. Transfection of a luciferase gene driven by a wild-type LTR, but not by an NFkB binding site-deleted LTR, into Hela cells transduced with S1P1 induced luciferase production, indicating that NFkB is involved in this phenomenon. Accordingly, S1P1 expression in MT4 cells activated p65 NFkB, and increased the production of an X4 HIV-1 strain, as long as the LTR of this strain contained intact NFkB binding sites.
Finally, S1P1 and SEW2871 induced HIV-1 production by peripheral blood and lymph node mononuclear cells latently infected in vitro (112 ± 94 and 26 ± 21 pg of p24/mL produced by PBMC after 9 days in presence or absence of SEW2871, respectively, p = 0.027).
Conclusions: S1P1 activation, induced by the presence of S1P in the culture medium and reinforced by S1P1 agonists, induces HIV-1 genome expression via NFkB activation. The effect of S1P1 agonists need to be further tested ex vivo on HIV-1 reservoir cells and in combination with other LRA, inasmuch as the S1P1 ligand FTY720 is already used in multiple sclerosis. We have identified two other GPCR presenting with the same characteristics.

WEPEA0210

Monocyte co-culture can reverse pre-activation but not post-activation latency

S.D. Rezaei, H.K. Lu, A. Rhodes, R.M. Van der Sluis, S.R. Lewin, P.U. Cameron
The Peter Doherty institute, Microbiology and Immunology, Melbourne, Australia
Presenting author email: simin.rezaei@unimelb.edu.au

Background: The "Shock and kill" strategy aims to activate and eliminate latently infected cells, but not all intact latent viruses are induced, even with potent mitogen or T-cell receptor stimulation. T-cell activation and virus expression from latency may not be directly linked and other stimuli required to activate HIV expression. We hypothesized that responses to latency-reversing agents (LRA) depend on how latency is established and tested virus activation in two models of HIV latency.
Methods: Latency was established in primary CD4+ T-cells using X4 tropic, nef-competent, enhanced green fluorescent protein (EGFP)virus following 1] direct infection of CCL19-treated resting CD4 (pre-activation latency) and 2] infection of naïve T-cells activated with antiCD3/28 (post-activation latency). EGFP-negative cells were sorted 5-7d post-infection and stimulated for 72hrs with Dimethyl sulfoxide (DMSO), allogeneic monocytes (mo, at a ratio of 1:10 to T-cells) +/- antiCD3 (20µg/ml), antiCD3/28 and other LRAs. EGFP expression and T-cell proliferation using cell proliferation dye were measured by flow cytometry. Wilcoxon matched pairs signed-rank test was used for comparisons.
Results: At 5-7d post-infection there were more productively infected cells (EGFP+ cells) in the post-activation compared to pre-activation model (74 and 144 EGFP+/10^4 cells, p< 0.0001, n=8). In the pre-activation latency model, EGFP expression was induced from latency following stimulation with mo/antiCD3 and antiCD3/28 compared to DMSO (43, 22 and 3 EGFP+ cells/10^4 cells respectively, p< 0.001). In the post-activation latency model, the addition of antiCD3/28 but not mo/antiCD3 increased the mean number of EGFP+ cells compared to DMSO (145, 15, 22 EGFP+ cells/10^4 cells respectively, p< 0.001). The magnitude of EGFP expression post-stimulation correlated with T-cell proliferation in the pre-activation latency (r=0.34, p=0.003) but not the post-activation latency model (r=0.05, p=0.72). Following LRA (panobinostat, romidepsin, JQ1) stimulation, an increase in EGFP expression compared to DMSO was observed in the pre-activation latency model (8, 16, 6 and 3 EGFP+ cells/ 10^4 live cells respectively, p< 0.01, n=4-5, paired student t-Test).

Conclusions: Multiple stimuli can reverse latency in a pre-activation model of latency, which differs from a post-activation latency model. The pathway by which latency is established is linked to the efficacy of specific latency reversal strategies.

Presenting author email: smguillen@salud.madrid.org

Background: We have shown that maraviroc (MVC) reactivates latent HIV-1 in resting CD4+ T cells in patients who received 10 days MVC, added to a stable antiretroviral regimen, through activation of NF-kB. To elucidate the mechanism of NF-kB activation by MVC, we have evaluated in an in vitro model if MVC could be acting as a partial CCR5-agonist, with no other mechanisms or pathways involved.
Methods: We used HeLa P4C5 cells, which stably express CCR5. Cells were seeded for 2, 6, 12, 24 and 48h in the absence or presence of MVC (5, 10, 20 and 40mM). NF-kB activation was detected by ELISA. The functionality of NF-kB was analysed by measuring the differential target gene expression by real-time PCR. As controls, we used TAK-779, a CCR5 antagonist, and PMA, a positive control of NF-kB activation. To check if the activation of the NF-kB signalling pathway is due to the binding of MVC to CCR5, HeLa cells, which do not express CCR5, were treated with MVC.
Results: NF-kB activation was observed after 2 and 6h of MVC treatment at all the concentrations tested in HeLa P4C5. We did not detect activation of NF-kB at 12, 24 and 48h at any of the concentrations included. The greatest increase in NF-kB activation levels was observed in the presence of MVC in HeLa P4C5 at 2h, with the maximum peak being induced with 5mM MVC. This significant increase in NF-kB was also observed at 6h in the presence of 5mM MVC. NF-kB activation was not detected in the presence of TAK-779. No activation of NF-kB was found in HeLa at any of the concentrations and times tested, with the exception of PMA. The expression of the target genes was in agreement with the activation observed in NF-kB.
Conclusions: This in vitro study suggests that MVC-induced latency reversal of HIV-1 is mediated by MVC binding to CCR5, acting as a partial agonist, and the subsequent downstream signalling. Taking altogether, the information from the previous clinical trials and this confirmatory mechanistic in vitro study provides a strong background for MVC to be used as a latency reversal agent.

WEPEA0212

Antiretroviral drug transporters and metabolic enzymes expressed in the testes could potentially contribute to low tissue drug concentrations and HIV-1 persistence

S.-K. Whyte-Allman[1], Y. Huang[1], M.T. Hoque[1], M.-A. Jenabian[2], V. Kishanda[3], N. Sheenan[4], P. Brassard[5], M. Belanger[5], N. Chomont[6], C. Fletcher[7], J.-P. Routy[3], R. Bendayan[1], The Orchid Study Group

Presenting author email: r.bendayan@utoronto.ca

Background: Human immunodeficiency virus (HIV-1) is capable of persistent infection in the testis, where inadequate ARV penetration could be due in part to the functional expression of drug efflux transporters at the blood-testis barrier (BTB). In this study, we characterized the expression and localization of drug transporters and metabolic enzymes in human testes and quantify antiretroviral drug (ARV) concentrations in HIV-infected testicular tissue. Since ligand-activated transcription factors (i.e., nuclear receptors) are known to induce the functional expression of drug transporters and metabolic enzymes in various tissues, we also investigated the regulation of ATP-binding cassette (ABC) efflux transporters expressed at the BTB by pregnane X receptor (PXR) and constitutive androstane receptor (CAR).
Methods: mRNA and protein expression of the ABC and solute carrier (SLC) transporters, CYP450 metabolic enzymes, and nuclear receptors were evaluated in testicular tissue obtained during gender reassignment surgery from uninfected (n=8) and HIV-1 infected (n=5) individuals on ARV therapy, by qPCR analysis and western blotting respectively. Localization of transporters and metabolic enzymes was determined by confocal microscopy. ARV concentrations in testicular tissue or plasma were quantified by LCMS/MS. TM4 Sertoli cells, a continuous cell line representing the mouse BTB, were exposed to nuclear receptor ligands and targeting siRNA. The mRNA and protein levels of efflux transporters were quantified in these cells to determine their regulation.
Results: Expression and localization of ABC (P-gp, BCRP, MRPs) and SLC (OATP, OAT, OCT, CNT, ENT) transporters, as well as CYP3A4 and CYP2D6 were confirmed in human testes. Several ARVs that are known substrates for ABC transporters displayed low testicular tissue concentration. Nuclear receptors, PXR and CAR, were also expressed in human testicular tissue and TM4 mouse Sertoli cells and mediated the induction of P-gp, BCRP and MRP4 at the BTB.
Conclusions: Our findings suggest that drug transporters, metabolic enzymes and nuclear receptors involved in ARV disposition are present in the testes, and could limit ARV tissue penetration in HIV-1 infected individuals; this could potentially contribute to persistent HIV-1 infection and formation of a viral sanctuary in this tissue.

Blood CXCR3+ CD4 T cells are enriched in inducible replication competent HIV

R. Banga[1], F. Procopio[1], M. Cavassini[2], G. Pantaleo[1,3], M. Perreau[1]
[1]Lausanne University Hospital, Lausanne, Switzerland, [2]Lausanne University Hospital, Infectious Diseases, Lausanne, Switzerland, [3]Swiss Vaccine Research Institute, Lausanne, Switzerland
Presenting author email: riddhima.banga@chuv.ch

Background: We recently demonstrated that Lymph node (LN) PD-1+/T follicular helper (Tfh) cells from anti-retroviral therapy (ART) treated HIV-infected individuals were enriched in cells containing replication competent virus. However, the distribution of cells containing inducible replication competent virus has been only partially elucidated in blood memory CD4 T-cell populations.
Methods: We have investigated the distribution of 1) total HIV-1 infected cells by Alu PCR and 2) cells containing replication competent HIV using virus outgrowth assay (VOA) within blood memory CD4 T-cell populations defined by chemokine receptor expression i.e CXCR3+CXCR5- (Th1), CXCR3-CXCR5+ (cTfh), CXCR3+CXCR5+ (Th1 cTfh), CCR4+CCR6- (Th2), and CCR4+CCR6+ (Th17) cells in ART treated (0.1-8.2 years) aviremic (< 20 HIV RNA copies/ml) individuals (N=15).
Results: No significant differences in the frequency of integrated HIV DNA in the different memory CD4 T-cell populations were found (P>0.05) However, Th1 cells were significantly enriched in cells containing replication competent virus as compared to any other blood CD4 T-cell population (P< 0.05). The mean frequency of Th1 cells containing inducible replication competent virus was about 13 cells per million as assessed by RNA-Unit Per Million. Blood Th1 cells were also the largest contributor (54%) to the total pool of blood HIV-infected cells containing replication competent virus in the cohort. Interestingly, the fraction of HIV provirus induced by VOA was higher in Th1 cells as compared to any other blood CD4 T-cell subpopulations, suggesting that Th1 cells contained either more intact or more inducible provirus. Of note, blood CD4 T-cell populations were not significantly different in terms of
1) level of activation as assessed by HLA-DR or Ki-67 expression,
2) CCR5 and CXCR4 HIV co-receptor expression and
3) SAMHD1 HIV restriction factor expression (P>0.05).
However, both Th1 and cTfh cells were significantly enriched in PD-1 expressing cells as compared to Th2 and Th17 (46% and 42%, respectively) (P< 0.05), but only the levels of HIV RNA of Th1 VOA culture supernatants directly correlated with the frequency of PD-1 expression on Th1 cells (P< 0.05).
Conclusions: Taken together, these results indicate that blood Th1 cells represent the major blood compartment containing inducible replication competent virus in treated aviremic HIV-infected individuals.

Latency reversing agents induce differential responses in distinct memory CD4+ T cell subsets in virally suppressed individuals

M. Pardons, R. Fromentin, A. Pagliuzza, N. Chomont
Centre de Recherche du CHUM and Université de Montréal, Department of Microbiology, Infectiology and Immunology, Montreal, Canada
Presenting author email: remi.fromentin@umontreal.ca

Background: HIV primarily persists in three subsets of memory CD4+ T cells [central (Tcm), transitional (Ttm) and effector (Tem) cells]. Given their functional differences, we hypothesized that HIV latency results from different mechanisms in these three memory subsets and that distinct reactivation strategies might be needed to simultaneously reactivate latent HIV in all cellular reservoirs.
Methods: Histone acetylation (H3K9, H4K5/8/12/16), active NF-κB (pS529), and active P-TEFb (pS175 CDK9) were measured by flow cytometry in Tcm, Ttm and Tem from virally suppressed individuals. We tested the ability of latency reversing agents (HDACi, NF-κB inducers, P-TEFb inducers) at modulating these factors in each subset. HDACi uptake in all the subsets was assessed by LC-MS/MS analysis.
Results: Baseline levels of acetylated H4 were higher in Tem ($p<0.05$) when compared to Tcm and Ttm, whereas no significant differences in baseline levels of acetylated H3 were noted. pNF-κB levels were maximal in Tcm and decreased with the differentiation stage (Tcm>Ttm>Tem, $p<0.05$), whereas baseline pCDK9 levels tended to be higher in Ttm.
Dose responses with a panel of LRAs revealed that vorinostat was more potent at acetylating histones in Tcm than in Tem (median EC50 for H3 and H4: 534 VS 938nM and 502 VS 955nM, respectively), whereas romidepsin was more potent at acetylating histones in Tem than in Tcm (median EC50 for H3 and H4: 15,6 VS 8,6nM and 11,3 VS 7,6nM; respectively).
Of note, HDACi uptake was similar between the subsets. Fold increases at the top plateau showed that NF-κB inducers (bryostatin, prostratin, ingenol) increased NF-κB phosphorylation with a higher efficacy in Tcm ($p\leq0.0002$ for all inducers). P-TEFb inducers (JQ-1, I-BET) had no significant effect on CDK9 phosphorylation, while bryostatin and ingenol readily induced CDK9 phosphorylation, particularly in Tem.
Conclusions: Our results indicate that the baseline levels of cellular factors involved in HIV latency differ between the memory CD4+ T cell subsets that serve as reservoirs for HIV during ART. Importantly, LRAs exert different activities in distinct cellular reservoirs, suggesting that their anti-latency activities may be subset-restricted.

A novel strategy to circumvent cytokine release associated with HIV latency reversal

A. Spivak[1], E. Larragoite[1], M. Coletti[1], A. Macedo[2], L. Martins[1], A. Bosque[2], V. Planelles[1]

Background: Antiretroviral therapy (ART) does not cure HIV-1 infection due to the persistence of replication-competent proviruses in long-lived resting T cells. Strategies to target these latently infected cells will be necessary to eradicate HIV-1 in infected individuals. Protein kinase C (PKC) activation is a promising pathway to reactivate latent proviruses and allow for recognition and clearance of infected cells by the immune system. Ingenol derivatives are PKC agonists that reliably induce latency reversal ex vivo. PKC agonists, including ingenols, can induce pro-inflammatory cytokine release and T cell activation. These undesirable properties have precluded consideration of PKC agonists as candidate latency reversal agents to date.
We hypothesized that a kinase inhibitor combined with an ingenol compound could decrease PKC-induced pro-inflammatory cytokine release without affecting latency reversal. This strategy could allow PKC agonists, including ingenol compounds, to be safely tested in pilot HIV-1 eradication trials.
Methods: We performed an in vitro screen of kinase inhibitors to identify compounds that could decrease pro-inflammatory cytokine release induced by ingenol derivatives. Hits were defined as compounds that reduced interleukin-6 (IL-6) by four-fold or greater without altering cell viability compared to cells exposed to ingenol alone. We subsequently tested one screening hit, the FDA-approved Janus Kinase (JAK) inhibitor ruxolitinib, with regard to cytokine release and latency reversal in the presence of ingenol compounds using cells obtained from HIV-positive participants ex vivo.
Results: Kinase inhibitor screening identified several candidate hits that attenuated ingenol-induced IL-6 release. Ex vivo exposure to ruxolitinib, a selective inhibitor of JAK1 and 2, significantly reduced release of pro-inflammatory cytokines but did not impair latency reversal induced by ingenol-3,20-dibenzoate in cells from HIV-1 positive donors on ART. In addition, Ruxolitinib did not induce T cell activation or apoptosis.
Conclusions: Ingenol-3,20-dibenzoate reactivates latent HIV-1 to levels similar to positive control (T cell receptor stimulation) and induces release of pro-inflammatory cytokines ex vivo. Ruxolitinib, an FDA-approved JAK inhibitor, reduced pro-inflammatory cytokine release by >90% but did not diminish latency reversal induced by ingenol. PKC activation combined with JAK inhibition represents a novel HIV-1 eradication strategy that merits in vivo evaluation.

Presenting author email: charline.souffan@gmail.com

Background: HIV persistence during antiretroviral therapy (ART) is predictably dependent upon the relative turnover of CD4+ T cell subpopulations harboring HIV genomes. We present here an analysis of the in vivo turnover and HIV content of various CD4+ T cell subpopulations as a function of the time of initiation and duration of suppressive ART.
Methods: We enrolled 24 participants treated either within 3 months or after 12 months of infection and for <3 years or >7 years. Using established labelling techniques, we measured CD4+ T cell turnover based on in vivo incorporation of deuterium into genomic DNA in sort-purified HLADR-negative CD4 T naïve (TN), stem-cell memory (TSCM), central-memory (TCM), transitional-memory (TTM), effector-memory (TEM), and effector (TEMRA) cells, after oral administration of deuterated water. We also quantified integrated HIV-DNA (Int-DNA) and cell-associated HIV-RNA (caRNA).
Results: Overall, the half-life of CD4+ T-cell subpopulations decreased significantly with increasing maturation status ($p<0.04$), except for TEMRA. A shorter cellular half-life was associated with higher levels of Int-DNA and caRNA content ($r=-0.53$, $p<0.0001$), with enrichment of virus in shorter-lived subpopulations, e.g., TEM, TTM, and TCM ($p<0.019$). Compared to delayed ART, early ART initiation was associated with longer half-lives for TSCM, TCM, TTM, and TEM and decreased Int-DNA levels within TTM ($p<0.037$). Long-term ART was associated with a longer half-life and lower levels of Int-DNA within TTM ($p<0.033$), and a lower relative contribution of infected TSCM and TEMRA to the total HIV reservoir ($p<0.038$), compared to short-term ART.
Conclusions: We conclude that HIV persistence in CD4+ T cells can be maintained within two subpopulations with markedly different characteristics: most of the reservoir is composed of relatively short-lived differentiated cells that proliferate at a high rate while a smaller portion persists within less-differentiated cells that survive for longer periods of time. Notably, long-term maintenance of early ART is associated with a lower contribution to the reservoir load within these latter long-lived subpopulations, and may accordingly favor interventions to eradicate HIV.

Median [IQR] for all 24 participants	TN	TSCM	TCM	TTM	TEM	TEMRA
Half-life (days)	933 [715-1181]	157 [129-196]	128 [104-147]	100 [94-126]	88 [71-127]	249 [207-300]
Integrated HIV DNA (copies/million cells)	28 [8-145]	161 [42-420]	290 [66-1343]	770 [154-2510]	838 [257-3029]	205 [32-973]
Contribution to the reservoir (%)	5 [2-16]	0.6 [0.3-1.3]	34 [17-46]	27 [17-33]	20 [10-28]	2 [1-7]
Cell-associated HIV RNA (copies/million cells)	29 [12-105]	183 [60-578]	590 [91-2533]	1313 [159-4124]	2729 [222-4871]	644 [98-3992]

Presenting author email: huang61288@gmail.com

Background: Primary-cell models of HIV latency are often used in HIV cure studies. However, these models may not reflect the full complexity of natural viral reservoirs. Here, we investigate whether the "shock-and-kill" paradigm (utilizing immune effectors, in combination with latency-reversing agents (LRAs)), can drive reductions in natural HIV reservoirs. CD4+ T-cells, from HIV+ donors on long-term ART, were treated with LRAs and autologous HIV-specific CTL clones targeting non-escaped epitopes, then assessed for decreases in total and inducible provirus.
Methods: HIV-specific CTL clones targeting known HIV epitopes were isolated from ARV-treated subjects by limiting dilution; killing activities were confirmed by flow cytometric assays. We tested the abilities of these CTLs to reduce viral reservoirs in an HIV eradication assay, using the following LRAs and immunotherapeutics either singly or in combination: HDACi's, bryostatin, JQ1, IL-15SA, Pam$_3$CSK$_4$, anti-PD-1, anti-hTim3, or PMA/Ionomycin. Resting CD4+ T-cells were co-cultured with LRAs and CTLs for 4 days with ARVs, then isolated and assessed for activation/memory phenotypes, and measured for cell-associated HIV DNA (ddPCR) and inducible HIV by quantitative viral outgrowth assay (QVOA).
Results: Most combinations of LRAs with HIV-specific CTL saw significant decreases in cell-associated HIV DNA, with PMA/Ionomycin or bryostatin treated conditions achieving the greatest effects (up to 50% reductions, p< 0.01). Critically, reductions in HIV DNA were not reflected by measurable reductions of inducible virus, regardless of the CTL/LRA combination used (powered to detect >2-fold reductions with 95% confidence). CTL combinations with PMA/ionomycin, also failed to deplete the viral reservoir. Additionally, CTLs degranulated (CD107a) in response to autologous activated CD4+ T-cells that were infected with virus from positive QVOA wells, ruling out a role for immune escape.
Conclusions: This HIV eradication assay utilizes highly functional CTLs that target non-escaped epitopes, and overcomes latency with potent combinations of LRAs and immunotherapeutics. Even after maximal activation with PMA/Ionomycin, CTLs failed to reduce the viral reservoir. These data suggest the existence of additional, previously unknown, barriers to CTL-mediated reservoir elimination. Our recent experiments indicate that Nef-mediated downregulation of MHC-I, may limit CTL action against the intact-inducible reservoir. Discerning and solving these novel barriers is key to successful shock-and-kill interventions.

[1]Instituto de Salud Carlos III, AIDS Immunopathology Unit, Madrid, Spain, [2]Universidad Complutense de Madrid, Pharmacology Department, Madrid, Spain, [3]Centre National de la Recherche Scientifique, Institut de Chimie des Substances Naturelles, Paris, France, [4]University of Corsica, Laboratoire de Chimie de Produits Naturels, Corte, France
Presenting author email: erick2388@hotmail.com

Background: Antiretroviral therapy (ART) cannot eliminate HIV infection due to the persistence of HIV in latently infected cells in the blood and lymphoid organs. Viral reactivation has been proposed as ART adjuvant therapy to eradicate viral reservoirs. To achieve this goal, a new generation of drugs termed "Latency Reversal Agents" (LRA) displaying high potency and low toxicity is needed.
Methods: Anti-HIV-1 and LRA activity of 4-deoxyphorbols were evaluated in vitro in MT-2 cells and human PBMCs using a recombinant virus assay. Receptor expression was evaluated by single-, double- or three-color immunophenotyping in a FACScalibur flow cytometer. HIV reservoir reactivation activity was evaluated in a resting PBMCs based latency model. Pathways involved in the mechanism of action of 4dPE-A were studied by pharmacological inhibition of different isoforms of PKCs and MEK kinases and SAMHD1 phosphorylation was assessed by western blot.
Results: In an initial screening of 4-deoxyphorbols one of them, 4dPE-A, showed the strongest antiviral activity with an IC_{50} of 3 nM in infection with X4-tropic HIV-1 in MT-2 cells and 0.3/0.2 nM in infections with X4/R5 tropic HIV-1 in IL-2 preactivated PBMCs. Specificity index was >10000, and no long-term toxicity was observed in PBMCs even 2 weeks after treatment. The compound was active at different steps of the HIV cycle:
(1) 4dPE-A induced the internalization of CD4, CXCR4 and/or CCR5 lymphocyte receptors and this activity was independent of PKCs and MEK.
(2) As, LRA 4dPE-A was able to trigger NF-kB activity and viral transcription in HIV-1 transfected MT-2 cells and PBMCs at concentrations as low as 10nM. This activity was strongly dependent on the activation of PCK-theta isoform and MEK and thus, different pathways would be involved in 4dPE-A action.
(3) Finally, 4dPE-A induced SAMHD1 phosphorylation in resting PBMCs.
Conclusions: 4dPE-A is a novel compound with a potent dual activity in the HIV replication cycle, both as a viral entry inhibitor and viral reservoir reactivator. 4dPE-A represents a LRA candidate that could be further developed as ART adjuvants to achieve a functional cure in HIV-1 infected people.

Stress increases HIV transcription in HIV-infected individuals on antiretroviral therapy: implications for biomarkers of HIV persistence

R. Hecht[1], P. Moran[1], W. Mendes[1], L. Cockerham[2], W. Hartogenesis[1], P. Bacchetti[1], J. Chang[3], P. Cameron[3,4], S. Deeks[1], S. Lewin[3,4]
[1]University of California, San Francisco, United States, [2]Medical College of Wisconsin, Milwaukee, United States, [3]The University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [4]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia
Presenting author email: sharon.lewin@unimelb.edu.au

Background: Cell-associated unspliced (CA-US) HIV RNA is a measure of transcriptionally active cells and is an important biomarker for quantifying the efficacy of latency reversing agents (LRAs). We recently observed that CA-US RNA levels may vary due to stress, circadian rhythms, or both. We performed an experimental clinical study aimed at defining the impact of stress on HIV RNA production in individuals on antiretroviral therapy (ART).
Methods: Participants were on ART with plasma HIV RNA < 50 copies/ml for > 3 years. All participants underwent a Trier Social Stress Test (TSST), a procedure in which participants are asked to give a speech and perform a math task before an audience that provides no positive verbal or non-verbal feedback. On the TSST day, we obtained blood before and 30 and 65 minutes after the stress tasks. Salivary cortisol was also quantified. We used physiological monitoring to measure autonomous nervous system activity:
(1) respiratory sinus arrhythmia (RSA), a measure of parasympathetic activity, with lower values indicating less parasympathetic tone; and
(2) pre-ejection period (PEP) for sympathetic activity, with lower numbers indicating greater sympathetic tone. On a control day in the absence of the TSST, the identical tests were performed.
Results: Mean cortisol levels immediately post-stressor were 9.63 nmol/L on the TSST day and 4.87 on the control day (n=25; P=0.0003), and RSA and PEP both declined significantly during the stress tasks. There was an estimated 1.49-fold increase in CA-US RNA at the TSST visit relative to the control day (95%CI: 1.15 to 1.93-fold increase, p=0.002). HIV DNA did not change significantly. Decreases in PEP predicted increased CA-US HIV RNA during the TSST (rho=-0.59, P=0.002).
Conclusions: Psychological stress induces an increase in CA-US HIV RNA in a range that would be considered significant in clinical trials of LRAs and needs to be considered in clinical study design. The increase is likely to be related to sympathetic nervous system enhancement of HIV transcription, which is consistent with prior data indicating sympathetic activation may enhance HIV replication. Further understanding of the mechanisms involved may reveal new targets for inducing the latent HIV reservoir.

HIV-1 Nef blockade improves the immune recognition and clearance of primary latently HIV-1-infected CD4 T cells by autologous CD8 T cells

S. Mujib[1], A. Saiyed[2], S. Fadel[2], A. Bozorgzad[2], N. Aidarus[2], E. Yue[2], E. Benko[3], C. Kovacs[2,3], T. Smithgall[4], L. Emert-Sedlak[4], M. Ostrowski[1,2,5]
[1]University of Toronto, IMS, Toronto, Canada, [2]University of Toronto, Medicine, Toronto, Canada, [3]Maple Leaf Medical Clinic, Toronto, Canada, [4]University of Pittsburgh, Microbiology and Molecular Genetics, Pittsburgh, United States, [5]St. Michael's Hospital, Keenan Research Centre for Biomedical Science, Toronto, Canada
Presenting author email: shariqm@gmail.com

Background: Eradication of the HIV-1 latent reservoir represents the current obstacle towards the development of a cure for AIDS. Latently infected cells persist by effectively evading HIV-specific CD8 T cells that are critical for control of HIV-1 infection. One strategy employed by the virus to promote immune evasion from CD8 T cells is the downregulation of MHC-I from the surface of infected cells mediated by the HIV-1 Nef protein. Indeed, Nef transcripts and protein are detectable in the PBMCs of individuals on suppressive HAART indicating that Nef expression in latently infected cells plays a key role in viral persistence. Thus, we hypothesized that Nef blockade would restore optimal CD8 T cell mediated immune surveillance and result in the elimination of latently infected CD4 T cells.
Methods: In a proof-of-concept study, we have tested a single dose of four recently characterized small molecule inhibitors of HIV-1 Nef: DQBS (diaminoquinoxaline benzenesulfonamide), B9 (diphenylpyrazolyldiazene scaffold) and next-gen B9 analogs JZ-96-21 and JZ-97-21, in an in vitro primary CD4 T cell latency model. We cocultured Nef inhibitor treated latently infected CD4 T cells with autologous HIV-peptide expanded CD8 T cells and measured CD8 T cells' ability towards immune recognition and elimination of latently infected targets
Results: Three out of four compounds significantly enhanced the recognition of latently infected CD4 T cells by autologous CD8 T cells ($p < 0.05$) relative to control in an IFN-γ release assay. Importantly, Nef blockade by each of the inhibitors facilitated significantly greater elimination of latently HIV-1 infected CD4 T cells by HIV-peptide expanded CD8 T cells ($p < 0.05$) as measured by viral outgrowth assays quantitating HIV-Gag p24 via ELISA and flow cytometry following coculture.
Conclusions: We demonstrate for the first time, using primary T cells, that Nef blockade, in combination with HIV-specific CD8 T cell expansion, might be a feasible strategy to target and eradicate the HIV-1 latent reservoir. Our study sets the precedent to test Nef inhibitors for future in vivo studies geared towards a cure.

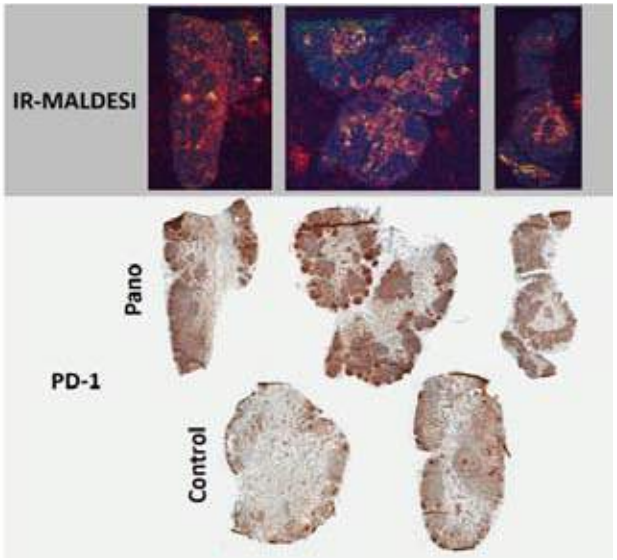
Presenting author email: eli@unc.edu

Background: Panobinostat (Pano), a potent HDAC inhibitor, may act as a latency reversing agent within tissue reservoirs. We have characterized the spatial distribution of Pano in RT-SHIV+ rhesus macaques (RM) receiving HAART to evaluate penetration into key tissues using a novel approach to mass spectrometry imaging (MSI).
Methods: 3 RT-SHIV+ RM were administered 44-weeks of HAART with biweekly Pano (0.667 mg/kg (n=2) and 2.0 mg/kg (n=1) for 3 weeks prior to necropsy. 2 control animals on HAART were also sacrificed at week 47. MSI of snap frozen cryosections (10µm) of lymph nodes (LN) were analyzed using an infrared matrix-assisted laser desorption electrospray ionization (IR-MALDESI) source. Response was calibrated by standards on blank tissue, with 88 fg/voxel limit of detection (LOD). Serial sections of tissue were stained for immunohistochemistry (IHC: PD-1, CD3, and CD4 expression), and analyzed by LC-MS/MS (LOD=0.01 ng/ml homogenate) to validate MSI results.
Results: MSI revealed that LN Pano concentrations (LC-MS/MS: 206±34 ng/g) were distributed heterogeneously in tissue (Figure 1). Using IHC microscopy and in silico micro-dissection of MSI results, an estimated 45-68% of total Pano exposure was localized in vasculature. Parenchymal Pano concentrations were estimated to be 86±33 ng/g (260nM, based on tissue density of 1.06 g/cm^3), representing a 1.6 to 4-fold increase over plasma concentrations. Higher (3-fold) Pano dosing marginally increased Pano tissue homogenate concentrations (1.1-fold), but yielded 1.6-fold higher penetration into parenchyma. While parenchymal Pano exceeded concentrations required for in vitro HIV activation (EC50=10nM, EC90=100nM), no difference was found in PD-1 expression intensity between Pano and control tissues (6.1±2e5 and 6.5±0.6e5, respectively).
Conclusions: This study is the first to map the biodistribution of panobinostat in putative viral reservoir tissues following anti-latency therapy. Stimulating dormant virus out of latency requires adequate penetration into tissues where it resides, and IR-MALDESI MSI can provide key information to evaluate the efficacy of treatment strategies.



[Localization of panobinostat in vascular regions of RM lymph node]

WEPEA0222

Vorinostat renders the replication-competent latent reservoir of HIV vulnerable to clearance by CD8 T cells

J. Sung[1], M. Bednar[2], S. Joseph[2], K. Sholtis[1], J. Kuruc[1], C. Gay[1], R. Swanstrom[2], J. Nordstrom[3], C. Bollard[4], N. Archin[1], D. Margolis[1]

Background: Latently HIV-infected cells are transcriptionally quiescent, and thus invisible to clearance by the immune system. We wished to demonstrate that the latency reversing agent (LRA) vorinostat induces a window of vulnerability in the latent HIV reservoir, defined as the triggering of viral protein antigen production sufficient in quantity and duration to allow for clearance of persisting infection.
Methods: We created a latency clearance assay, by modifying the quantitative viral outgrowth assay to allow the addition of immune effectors capable of clearing cells expressing viral antigen. A reduction in the recovery of replication-competent virus recovery following addition of immune effectors provides evidence that LRA exposure leads to sufficient production of viral protein to allow detection and clearance of latent infection.
Results: The 14 participants studied were all suppressed for at least 2 years, with a median duration of suppression of 6 years (range 2-8.5) and a wide range of latent reservoir sizes as measured by the standard quantitative outgrowth assay (median 0.57, range 0.04 to 2.30 infectious units per million resting CD4 T cells). Following a 6 hour exposure of resting CD4 T cells to 335nM of vorinostat, chosen to mimic physiologically achievable levels in vivo, the number of p24+ wells recovered as a percentage of total wells plated was significantly reduced when a variety of immune effectors were exposed to infected cells overnight, and then removed prior to the viral outgrowth step of the assay. Autologous CD8 cells (in some cases), autologous CD8 cells expanded in the presence of viral peptides (HXTCs, ref. Sung JID 2015), or autologous CD8 cells with bispecific antibody-derived molecules (Sung, JCI 2015) all significantly reduced the recovery of replication-competent HIV from resting CD4+ T cells in the latency clearance assay.
Conclusions: We show that a pharmacologically relevant exposure to vorinostat induces viral protein expression in resting CD4 T cells from antiretroviral suppressed, HIV-infected individuals, creating a window of vulnerability within this latent reservoir. In ongoing clinical studies, we will seek evidence that clearance activity assessed in this ex vivo assay using autologous HIV+ participant´s cell can predict in vivo responses.

HIV-1 Nef is required for efficient latency reversal in a T cell line

X.T. Kuang[1], T.M. Markle[1], M.A. Brockman[1,2]
[1]Simon Fraser University, Burnaby, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada
Presenting author email: xtk@sfu.ca

Background: Nef is a crucial accessory protein that enhances HIV pathogenesis, in part through evasion of host immune responses. Nef is reported to modulate T cell signaling events, which may alter cellular activation status, but Nef's contribution to the establishment and maintenance of viral latency remain elusive. To investigate this, we examined the reactivation efficiency of clonal CEM T cell lines latently infected with HIV strains encoding functional or defective Nef.
Methods: Latent CEM-A*02 (CLat) T cell clones were generated using NL4.3ΔEnv viruses encoding Nef_{SF2}GFP, Nef_{G2A}GFP, or $Nef_{NL4.3}$-IRES-GFP. The nef gene was subsequently disrupted in a selected CLat clone using CRISPR/Cas9. Viral reactivation induced by TNFα, panobinostat or prostratin was assessed using flow cytometry to measure GFP or intracellular Gag-p24 expression. Surface CD4 and HLA-A*02 expression was quantified following reactivation to confirm Nef function.
Results: A panel of CLat-Nef_{SF2}GFP [N=11] and CLat-Nef_{G2A}GFP [N=41] clones with low background GFP expression (< 10%) was generated. For all latency reversal agents tested, we observed that viral reactivation was generally poorer in clones encoding defective Nef_{G2A}GFP compared to those encoding wild-type Nef_{SF2}GFP. In particular, median fluorescent intensity of GFP was lower in reactivating CLat-Nef_{G2A}GFP clones (GFP_{MFI}=133 [IQR 112-151]) compared to CLat-Nef_{G2A}GFP clones (GFP_{MFI}=375 [272-474]; p<0.0001). Additionally, CLat-Nef_{G2A}GFP clones were less responsive to stimulation using histone deactylase inhibitor (panobinostat) compared to CLat-Nef_{SF2}GFP clones (median [IQR] % GFP+ cells: 9 [7-12]% versus 48 [38-62]%; p<0.0001). To overcome potential bias associated with differences in DNA integration site between clones, we disrupted the Nef gene in a CLat clone encoding $Nef_{NL4.3}$-IRES-GFP. As expected, all Nef knockout clones (N=38] lacked the ability to downregulate CD4 and HLA-A*02. Knockout clones displayed variable reactivation profiles (85 [65-99]% GFP+ cells), but notably, the median fluorescent intensity of GFP was lower in Nef knockout clones (GFP_{MFI}=157 [118-229]) than in the parental clone (96% GFP+; GFP_{MFI}=459±16), and fewer Gag-p24+ cells were observed.
Conclusions: These results suggest that HIV-1 Nef contributes to viral reactivation from latency. In addition to Nef's role in immune evasion, our data indicate that Nef can modulate the efficiency of viral reactivation in the context of latency reversal agents.

Presenting author email: mdemulder@gwu.edu

Background: Antiretroviral therapy (ART) potently suppresses HIV-1, but viral eradication remains unachievable due to the persistence of reservoirs. Current eradication strategies rely on histone deacetylase inhibitors and related compounds, in conjugation with ART, to reactivate and kill infected cells within the reservoir. Components of intrinsic immunity, such as restriction factors possess potent anti-HIV-1 activities by interfering with the virus life cycle.
Methods: Using a well-established ex vivo model we generated latently infected CD4+ T-cells and identified IFITM1, a transmembrane antiviral factor, as being overexpressed in latently infected cells.
Results: We found that the expression of IFITM1 and SAMHD1 were 4-fold and 2-fold increased, respectively, in resting latent cells when compared to reactivated cells. We also tested the capacity of NK cells to recognize and kill IFITM1-expressing cells by antibody-dependent cell-mediated cytotoxicity (ADCC). We detected significant killing of ACH-2 cells labeled with anti-IFITM1 antibody (79±4.5%), when compared to control (25±1.3%) and this was associated with a significant increase (p=0.0286) in the frequency of IFN-γ+CD107a+ NK cells (1.345±1.3%).
Conclusions: Our results reveal an important and unreported finding that suggests a role for IFITM1 during HIV-1 latency. The efficient killing of latently infected cells through the engagement of an anti-IFITM1 antibody may shed light into new strategies for the efficient eradication of latently infected cells. These novel insights could be explored to develop clinical therapeutic approaches to effectively eradicate HIV-1.

WEPEA0225

Early treatment of SIV+ macaques with an $\alpha_4\beta_7$ mAb alters virus distribution and preserves $CD4^+$ T cells in later stages of infection

P. Santangelo[1], S. Byrareddy[2], C. Cicala[3], K. Ortiz[4], D. Little[4], S. Gumbar[5], K. Jelicic[3], C. Zurla[1], F. Villinger[6], A. Ansari[4], A. Fauci[3], J. Arthos[3]
[1]Georgia Institute of Technology, Atlanta, United States, [2]University of Nebraska, Omaha, United States, [3]National Institute of Allergy and Infectious Disease, Laboratory of Immunoregulation, Bethesda, United States, [4]Emory University School of Medicine, Atlanta, United States, [5]Yerkes National Primate Center, Atlanta, United States, [6]New Iberia Research Center, Louisiana, United States
Presenting author email: jarthos@nih.gov

Background: SIV infected macaques treated with ART in combination with an anti-α4β7 mAb controlled plasma viremia for up to two years following discontinuation of all therapy. The mechanism of control is unknown.
Methods: We employed whole body immuno-PET/CT imaging to detect the distribution of virus and CD4+ T cells in treated animals both before and after therapy interruption. Flow cytometry and immunohistochemistry was used to confirm PET/CT results.
Results: We were able to detect virus in various lymphoid and mucosal tissues including gut in animals treated with either ART plus control IgG or ART plus anti-α4β7 mAb. Anti-α4β7 mAb promoted a redistribution of virus, with a pronounced decrease in the large intestine. The reduction in viral replication in gut tissues occurred despite the fact that anti-α4β7 mAb treatment did not result in a decrease in $CD4^+$ T cells within the gut.
Conclusions: These results demonstrate that an anti-α4β7 mAb impacts the distribution of virus while promoting the restoration of CD4+ T cell in the gut and other lymphoid tissues following experimental infection and treatment with ART. The redisrtibution of virus and the subsequent CD4+ T cell restoration may underlie the mechanism of viral control in macaques treated with ART plus anti- α4β7 mAb.

WEPEA0226

The central nervous system as a reservoir of HIV-1 variants resistant to broadly neutralizing antibodies

K. Stefic[1,2], A. Chaillon[3], G. Gras[4], F. Bastides[4], L. Bernard[4], F. Barin[1,2]
[1]Université Francois Rabelais, INSERM U 966 MAVIVH, Tours, France, [2]Bretonneau University Hospital Center, Department of Virology, Tours, France, [3]University of California San Diego, Division of Infectious Disease, Department of Medicine, La Jolla, United States, [4]Bretonneau University Hospital Center, Department of Infectious Diseases, Tours, France
Presenting author email: karl.stefic@univ-tours.fr

Background: Clinical studies using broadly neutralizing antibodies (bNAbs) as therapeutic or prophylactic agents are moving forward at increasing pace. The emergence of resistant escape mutants has already been reported. Envelope glycoprotein evolve quickly under the selective pressure by autologous antibodies but also by adaptating to cell tropism in different compartments of the body, as it is the case for compartmentalized viruses isolated in the cerebrospinal fluid (CSF). This could impact the sensitivity to bNAbs. We analyzed the sensitivity to bNAbs of variants isolated from paired CSF and blood samples.
Methods: Paired contemporaneous CSF and blood plasma samples of 6 subjects with HIV-associated neurocognitive disorder infected by HIV-1 strains of 5 different clades were analyzed by single genome sequencing. Pseudotyped viruses expressing envelope glycoproteins representative of the quasi-species present in each compartment were generated. Their sensitivity to neutralization was measured using a TZM-bl assay and bNAbs targeting the N160-V1V2 site (PG16, PGT145), the N332-V3 site (PGT121), the CD4-binding site (VRC03), the membrane-proximal external region (MPER) of gp41 (10E8) and a conformational epitope overlapping both envelope subunits (8ANC195). Sensitivity to sCD4 was assessed as well.
Results: Phylogenetic analyses revealed significant compartmentalization of HIV populations between blood and CSF in 4 out of 6 patients. In 5 patients, we observed major differences of sensitivity to at least one bNAb targeting the N160-V1V2 site, the N332-V3 site or the CD4bs, between blood and CSF variants, even for patients without compartmentalization. The last patient was highly resistant to all bNAbs but a 22-fold resistance to sCD4 of CSF variants was observed. Three patients had CSF variants with enhanced resistance to either PGT121 and PG16 (9 and 43 fold, respectively), PGT145 and VRC03 (15 and 16 fold, respectively), or PGT145 alone (7 fold) compared to blood variants. Sensitivity to 10E8 was similar in both compartments for all patients.
Conclusions: Our data show the presence of bNAbs-resistant viruses in patients naive from bNAbs. Considering the low blood-brain barrier penetration of IgGs and the possible migration of HIV-1 from CSF to blood, these results should warn us on the potential role of CNS as a reservoir for selection of bNAbs resistant viruses.

WEPEA0227

Knockdown of CCR5 expression in antigen-specific CD4 T cells

J. Zaunders[1,2], A. Howe[3], S. Ledger[3], A. Kelleher[1], J. Murray[3], G. Symonds[4]
[1]UNSW Sydney, Kirby Institute, Sydney, Australia, [2]St Vincent's Hospital, Centre for Applied Medical Research, Sydney, Australia, [3]UNSW Sydney, School of Mathematics, Sydney, Australia, [4]UNSW Sydney, School of Medicine, Sydney, Australia
Presenting author email: j.zaunders@amr.org.au

Background: Approximately half of memory CD4 T cells are CCR5+ and therefore susceptible to HIV-1 infection. Gene therapy presents an opportunity to modify CCR5 expression. We aimed to investigate use of short-hairpin (sh) RNA to knock-down CCR5 in recall antigen (Ag)-specific CD4 T cells in vitro.
Methods: 30 to 40 million PBMC from healthy HIV-uninfected adults were incubated for 48 hr with recall antigens, CMV lysate or tetanus toxoid, respectively. Non-Treg Ag-specific CD4 T cells were identified and cell sorted using up-regulation of CD25 and CD134 (OX40) and lack of CD39. Purified Ag-specific CD4 T cells were transduced with a lentiviral vector containing shRNA specific for CCR5 under the control of the H1 promoter, and GFP under control of ubiquitin C promoter, in the presence of IL-2 for 3 days. After 3 weeks incubation in IL-2 containing medium in the presence of feeder cells, GFP+ cells were cell sorted and further expanded. Expanded GFP+ cells were analysed by fluorescence microscopy and flow cytometry.
Results: From 10,000 to 30,000 CD25+CD134+CD39neg recall Ag-specific CD4+ T cells were isolated by cell sorting. Approximately 3-10% of purified Ag-specific cells were transduced with GFP, by fluorescence microscopy, compared with 50% transduction of positive control SEB-stimulated PBMC. Autologous monocyte-derived dendritic cells (Mo-DC) were used as feeder cells during expansion, and 4-6 weeks was required to obtain ≥ 2 million GFP+ Ag-specific CD4+ T cells. Using optimized sensitive flow cytometric detection, GFP+ CD4+ T cells were CCR5-negative, and had a Granzyme B+ cytotoxic phenotype.
Conclusions: Using the OX40 assay, Ag-specific CD4+ T cells can be isolated for genetic modification of CCR5 expression via stable transduction with lentiviral shRNA. Cell therapy with in vitro expanded Ag-specific T cells has proved beneficial in the clinical setting of opportunistic infections during lymphopenia following hemopoietic stem cell transplant. Our results suggest that CCR5-negative Ag-specific CD4+ T cells may also be produced in vitro for possible augmentation of immunity in HIV+ subjects.

WEPEA0228

Structures within the coreceptor binding site account for the broad neutralizing activity of single chain variable fragments (scFv) targeting CD4-induced epitopes

K. Tanaka[1], T. Kuwata[1], M. Alam[1], S. Takahama[1], M. Shimizu[1], A. Roitburd-Berman[2], J.M. Gershoni[2], S. Matsushita[1]
[1]Matsushita Project Laboratory, Center for AIDS Research, Kumamoto University, Kumamoto, Japan, [2]George S. Wise Faculty of Life Sciences, Tel Aviv University, Department of Cell Research and Immunology, Tel Aviv, Israel
Presenting author email: 130r5138@st.kumamoto-u.ac.jp

Background: A CD4-induced (CD4i) epitope, which overlaps with the coreceptor binding site, is highly conserved, and is a favorable target for neutralizing monoclonal antibodies (nMAbs). However, the CD4i epitope is hidden inside trimeric Env, before CD4 binds gp120. Moreover, the close physical proximity of gp120 and the cellular membrane blocks the access of anti-CD4i Abs to this CD4i epitope after the CD4-gp120 interaction. In order to overcome this problem, single-chain variable fragments (scFv) of anti-CD4i nMAbs were tested for neutralization to multi-clade HIV-1 strains.
Methods: Single-chain variable fragments (scFv) from three anti-CD4i nMAbs, 16B2, 4E9C and 25C4b, were produced in E. coli, and their neutralization activities were compared with their counterparts. The binding properties of anti-CD4i nMAbs were determined by ELISA using $gp120_{BaL}$ mutants.
Results: The full length IgGs corresponding to the scFvs in this study were unable to neutralize Clade B HIV-1. In contrast, the anti-CD4i scFvs neutralized the tier 2 and tier 3 viruses of clade B. Futhermore, the neutralizing activities of scFvs were significantly higher than those of the corresponding Fabs. Moreover, neutralization assays using 66 pseudoviruses belonging to 7 subtypes revealed broad neutralization coverage by scFvs, 16B2 (100 %), 4E9C (83 %), 25C4b (92 %). Post-attachment neutralization assay, which regulated a fusion process by temperature, showed that the scFvs neutralized viruses resistant to the corresponding IgGs after the virus-cell attachment. Binding profiles of 25C4b against the series of gp120 mutants were comparable to 17b which interacts with the hairpin 1 (H1), hairpin 2 (H1) and requires the V3-base.
On the other hand, binding of 4E9C was found to be dependent of V3-base region. Finally, 16B2 was found to recognize a CD4-bound structure composed of H1 and H2.
Conclusions: Anti-CD4i scFvs can effectively neutralize multi-clade HIV-1 strains after the CD4-gp120 interaction. The gp120 structure induced by CD4-binding targeted by the neutralizing scFvs is associated with conserved regions including hairpins H1 and H2.

Jak inhibitors employ novel mechanisms to block reservoir seeding and HIV persistence

C. Gavegnano[1], J. Brehm[2], F. Dupuy[3], A. Talla[2], S. Santos[4], S. Hurwitz[1], J.-P. Routy[5], V. Marconi[6], R. Sekaly[2], R. Schinazi[1]
[1]Emory University, Pediatrics, Atlanta, United States, [2]Case Western Reserve, Pathology, Cleveland, United States, [3]MUHC, Pathology, Montreal, Canada, [4]Unconditional Love, Melbourne, United States, [5]McGill University, Hematology, Montreal, Canada, [6]Emory University, Infectious Diseases, Atlanta, United States
Presenting author email: cgavegn@emory.edu

Background: Ruxolitinib is a Jak 1/2 inhibitor (JAKI) that is FDA-approved for myelofibrosis and polythema vera. We evaluated the ability of JAKI to block events preventing eradication, including
1) HIV replication,
2) bystander infection/activation,
3) markers of homeostatic proliferation and reservoir lifespan,
4) reservoir size, and
5) reservoir expansion.
Methods: #CD4 T-cells from HIV^+ donors were cultured for 6 days with JAKI+IL-15 or AZT+EFV+RAL prior to Alu-PCR. pSTAT5, HLADR/CD38, and PD1 were quantified on T cells from HIV^+ individuals ex vivo. MΦ were infected with $HIV\text{-}1_{BaL}$ for 28 days; PMA-induced reactivation +/- JAKI was quantified after 24 hr (p24 ELISA). CFSE-stained CD4 T-cells were infected with LAI +/- JAKI for 3-6 days prior to quantification of non-dividing $p24^+$ cells, bcl-2 and activation markers. pSTATs were measured in CD4 T-cells + IL-2, 6, 7, 10, 15 or IFN-a +/- JAKI. MΦ were infected with $HIV\text{-}1_{BaL}$ for 6 days +/- JAKI prior to quantification of HLADR/CD163.
Results: In vivo (HIV^+ individuals), increased pSTAT5, HLADR/CD38 and PD1 expression correlated with increased integrated HIV DNA ($p< 0.001$). JAKI demonstrated nanomolar inhibition of viral replication in vitro and ex vivo in CD4 T-cells ($EC_{50/90}$ 0.007/0.01μM). JAKI blocked
1) IL-2, IL-7, IL-15 induction of reservoir lifespan marker Bcl-2 in T_{cm}, T_{tm}, T_{em} ($EC_{50/90}$ 0.01/0.3μM),
2) HIV-induced upregulation of CCR5 (CD4 T-cells; $EC_{50/90}$ 0.06/0.2μM) and HLADR/CD163 (MΦ) ($EC_{50/90}$ 0.006/0.2μM),
3) IL-15 or PMA (MΦ) induced reactivation (EC_{5090} 0.006/0.2μM),
4) bystander cell proliferation and infection (CD4 T-cells; $EC_{50/90}$ 0.01/0.2μM),
5) frequency of CD4 T-cells harboring integrated HIV DNA, and non-dividing $p24^+$ CD4 T-cells $EC_{50/90}$ 0.009/0.1μM).
Conclusions: Activation of the Jak-STAT pathway correlates with markers of viral persistence in HIV^+ individuals, including size of the viral reservoir, underscoring therapeutic relevance for blockade of this pathway as a tool to mitigate these events. JAKI significantly reduce markers of viral persistence, including viral replication, HIV-induced activation, inflammation, and reservoir size, maintenance and expansion in vitro and ex vivo in T cells and MΦ. These data suggest that JAKI can act as an immune checkpoint blocker, which may allow for eventual withdrawal of antiretroviral agents in stably controlled infected individuals without viral rebound, which could result in a functional cure.

CTL-based vaccine-induced control is associated with induction of high follicular to extra-follicular ratios of virus-specific $CD8^+$ T cells

H. M Abdelaal[1], S. Li[1], R. Sawahata[1], K. Fraser[2], G. Mylvaganam[3], M. Martins[4], G. Mwakalundwa[5], D. Masopust[2], R. Amara[3], D. Watkins[4], E. Connick[6], P. Skinner[1]
[1]University of Minnesota, Department of Veterinary and Biomedical Sciences, Minneapolis, United States, [2]University of Minnesota, Department of Microbiology, Center for Immunology, Minneapolis, United States, [3]Emory University School of Medicine, Department of Microbiology and Immunology, Atlanta, United States, [4]University of Miami, Department of Pathology, Miami, United States, [5]University of Minnesota, Veterinary and Biomedical Sciences, Saint Paul, United States, [6]University of Arizona, Division of Infectious Diseases, Tucson, United States
Presenting author email: moham698@umn.edu

Background: There is an urgent need to develop an effective HIV vaccine. We previously showed that during chronic HIV-1 and SIV infections, HIV and SIV replication is concentrated within B cell follicles, whereas HIV and SIV-specific $CD8^+$ T

cells are largely excluded from these sites suggesting that the inability of HIV and SIV-specific CD8+ T cells to fully suppress virus replication may be due to their deficiency in B cell follicles. We hypothesize that a successful HIV vaccine will either prevent HIV seeding B cell follicles or induce high levels of virus-specific CD8+ T cells in B cell follicles.
Methods: Here we investigated whether control associated with three CTL inducing SIV vaccines was associated with levels of SIV-specific CD8+ T cells in follicular (F) and extrafollicular (EF) compartments in lymph nodes of vaccinated animals after challenge with pathogenic SIV relative to a cohort of non-vaccinated chronically infected animals using in situ tetramer staining with MHC Class I tetramers combined with immunohistochemistry. Control was defined a set point plasma viral load of ≤10^4.
Results: We found lower levels of tetramer+ SIV-specific CD8+ T cells in F compared to EF areas of non-controller animals (P<0.0001), but not in controller animals (P=0.13). Although similar levels of tetramer+ SIV-specific CD8+ T cells were detected in F and EF areas between the controller and non-controller animals (P=0.62) and (p=0.51) respectively, the controller animals had significantly higher F: EF ratios of tetramer+ SIV-specific CD8+ T cells (P=0.028). Also, there was a significant inverse correlation between F: EF ratio of tetramer+ SIV-specific CD8+ T cells and plasma VL in the controller (r=-0.75, P=0.0046) but not in non-controller animals (r=0.01, P=0.97).
Conclusions: These results support developing CTL-based HIV vaccines that augment relative levels of virus-specific CTL within B cell follicles.

WEPEA0231

Deciphering the first steps of the local immune response after intradermal vaccination with recombinant MVA

P. Rosenbaum[1,2,3], L. Stimmer[4], S. Tricot[1,2,3], N. Bosquet[1,2,3], A.-S. Beignon[1,2,3], C. Chapon[1,2,3], R. Le Grand[1,2,3], F. Martinon[1,2,3]
[1]CEA, DRF, IDMIT Infrastructure, ImVA, Fontenay aux Roses, France, [2]INSERM U1184, Fontenay aux Roses, France, [3]Université Paris-Sud, UMR 1184, Orsay, France, [4]CEA, DRF, MIRCen, Fontenay aux Roses, France
Presenting author email: frederic.martinon@cea.fr

Background: Live attenuated vectors, such as modified vaccinia virus Ankara (MVA), are considered as powerful cell-based vaccines. In order to better understand the early immune response, which may be crucial for vaccine efficacy, we deciphered dynamics of infection and kinetics of inflammation induced from 0h to 72h after intradermal administration of a MVA based vaccine in a non-human primate (NHP) model.
Methods: NHPs were injected intradermaly with recombinant MVA expressing either eGFP or HIV Gag-Pol-Nef. Blood, skin and draining lymph node samples were collected during 72h following the injection. Inspired by system vaccinology approach, we used a wide set of techniques involving histology, ex vivo and in vivo imaging, flow cytometry, Luminex and transcriptomic assay covering macroscopic to molecular immune events. Using this rich and heterogenic dataset, we then designed a coexpression network, based on significant correlations over the time between studied effectors, dedicated to identify major effectors of this immune response.
Results: MVA was able to infect a wide set of skin cells from 14h to 72h post intradermal injection. The vaccine also induced a strong local inflammatory response. Indeed, we highlighted an important granulocytes and macrophages recruitment associated with pro-inflammatory cytokines releasing such as GM-CSF, IL6, IL1β, MIP1α, MIP1β or TNFα between 24h and 48h post-injection, with an increased diversity at 72h (IL2, TGFα, IL15 but also G-CSF). MVA injection also impacted on the systemic responses, with an early increase of $CD66^{high}$ granulocytes and $CD14^+CD16^+$ monocytes associated with IL6 and IL1ra releasing. Draining lymph node activation was rather characterized by cytokine production than cell subset dynamics. Finally, the coexpression network highlighted a hub of correlation between local and lymph node cytokine productions.
Conclusions: Altogether, this study provided insights to better understand the innate immune response process triggered by MVA, characterizing the innate response in the deep details. The use of an innovative integrative approach showed the complexity and the multiplicity of this response and highlighted several key innate effectors, such as TNFα, TGFα and cells expressing a $CD14^+$MDSCs phenotype, susceptible to lead the first steps of the adaptive response in the draining lymph node.

WEPEA0232

Innate myeloid responses are highly diverse and strongly differ after the priming and the boosting immunizations

J.-L. Palgen[1], N. Tchitchek[1], J. Elhmouzi-Younes[2], S. Delandre[1], I. Namet[1], Y. Lévy[3], A. Cosma[2], R. Le Grand[1], A.-S. Beignon[1]
[1]CEA - Université Paris Sud 11 - INSERM U1184, Immunology of Viral Infections and Autoimmune Diseases, LabEx Vaccine Research Institute (VRI), Fontenay aux Roses, France, [2]CEA - Université Paris Sud 11 - INSERM U1184, Immunology of Viral Infections and Autoimmune Diseases, Fontenay aux Roses, France, [3]INSERM, U955, Team 16, Clinical and Infectious Diseases Department, Hospital Henri Mondor, University of Paris East, LabEx Vaccine Research Institute (VRI), Créteil, France
Presenting author email: jean-louis.palgen@cea.fr

Background: Better understanding the innate immune response to vaccines is required to comprehend and orientate the consecutive adaptive immune response toward a stronger, more efficient protection against pathogens. A better characterization of innate cells populations and a deeper understanding of how vaccination impact them is then highly valuable to rationally optimize future HIV vaccines.
Methods: Here, as animal and vaccine model we used cynomolgus macaques immunized with the recombinant MVA HIV-B vaccine, which is currently tested in phase I/II clinical trial by the VRI. 5 animals were immunized with a homologous prime-boost at two months apart, and blood samples were collected longitudinally at 15 timepoints. We took advantage of mass cytometry technology as well as longitudinal blood sampling and focus on the innate myeloid cells using a 32-markers antibody panel to phenotype them in deep and decipher their dynamics post-immunizations.
Results: Our results unveiled a high phenotypic diversity among blood granulocytes, monocytes and dendritic cells populations. Most of these subpopulations were significantly impacted in number by MVA injections and a large part of them behave differently after the first and second injection. Some populations expanded only after the prime while other ones solely expanded after the boost. Strikingly, subpopulations responding mainly to the boosting injection showed a higher expression of maturation markers such as CD11b, CD32 and CCR7. This shows that innate myeloid responses differ between the first and second vaccine encounter while it is often admitted that innate immunity behaves each time similarly. We hypothesize that the primary memory response and more particularly immune complexes and soluble factors produced by memory T cells in response to their cognate antigen, license innate cells to respond differently at the boost.
Conclusions: These results pave the way for further studies to better understand the reciprocal relationships between innate and adaptive immunity.

Background: HIV sequence diversity and the propensity of eliciting immunodominant responses targeting variable regions are hurdles in the development of an effective AIDS vaccine. We demonstrated that a vaccine comprising conserved elements (CE) of HIV-1 $p24^{gag}$ as prime followed by a combination of CE+gag pDNA as boost elicits broad, potent and durable T cell responses targeting these conserved regions, efficiently overcoming the dominance imposed by the Gag variable regions. This vaccine concept is currently developed for a clinical trial HVTN 119. To improve the vaccine efficacy and combine the benefit of cellular and humoral responses, we developed pDNA immunogens encoding conserved elements within SIV gag and the HIV-1 Env protein and evaluated the immunogenicity in macaques.
Methods: DNA plasmids were constructed encoding 7 conserved segments of Gag (p27CE) or encoding 12 conserved segments from HIV-1 Env (Env-CE). Macaques were immunized by IM injection followed by vivo electroporation with p27CE+Env-CE pDNA or with p27CE+gp145 env pDNA. Cellular responses were measured by multi-color flow cytometry, and vaccine-induced antibody responses were measured.
Results: Cellular responses towards SIV Gag CE were severely reduced upon vaccination with a combination of p27CE+gp145 env pDNA, indicating that sequences within Env exert an immunodominant interference with the conserved Gag epitopes. In contrast, macaques immunized with p27CE+Env-CE developed high and

broad cellular responses targeting both Gag and Env CE. Both, Gag and Env CE pDNAs induced antibody responses in immunized animals and these antibodies cross-reacted with the WT molecules. These data demonstrate that a vaccine combining Gag+Env CE pDNA profoundly alters the immunodominance exerted by the variable regions of both Gag and Env, and provides a balanced immune response.
Conclusions: HIV/SIV vaccine regimens comprising CE pDNA prime and CE+gag/env pDNA boost redirects cellular responses to subdominant and more vulnerable viral targets, and augment cytotoxic T cell responses to highly conserved epitopes in the viral proteome maximizing response breadth. The balanced immunity, both cellular and humoral responses, induced by this vaccine regimen makes this an interesting candidate for the prevention of HIV-infection and therapy.

Background: Effective priming of functional HIV-1-specific CD8+ T cells from naïve T cells is crucial for AIDS vaccines and immunotherapy. However, the study of HIV-1-specific CD8+ T cell priming is limited by the lack of established in vitro approaches. Here we sought to establish an in vitro priming method in order to induce functional HIV-1-specific CD8+T cells from naïve T cells.
Methods: CD8+ T cells specific for the HLA-A24:02-restricted immunodominant CTL epitope Nef RF10 were primed from HLA-A*24:02+ HIV-1-seronegative donor-derived PBMCs in the presence of TLR4 ligand (LPS) or STING ligand (3'3'cGAMP) combined with Flt3 ligand. We used specific tetramers to evaluate the induction of RF10-specific CD8+ T cells upon day 11 of priming and established RF10-specific CD8+ T cell lines to investigate various functional properties of primed
T cells.
Results: Consistent priming of RF10-specific CD8+ T cells from naïve T cells was obtained with LPS or 3'3'cGAMP although no significant difference was observed between the two. All primed T cells had ability to produce IFN-g, IL-2, TNF-a, and MIP-1b in response to RF10 peptide. However, LPS primed T cells expressed low level of granzyme B and perforin, and failed to suppress HIV-1 replication. Some of these cells showed also low TCR avidity. In contrast, 3'3'cGAMP primed T cells exhibited higher expression of granzyme B and perforin and carried higher avidity TCRs than LPS primed ones, and a strong ability to suppress HIV-1 replication.
Conclusions: The present study demonstrates that functional HIV-specific CD8+ T cells having ability to suppress HIV-1 can be induced from naïve T cells primed with 3'3'cGAMP, indicating that STING ligand may be a useful adjuvant for the design of AIDS vaccine and therapy.

Background: Recognition of Pathogen-associated molecular patterns (PAMPS), through specific TLR (Toll Like receptors) or NLR (NOD-Like receptor) and identification of synthetic ligands, has opened a new area in adjuvant research. As such molecules could be encapsulated in biodegradable nanoparticles (NP), we could co-deliver to the same Antigen Presenting Cell (APC), either Env Trimer or gag HIV and immune stimulatory molecules.
Methods: Both p24 and BG505 adsorption on NP was optimized, caracterized and modelized. Then SKH-1 and CB6F1 mice have been immunized in order to analyze:
(i) nanoparticles biodistribution by tomography,
(ii) germinal center (GC) responses in the draining lymph node by confocal microscopy,
(iii) immune responses in blood sample by ELISA.
Results: We are able to adsorbed 50 BG505 per NPs and we show that BG505 is adsorbed into NPs through gp41 moities and gp120 epitopes are exposed as in native virion. Using fluorescent nanoparticles, we demonstrate by in vivo tomography that NPs allow a depot effect at the injection site during several weeks, compare to 7 days without nanoparticles. Furthermore, formulation with NPs increases the number of GC in draining lymph nodes. These GC response correlated with an enhancement of humoral responses highlighting the role for adjuvants in programming the durability of HIV vaccine response.
Conclusions: Our results indicate that PRR ligands delivered in biodegradable NPs coupled with BG505 or p24 offer a novel approach to engineer robust and durable humoral affinity with implications for HIV-1 vaccine developpement in humans.

Delivery of antigen to nasal-associated lymphoid tissue microfold cells through secretory IgA targeting local dendritic cells confers protective immunity

N. Rochereau[1], P. Vincent[2], B. Verrier[2], F. Jospin[1], A. Ensinas[1], C. Genin[1], B. Corthésy[3], S. Paul[1]
[1]GIMAP, Immunology, St Priest en Jarez, France, [2]Institut de Biologie & Chimie des Proteines, Lyon, France, [3]R&D Laboratory of the Division of Immunology and Allergy, Lausanne, Switzerland

Background: Transmission of mucosal pathogens relies on their ability to bind to the surfaces of epithelial cells, to cross this thin barrier, and to gain access to target cells and tissues, leading to systemic infection. This implies that pathogen-specific immunity at mucosal sites is critical for the control of infectious agents using these routes to enter the body. Although mucosal delivery would ensure the best onset of protective immunity, most of the candidate vaccines are administered through the parenteral route.
Methods: The present study evaluates the feasibility of delivering the chemically bound p24gag HIV antigen through secretory IgA (SIgA) in nasal mucosae in mice.
Results: We show that SIgA interacts specifically with mucosal microfold cells present in the nasal-associated lymphoid tissue. p24-SIgA complexes are quickly taken up in the nasal cavity and selectively engulfed by mucosal dendritic cell-specific intercellular adhesion molecule 3-grabbing nonintegrin- positive dendritic cells. Nasal immunization with p24-SIgA elicits both a strong humoral and cellular immune response against p24 at the systemic and mucosal levels. This ensures effective protection against intranasal challenge with recombinant vaccinia virus encoding p24.
Conclusions: This study represents the first example that underscores the remarkable potential of SIgA to serve as a carrier for a protein antigen in a mucosal vaccine approach targeting the nasal environment.

WEPEA0237

HIV-1 conserved mosaics delivered by regimens with integration-deficient, DC-targeting lentiviral vector induce robust T cells

E.G. Wee[1], B. Ondondo[1], P. Berglund[2], J. Archer[2], A.J. McMichael[1], D. Baltimore[3], J.H. ter Meulen[2], T. Hanke[1]
[1]University of Oxford, Oxford, United Kingdom, [2]Immune Design, Seattle, United States, [3]California Institute of Technology, Pasadena, United States
Presenting author email: tomas.hanke@ndm.ox.ac.uk

Background: To be effective against HIV-1, vaccine-induced T cells must selectively target epitopes, which are functionally conserved (present in the majority of currently circulating and reactivated HIV-1 strains) and, at the same time, beneficial (responses to which are associated with better clinical status and control of HIV-1 replication), and rapidly reach protective frequencies upon exposure to the virus. Heterologous prime-boost regimens using virally vectored vaccines are currently the most promising vaccine strategies, nevertheless, induction of robust long-term memory remains challenging. To this end, lentiviral vectors induce high frequencies of memory cells due to their low-inflammatory nature, while typically inducing only low anti-vector immune responses.
Methods: We constructed novel vaccines vectored by DC-targeted, integration-deficient lentiviral vector platform ZVex® delivering conserved regions of HIV proteins designed as bivalent mosaics with a high global HIV-1 match. We characterized the vaccine-induced T cells in mice using the IFN-γ ELIPOT assay and polychromatic flowcytometry.
Results: The novel candidate vaccines ZVex.tHIVconsv1 and ZVex.tHIVconsv2 were individually immunogenic. When administered together in heterologous prime-boost regimens with chimpanzee adenovirus ChAdOx1 and/or poxvirus MVA vaccines to BALB/c and outbred CD1-Swiss mice, they induced median frequency of over 6,000 T cells/10^6 splenocytes, which were plurifunctional, broadly specific and recognized epitope variants beyond those present in the tHIVconsvX immunogens.

Conclusions: These data support further development of a conserved mosaic HIV-1 immunogen-based strategies, utilizing heterologous prime-boost approaches of the ZVex®, MVA and/or ChAdOx1 platforms. For the tHIVconsvX as well as other immunogens, we envisage a panel of vectors delivering the same transgene, which will allow a personalized delivery avoiding known pre-existing anti-vector immunity, multiple heterologous boosts for low responders, a maintenance of protective levels of immunity over a prolonged period of time and more flexibility for combining future effective T and antibody vaccines into one regimen for the best HIV-1 control.

Presenting author email: jerome.kervevan@inserm.fr

Background: A rationale approach for vaccine design is to target HIV antigen to specific receptor of dendritic cells (DCs) via fused monoclonal antibodies (mAb) with the intention to favor antigen presentation and activation of HIV-specific T- and B-cell responses. In animal models (Epaulard O. et al JI 2014), targeting of Langerhans cells (LCs) residing in the skin with anti-Langerin mAbs fused with HIV antigens (aLC/HIV) drives antigen-specific humoral responses.
The development of these immunization strategies in humans requires a better understanding of early immune events driven by targeted LCs. The present study investigates the effects of aLC/HIV-Env on the differentiation of naïve CD4+ T-cells.
Methods: Anti-human Langerin recombinant human (Hu) IgG4 antibody fused with HIV-Env antigen at the C-terminus of the H-chain were produced in CHO cells. Purified cord blood CD34+ progenitor cells were differentiated into LCs (Caux C. et al. Blood 1997), briefly incubated with aLC/HIV-Env, and co-cultured with autologous purified naïve CD4+ T-cells. The phenotype of differentiated T-cells was assessed by flow cytometry.
Results: We first show that aLC/HIV candidate vaccine specifically target LCs ($CD1a^{high}$/$CD207^{+}$) as demonstrated by flow cytometry and immunohistostaining on vaginal or skin explants. aLC/HIV mAbs are endocytosed by targeted LCs. We confirm that in vitro CD34-derived LCs exhibit a phenotype similar to ex vivo isolated LCs from human skin. After being treated with aLC/HIV-Env, CD34-derived LCs induce the differentiation of co-cultured autologous naïve CD4+ T-cells towards Tfh-like cells ($CD45RA^{-}$ $CXCR5^{+}$ $PD1^{+}$ $Bcl6^{+}$ $ICOS^{+}$) significantly as compared to culture conditions with control HuFc-IgG4 or aCD40 HIV fusion antibodies. Strikingly, in the same culture conditions, monocyte-derived DCs and BDCA1+ primary DCs does not promote this differentiation of naïve CD4+ T cells.
Conclusions: These results revealed that LCs activated through CD207 promote the differentiation of naïve CD4+ T-cells towards Tfh cells. We are deciphering functional (cytokines/chemokines, co-stimulatory molecules) and gene expression profile of vaccine targeted LC and differentiated Tfh cells. These data support the development of novel DC targeting vaccine approaches.

Presenting author email: sean.rourke@utoronto.ca

Background: Effective cognitive screening instruments are needed to differentially assess and manage milder forms of HIV-associated neurocognitive disorders (HAND). We assessed concurrent validity of four screening tests against the gold standard for HAND diagnosis in people living with HIV.
Methods: 220 adults (mean age: 51 years; mean education: 14 years; 86% men) attending one HIV outpatient clinic in Toronto were included in our analyses. Four neurocognitive screening tests: Cogstate Brief Battery (CBB), HIV Dementia Scale (HDS), Computer Assessment of Memory and Cognitive Impairment (CAMCI), and Montreal Cognitive Assessment (MoCA) were administered. Impairment was defined as raw score of >10 (HDS), ≥30 percentile (CAMCI), a score of >26 (MoCA), and impairment in two or more domains (CBB). Participants completed comprehensive neuropsychological battery assessing processing speed, attention/working memory, learning/memory, and executive functions. Clinical HAND diagnosis was made according to Antinori (2007) criteria independent of screening test scores. Validity of tests was assessed using sensitivity, specificity, and area under the curve (AUC) estimates against the gold standard.
Results: 129 participants (59%) had a clinical diagnosis of HAND (ANI=20; MND=94; HAD=15). Sensitivity estimates were: 72% (MoCA), 61% (CBB), 42% (HDS), and 31% (CAMCI). Specificity estimates were: 98% (CAMCI), 95% (HDS), 82% (CBB), and 73% (MoCA). AUC estimates were 0.723 (MocA), 0.714 (CBB), 0.682 (HDS), and 0.644 (CAMCI). Combining of any two screening tests (test positive by either one or both tests) resulted in modest classification accuracy improvements (AUC ranges: 0.736-0.758). All four screening tests were better at detecting symptomatic HAND (10%-32% higher AUC) compared to non-symptomatic HAND.
Conclusions: Our results suggest that the MoCA and CBB screening tests have only modest global classification accuracy for assessing mild HAND in people with HIV. Work is underway in our laboratory to determine the clinical utility and generalizability of newer instruments which may have better diagnostic accuracy.

The impact of age and time of disease on HIV-associated neurocognitive disorder: a Japanese nationwide multicenter study

E. Kinai[1], K. Komatsu[1], M. Sakamoto[2], T. Taniguchi[3], A. Nakao[4], H. Igari[3], K. Takada[4], A. Watanabe[1], S. Oka[1], HIV-associated neurocognitive disorders in Japanese (J-HAND) study group
[1]National Center for Global Health and Medicine, Tokyo, Japan, [2]Saga University, Center for Comprehensive Community Medicine, Saga, Japan, [3]Chiba University, Chiba, Japan, [4]Ehime University, Matsuyama, Japan
Presenting author email: ekinai@acc.ncgm.go.jp

Background: The impact of age and time of disease on HIV-associated neurocognitive disorders (HAND) are still controversial due to multiple variation factors such as language or educational differences. Japanese are suitable population for exploration of the factors and neurocognitive characteristics because they have relatively uniform background.
Methods: We conducted a multicenter, prospective and cross-sectional study of 17 facilities with strict random recruitment manner. The eligible participants completed 14 neuropsychological tests for eight domains. The Frascati criteria were used for diagnosis of HAND.

Results: Of 1399 randomly recruited HIV-infected patients, 729 were eligible and 406 were declined due to the exclusion criteria. Prevalence of HAND was 26.1% [13.7% asymptomatic neurocognitive impairment, 11.0% mild neurocognitive disorder (MND), and 1.4% HIV-associated dementia (HAD)]. Trail Making Test B and Rey-Osterreith Complex Figure Test presented the better diagnostic accuracy for HAND (78.9% and 77.3% by receiver operating curve, respectively).
In multivariate analysis, older than 50 years (OR 2.119, 95% confidence interval (CI) 1.289-3.752), lower education level (OR 1.679, 95% CI 1.006-2.802) and incomplete viral suppression (OR 1.969, 95% CI 1.015-3.819) were risk factors, whereas current ART (OR 0.067, 95% CI 0.025-0.180) and currently employed (OR 0.534, 95% CI 0.311-0.918) were improvement factors.
The prevalence of HAD or MND decreased along the time since diagnosis in the early stage (from 11% in < 2 years to 7% in 2-5 years, p=0.022), then re-increased in the later stage [to 17% in 6-10 years and 21% in >10 years, p=0.020 and 0.009 (vs. 2-5 years), respectively]. Older patients have more often HAD or MND than younger ones in the early stage (27 vs. 9% in <2 years and 20 vs. 4% in 2-5 years, p=0.027 and p<0.001, respectively), while there was no significant difference between them in the later stage (17 vs. 11% in 6-10 years and 23 vs. 13% in >10 years, p=0.441 and p=0.332, respectively).
Conclusions: Executive and visuospatial function are susceptible cognitive domains in HIV-infected Japanese. The prevalence of HAND in Japanese presented biphasic pattern along the time since diagnosis. Older patients are more likely to have neurocognitive decline at early stages of HIV infection.

WEPEB0478

Baseline Framingham risk predicts HAND after two years in HIV+ Ugandan cohort

N. Sacktor[1], G. Nakigozi[2], N. Nakasujja[3], K. Robertson[4], R. Gray[5], M. Wawer[5], D. Saylor[1]
[1]Johns Hopkins University School of Medicine, Neurology, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]Makerere University, Kampala, United States, [4]University of North Carolina, Chapel Hill, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States
Presenting author email: sacktor@jhmi.edu

Background: Cardiovascular risk factors are hypothesized to be important risk factors for the development of HIV-associated neurocognitive disorder (HAND) in the antiretroviral therapy (ART) era. However, the role of these factors in the development of HAND in Sub-Saharan Africa, where rates of hypertension, hyperlipidemia, and diabetes are much lower than in Western populations, is unknown. We hypothesized that Framingham risk scores would predict HAND in HIV+ adults in rural Uganda.
Methods: 254 HIV+ adults from Rakai District, Uganda, enrolled in a longitudinal cohort of neurological complications of HIV, and were evaluated at baseline and after 2 years of follow-up. All were ART-naïve at baseline, and 92% were on ART at follow-up. Participants underwent sociodemographic interviews, neurological and medical evaluations, and a neurocognitive test battery at each visit. HAND stage was determined using Frascati criteria and normative data derived from 400 HIV- adults in Rakai. ANOVA and logistic regression were used to assess relationships to Framingham scores and HAND.
Results: Participants were 50% male, with mean(SD) age=36(9) and mean(SD) education=5(3) years. 72 participants (28%) had CD4 counts <200 at baseline. Baseline Framingham risk score and HAND were not related (p=0.50). Framingham risk score at the follow-up visit did not vary by HAND stage at follow-up (p=0.06) (Table 1). However, higher baseline higher Framingham risk score was associated with HAND stage at the two-year follow-up visit (p=0.004). Participants with a baseline Framingham baseline risk score of ≥5 had higher odds of symptomatic HAND at their two-year follow-up visit (OR=3.2, p=0.01).

	Baseline Framingham Score [mean (SD)]	p value	Follow-up Framingham Score [mean (SD)]	p value
HAND stage at follow-up				
Normal cognition (n=219)	2.7(2.6)	0.004	2.9(2.8)	0.06
Asymptomatic neurocognitive impairment (ANI) (n=7)	2.3(2.3)		2.6(1.9)	
Minor neurocognitive disorder (MND) (N=24)	5.7(10.0)		5.0(8.1)	
HIV-associated dementia (HAD) (n=4)	4.8(4.1)		3.7(2.9)	

[Table 1]

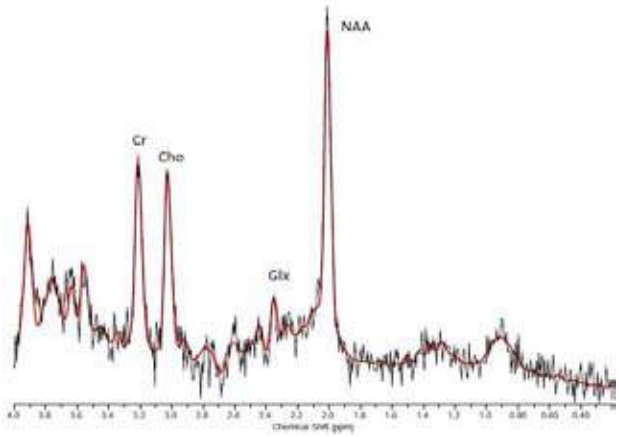
Conclusions: Cardiovascular risk factors as approximated by the Framingham risk score were associated with subsequent risk of more severe neurocognitive impairment in HIV+ rural Ugandans. This suggests cardiovascular risk factors are important in the development of HAND in patients on ART, even in populations with low levels of traditional risk factors.

WEPEB0479

Neurocognitive decline in people living with HIV in India and correlation with 3T magnetic resonance spectroscopy: a case-control study

K. Gupta[1], V. Kumar[2], S. Sinha[1], N. Jagannathan[2]
[1]All India Institute of Medical Sciences, Medicine, New Delhi, India, [2]All India Institute of Medical Sciences, NMR, New Delhi, India
Presenting author email: kartik.gupta127@gmail.com

Background: Neurocognitive decline in asymptomatic HIV patients and its correlation with metabolic changes in brain has not been studied in developing countries like India. In the present study we aim to examine the correlation between cognitive decline and changes in brain metabolites using MRS.
Methods: ART naïve HIV-positive patients, in the age group 20-50 years attending ART center of the hospital from July to December 2016 were included in the study. All patients underwent evaluation using MRS of left frontal white matter (FWM) and left basal ganglia (BG). Levels of N-acetyl aspartate (tNAA), choline (tCho), creatine (tCr), lipids and macromolecules at 0.9ppm (Lip09+MM09) were measured. Cognition was tested using a battery validated for Indian population. Locally normalized z-scores were used to calculate brain dysfunction score. Spearman correlation coefficient was used to assess the correlation between two continuous variables. There were 28 (29% female and 71% male) cases and 30 (37% female and 63% male) controls
Results: The mean age was comparable in the 2 groups (33 and 34 years). There was a significant difference (p< 0.05) in the concentration (mmol/kg) of tNAA (9.29±311 vs 7.45±0.64), tCho (2.08±0.70 vs 1.74±0.25), tCr (6.95±2.56 vs 5.43±0.61), in the FWM and Lip09 + MM09 (5.87±1.05 vs 4.80±0.35) in BG, with higher levels in controls. There was no significant correlation between CD4 count and metabolites or overall dysfunction score and metabolites except Cr in FWM with more dysfunction associated with lower concentration. Fig 1 shows MR spectrum acquired from FWM of a patient



[Figure 1]

Conclusions: The results show that HIV-associated changes are present in asymptomatic people which may be contributing to the early neurocognitive decline. Knowledge of metabolic changes within studied brain regions can help understand the pathology and design interventions to cater to this unmet need in people living with HIV.

Assessing depression's impact on neurocognitive performance in the Metabolic and Ageing Cohort of the Swiss HIV Cohort Study

G.M.A. Santos[1], I. Locatelli[1], M. Métral[1], A. Berney[1], T. Doco Lecompte[2], A. Calmy[2], H. Kovari[3], P. Tarr[4], P. Schmid[5], U. Kunze[4], I. Nadin[2], K. Gutbrod[6], P. Brugger[3], K. Darling[1], R. Du Pasquier[1], M. Cavassini[1], NAMACO Study Group
[1]Lausanne University Hospital Center, Lausanne, Switzerland, [2]Geneva University Hospitals, Geneva, Switzerland, [3]University Hospital Zurich, University of Zurich, Zurich, Switzerland, [4]Kantonsspital Baselland, University of Basel, Basel, Switzerland, [5]St. Gallen Canton Hospital, St. Gallen, Switzerland, [6]University Hospital of Bern, Bern, Switzerland
Presenting author email: santos.galia@gmail.com

Background: In the era of potent antiretroviral therapy with suppressed blood HIV replication, HIV-associated neurocognitive disorder (HAND) remains a concern. This study aims to analyze the link between the presence of depressive symptoms and HAND in the Metabolic and Ageing Cohort of the Swiss HIV Cohort Study (SHCS).
Methods: The Neurocognitive Assessment in the Metabolic and Ageing Cohort (NAMACO) of the SHCS is an ongoing observational cohort study, which recruited 981 HIV-infected SHCS participants aged 45 years old or more from seven Swiss hospital centers between Jan 2013 and Nov 2016. All participants underwent a comprehensive neurocognitive examination by neuropsychologists and were classified into different categories of neurocognitive impairment based on the revised American Academy of Neurology diagnostic criteria for HAND. Depressive symptoms were assessed with the Center for Epidemiologic Studies Depression (CESD) scale. Demographic and HIV-infection associated characteristics as well as comorbid conditions were extracted from the SHCS database. A cross-sectional multivariate analysis was performed on baseline data using regression models controlling for demographics, after exclusion of individuals with known neurological conditions increasing the risk of cognitive impairment.
Results: 314/878 patients (35.8%) had HAND, including 279/878 (31.8%), 19/878 (2.2%) and 16/878 (1.8%) with asymptomatic neurocognitive impairment, mild neurocognitive impairment and HIV-associated dementia, respectively. The median CESD score was 9 (IQR 4-16). According to a 16/60 reference cut-off, 248/875 patients (28%) suffered from depression. The CESD scale was associated with HAND in the univariate analysis (OR 1.05 [95% CI 1.04-1.06], P <0.001) and in multivariate analysis (OR 1.05 [95% CI 1.03-1.07], P <0.001) adjusting for sex and age (female sex OR 2.33 [95% CI 1.63-3.35], P <0.001, age OR 1.05 [95% CI 1.03- 1.07], P <0.001). Female sex was also significantly related to the CESD scale (P = 0.0003, Wilcoxon rank-sum test).
Conclusions: Depression is an important confounding factor when assessing neurocognitive performance in HIV-infected individuals, even with moderate depressive symptoms. In our study, female sex was a major risk factor for both depression and HAND. Better addressing depressive symptoms, especially in HIV-infected women, might potentially improve the neurocognitive outcome of HIV-infected patients.

Prevalence over time and predictive factors of HIV-associated neurocognitive disorder (HAND) in HIV-positive patients

I. Mastrorosa, C. Pinnetti, P. Lorenzini, P. Balestra, R. Libertone, M. Ricottini, S. Menichetti, M.M. Plazzi, V. Mazzotta, M. Zaccarelli, A. Ammassari, A. Antinori
National Institute for Infectious Diseases, L. Spallanzani, Rome, Italy
Presenting author email: ilariamastrorosa@gmail.com

Background: Despite benefits on morbidity and mortality due to combined antiretroviral therapy (cART), HAND remains common in HIV individuals, with a variable prevalence in different cohorts. Aim of our study was to evaluate prevalence and predictive factors of HAND in more recent years.
Methods: Single-centre, retrospective, cross-sectional analysis of neurocognitive profile in HIV-infected ART-treated patients. All underwent neuropsychological assessment (NPA) by standardized battery of 14 tests on 5 different domains. Persons were classified as having HAND according to Frascati's criteria. Chi-square for trend and multivariable logistic regression were fitted.
Results: A total of 1,289 NPA over 771 HIV-infected individuals were collected from 2009 to 2016. Main characteristics: male 80.2%; MSMs 48.6%; HCVAb+ 18.6%; HIV-RNA < 40 cp/mL at NPA 84.9%; median of 8.6years (3.9-17.6) of infection and 13years (8-15) of education; median of 233 cell/mm^3 CD4+ nadir and 587 (419-772) cell/mm^3 current CD4+. At NPA, 50.7% of pts were receiving NRTI+NNRTI, 28.3% NRTI+PI/r and 3.8% NRTI+INSTI. In 461/1,289 (35.8%) tests a cognitive complaint in deficit of memory, attention or concentration was reported. HAND prevalence was 45.5% in complaining (ANI=24%; MND=18%; HAD=3%) and 14% in non-complaining patients (ANI=11%; MND=3%; HAD=0). Prevalence over time of HAND was stable in complaining (p at chi square for trend=0.134), but decreased in 2013-2016 in non-complaining (p <0.001). Factors associated to HAND by multivariable logistic regression were older age, lower educational level, lower CD4+ count and detectable HIV-RNA at NPA (Table). Patients tested in more recent years show a reduced risk of HAND.
Conclusions: A decreasing prevalence of HAND was observed in more recent years among patients without a cognitive complaint. Better viroimmunological state was correlated to a lower risk of HAND, while worse educational level and older age to a higher one. Besides HIV-related factors, patient characteristics, more than treatment-associated variables, affect risk of neurocognitive impairment.

Magnetic resonance imaging of cerebral small vessel disease in HIV-positive and HIV-negative men aged 50 and above

L. Haddow[1], C. Sudre[2], M.J. Cardoso[2], R. Gilson[1], X. Golay[3], S. Ourselin[2], A. Winston[4], C. Sabin[1], R. Jäger[3]
[1]University College London, Research Department of Infection and Population Health, London, United Kingdom, [2]University College London, Centre for Medical Image Computing, London, United Kingdom, [3]University College London, Research Department of Brain Repair and Rehabilitation, London, United Kingdom, [4]Imperial College London, Department of Medicine, London, United Kingdom
Presenting author email: lewis.haddow@ucl.ac.uk

Background: We assessed whether HIV serostatus was associated with white matter hyperintensities (WMH), a neuroimaging correlate of cerebral small vessel disease, in men aged ≥50 years.
Methods: Virologically-suppressed HIV-positive and demographically matched HIV-negative men aged ≥50 in the multicentre POPPY cohort underwent magnetic resonance imaging (MRI) at 3 Tesla. WMH volume (WMHV) was extracted from volumetric 3D T1 and FLAIR images using automated image processing algorithms and compared between groups (Mann-Whitney test). The association between HIV serostatus and WMHV as a proportion of intracranial volume (ICV; log-transformed) was estimated using a multivariable linear regression model with adjustment for age and associated factors identified in bivariate models (age, waist circumference, high-density lipoprotein concentration).
Results: Forty HIV-positive (median age 59 [interquartile range, IQR 54-64]) and 37 HIV-negative (59 [54-63]) men were included. HIV-positive participants had CD4+ count 570 (470-700) cells/μL and time since diagnosis of 20 (12-24)

years. Clinical characteristics were similar between groups including body mass index 25.4 kg/m^2 (23.4-18.2), waist circumference 91cm (86-100), blood pressure systolic 126 mmHg (116-137) over diastolic 78 mmHg (73-83), total cholesterol 5.0 mmol/L (4.0-5.4) and 10-year risk of cardiovascular disease (Framingham) 6.9% (5.2-9.9). Seventeen (22%) were current smokers and 24 (31%) recently used recreational drugs. Three (7.5%) HIV-positive men reported a history of stroke or transient ischaemic attack (TIA) and five (12.5%) reported ischaemic heart disease (IHD) compared to none of the controls (p=0.24 for stroke/TIA; p=0.06 for IHD). HIV-positive participants had more previous syphilis (47.5% vs. 21.6%; p=0.02) and current hepatitis C (7.5% vs. 0%; p=0.24). There were no differences in WMH between groups (Table). In the multivariable model, WMHV/ICV was not associated with HIV serostatus (p=0.82) but was associated with increasing age (1.7-fold increase in WMHV/ICV per +10 years, 95% confidence interval [CI] 1.1-2.7, p=0.03) and waist circumference (1.3-fold increase in WMHV/ICV per +10 cm, 95% CI 1.0-1.6, p=0.05).

	HIV positive (n=40)	HIV negative (n=37)	p
Median (IQR) WMHV, µL	929 (430-2311)	825 (347-1969)	0.33
Median (IQR) total intracranial volume (ICV), mL	1548 (1458-1601)	1556 (1454-1645)	0.36
Median (IQR) WMHV, % of ICV	0.06 (0.03-0.15)	0.05 (0.02-0.13)	0.31

[White matter hyperintensity volumes (WMHV)]

Conclusions: We found no difference in WMHV between middle aged HIV-positive men and demographically-matched HIV-negative controls.

WEPEB0483

Acceptability and safety of lumbar puncture for research in HIV-positive patients, Rakai, Uganda

G. Nakigozi[1], N. Nakasujja[2], N. Saktor[3], D. Saylor[3], F. Nalugoda[4], G. Kigozi[4], R.M. Galiwango[4], A. Anok[4], R. Mayanja[4], K. Robertson[5], R. Gray[6], M. Wawer[6]
[1]Rakai Health Sciences Program, Clinical Services, Kalisizo, Uganda, [2]Makerere University, Kampala, Uganda, [3]Johns Hopkins University School of Medicine, Baltimore, United States, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]University of North Carolina, Chapel Hill, Uganda, [6]Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States
Presenting author email: gnakigozi@rhsp.org

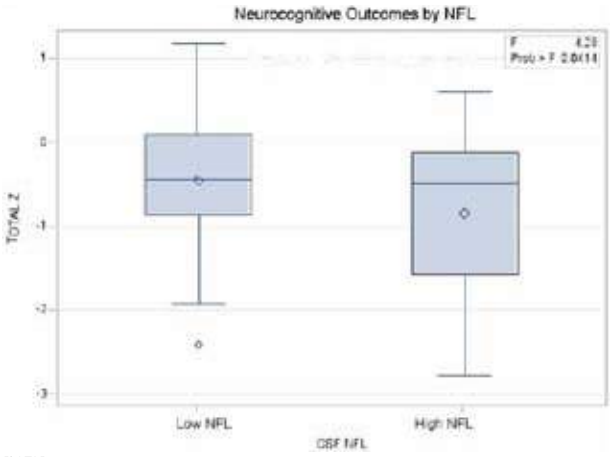
Background: HIV-associated neurocognitive disorders (HAND) are a common neurological sequelae of HIV infection. Collection of cerebrospinal fluid (CSF) by lumbar puncture (LP) is essential for the analysis of CSF biomarkers in research on HAND. However, there are concerns about the acceptability of LPs and post-LP side effects.
Methods: Four hundred antiretroviral therapy naïve HIV-positive patients aged 20-68 years with severe (CD4 ≤ 200; n=200) or moderate (CD4 351-500; n=200) immune suppression participated in a study to assess the neurological sequelae of HIV infection in Rakai, Uganda. Participants were offered the opportunity to have an LP to assess CSF virological compartmentalization and inflammatory markers. Up to 10mls of CSF were collected using the Tro-Spinoject 22 gauge atraumatic spinal needle in consenting participants. Following LP participants received recumbent rest and oral analgesics. We assessed the acceptability and safety of LP by interview and examination. Acceptability of LP was analyzed by key socio-demographic characteristics and baseline CD4 count.
Results: Two hundred seventeen out of 400 (54.3%) research study participants consented to LP.LP acceptance was significantly higher among patients with moderate immune suppression than with severe suppression (65% versus 44%; p< 0.001), but did not differ by age, gender or education. 198 (91.2%) of the LPs were successfully completed. The frequency of any adverse event was 12% and clinically significant adverse events (e.g., transient hypotension) was 0.9%. 11.1% experienced post-lumbar puncture headache, 1.0% backache and 1.0% neck pain. All post-LP effects resolved within a week and none required hospitalization. The risk of post-LP adverse event was unrelated to age, gender, education or immune suppression.
Conclusions: Research using lumbar puncture was acceptable among HIV-positive study participants. Using a 22 gauge spinal needle, the LP procedure can be performed with a very low rate of clinically significant adverse events.

WEPEB0484

Neuronal damage estimated by CSF NFL and association with neurocognition in HIV

K. Robertson[1], S.B. Joseph[2], S. Yosief[3], J. Eron[4], L. Kincer[4], N.M. Bowman[4], H. Zetterberg[5], M. Gisslen[6], R. Swanstrom[2], S. Spudich[7], R. Price[8], THINC
[1]University of North Carolina, Neurology, Durham, United States, [2]UNC Chapel Hill, Virology, Chapel Hill, United States, [3]UNC Chapel Hill, Neurology, Chapel Hill, United States, [4]UNC Chapel Hill, Infectious Diseases, Chapel Hill, United States, [5]University of Gothenburg, Gothenburg, Sweden, [6]University of Gothenburg, Infectious Diseases, Gothenburg, Sweden, [7]Yale University, Neurology, New Haven, United States, [8]UCSF, Neurology, San Francisco, United States
Presenting author email: kevinr@neurology.unc.edu

Background: HIV enters the central nervous system (CNS) early and persists in some, resulting in HIV Associated Neurocognitive Disorders (HAND) despite effective antiretroviral treatment (ART). The CNS represents both a compartment and reservoir, and is a barrier to curing HIV. Neurofilament light chain (NFL) is a biomarker reflecting CNS neuronal damage in Cerebrospinal Fluid (CSF), and we assessed the relationship to neurocognitive status in the THINC cohort.
Methods: THINC participants were administered neurocognitive testing (NP) and lumbar puncture (LP) after being on ART for at least one year. The NP battery assessed a number of domains, with summary Total z and GDS scores. NFL was determined in CSF and we assessed the cross sectional relationship to neurocognition.
Results: The 96 participants were 87% male, 60% Caucasian, had a mean (SD) age of 49 (11), education of 14 (3), CD4+ of 540 (253), Total z score -0.60 (.81) and CSF NFL 643 (564). There was a significant correlation between high CSF NFL (>700) and impaired total z score (r=-.21, p< .05). Controlling for age, we found significant (F(1, 92) = 4.04, p< .05) increased neurocognitive impairment in those with high CSF NFL. Similarly, the impaired (GDS >1.33) neurocognition group had significant increase in CSF NFL (847) over neurocognitively normal (CSF NFL (570); F(1,92) = 4.24, p< .05).



[NFL]

Conclusions: Biomarkers reflecting active neuronal damage and the impact on neurocognitive and functional status are important in estimating the CNS reservoir and managing effective treatment in those living with HIV. CSF NFL is a promising biomarker reflecting current neurocognitive functional status. We found a significant relationship between increased CSF NFL and neurocognitive impairment in these HIV participants. Future work could assess the use of CSF NFL as a marker of ongoing neuronal damage due to viral replication or neuroinflammation, and potentially guide treatment.

WEPEB0485

Screening positive for depression and illegal poly-substance use are among the factors independently associated with lower health-related quality of life of people living with HIV in Rio de Janeiro

R. Castro[1,2], R.B. De Boni[1], P.M. Luz[1], L.D.S. Velasque[3], L.V. Lopes[1], S.W. Cardoso[1], M.S. De Oliveira[1], R.K. Friedman[1], B. Grinsztejn[1], V.G. Veloso[1]
[1]*Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil,* [2]*Universidade Federal do Estado do Rio de Janeiro, Instituto de Saúde Coletiva, Rio de Janeiro, Brazil,* [3]*Universidade Federal do Estado do Rio de Janeiro, Departamento de Matemática e Estatística, Rio de Janeiro, Brazil*
Presenting author email: rodolfo.castro@ini.fiocruz.br

Background: The HIV-treatment primary goal of reducing viral load to an undetectable level can improve patients' quality of life. However, multiple factors can affect the Health-related Quality of Life (HRQoL) of people living with HIV/Aids (PLWHA) and influence treatment outcomes. This work aimed to estimate the factors associated with HRQoL among PLWHA in Rio de Janeiro, Brazil.
Methods: This was a cross-sectional study with patients receiving HIV-care at the National Institute of Infectious Diseases Evandro Chagas (INI-Fiocruz) enrolled between 2014-2016. EQ-5D-3L measured HRQoL; PHQ-2 screened depression; and, ASSIST measured substance use. Illegal poly-substance use was considered as the use of more than one illegal substance in the last three months. Structured questions evaluated intimate partner violence, sexual activity, and relationship status. Viral loads were obtained from the clinical cohort database if available within a 6-month interval before and after the study visit. A multiple linear regression model was conducted to estimate factors associated with HRQoL.
Results: The median age of the 1445 participants was 43.09 (IQR: 34.64-50.83) and of EQ-5D-3L scores was 0.80 (IQR: 0.74-1.00). The model results (estimate; p-value) showed that: screening positive for depression (-0.098; <0.001); illegal poly-substance use (-0.076; <0.01); older age [≥60-y vs.< 30](-0.070; <0.001), [40-59-y vs.< 30](-0.030; <0.05), [30-39 vs. <30](-0.002; 0.869); intimate partner violence (-0.059; <0.01); female sex at birth (-0.040; <0.001); detectable viral load [≥50 copies/ml vs. undetectable] (-0.040; <0.001), [missing viral load (22.56%) vs. undetectable] (-0.010; 0.322); 12-month sexual inactivity (-0.034; <0.01); lower educational level [≤ fundamental vs. medium](-0.029; <0.01), [superior vs. medium](0.014; 0.185); tobacco use (-0.027; <0.01); and, not being in a relationship (-0.022; <0.05), were factors independently associated with lower HRQoL.
Conclusions: These results suggest that most of the participants have low impact on quality of life, considering that the weights used for HRQoL calculation were obtained recently from a representative Brazilian general population, and that a EQ-5D-3L of 1.00 represents a "perfect health state". Moreover, regarding the associations in the model, both biological and sociobehavioral factors should be targeted for improving quality of life of HIV patients.

WEPEB0486

Co-prescription of benzodiazepines and opioids on hospitalization rates among people living with HIV in British Columbia, Canada

L. Ti[1,2], S. Nolan[1,2], B. Nosyk[1,3], M. Ye[1], J. Chia[1], Z. Cui[1], R. Barrios[1,4], J. Montaner[1,2], STOP HIV/AIDS Study Group
[1]*BC Centre for Excellence in HIV/AIDS, Vancouver, Canada,* [2]*University of British Columbia, Department of Medicine, Vancouver, Canada,* [3]*Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada,* [4]*Vancouver Coastal Health Authority, Vancouver, Canada*
Presenting author email: mintti@cfenet.ubc.ca

Background: Co-prescription of benzodiazepines and opioids, which are prescribed primarily for anxiety and pain, respectively, are associated with various health harms, including mortality. People living with HIV (PLHIV) are often prescribed these medications given the intersections between HIV/AIDS, mental health, pain, and addiction, making them particularly vulnerable to these harms. While studies have examined the use of opioids on hospitalization rates, little is known about the effect of benzodiazepine and opioid co-prescription on this outcome. The objective of this study is to examine whether co-prescription of benzodiazepines and opioids is associated with higher hospitalization rates among PLHIV in British Columbia, Canada.
Methods: Using a comprehensive linked population-level database of PLHIV in British Columbia, we included individuals following their first dispensation of highly active antiretroviral therapy (HAART). Generalized estimating equation regression models were constructed to determine the relationship between co-prescription of benzodiazepines and opioids, which was defined as an overlapping prescription of at least one day of both medications, on all-cause hospitalization rates.
Results: Between 1996 and 2013, a total of 8,993 individuals were included in the study; 1,694 (18.8%) were female and the median age at baseline was 40 years (Q1-Q3: 33-47 years). In a multivariable model adjusted for various demographic and clinical confounders, there was a positive association between the prescription of benzodiazepines and/or opioids and hospitalization rates compared to not being prescribed either medication: benzodiazepine only (adjusted rate ratio [ARR] = 1.36; 95% confidence interval: 1.26 - 1.47); opioid only (ARR = 1.83; 95%CI: 1.70 - 1.97); and co-prescription of both medications (ARR = 1.58; 95%CI: 1.41 - 1.77).
Conclusions: In this study, we found that PLHIV who were co-prescribed benzodiazepines and opioids had higher hospital utilization rates, which consequently exacerbates the burden on the healthcare system. The findings should be interpreted with caution - in particular, co-prescription of these medications is not necessarily always inappropriate. However, these findings demonstrate the need for systems- and policy-level interventions to monitor and tease out inappropriate prescribing practices in this setting.

WEPEB0487

Post HIV status disclosure assessment of behavioral health patterns among adolescents living with HIV: a Nigerian study

I. Nwakamma[1], K. Onu[2], G. Okoro[3], D. Ogbang[4]
[1]*African Centre for Health Leadership, Research, Amuwo, Nigeria,* [2]*AIDS Healthcare Foundation, Clinical Services, Abuja, Nigeria,* [3]*University of Benin, Nursing and Family Health (Graduate Program), Benin, Nigeria,* [4]*African Centre for Health Leadership, Research, Abuja, Nigeria*
Presenting author email: amolabora2@gmail.com

Background: Psychosocial and Mental health needs of adolescents living with HIV are major concerns in the global HIV response as they are major predictors of treatment outcome and prevention of new infections. Nigeria is among the largest contributors to the global HIV burden among adolescents, yet behavioural health patterns of this group in Nigeria are largely unknown.
Methods: In-depth interviews were conducted with care givers of 61 adolescent aged 10-18 years (male 34, female 27) and focus group discussions conducted with the adolescents who were purposively selected. There was comparative assessment of the psychosocial/behavioural health patterns pre and post HIV status disclosure along five themes: academic performance, mood, and participation in activities, relationship with friends and family, and treatment adherence. The information was transcribed, coded and content analysis performed
Results: Majority of the adolescents acknowledged that their status should not affect their education, and expressed worries over bearing the burden of silence in school with the resultant feeling of loneliness. A pattern of occasional withdrawal and low spirit was observed (72%), aggression & depression more in the female, and the older group largely indicated unwillingness to disclose their status not even to their best friends. Poor performance in School was more in the male, "sometimes I wonder why I am going to school" [boy, 17]. Eight (2 boys, 6 girls) engaged in sexual activities, 3 (females) without condom. Poor adherence to therapy was observed as they grew older. All the care givers agreed that it is difficult to hide the status from the adolescents for long, and even more difficult to disclose, "I got tired of lying to him about the drugs, I and the father had to break the news" [a mother].
Conclusions: There is an emergence of large number of adolescent living with HIV, yet the care-givers and most HIV service providers are not adequately prepared to manage the new challenge of HIV infection - mental health. Integrating mental health services into the HIV Program is necessary at this point to secure the wellbeing of the young population and promote right behaviour for effective prevent of new HIV infection.

Factors associated with the occurrence of suicide among French people living with HIV in the HAART era: a nested case-control study

M. Hentzien[1], A. Kaladjian[2], P. Pugliese[3], E. Billaud[4], L. Cuzin[5], C. Duvivier[6], M.-A. Valantin[7], M. Dramé[8], F. Bani-Sadr[1], Dat'AIDS Study Group
[1]Reims Teaching Hospitals, Robert Debré Hospital, Department of Internal Medicine, Infectious Diseases, and Clinical Immunology, Reims, France, [2]Reims Teaching Hospitals, Robert Debré Hospital, Department of Psychiatry, Reims, France, [3]University of Nice, CHU L'Archet, Infectious Diseases Department, Nice, France, [4]University of Nantes, Infectious Diseases Department, Nantes, France, [5]INSERM, Université de Toulouse III, UMR 1027, Toulouse, France, [6]Assistance publique - Hôpitaux de Paris - CHU Necker, Infectious Diseases Department, Paris, France, [7]Assistance Publique - Hôpitaux de Paris, La Pitié-Salpêtrière Hospital, Department of Infectious and Tropical Diseases, Paris, France, [8]University of Reims Champagne-Ardenne, Faculty of Medicine, EA 3797, Reims, France
Presenting author email: mhentzien@chu-reims.fr

Background: People living with HIV (PLHIV) are at higher risk of dying from suicide than general population. Suicide is the first cause of death among French PLHIV in immunovirological success. The main objective of the present study was to identify factors associated with dying from suicide among French PLHIV.
Methods: It was a multicenter case-control study nested in the French multicenter Dat'AIDS cohort, in the HAART era, from January 2000 to July 2013. Cases were all deceased PLHIV who died from suicide. Control selection (up to four controls for each case) was done using incidence density sampling, allowing to estimate relative risks. Controls were also matched on time from HIV diagnosis and clinical center. The following potential explanatory variables were extracted: date of birth, gender, country of origin, education level, socioprofessional category, marital status, having one or more children, HIV transmission group, Nadir of CD4, CD4 cell count, CDC stage, HIV viral load, antiretroviral therapy, hepatitis co-infections, tobacco use, alcohol use, toxicomania, history of anxious disorder, depression, bipolar disorder, schizophrenia or suicide attempt, and psychotropic drugs use (anxiolytics, anti-depressive, neuroleptics, thymoregulators). Medical files were also checked and multiple imputation was used for dealing with missing data. Univariable then multivariable conditional logistic regression models were performed.
Results: Among 349 patients included in the present study, 70 patients died from suicide and 279 were controls (69 cases had 4 controls, 1 case had 3 controls). By multivariable analysis, having children was protective against the risk dying from suicide (adjusted relative risk (aRR)=0.23, 95% confidence interval (95%CI) [0.10 - 0.70]), whereas active or substituted toxicomania (aRR=3.29, 95%CI[1.10 - 9.85]), alcohol intake >20g/day or history of abuse (aRR=3.56, 95%CI[1.43 - 8.88]), history of depressive disorder (aRR=3.76, 95%CI[1.49 - 9.50]), history of suicide attempt (aRR=5.93, 95%CI[1.58 - 22.24]) and psychotropic drugs intake (aRR=6.37, 95%CI[2.56 - 15.85]) were independently associated with an increased risk of dying from suicide.
Conclusions: Identification of factors associated with an increased risk of dying from suicide may help recognizing PLHIV that may the most benefit from an intervention to prevent suicide.

WEPEB0489

Adjustment disorders predict HIV viral load in patients seeking to improve self-efficacy regarding antiretroviral therapy adherence

H. Arroyo[1], E. Kaplan-Lewis M.D.[2], C.E. Aberg[3], J. Buck M.A.[3], B. Duah[3], A. Abrams-Downey[4], M. Cespedes, M.D.[4], A. Ventuneac Ph.D.[2], J.A. Aberg[4]
[1]Icahn School of Medicine at Mount Sinai Hospital, Psychiatry, New York, United States, [2]Icahn School of Medicine at Mount Sinai Hospital, New York, United States, [3]Mount Sinai Medical Center, New York, United States, [4]Icahn School of Medicine at Mount Sinai Hospital, Infectious Disease, New York, United States
Presenting author email: hansel.arroyo@mssm.edu

Background: Adherence to the antiretroviral therapy (ART) is a crucial determinant of effective HIV treatment. ART adherence is impacted by socioeconomic, psychological, and health challenges. Previous studies have documented an association between disclosure of HIV status and adherence.
This study examined the relationship between psychiatric diagnosis, adherence, disclosure, and HIV outcomes.
Methods: HIV-infected patients receiving care at Mount Sinai were enrolled in Rango, a program developed by VillageCare Wellness Innovations using technological resources to improve treatment adherence. All participants signed consent approved by the Mount Sinai IRB. Eligibility criteria included HIV infection on ART, NYC residence, and being a Medicaid and/or Medicare beneficiary. Patients completed self-report on mental health, substance use and determinants of adherence including disclosure of HIV status. Data were extracted about mental health disorders and HIV outcomes from both the Rango database and EMRs as per protocol.
Results: 289 patients enrolled in the program during the review period. Participants identified as African-American (41%), Hispanic (41%), White, non-Hispanic (8%), mean age was 50, and the majority was male (60%). One-fifth reported missing HIV medications in the prior 3 days, 35% had a detectable viral load (VL). 15% disclosed their HIV status to all family and friends, while 14% had not disclosed to anyone. White participants were more likely to have disclosed to all family and friends. Half of the participants had a psychiatric diagnosis documented in their electronic health records: 28% unipolar disorder, 14% anxiety disorder, and 9.7% bipolar disorder. Having an adjustment disorder and using substances were associated with missed medications or a detectable VL ($p<0.05$). Logistic regression adjusting for age, gender, race, adherence, HIV disclosure, and substance use showed that patients with adjustment disorders had 5.32 times the odds of having a detectable viral load compared to patients without adjustment disorders (95% CI: 1.25-22.70).
Conclusions: In our cohort, occurrence of adjustment disorders seems to play a prominent role in HIV outcomes compared other psychiatric diagnoses. Despite previous studies, no association was found between virologic suppression, disclosure or having a psychiatric diagnosis. These data suggest that patients with adjustment disorder may benefit from treatment intervention.

WEPEB0490

Effects of adaptive behavioral interventions to reduce alcohol use among HIV-positive patients in primary care: the health and motivation study

D. Satre[1,2], W. Leyden[2], A. Leibowitz[2], B. Hare[2], H. Jang[2], S. Catz[3], M. Horberg[4], M. Silverberg[2]
[1]University of California, Psychiatry, San Francisco, United States, [2]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [3]University of California, Nursing, Davis, United States, [4]Kaiser Permanente, Mid Atlantic Permanente Research Institute, Rockville, United States
Presenting author email: derek.satre@ucsf.edu

Background: Drinking alcohol at hazardous levels can compromise antiretroviral therapy (ART) response, and increase rates of medical and psychiatric problems, unsafe sexual practices, and mortality for people living with HIV. This randomized controlled trial examined two brief intervention models to reduce alcohol use.
Methods: Participants included 614 HIV-positive patients recruited from a Kaiser Permanente Northern California (KPNC) San Francisco Medical Center primary care HIV clinic. Subjects were eligible if they reported hazardous drinking during the prior year. Participants were recruited by telephone and randomized to either 3-sessions of a motivational interviewing (MI) behavioral intervention with a psychologist to enhance motivation to reduce drinking, emailed feedback (EF) containing information on alcohol use risks via the KPNC patient portal, or usual care alone (i.e., clinic-based alcohol screening/intervention by usual care providers). Participants who reported hazardous drinking at 6 month interviews post-intervention were offered additional (i.e., booster) treatment within the MI and EF arms. The primary study outcome was hazardous drinking rate (any 4+/5+ drinks in a single day for women/men) at 12 month follow-up study interviews; secondary outcomes were based on clinic-based alcohol screening measures. Hazardous drinking by intervention group and other demographic, psychological and substance use predictors (baseline age, education, race, income, sex, marital status, depression, anxiety, marijuana use, and hazardous drinking) was evaluated by multivariable logistic regression.
Results: The sample was 97% male; 63% White, 16% Hispanic, 10% African American, and 7% other ethnicities; with mean age of 49 years. In the 30 days prior to enrollment, 48% reported hazardous drinking, which was reduced to 25% at 12 months; no significant differences were noted by treatment group. Similar drinking reductions were noted for clinic-based alcohol measures. Factors associated with worse survey-reported hazardous alcohol use included younger age ($p=.006$), not being married or partnered ($p=.069$), and greater frequency of hazardous drinking at baseline ($p<0.001$).
Conclusions: Among HIV patients engaged in primary care, substantial reduction in hazardous drinking over time was observed for all 3 study arms. Patient demographic and clinical characteristics were identified that could help target individuals at risk for worse alcohol-related outcomes over time, to enhance future intervention development.

WEPEB0491

Role of basal ganglia in depression in HIV-infected individuals

M. Weber, Y. Zhuang, A. Tyrell, L. Wang, M. Tivarus, J. Zhong, G. Schifitto
University of Rochester, Rochester, United States
Presenting author email: giovanni_schifitto@urmc.rochester.edu

Background: Depression is the most common psychiatric comorbidity in HIV+ individuals that has persisted in the era of combination antiretroviral therapy (cART). Major depression is associated with abnormalities in the striatum and frontal cortex, in particular decreased functional connectivity between ventral striatum and ventromedial prefrontal cortex and anterior cingulate cortex. Given that basal ganglia injury is frequent in HIV infection, it could in part explain the higher prevalence of depression in HIV+ individuals. The aim of the current study was to determine if basal ganglia dysfunction (as measured by brain metabolites) is associated with depression and if these brain metabolites differ between HIV+ and HIV- individuals with depression.
Methods: As part of an ongoing longitudinal study of the effect of cART on brain structure and function, thirty-seven treatment naïve HIV+ individuals and 95 HIV- individuals underwent psychological and neuroimaging assessment.
Depressive symptomatology was assessed by the Center for Epidemiological Studies Depression Scale (CES-D). MR Spectroscopy (volume size = 15´15´15 mm^3, TE=35ms, TR = 2000ms) was acquired at basal ganglia region for metabolite concentrations. MRS data was calculated with the linear combination of model spectra. We collected the following metabolite concentrations in our study: glutamate(GLU), N-acetylaspartate(NAA), choline (CHO), myo-inositol(INS), and creatine(CRE).
Results: 37 HIV+ individuals (age 33.2±15.0) and 91 HIV- (age 42.2±14.4) (age p=0.09) were compared. HIV+ individuals prior to starting cART had a CD4 cell count of 500.6 cells/mm^3± 265 cells/mm^3 and viral load 5.08 log_{10} copies/ml ± 5.37 log_{10} copies/ml. Twelve of 91 (13%) HIV- and 17 of 37 (46%) HIV+ individuals prior to starting ARVs had depression (CES-D score ≥ 16) (p<0.01). After 12 weeks of cART, depression persisted in 38% of HIV+ individuals. Of the MRS metabolites, CHO/CRE was elevated in the HIV+ depressed individuals compared to the HIV+ non depressed individuals (p=0.01). HIV- depressed individuals tended to higher levels of CRE and INS (p= 0.057 and p=0.06 respectively.
Conclusions: Basal ganglia dysfunction is associated with depression in HIV+ individuals. The increase in CHO/CRE suggests that glia dysregulation may be contributing to the symptoms. HIV- depressed individuals tend to have less glia dysfunction in the basal ganglia than HIV+.

WEPEB0492

Risk factors associated with aortic stiffness in HIV-positive individuals compared to two HIV-negative groups: results of INI-ELSA-Brasil

R.C. Moreira[1,2], J. Mill[3], B. Grinsztejn[1], V. Veloso[1], M.J. Fonseca[4], R.H. Griep[5], I. Bensenor[6], D. Chor[4], A.G. Pacheco[2], INI-ELSA-Brasil
[1]FIOCRUZ, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]FIOCRUZ, Programa de Computação Científica (PROCC), Rio de Janeiro, Brazil, [3]Universidade Federal do Espírito Santo, Espirito Santo, Brazil, [4]FIOCRUZ, Departamento de Epidemiologia e Métodos Quantitativos, Rio de Janeiro, Brazil, [5]FIOCRUZ, Laboratory of Health and Environment Education (LEAS), Rio de Janeiro, Brazil, [6]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil
Presenting author email: rodrigo.moreira@ini.fiocruz.br

Background: HIV-infected patients are at increased risk for cardiovascular (CV) disease. Aortic stiffness (AS) measured by carotid-femoral pulse wave velocity (cf-PWV) is a marker of subclinical atherosclerosis. We studied the association of risk factors and HIV infection with AS in a cross-sectional analysis.
Methods: Cf-PWV was determined using a validated device. We used multivariable linear regression models to investigate the relationship between traditional and HIV-related CV factors with cf-PWV in a group of 649 HIV+ patients and two comparison groups, separately: 106 HIV-negative individuals and 15105 participants of the ELSA-Brasil study. A marker of poor health management was defined as having hypertension, diabetes or dyslipidemia without treatment at the moment of the clinical visit. Propensity scores (PS) were used to account for imbalances between the compared groups.
Results: Out of 15860 participants, 15622 (98.5%) with complete cf-PWV examinations were included. Overall, 46.0 % were male, median age was 51 [interquartile range (IQR) 45-58] years. Median cf-PWV in m/s (IQR) were 9.3 (8.4-10.5) in males and 8.7 (7.8-9.8) in females (p <0.001). For ELSA-Brasil, HIV- and HIV+ groups, cf-PWV were 9 (8.1-10.2), 8.7 (7.9-10.2) and 8.48 (7.66-9.4), respectively (p<0.001). Most of HIV+ individuals (88.7%) has ever been on ART, and 71.3% were virologically suppressed with a median CD4 count (IQR) of 540(371-741). In the adjusted model, age, hypertension, body mass index, systolic and diastolic pressure, and CD4 count, were associated with increased cf-PWV in HIV+. In the final models HIV+ was not associated with cf-PWV compared to HIV- group (β=-0.05;95%CI=-0.15,0.26;p=0.58), whereas lower levels of cf-PWV were observed when compared to ELSA-Brasil (β=-0.18;95%CI=-0.33,-2.97;p=0.01). Poor management was more frequent in the HIV- group (55.24%), compared to ELSA-Brasil (53.36%) and HIV+ (43.97%) groups (p<0.001) and was significantly associated with AS in the model comparing HIV+ with ELSA-Brasil groups (β=0.33;95%CI= 0.17,4.88;p<0.001).
Conclusions: Traditional CV risk factors and CD4 counts were associated with increased cf-PWV in HIV+ subjects. HIV infection was not a risk factor for increased cf-PWV, which was even higher for the ELSA-Brasil group. Better management of traditional CV risk factors combined with a good virologic control could explain these results.

WEPEB0493

The prevalence of cerebral microbleeds in HIV-infected hemophilia patients

T. Endo[1,2], N. Miyashita[1,3], K. Kasahara[1,3], T. Ara[1], K. Okada[1], S. Shiratori[1], H. Goto[1], J. Sugita[1], M. Onozawa[1], D. Hashimoto[1], K. Kahata[1], K. Fujimoto[1,2], T. Kondo[1], S. Hashino[2,4], T. Teshima[1,2]
[1]Hokkaido University Hospital, Hematology, Sapporo, Japan, [2]Hokkaido University Hospital, HIV Infection Medical Support Center, Sapporo, Japan, [3]Japan Foundation for AIDS Prevention, Tokyo, Japan, [4]Hokkaido University Health Care Center, Sapporo, Japan
Presenting author email: t-endo@fd5.so-net.ne.jp

Background: Several studies have shown that rates of cerebrovascular events in HIV-infected patients are increased in comparison to uninfected individuals. In addition, cerebral hemorrhage represents a serious complication in hemophilia patients. Recently, asymptomatic cerebral microbleeds (CMBs), which can be detected by highly sensitive techniques such as T2*-weighted magnetic resonance imaging (MRI), have emerged as an important marker for predicting symptomatic cerebral hemorrhage. The aim of the present study was to investigate the prevalence of CMBs in HIV-infected hemophilia patients and to evaluate the association between HIV infection and cerebral hemorrhage.
Methods: All of the HIV-infected hemophilia patients (HIV+ HemPts) who visited our hospital from January 2015 to December 2016 were enrolled in this study. In addition, all of the HIV-uninfected hemophilia patients (HIV- HemPts) who visited our hospital in the same period were enrolled as controls. CMBs were assessed using T2*-weighted MRI. The relationship between cerebral hemorrhage and the patients' clinical factors, such as age, the severity of hemophilia, hepatitis virus and HIV infection statuses, hypertension, hyperlipidemia, diabetes mellitus, and smoking status was examined.
Results: Two HIV+ HemPts had symptomatic cerebral hemorrhage during the study period. Twenty-one asymptomatic HIV+ HemPts and 12 HIV- HemPts underwent T2*-weighted MRI. CMBs were observed in 7 HIV+ HemPts and 1 HIV- HemPt. In the logistic regression analysis, HIV infection was the only risk factor for cerebral hemorrhage (Odds ratio: 7.07, p-value: 0.04).
Conclusions: This is the first report to investigate the prevalence of CMBs in HIV-infected patients. The prevalence of CMBs or symptomatic cerebral hemorrhage in HIV+ HemPts was extremely high (39.1%) in comparison to that in HIV+ HemPts (8.3%). Brain screening by T2*-weighted MRI led to more strict management of the blood pressure, re-evaluation of hemophilia treatment, and lifestyle improvements such as smoking cessation to prevent symptomatic cerebral hemorrhage in patients in whom CMBs were detected. The screening test seems to be meaningful for HIV+ HemPts.

WEPEB0494

Vitamin D and progression of carotid intima-media thickness in HIV-positive Canadians

H.F. Huff[1,2], A.T. Merchant[1,3], E. Lonn[1], E. Pullenayegum[1,4], F. Smaill[1], M. Smieja[1]
[1]McMaster University, Hamilton, Canada, [2]Canadian College of Naturopathic Medicine, Clinical Education, Toronto, Canada, [3]University of South Carolina, Arnold School of Public Health, Columbia, United States, [4]SickKids, Toronto, Canada
Presenting author email: hhuff@ccnm.edu

Background: Based on evidence implicating vitamin D deficiency in the development of cardiovascular disease (CVD) we hypothesized that in HIV-positive Canadians, low 25-hydroxyvitamin D (25(OH)D) concentration would be associated with increased progression of vascular disease. Vitamin D deficiency represents a unique problem in the HIV context. The antiretroviral drug efavirenz may impair vitamin D metabolism, and deficiency has been associated with increased HIV progression, all-cause mortality and carotid artery intima-media thickness (CIMT)-a measure of subclinical vascular disease.

Methods: We prospectively studied the relationship between baseline 25(OH)D (continuous) and CIMT progression (as CIMT change per year) between 2002 and 2011 in the multicentre Canadian HIV Vascular Study. Linear regression models were adjusted for Framingham risk, ethnicity, CD4 count and nadir, and years since HIV diagnosis (parsimonious model; variables included if P ≤ 0.20 in univariable associations). Full models were adjusted for age, sex, smoking, total cholesterol-to-HDL ratio (TC:HDL), ethnicity, BMI, antiretroviral therapies, CD4 nadir, lipid medications, physical activity, years since HIV diagnosis, kidney disease, and season (full model variable selection facilitated by construction of directed acyclic graphs).
Results: Of the 128 participants, 89.1% were men, mean age (SD) was 46.5 (8.2) years, 93.8% were white, and 36.7% were smokers. Mean (SD) annual CIMT follow up was 5.7 years (2.0; min 1.5, max 8.5). Mean CIMT progression (SD) was 0.027 mm/year (0.030 mm/year). Mean (SD) 25(OH)D was 95.0 (46.9) nmol/L. Only 13.3% were vitamin D deficient (25(OH)D < 50 nmol/L), whereas 61.7% met sufficiency status (75 nmol/L). Vitamin D quartiles were inversely associated with BMI (ANOVA, P = 0.034), TC:HDL (P = 0.001), parathyroid hormone (P = 0.003), but not efavirenz exposure (chi-square, P = 0.141). In linear regression analyses, baseline 25(OH)D was inversely associated with CIMT progression in all models (Table 1).

Baseline 25-hydroxyvitamin D (log) estimates for annualized carotid IMT progression weighted by years of follow-up

Models (n=128)	Estimate (95% CI)	Standard error	P value
Univariable	-0.04 (-0.049, -0.031)	0.005	<0.001
Parsimonious	-0.035 (-0.046, -0.024)	0.006	<0.001
Full	-0.04 (-0.052, -0.027)	0.006	<0.001

[Table 1]

Conclusions: Plasma 25(OH)D is associated with CIMT progression in this relatively vitamin D replete, predominately white and male, Canadian HIV positive population. Future research needs to establish causality as this could warrant more targeted screening and/or supplementation.

Death after myocardial infarction (MI): incidence and risk factors by MI type in HIV

R. Nance[1], J. Delaney[1], S. Heckbert[1], D. Drozd[1], M. Budoff[2], M. Feinstein[3], J. Willig[4], W. Mathews[5], R. Moore[6], J. Eron[7], S. Napravnik[7], P. Hunt[8], E. Geng[8], P. Hsue[8], W. Lober[1], C. Grunfeld[8], K. Crothers[1], M. Saag[4], M. Kitahata[1], H. Crane[1]
[1]University of Washington, Medicine, Seattle, United States, [2]UCLA, Medicine, Los Angeles, United States, [3]Northwestern, Medicine, Chicago, United States, [4]UAB, Medicine, Birmingham, United States, [5]UCSD, Medicine, San Diego, United States, [6]Johns Hopkins, Baltimore, United States, [7]UNC, Medicine, Chapel Hill, United States, [8]UCSF, Medicine, San Francisco, United States
Presenting author email: hcrane@uw.edu

Background: People living with HIV (PLWH) are at higher risk for MI. The Universal Definition of MI divides MIs into types. Type 1 MIs (T1MI) result spontaneously from atherosclerotic plaque instability. Type 2 MIs (T2MI) occur in the setting of oxygen demand-supply mismatch, such as with sepsis or cocaine-induced vasospasm. The purpose was to evaluate survival rates after each MI type and predictors of death following MIs in PLWH.
Methods: This study was conducted in the CNICS cohort of PLWH in care at six U.S. sites. MIs were centrally adjudicated and death dates were collected via national registries, death certificates and hospital records. Possible predictors of death after MI included age, sex, race, CD4 count, HIV viral load (VL), diabetes, estimated glomerular filtration rate (eGFR) < 30, statin use, and treated hypertension all assessed prior to the MI event. We compared percentages of those who died within 1 year of T1MI and T2MI with chi-square tests. Predictors of death within 1 year after T1MI or T2MI were tested using relative risk regression.
Results: 643 PLWH had MIs (317 T1MI, 326 T2MI) between 2000-2014; 77% male, 37% white, 54% black, and 7% Hispanic, with a mean age of 50 (SD 10). 26% died within 1 year; the rate was significantly higher for T2MI (37%) than T1MI (14%). PLWH with diabetes had significantly higher risk of death within 1 year of MI than those without for both T1MI (Relative Risk [RR] 1.9, 95% CI:1.1-3.4) and T2MI (RR 1.5, 95% CI:1.1-2.2). For T1MI but not T2MI, additional significant predictors of death were older age (RR 1.7 per 10 years, 95% CI:1.3-2.2), VL>400 copies/mL (RR 2.3, 95% CI:1.3-4.1), eGFR < 30 (RR 2.1, 95% CI:1.1-4.1) and not using a statin (RR 2.0, 95% CI:1.1-3.9).
Conclusions: Death within 1 year of MI was common in PLWH, particularly after T2MI. Predictors of death included modifiable risk factors, suggesting treatments such as statin use and effective ART could be used to prevent death following MI, principally T1MI. The significant differences in the rate and predictors of death for T1MI vs. T2MI enforces the importance of considering these outcomes separately.

WEPEB0496

Distribution and performance of cardiovascular risk scores in a mixed population of HIV-infected and community-based HIV-uninfected individuals in Uganda

A. Muiru[1], P. Bibangambah[2], L. Hemphill[3], R. Sentongo[2], J.-H. Kim[4], V. Triant[3], D. Bangsberg[5], A. Tsai[3], J. Martin[1], J. Haberer[3], Y. Boum II[6], J. Plutzky[4], P. Hunt[1], O. Samson[2], M. Siedner[3]

Presenting author email: anthony.muiru@ucsf.edu

Background: To compare and validate CVD risk profiles with carotid intima media thickness among a population of HIV-infected people on antiretroviral therapy (ART) and age and gender-matched HIV-uninfected people in Uganda.
Methods: We estimated CVD risk and contrasted profiles by HIV serostatus using the 1) Framingham laboratory-based score (FRS-Lipids); 2) Framingham non-laboratory score (FRS-BMI); 3) Reynolds score (RRS); 4) American College of Cardiology and American Heart Association score (ACC/AHA); and 5) the Data-collection on Adverse Effects of Anti-HIV Drugs (D:A:D) score. We compared absolute risk scores and risk categories across each score using Spearman rank correlations, and kappa statistics, respectively. Finally, we fit linear regression models to validate each risk score with common carotid artery intima media thickness (c-IMT) as a surrogate marker of CVD.
Results: Of 205 participants, half were female and the median age was 49 (IQR 46-53). Median CD4 count was 430 cells/mm^3 (IQR 334-546), with a median of 7 years of ART exposure (IQR 6.4-7.5). Compared with HIV-infected comparators, HIV-uninfected participants had a higher median systolic blood pressure (121 mmhg IQR [111-135 mmhg] versus 110 mmhg [100-121 mmhg], P<0.001), and higher prevalence of current smoking (18% versus 4% P=0.001) correlating with higher median CVD risk scores (p<0.003), and evidenced by greater c-IMT (0.68 vs. 0.63 P=0.003). Although all calculators were generally highly correlated (Spearman rank >0.80) and demonstrated increasing c-IMT with increasing risk category, FRS-BMI performed best among HIV-uninfected participants (R^2=0.20, P<0.001). FRS-Lipids, FRS-BMI and D:A:D performed similarly among the HIV-infected (R^2=0.13-0.15, P<0.004). ACC/AHA had the lowest association with c-IMT in both groups (R^2= 0.09, P=0.01). Notably, the HIV-specific D:A:D score categorized a significantly higher proportion of HIV-infected individuals as moderate or high risk (73%), than the other risk scores (9-13%).
Conclusions: A non-laboratory based risk score (FRS-BMI) correlated well with pre-clinical atherosclerosis in both HIV-infected and uninfected individuals, and may be of particular use in low-resource settings. Age and gender-matched, community based HIV-uninfected individuals had higher CVD scores than HIV-infected individuals in care in rural Uganda, and the difference appeared to be driven by modifiable factors such as smoking and high blood pressure.

WEPEB0497

Increasing cardiovascular disease incidence in HIV-positive adults in Asia: projections for 2017-2026

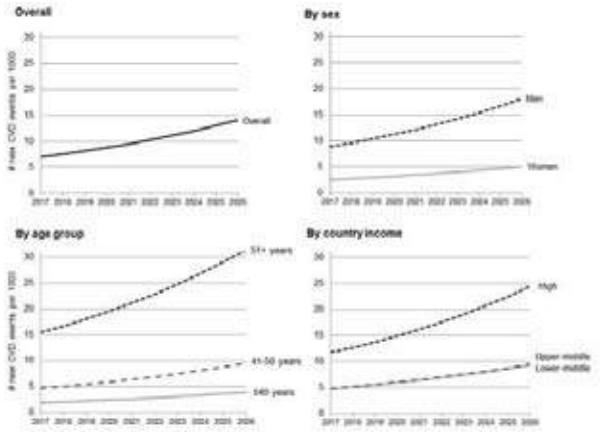
Presenting author email: rimkebijker@hotmail.com

Background: HIV is estimated to increase cardiovascular disease (CVD) risk in HIV-positive people by about two-fold. The number of people experiencing co-morbid CVD is expected to rise as the HIV population ages, but CVD risk and management have received limited attention in HIV-positive adults in Asia. We aimed to project the 10-year incidence of CVD based on a heterogeneous Asian HIV-positive cohort.
Methods: Analyses were based on patients recruited to the TREAT Asia HIV Observational Database (TAHOD), consisting of 20 sites in 12 countries. Patients were included if they started antiretroviral therapy, were alive, had no previous CVD history, and had data available on CVD risk factors. The D:A:D CVD risk equation was used to estimate annual new CVD events for 2017-2026, accounting for age- and sex-adjusted mortality. Projections were stratified by sex, age, and country income level.
Results: Of 3406 patients who met the inclusion criteria, 69% were male, median age was 45 (IQR 39-52) years, and median time since ART initiation was 8.1 (IQR 5.8-12.5) years. We projected that cohort incidence rates of CVD events will increase from 7 per 1000 person-years (/1000pys) in 2017 to 14/1000pys in 2026 (Figure). Stratified projections for 2026 showed a higher CVD event rate in men than women (18 vs 5 events/1000pys), in older patients (31, 9 and 4 events/1000pys in those aged 51+, 41-50 and ≤40 years, respectively) and in high-income countries (24 vs 9 in upper-middle and 9 in lower-middle income countries).
Conclusions: Our projections suggest that CVD incidence rates in Asian HIV-positive adults in our cohort will double in the next decade. Risk screening, specifically in men, older patients and high-income countries, is needed to support timely intervention and to reduce future CVD burden.



[Figure: Estimated CVD event rate for 2017-2026]

WEPEB0498

TLR4 Asp299Gly polymorphism is associated with cardiovascular disease in HIV-infected patients

L. Tarancón-Díez[1], M. Genebat[1], J.L. Jimenez[2], R.S. de Pablo-Bernal[1], M.Á. Muñoz-Fernández[2], M. Rafii-El-Idrissi Benhia[1], Y.M. Pacheco[1], E. Ruiz-Mateos[1], M. Leal[1]
[1]Biomedicine Institute of Seville, Sevilla, Spain, [2]General University Hospital Gregorio Marañón, Madrid, Spain
Presenting author email: ltarancon@alumni.unav.es

Background: Non-AIDS-related events (nADEs), especially cardiovascular diseases (CVDs), are the main cause of morbi-mortality in HIV-patients on suppressive antiretroviral therapy. The association of variants in the lipopolysaccharide (LPS) toll-like receptor 4 (TLR4), with the occurrence of CVDs in non-HIV-population is controversial. In HIV-infected patients, the role of TLR4 variants in the onset of CVDs remains unknown. The objective was to study the impact of the Asp299Gly polymorphism in the onset of CVDs in HIV-infected patients and to analyze the functional consequences of this polymorphism.
Methods: Patients, who consecutively visited the Virgen del Rocío University Hospital in Seville (Spain) between 1989 and 2016, with nADEs recorded information and DNA samples available, were included. TLR4 polymorphism, Aps299Gly (rs4986790), was determined in total DNA by real time PCR. Asp299Gly association with CVDs was analyzed by logistic regression after adjusting for potential confounders. Ex vivo activation and in vitro response after LPS stimulation on classical, intermediate and patrolling monocytes was assessed by multiparametric flow cytometry in a group of healthy donors and HIV-infected patients who carried the TLR4 polymorphism and compared with wild-types with available fresh whole blood samples. The percentage of monocytes producing intracellular IL1α, IL1β, IL6, IL8, TNFα and IL10 was determined. Soluble IL-6 was measured in plasma samples.
Results: From the total 253, 26 patients presented a recorded CVD (10%). Asp299Gly allele was directly and independently associated with the onset of CVDs (OR (IC95%)=3.35 (1.19-9.41), p=0.02) after adjusting with CD4-T-cell nadir, Hepatitis C virus-infection, bacterial pneumonia and diabetes. After LPS in vitro stimulation, healthy donors carrying the polymorphism showed a high percentage of $IL1\alpha^{-}IL1\beta^{-}IL6^{+}IL8^{-}IL10^{-}TNF\alpha^{-}$ intermediate monocytes and $IL1\alpha^{+}IL1\beta^{-}IL6^{-}IL8^{+}IL10^{-}TNF\alpha^{-}$ patrolling monocytes comparing with wild-type subjects (p=0.037 and p=0.046 respectively). IL-6 soluble levels, were correlated with the percentage of $IL1\alpha^{-}IL1\beta^{-}IL6^{+}IL8^{-}IL10^{-}TNF\alpha^{-}$ intermediate monocytes only in carriers (r=0.89; p=0.01). Regarding HIV-infected individuals, patients carrying the polymorphism for TLR4 showed higher percentage of intermediate monocytes expressing proinflammatory combinations of cytokines that included $IL8^{+}$ and $IL10^{+}$ compared with wild-type patients.
Conclusions: TLR4 Asp299Gly polymorphism is a risk factor in the onset of CVDs in HIV-infected patients. The proinflammatory profiles of this variant could be involved in the development of atherosclerotic pathologies.

WEPEB0499

Hypertension does not affect long-term retention on ART in a Ugandan cohort

J. Gonzalez Perez[1], J. Ssali[2], J. Kiwanuka[2], J. Ikapule[2], M. Ssemakadde[3], K. Ssamula[2], L. Buzaalirwa[2], P. Iutung Amor[2]
[1]AIDS Healthcare Foundation, Kigali, Rwanda, [2]AIDS Healthcare Foundation, Kampala, Uganda, [3]IeDEA, Masaka, Uganda
Presenting author email: juan.perez@aidshealth.org

Background: A few studies have reported prevalence of hypertension in HIV patients in Sub-Saharan Africa but information on how it affects clinical outcomes in our context is scarce. Here we analyze data on hypertension from a large HIV program in rural Uganda.
Methods: Data from adult patients started on antiretroviral treatment (ART) between January 2001 and November 2016 with at least two blood pressure (BP) measurements was included in the study. We used Kaplan-Meier survival methods to estimate retention on ART, Cox proportional hazards methods to adjust for potential confounders and multivariate logistic regression to identify factors associated to development of hypertension.
Results: 6,244 patients met the inclusion criteria. 65% were women, median age was 35 years and median CD4 was 171 cells. Hypertension was diagnosed in 1,513 patients (24.2%). 70.1% of all cases were diagnosed before ART initiation or during the first year on treatment. Development of hypertension in the first year on ART had a significant positive association with age and weight and negative with CD4 baseline in the multivariate analysis. Treatment with Stavudine (d4T) -containing regimens was also associated to increased risk of developing hypertension during the first year (OR: 1.59 p=0.01 using as reference Zidovudine-containing regimens). Three and five years retention on ART for those that had a diagnosis of hypertension was 92.8 and 88.2% (versus 91.8 and 88% for patients without

hypertension). There was no association between hypertension and attrition when adjusting by age, sex, CD4 baseline, WHO stage, weight and year of ART initiation in the Cox model.

Conclusions: Our analysis, in line with other studies, found that hypertension is common in HIV patients on ART. Development of hypertension in the first year on ART was associated with the use of d4T regimens and with lower CD4 counts. Despite poor BP control, our study found that HIV patients with hypertension have similar outcomes (in terms of long term retention on ART) than normotensive patients. The low prevalence of other cardiovascular risk factors in our context (reducing the morbidity associated to hypertension) and the closer follow up in patients with chronic diseases could partially explain these findings.

WEPEB0500

Comparing CVD risk factors in HIV-infected and HIV uninfected individuals from the general population in Greece

Presenting author email: gtouloum@med.uoa.gr

Background: Although triple antiretroviral therapy substantially decreased mortality in HIV-infected individuals, mortality remains higher compared to general population, mainly due to higher prevalence of non-AIDS related comorbidities, including cardiovascular diseases (CVD). Study compared the prevalence of CVD risk and its factors, and 'Heart age' between HIV-infected and HIV-uninfected individuals in Greece.

Methods: HIV-infected data was derived from the AMACS study (Athens-Multicenter-AIDS-Cohort-Study), and control data from general population from the health examination survey „National Study of Morbidity and Risk factors" (E.ME.NO.). Multistage stratified random sampling based on 2011 census was used; data was collected between 2014-2015 and weighted to reflect Greek population by age, gender, and geographical distribution. All HIV-infected adults with ≥1 visit between 2012-2014 and all E.ME.NO control-group adults were included. 10-year risk of CVD-event was estimated using the Framingham risk score (FRS). Individual estimated risk was used to calculate 'Heart age' described as a person's predicted vascular system age based on his/her cardiovascular risk factor profile. Weighted multivariable logistic, fractional logistic and multivariable linear regression models were applied for analysis.

Results: 5305 HIV-infected (median age:42.7 years, 85.0% males) and 5950 non-HIV-infected (median age:47.9 years, 48.4% males) individuals were included. Crude prevalence of hypertension, diabetes and high FRS was significantly higher in the control group, but adjusted for age, gender and origin, high FRS was significantly higher in HIV-infected individuals with no significant differences between the two groups in hypertension and diabetes. Smoking and dyslipidemia were more prevalent in HIV-infected whereas obesity was more prevalent in the general population. Adjusted mean difference (for white/men/45yrs) between heart and chronological age was higher by 1.7 years in the HIV-infected-individuals (Table).

Conclusions: Dyslipidemia, smoking and increased CVD risk, were more prevalent in HIV-infected compared to the control group. Assessment and management for CVD and its risk factors are of high priority for HIV-infected patients' care, potentially leading to improved health outcomes.

	HIV infected	HIV un-infected	OR (HIV-infected/HIV-uninfected) (95% CI)	p-value
Hypertension (%; 95%CI)	34.2 (31.7, 36.6)	35.1 (32.4, 37.7)	0.96 (0.83, 1.12)	0.598
Diabetes Mellitus (%; 95%CI)	6.2 (5.4,7.0)	5.8 (4.9, 6.8)	1.06 (1.06, 1.07)	0.588
Dyslipidemia (%; 95%CI)	52.6 (50.8, 54,3)	46.9 (44.5, 49.4)	1.25 (1.12, 1.14)	<0.001
Current smoking (%; 95%CI)	66.8 (64.7, 68.9)	46.5 (44.3, 48.8)	2.31(2.04, 2.61)	<0.001
Obesity (BMI>30) (%; 95%CI)	10.2 (8.6, 11.9)	26.7 (24.6, 28.6)	0.32 (0.26, 0.39)	<0.001
High FRS (>20%) (%; 95%CI)	19.6 (16.8, 22.5)	15.3 (13.1, 17.6)	1.35 (1.07,1.71)	0.013
FRS (Mean; 95% CI)	13.1 (13.0, 13.1)	11.9 (11.8, 11.9)	1.12 (1.11, 1.13)	<0.001
'Heart age'-chronological age (years) (Mean; 95% CI)	13.4 (12.6, 14.2)	11.7 (11.0, 12.4)	Adjusted difference:1.72 (0.68, 2.76)	0.001

cART induced macrophage p90RSK activation: a potential mechanism for cART-associated atherosclerosis

M. Singh[1], K.-S. Heo[2], N. Stirpe[1], K.A. Ko[2], Y. Tao[2], J. Medina[2], T. Thomas[2], L. Wang[1], K. Gates[1], X. Qui[1], K. Fujiwara[2], N.-T. Le[2], S. Maggirwar[1], G. Schifitto[1], J.-I. Abe[2]

Presenting author email: giovanni_schifitto@urmc.rochester.edu

Background: Increased incidence of cardiovascular disease (CVD) in HIV infected patients is well established, but the role and potential mechanisms that combined anti-retroviral therapy (cART) may play in CVD remains unclear. Endothelial cells and macrophages play a key role in atherosclerosis (AS) and thus CVD. Our previous studies have shown that activation of endothelial p90RSK, a redox-sensitive kinase, is a critical event in the development of AS. Given that activation of macrophage p90RSK has also been reported to affect macrophage function, we have investigated whether cART may affect macrophage p90RSK kinase thus contributing to AS.

Methods: To determine the role of macrophage p90RSK in atherosclerosis, we generated macrophage-specific wild type (WT) and dominant negative (DN) p90RSK transgenic mice, crossed with $LDLR^{-/-}$ mice and fed a high-cholesterol diet.
To investigate the role of p90RSK in human, whole blood monocytes from 25 HIV infected individuals on stable cART for at least 1 year and with viral load ≤50 copies/mL and 53 HIV negative and non-cART treated controls matched for age, gender, environment and Reynolds CVD risk score were analyzed by flow cytometry.

Results: Efferocytosis-related signaling and phagocytic capacity were upregulated and inflammatory gene expression were down-regulated in macrophages in an p90RSK activity-dependent manner; p90RSK directly phosphorylating ERK5 S496 and consequently inhibiting ERK5 transcriptional activity. In mice, we found that p90RSK activation accelerated plaque formation by inducing pro-atherogenic phenotypes such as reduced efferocytotic activity and enhanced M1 polarization. While backbone regimen of tenofovir (TDF) plus emtricitabine (FTC) did not activate p90RSK, the combination with maraviroc (MVC), rilpivirine (RPV) and atazanavir (ATV)/ritonavir (RTV) significantly increased p90RSK activation, reduced efferocytosis, and increased M1-type related gene expression.
In study participants, we found significantly increased p90RSK activation in the cART-treated group, and additional treatment of low dose of H_2O_2 (200 nM) accelerated p90RSK activation more in the monocytes from cART-treated patients than those in controls in vitro.

Conclusions: Our results demonstrate that p90RSK is robustly activated by cART. This activation culminates in reduced activity of macrophage efferocytosis, thereby accelerating atherosclerotic plaque formation. Monocyte/macrophage p90RSK can be a good target and an excellent biological marker to prevent and predict cART-induced CVD.

Awareness of the 2013 American College of Cardiology/American Heart Association (ACC/AHA) blood cholesterol guideline by providers who take care of people living with HIV

L. Non, R. Patel, G. Escota, R. Presti
Washington University in St. Louis, Infectious Diseases, St. Louis, United States
Presenting author email: l.non@wustl.edu

Background: Atherosclerotic cardiovascular diseases (ASCVD) have emerged as an important cause of morbidity and mortality among HIV-infected individuals. Statins reduce this risk, but their use among HIV-infected people has been sub-optimal. The ACC/AHA updated the guideline on blood cholesterol management in 2013, but awareness of this guideline among providers who take care of people with HIV is unknown.
Methods: We administered an anonymous online survey to providers who take care of HIV-infected individuals in St. Louis, Missouri. Knowledge of the guideline and agreement with the recommendations were assessed using multiple-choice and case-based questions with Likert scale items. Data were then summarized using descriptive statistics.
Results: Ninety providers responded to our survey, of which 77.3% were physicians and 12.5% were physicians in training. 63.4% were males. Majority of the providers were from Infectious diseases (64.4%), followed by Internal Medicine (25.3%), and Cardiology (4.6%). Majority (95.1%) believed that HIV-infected individuals are at a higher risk for ASCVD. An overwhelming majority (97.5%) were aware of the guideline, and 68.8% agreed with its recommendations. The top 3 identified barriers to prescribing statins were concerns for drug-drug interaction (47.5%), polypharmacy (47.5%), and poor medication adherence (46.3%). Only 35% routinely use the guideline-recommended ASCVD 10-year risk calculator, however, majority (76.3) were aware of the ≥7.5% 10-year risk threshold for discussing statin therapy. The different patient groups identified by the guideline for whom statin therapy is recommended were correctly identified by majority (>72.3%) of the responders, except for the patient group with a low-density lipoprotein cholesterol of 200 mg/dl or more, for whom only 52.7% of the providers would prescribe statins. Majority (80%) believed that following the guideline would lead to an improvement in the cardiovascular outcomes of HIV-infected individuals.
Conclusions: Most providers who take care of HIV-infected individuals have some awareness of the 2013 ACC/AHA guideline, but few routinely use the ASCVD 10-year risk calculator in their patients. Many providers also cite medication-related issues as barriers to prescribing statins. Interventions are needed to address these gaps.

Cardiovascular disease (CVD) and chronic kidney disease (CKD) event rates in HIV-positive persons at high predicted CVD and CKD risk: results from the D:A:D study

M.A. Boyd[1], A. Mocroft[2], L. Ryom[3], A. d'Arminio Monforte[4], C. Sabin[2], W. El-Sadr[5], C.I. Hatleberg[3], S. De Wit[6], R. Weber[7], E. Fontas[8], A. Phillips[2], F. Dabis[9], P. Reiss[10], J. Lundgren[3], M. Law[1], D:A:D Study Group
[1]Kirby Institute, University of New South Wales, Infection and Population Health, Sydney, Australia, [2]University College London, Infection and Population Health, London, United Kingdom, [3]University of Copenhagen, Infectious Diseases, Copenhagen, Denmark, [4]Universitario San Paolo, Dipartimento di Scienze della Salute, Milan, Italy, [5]Columbia University and Harlem Hospital, Infectious Diseases, New York, United States, [6]Saint Pierre University, Infectious Diseases, Brussels, Belgium, [7]University of Zurich, Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland, [8]Nice University Hospital, Public Health, Nice, France, [9]Universite de Bordeaux, Talence, France, [10]University of Amsterdam, Global Health and Infectious Disease, Amsterdam, Netherlands
Presenting author email: mark.boyd@adelaide.edu.au

Background: The D:A:D study has developed predictive risk-scores for CVD and CKD (confirmed eGFR < 60 ml/min/1.72m^2) events in HIV-positive individuals. We hypothesised that D:A:D participants at high (>5%) CVD and CKD predicted risk would be at even greater risk for CVD and CKD event outcomes.
Methods: We included all participants with complete risk covariate data, baseline eGFR >60 ml/min/1.72m^2 and ≥3 eGFRs thereafter to calculate CVD and CKD scores. We calculated CVD and CKD event rates by predicted 5-year CVD and CKD risk-strata (< 1%, 1-5%, >5%) and fitted Poisson models to assess whether CVD and CKD risk-strata effects were multiplicative.
Results: 27,215 participants contributed 202,034 person years of follow-up; 74% male, median (IQR) age 42 (36,49) years, baseline year of follow-up 2005 (2004,2008). D:A:D risk equations predicted 3560 (13.1%) participants at high CVD, 4996 (18.4%) participants at high CKD risk and 1585 (5.8%) participants at both high CKD and CVD risk. CVD and CKD event rates by predicted risk-strata were multiplicative **(Figures 1a and 1b).** Participants at high CVD risk had a 563% increase in CKD events (p< 0.001); participants at high CKD risk had a 31% increase in CVD events (p=0.005). Participants' CVD and CKD risk-strata appeared to have multiplicative predictive effects with no evidence of an interaction (p=0.329 and p=0.291 for CVD and CKD respectively).
Conclusions: We found that combining CVD and CKD risk-scores improved prediction of CVD and CKD events, especially CKD. This suggests CVD and CKD risk in HIV positive persons should be assessed in tandem.

WEPEB0504

Incidence and factors associated with atrial fibrillation in people living with human immunodeficiency virus (PLHIV) in British Columbia, Canada

P. Vizcarra[1], O. Eyawo[2], M. Ye[2], M. Lu[2], M. Bennett[3], R. Hogg[4], J. Montaner[2], S. Guillemi[2]
[1]Universidad Nacional de La Plata, Infectious Disease, La Plata, Argentina, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, Medicine, Div Cardiology, Vancouver, Canada, [4]Simon Fraser University, Health Sciences, Vancouver, Canada

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia in the general population and little is known about its incidence and related factors in PLHIV. The aim of this study was to compare the incidence of AF amongst PLHIV and the HIV negative individuals, as well as to describe its association with markers of HIV infection and treatments.
Methods: A population-based dataset was created via linkage between the BC Centre for Excellence in HIV/AIDS and Population Data BC. PLHIV aged 19 years and older were compared to a random 10% sample of HIV negative population. We used the International Classification of Diseases 9 and 10 codes to identify AF diagnosis from 1996 to 2013. Generalized estimating equation (GEE) models were constructed to examine the relationship between the incidence rate of AF in PLHIV and demographic/clinical variables. The age-adjusted incidence rates were calculated using the age distribution of 2011 Canadian standard population.
Results: 528,859 individuals were assessed; 13,907 were identified as PLHIV and 514,952 as HIV negative individuals. Of those, 265 (1.91%) and 20,244 (3.93%) developed AF respectively during the follow up period (median of 7.15 and 12.42 years). AF occurred at a median age 61 years (Q1, Q3=52, 70) in PLHIV vs 75 years

(Q1, Q3= 66, 82) (P< 0.001) in the HIV negative individuals. The age standardized incidence rate per 1000 person year was 2.88 (95% CI: 2.26-3.50) in PLHIV and 2.68 (95% CI: 2.65-2.75) in the HIV negative individuals with a rate ratio of 1.07 (95% CI: 0.84-1.30). In adjusted models , variables associated with a higher rate of developing AF in PLHIV included: older age, male sex, lower CD4 cells at baseline and having a prior AIDS defining illness. Earlier initiation of antiretroviral therapy (ART) and use of either protease inhibitors or NNRTIs were negatively related to development of AF.
Conclusions: In this study the age standardized incidence rate for AF in PLHIV was similar to the HIV negative individuals. PLHIV had a higher rate of developing AF if they were older, male, and had indicators related to advanced HIV infection, irrespective of their ART.

WEPEB0505

Blood thrombogenicity is increased in antiretroviral-treated HIV infection

M. O'Brien, I. Okoroafor, A. Heyison, M.U. Zafar, J. Rodriguez, K. Cavanagh, J. Aberg, J.J. Badimon
Icahn School of Medicine at Mount Sinai, Medicine, Infectious Diseases, New York, United States
Presenting author email: judith.aberg@mssm.edu

Background: HIV infection is associated with accelerated atherosclerosis and an increased rate of arterial thrombotic complications. This exploratory study was aimed to evaluate quantitative aspects of thrombus as it relates to platelet reactivity, thrombus kinetics, monocyte platelet aggregates (MPA), and monocyte subsets (MS).
Methods: Age and gender matched HIV infected (HIV+) participants (n=15) and seronegative controls (n=14) were enrolled. All HIV+ persons were on suppressive antiretroviral (ART) for >48 weeks. Blood thrombogenicity using the ex vivo Badimon perfusion chamber at low shear rate (LSR; venous) and high shear rate(HSR; arterial), platelet reactivity using light transmission aggregometry(LTA), thrombus kinetics using thromboelastography and fresh whole blood MS and MPA using flow cytometry were evaluated.
Results: HIV infected participants had a median age of 47 years with 53% males and 20% smokers. Controls' median age was 45 years with 50% male and 10% smokers. ART regimens included integrase inhibitor 53%, protease inhibitor 40%, abacavir 20% and NNRTI 13%. As measured by the Badimon chamber, HIV infected participants had increased platelet-thrombus formation as compared to controls at LSR (mean±SD) 6444±932 μ(2)/mm vs 4959±1991 μ(2)/mm, p=0.004 and at HSR 10213±3177 μ(2)/mm vs 7731±3387 μ(2)/mm, p=0.03 and increased platelet reactivity (LTA). Both groups showed similar thrombus kinetics. Although classical(%CD14+CD16-), non-classical(%CD14dimCD16+), intermediate(%CD14+CD16+) MS, and classical MPA (%CD14+CD61+) and non-classical MPA (%CD14dimCD61+) did not differ between HIV+ and controls, platelet-thrombus formation at HSR correlated directly with nonclassical MS (r 0.69; p=0.006) nonclassical MPA (r 0.54; p=0.039), and inversely with classical MS (r -0.57; p=0.032) in HIV+ only.
Conclusions: Compared with age and gender matched controls, HIV+ persons on suppressive ART had increased blood thrombogenicity which may contribute to increased cardiac events observed in this population. Intriguingly, thrombus formation was associated with nonclassical MS and nonclassical MPAs. Nonclassical MS have been shown to highly express tissue factor in HIV+ persons. Future studies are needed to determine the mechanism of increased thrombus formation and to determine the potential clinical benefits of antithrombotic strategies in ART-treated HIV infection.

Bone mineral density at the hip declines twice as quickly among HIV-infected women than men

K. Erlandson[1], J. Lake[2], M. Sim[3], J. Falutz[4], C. Prado[5], A.R. Silva[6], T. Brown[7], G. Guaraldi[8]
[1]University of Colorado, Aurora, United States, [2]University of Texas Health Sciences Center, Houston, United States, [3]University of California-Los Angeles, Los Angeles, United States, [4]McGill University, Montreal, Canada, [5]University of Alberta, Edmonton, Canada, [6]Hospital Beatriz Angelo, Loures, Portugal, [7]Johns Hopkins University, Baltimore, United States, [8]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences for Children & Adults, Modena, Italy
Presenting author email: kristine.erlandson@ucdenver.edu

Background: Initial declines in BMD following ART initiation in HIV are well described, but data on long-term changes and risk factors for decline, particularly among women, are limited.
Methods: HIV-infected men and women in the Modena Metabolic Clinic underwent dual-electron X-ray absorptiometry (DXA) scans every 6-12 months for up to 10 years (median 4.6 years). Mixed methods regression models were created for women and men in combined and stratified models to determine factors associated with BMD. Models included variables described below; CD4 nadir, CD4 total and %, smoking, diabetes, and duration of protease inhibitor use were considered in univariate models but were not significant.
Results: 839 women and 1759 men contributed ≥2 DXA scans. The majority (82%) were ≤ 50 years old; 49% had HIV-1 RNA < 50 copies/mL at baseline; 15% of women were post-menopausal and 7% of men had hypogonadism; 30% and 27%, respectively, had hepatitis C virus co-infection. Significant adjusted average annual declines in hip and spine BMD among women and men were observed; women (hip: -0.008, L-spine -0.012 g/cm²/year) and men (hip: -0.004; L-spine: -0.007 g/cm²/year; all p< .0001). In combined mixed effect models, female sex was associated with lower hip but not spine BMD (p<0.0001). The effects of other variables on BMD are shown (Table). Sex-stratified models yielded similar results with notable exceptions: physical activity (women) and hepatitis C (men) were no longer significant in gender-specific models.

[Table. Effects of covariates on BMD (g/cm²) at the hip and lumbar spine in mixed regression models]

Conclusions: Bone density at the hip, a significant predictor of fracture risk, declined twice as quickly among women compared to men and sex was independently associated with lower hip BMD in adjusted models. In addition, the results further emphasize the importance of bone health evaluation in HIV-infected adults beginning after age 45, and identify modifiable factors that may limit BMD decline.

WEPEB0507

Bone mineral density in HIV-infected patients younger than 40 years: lower peak bone mass and high prevalence of osteoporosis

M. Llop[1], N. Espinosa[2], C. Maciá[1], W.A. Sifuentes[1], C. Gomez-Ayerbe[1], M.J. Vivancos[1], M. Vazquez[1], S. Moreno[1], J.L. Casado[1]
[1]Ramon y Cajal Hospital, Madrid, Spain, [2]Virgen del Rocio Hospital, Sevilla, Spain
Presenting author email: jcasado.hrc@gmail.com

Background: It has been observed a lower than expected bone mineral density (BMD) in young HIV-infected patients, especially in those infected perinatally or during adolescence. However, associated factors with reduced BMD and evolution during follow up has not been detailed in those patients with HIV infection acquired in adult age.
Methods: Prospective cohort study of BMD and associated factors in a study about the prevalence of different comorbidities in HIV-infected patients (ComorVIH; NCT 02116751). For the purpose of this study, we selected those patients younger tan 40 years. BMD was evaluated by DXA (Dual X-ray Absorptiometry) and classified according to WHO definition in osteoporosis and osteopenia.

Results: Overall, 279 patients (55 women) had ≤40 yrs and a DXA scan. Mean age was 32.8 yrs, BMI was 23,8 kg/m2, 83% were MSM. Median time of HIV infection was 55 months (32-104), nadir CD4+ count was 250 cells/mmc, and 50% were receiving first-line TAR, TDF-based in 200 cases, for a median time of 36 months. It was observed spine and hip osteoporosis in 14% and 2%, osteopenia in 43% and 42%, respectively. Importantly, osteoporosis was more prevalent in males (21% vs 13% lumbar, 4% vs 0 in hip). According to age strata, there was a marked decrease of BMD after the 20's (1.08, 0.89, 0.84, 0.83, and 0.78, for ≤20, 21-25, 26-30, 31-35, and 36-40 years, respectively). A lower BMD was observed in patients with lower BMI (r=0.35; p<0.01), longer time of HIV (r=-0.31; p=0.03), lower nadir CD4+ (r=0.21; p=0.04), and time on ART (r=-0.21; p=0.03). DXA scan was repeated after a median of 41 months, with worsening of bone status in 60% of cases (spine and hip osteoporosis in 19% and 4%, and osteopenia in 49% and 50%), associated with a longer time between DXAs (r=-0.31; p<0.01) and time on cART including TDF (-0.34; p<0.01).
Conclusions: HIV-infected patients, mostly males, had a lower peak bone mass and a high prevalence of osteoporosis/osteopenia, related with traditional risk factors such as BMI, and HIV-associated factors, especially time of HIV infection and use of TDF.

WEPEB0508

Vertebral fractures in asymptomatic HIV-infected patients older than 50 years: prevalence, relation with osteoporosis and prediction with the use of the FRAX equation tool

J.L. Casado, M. Llop, C. Maciá, C. Gomez-Ayerbe, M.J. Vivancos, M.J. Perez-Elías, A. Moreno, M. Vazquez, S. Moreno
Ramon y Cajal Hospital, Madrid, Spain
Presenting author email: jcasado.hrc@gmail.com

Background: The prevalence of osteoporotic vertebral fractures (VF) in HIV-infected patients has not been widely studied, neither the role of the FRAX equation tool in predicting these morphometric deformities.
Methods: Cross-sectional study of 130 patients ≥ 50 years, asymptomatic, using validated questionnaires about daily calcium intake and physical activity (IPAQ, International Physical Activity Questionnaire), thoracic-lumbar radiographs, bone DXA scan (dual X-ray absorptiometry), and bone biomarkers. VF were diagnosed and classified by semiquantitative morphometric criteria of Genant et al.
Results: Overall, 121 patients (34 women, 28%) were finally evaluated. Mean age was 54,1 yrs (50-75), mean BMI was 23.9 (15.8-33.5), nadir CD4+ was 220 (81-337), and 49% were HCV coinfected. Time of HIV infection was 257 months (205-301), and time on ART was 219 months (150-247). In spite of calcifediol monthly supplementation, 27% had hypovitaminosis D, and 17% had secondary hyperparathyroidism. In the IPAQ, low or moderate physical activity was observed in 80%. DXA scan showed lumbar and hip osteoporosis in 30% and 8%, and osteopenia in 45% and 64%, respectively. There was a significant correlation between the different bone biomarkers (r=0.72-0.75; p< 0.01), higher in case of osteoporosis/osteopenia (Bcrosslaps 0.46 vs 0.42 vs 0.31; p=0.05). Overall, 25 patients had VF (21%), associated with sex male (26% vs 6%; p< 0.01), homosexuality (31% vs 22%; p=0.01), a higher PTH (58.4 vs 50.5 pg/ml; p=0.02), lower serum phosphate (2.9 vs 3.2; p=0.04), and a trend to lower calcium intake (467 vs 578 mg daily), and to lower hip T score (-1.6 vs 1.3; p=0.1). Of note, FRAX was not predictive of VF (10-year risk of osteoporotic fracture, 2.98 vs 2.4; p=0.09; no patient above 10; risk of hip fracture 0.91 vs 0.61; p=0.15; two patients above 3). In a logistic regression analysis, older age (OR 6,2; p=0.02), use of TDF + PI (OR 1,15; p=0.04), a higher PTH (1.05; p=0.04), and time of HIV infection (1.01; p=0.04) were associated with VF.
Conclusions: The prevalence of vertebral fractures in asymptomatic HIV-infected patients older than 50 years is high, is not predicted by FRAX equation tool, and is associated with the use of TDF and secondary hyperparathyroidism.

WEPEB0509

Bone mineral density scanning rates among high-risk US veterans who were new users of antiretroviral treatments for HIV

J. LaFleur[1,2], J. Crook[2,3], S. Esker[4], P. Tebas[5], R. Bedimo[6,7]
[1]University of Utah College of Pharmacy, Pharmacotherapy, Salt Lake City, United States, [2]Salt Lake City Veterans Affairs Healthcare System, Research, Salt Lake City, United States, [3]University of Utah College of Pharmacy, Department of Pharmacotherapy, Salt Lake City, United States, [4]Bristol-Myers Squibb, New York, United States, [5]Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, [6]Veterans Affairs North Texas Health Care System, Dallas, United States, [7]University of Texas Southwestern Medical Center, Dallas, United States
Presenting author email: joanne.lafleur@pharm.utah.edu

Background: The 2015 HIV guidelines recommend dual-energy X-ray absorptiometry (DXA) scans in patients initiating HAART with fracture risk factors including prior fragility fractures, high fall risk, glucocorticoid use, males ≥50, or postmenopausal females. HAART-associated long-term T-score changes remain unclear.
Methods: In a national cohort of US veterans newly-initiating HAART in 2003-2015, we identified DXA procedures and results using procedure codes and natural language processing of radiology reports and clinical notes. We estimated the incidence of DXA scans overall and among high-risk patients and estimated adjusted hazards for DXA with risk factors. Among the subset with baseline and follow-up DXA's, we examined the annual change in T-scores from baseline.
Results: A total of 10,027 patients met eligibility criteria. The mean (SD) age was 50 (10.0), 97% were male, and 31% and 58% were White and African American, respectively. Over an average follow-up of 6.8 years, the incidences of DXA were 26.0 and 31.8 per 1,000 person-years overall and among patients with ≥1 risk factor. Incidences by risk factor and adjusted hazards ratios (HR) are summarized in the table. In general, risk factors increased the likelihood that a patient would be scanned; for example, age 50+ was associated with increased rates of screening in men (HR 1.46, p< 0.0001) and women (HR 3.46, p< 0.0001). However, unadjusted incidences were very small (ranging from 30.8 for prior steroid use to 70.3 for females age 50+). Among patients who received scans at baseline and during follow-up, there was a non-significant adjusted annual T-score increase of 0.15 SD units per year when controlling for age, sex, race, and body mass index.

Risk factor	N (%) of cohort with risk factor	% with DXAs of those with risk factor	Unadjusted incidence per 1000 PY	Adjusted HR (95% CI)	p
Male with age 50+	5150 (551.4%)	19.7%	32.2	1.46 (1.33, 1.61)	<0.0001
Female with age 50+	136 (1.4%)	39.7%	70.3	3.46 (2.60, 4.59)	<0.0001
Prior fragility fracture	169 (1.7%)	20.1%	39.1	0.91 (0.65, 1.28)	0.5917
Steroid use	1872 (18.7%)	19.7%	30.8	1.22 (1.09, 1.37)	0.0007

[DXA scans among 10,027 treated US veterans]

Conclusions: Guideline-recommended DXA screening rates remain very low in the HIV-infected US Veterans. Even though most risk factors were associated with small but significant increases in DXA rates, clinicians may lack awareness of the need to screen high-risk patients. Among the small subset with baseline and follow-up DXA, no significant bone loss could be detected.

WEPEB0510

Staphylococcus nasal carriage and peritoneal dialysis infective outcomes in patients with HIV and end-stage renal failure: a prospective cohort study in two South African hospitals

K.C.Z. Ndlovu[1,2], A. Assounga[1,2]
[1]University of KwaZulu-Natal, Nephrology, Congella, South Africa, [2]Inkosi Albert Luthuli Central Hospital, Nephrology, Durban, South Africa
Presenting author email: kczndlovu@gmail.com

Background: Staphylococcal infective complications can cause significant morbidity in HIV-positive dialysis populations. In poorly resourced countries, including those in sub-Saharan Africa, where the HIV is prevalent but access to renal replacement therapy is limited, continuous ambulatory peritoneal dialysis (CAPD) can be a cost-effective option. This study evaluated the effects of HIV infection on the Staphylococcus aureus nasal carriage, staphylococcal peritonitis, and catheter infection rates in patients with end-stage renal failure who were managed using CAPD.
Methods: Prospective cohort study carried out in King Edward VIII and Inkosi Albert Luthuli Central Hospitals, in Durban, South Africa. Follow-up for 18 months, included monthly nasal swabs for Staphylococcus aureus and surveillance for staphylococcal peritonitis (based on clinical presentation, CAPD effluent

staphylococcal culture and white blood cell counts ≥100) and catheter infection (comprising exit-site and tunnel infections) events.
Results: Sixty HIV-positive patients and 59 HIV-negative patients had S. aureus nasal carriage rates of 43.3% and 30.5%, respectively (p = 0.147), while the methicillin-resistant S. aureus (MRSA) nasal carriage rates were 31.7% and 13.6%, respectively (p = 0.018). The S. aureus peritonitis rates were similar in the HIV-positive and HIV-negative cohorts at 0.136 and 0.129 episodes/person-years, respectively, (hazard ratio [HR] 0.96, 95% confidence interval [CI] 0.36-2.60, p = 0.942). The HIV-positive cohort was associated with an increased coagulase-negative staphylococcal peritonitis rate compared with the HIV-negative cohort (0.435 vs 0.089 episodes/person-years; HR 5.27, 95% CI 2.13-13.04, p <0.001). The S. aureus catheter infection rate in the HIV-positive cohort was higher in the S. aureus nasal carriers (0.302 episodes/person-years) compared with the non-carriers (0.036 episodes/person-years) (HR 8.41, 95% CI 1.03-68.74, p = 0.047).
Conclusions: These findings suggest that HIV infection may be a risk factor for MRSA nasal colonization, and that it may increase the risks of coagulase-negative staphylococcal peritonitis and S. aureus catheter infections in association with S. aureus nasal carriage.

Low incidence of acute rejection within the six months after renal transplantation in HIV recipients treated with raltegravir: the ANRS 153 Treve trial

M.-B. Matignon[1], J.-D. Lelièvre[1,2], A. Lahiani[3], K. Abbassi[3], D. Desvaux[1], A. Diallo[4], M.-N. Peraldi[5,6], A.-M. Taburet[7,8], J. Saillard[4], C. Delaugerre[5,6], D. Costagliola[9], L. Assoumou[3], P. Grimbert[1], on behalf of the ANRS 153 TREVE Study Group
[1]APHP, Hôpital H. Mondor, Créteil, France, [2]VRI/Inserm, U 955, Equipe 16, Université Paris Est, Faculté de Médecine, Créteil, France, [3]Sorbonne Universités, INSERM, UPMC Univ Paris 06, Institut Pierre Louis d'Épidémiologie et de Santé Publique (IPLESP UMRS 1136), Paris, France, [4]ANRS, France Recherche Nord & Sud Sida-HIV Hépatites, Paris, France, [5]AP-HP, Hôpital Saint Louis, Paris, France, [6]Université Paris Diderot, Paris, France, [7]APHP, Hôpitaux Universitaires Paris-Sud Bicêtre, Le Kremlin Bicêtre, France, [8]INSERM UMR 1184, Le Kremlin Bicêtre, France, [9]Sorbonne Universités, INSERM, UPMC Univ Paris 06, Institut Pierre Louis d'épidémiologie et de Santé Publique (IPLESP UMRS 1136), Paris, France

Background: High rates of acute rejection (AR) have been reported during renal transplantation in HIV-infected individuals, probably due to interactions between antiretroviral treatment (ARV), mainly ritonavir-boosted protease inhibitors (PI) and immunosuppressive treatments via the cytochrome P450 system. Raltegravir (RAL) is not a substrate of CYP450 enzymes. We aimed to assess the incidence of clinical AR within the six months after transplantation in HIV recipients treated with ARV including RAL and no PI.
Methods: The ANRS 153 TREVE (NCT01453192) was a multicentre prospective open-label single arm trial in HIV-infected adults with end-stage renal disease, controlled viral load and CD4 count >200/µL, under a three-drug ARV regimen for ≥3 months, with viruses sensitive to RAL, awaiting kidney transplantation. After transplantation, the ARV regimen was based on 3 drugs including RAL and no PI. The trial aimed to demonstrate that the clinical AR rate after transplantation (≥20% increase of serum creatinine plus histology) was < 30%. A blind pathologist reviewed all biopsies.
Time to transplantation, patient survival after transplantation, and allograft survival were compared to a control group of HIV-negative recipients matched on age (±5 years), sex and date of registration on the waiting list (±3 months).
Results: A total of 26 HIV end-stage renal disease participants underwent renal transplantation: 69% were male and 62% were from Sub-Saharan Africa, with median age 48 years and CD4 count 387/µL. AR occurred in 2 participants, leading to an 8% acute rejection rate at 6 and 12 months (Kaplan-Meier estimate, 95%CI: 2-24). One subclinical rejection occurred 10 days after transplantation. HIV infection remained controlled in all patients except one who discontinued ARV transiently.
Median time to transplantation was longer in HIV-infected individuals than in controls (4.3 versus 2.8 years, p=0.002) and was not influenced by blood group. After transplantation, the 3-year survival was 89% in HIV infected individuals and 96% in controls (p=0.197). Three-year allograft survival was 82% in HIV+ and 83% HIV- groups (p=0.991).
Conclusions: After kidney transplantation, ARV including RAL is effective to prevent AR. Patients and kidney allograft survivals are similar to those of HIV negative recipients.

WEPEB0512

Current status of HIV-to-HIV transplants in the United States

C. Durand[1], A. Tobian[1], A. Redd[1,2], G. Bismut[1], N. Desai[1], A. Cameron[1], D. Brown[1], S. Halpern[1], S. Bagnasco[1], D. Ostrander[1], J. Locke[3], S. Mehta[3], P. Stock[4], S. Huprikar[5], S. Florman[5], L. Moulton[6], A. Massie[1,6], D. Segev[1,6]
[1]Johns Hopkins University School of Medicine, Baltimore, United States, [2]National Institutes of Health, Bethesda, United States, [3]University of Alabama at Birmingham, Birmingham, United States, [4]University of California, San Francisco, United States, [5]Icahn School of Medicine at Mount Sinai, New York, United States, [6]Johns Hopkins School of Public Health, Baltimore, United States
Presenting author email: cdurand2@jhmi.edu

Background: The HIV Organ Policy Equity (HOPE) Act allows transplantation using organs from HIV+ donors for HIV+ recipients in the United States. We evaluated the safety and efficacy of kidney and liver transplantation from HIV+ deceased donors, including those with false positive (FP) HIV antibody (Ab) or nucleic acid tests (NAT).
Methods: HIV+ transplant candidates without active opportunistic infections (OI) on antiretroviral therapy (ART) with CD4 >200 (kidney) or >100 cells/ul (liver) were eligible. HIV+ donors with any HIV RNA and CD4 count were allowed as long as effective ART in the recipient was described. FP donors had discordant HIV Ab/qualitative NAT results and no HIV history; FP status was confirmed by quantitative NAT (Abbott).
Results: Between March and December 2016, there were 3 HIV+ donors (Table1) resulting in 5 transplants (4 kidneys, 1 liver) and 6 FP donors resulting in 15 transplants (9 single-kidney, 1 double-kidney, 4 livers, 1 simultaneous-liver-kidney). FP donors were Ab positive/NAT negative (n=4) or Ab negative/qualitative NAT positive (n=2); all were quantitative NAT negative. No episodes of death, graft failure, or HIV breakthrough have occurred in recipients to date (Table2).

Characteristic	Donor 1	Donor 2	Donor 3
Age (yr)	35	46	31
Race	Caucasian	African American	African American
Sex	Female	Female	Female
Cause of death	Drug Intoxication	CVA/Stroke	Cardiovascular
Organs recovered	Liver, 1 kidney	2 kidneys	1 kidney
Most recent HIV RNA (copies/mL)	<20	475	140
Most recent CD4 (cells/mm^3)	1683	1533	190
Antiretroviral therapy	DTC 3TC DRV^R	TDF FTC ATV^r	FTC+TAF ATV/c

[Table 1. HIV-Positive Donors in US]

HIV-Positive Recipients	
Characteristic	**N = 20**
Age, years, median (range)	53 (26-66)
Female, N (%)	7 (35)
Race, N (%)	
White	2 (10)
African American	14 (70)
Hispanic	3 (15)
Asian	1 (5)
Length of follow up, months, median (range)	4 (1-10)
Undetectable HIV VL at 3 months, N (%)*	8 (100)
CD4 count at 3 months, cells/mm^3, median (range)*	425 (119-651)

*12 recipients have not yet reached 3 months

[Table 2]

Conclusions: We report the first HIV+-to-HIV+ transplants in the United States under the HOPE Act. These cases provide proof-of-concept that organs from HIV+ donors can increase access to transplant providing a public health benefit for everyone on the waitlist and in particular for HIV+ candidates with high waitlist mortality. In addition, the use of organs from donors with FP HIV tests has emerged as an unexpected benefit of the HOPE Act.

WEPEB0513

Optimizing care and improving outcomes in HIV+ kidney transplant recipients

M. Hemmersbach-Miller[1], M. Ellis[2], C. Wolfe[1]
[1]Duke University Medical Center, Dept. of Internal Medicine. Infectious Diseases Division, Durham, United States, [2]Duke University Medical Center, Dept. of Internal Medicine. Division of Nephrology, Durham, United States
Presenting author email: marion.hemmersbach@dm.duke.edu

Background: Kidney transplantation (KT) has increased over the last decade due to a longer life expectancy of HIV+ patients since the introduction of antiretroviral (ARV) treatment. Controversies remain regarding optimal management.
Methods: All KT performed on HIV+ recipients at Duke University were reviewed (2009-2016). Our primary aim was to compare HIV+ KT recipient mortality and graft survival rates against national statistics from UNOS (United Network for Organ Sharing) and data from the literature. Secondary outcomes included comparing HIV and transplant management strategies, rejection rates, and immunologic indices.
Results: 15 KT in HIV+ recipients had been done between 2009-2016, 14 were reviewed. 71.4% were males, with a median age of 48.5 years, 100% were African-American. The underlying diseases were as follows: HIV-AN 64%, hypertension 50%, diabetes 14% and PCKD 14%. 21.5% had a detectable hepatitis C PCR, 7.1% were HBsAg positive. 21% had a history of prior opportunistic infections, the median CD4 count before KT was 512(IQR 382-853). All patients had an undetectable HIV viral load when transplanted. ARV regimens varied: PI-based 29%, NNRTI based 36%, PI and NNRTIs 14%, Nucs 93% and INSTIs 93%. Induction therapy was performed with basiliximab (71%) or thymoglobulin (36%), whilst maintenance immunosuppression consisted of tacrolimus, mycophenolate mofetil and prednisone in all cases. Significant CD4 suppression occurred, especially in the thymoglobulin cohort, yet no postransplant OIs were recorded. 1 patient had acute cellular rejection treated successfully. Delayed graft function (DGF) was observed in 8 patients (57%). Viremia and ARV resistance occurred in only 1 patient, due to poor compliance. All grafts are functional and all patients are still alive to date.
Conclusions: The number of patients with well-controlled HIV, yet chronic renal failure is expected to increase worldwide. This data supports very favorable outcomes of KT in HIV+ recipients. Despite higher rates of DGF, graft and patient survival at one year are comparable to HIV-negative KT rates nationally, and exceed historical HIV-positive comparators. We postulate this is due to a better understanding of the interactions between ARV and immunosuppressive drugs, as well as the broader availability of INSTIs. KT should be considered a life-prolonging therapy for selected HIV+ recipients.

WEPEB0514

Prevalence of and risk factors for low bone mineral density in Spanish treated HIV patients

M. Cervero[1], R. Torres[1], J.J. Jusdado[1], S. Pastor[1], S. Moreno[2], J.L. Agud[1], V. Alvarez[3], C. García-Lacalle[4]
[1]H.U. Severo Ochoa, Internal Medicine, Leganés, Spain, [2]H.U. Ramón y Cajal/ Alcalá University, Infectious Diseases, Madrid, Spain, [3]H.U. Severo Ochoa, Endocrinology Service, Leganés, Spain, [4]H.U. Severo Ochoa, Biochemist Service, Leganés, Spain
Presenting author email: mcerverojj@gmail.com

Background: There are few published data on bone mineral density (BMD) in the post-HAART era in geographic very sunny areas. Although several studies implicate antiretroviral therapy in the pathogenesis of low BMD, others have not confirmed this association. In this study we analyzed the impact of HIV status, traditional risk factors and antiretroviral therapy in BMD.
Methods: We performed a cross-sectional analysis of 107 individuals infected with HIV and exposed to antiretroviral treatment to estimate prevalence of decreased BMD. Bone mineral density of lumbar spine or femoral neck was measured by dual-energy X-ray absorptiometry. Variables included in a multivariate analysis included HIV status, antiretroviral drugs and traditional risk factors.
Results: Low BMD was diagnosed in 48 participants (44.9%). Factors associated with decreased BMD in the multivariate analysis were an increasing age (b-0.008, p 0.001), a treatment based on IP/r and TDF (b-0.181, p 0.001 in lumbar spine and b-0.083, p= 0.038 in femoral neck) like have been exposed to TDF (b-0.108, p=0.008 in lumbar spine and b-0.122, p=0.004 in femoral neck).
In addition other factors like the intravenous drug users HIV transmission group (b+0,162, p=0,001 and b+0.117 and p=0.003 homosexual and heterosexual versus intravenous drug users respectively) and consumption of 3 alcohol units (b-0.106, p=0.008) were related to a decreased BMD at lumbar spine; while a lower BMI (b-0.007, p=0.037) was related to a decreased BMD at the femoral neck.
Conclusions: In the multivariate analysis we found that the antiretroviral regime based on PI/r and TDF, and the previous exposure to TDF was associated with decreased BMD.

[1]Ambroise-Paré Hospital, Infectious Diseases Unit, Boulogne-Billancourt, France, [2]Dron Hospital, Infectious Diseases Unit, Tourcoing, France, [3]Bicêtre Hospital, AP-HP, Internal Medecine Unit, Le Kremlin Bicêtre, France, [4]Lille Hospital, Hormonologie-Métabolisme-Nutrition & Oncologie, Centre de Biologie Pathologie, Lille, France, [5]Université Paris Sud, Université Paris Saclay, Faculté de Médecine Paris-Sud, INSERM, CESP U 1018, Le Kremlin Bicêtre, France, [6]Paris Descartes University, EA 7327, Paris, France
Presenting author email: antoine.cheret@aphp.fr

Background: Male hypogonadism (MH) is poorly defined in people living with HIV (PLHIV). Using a reliable free-testosterone (FT) assay, we examined the prevalence and risk factors of MH among PLHIV on effective antiretroviral therapy (ART).
Methods: The total Testosterone level is affected by altered sex-hormone-binding globulin (SHBG) levels in PLHIV, in whom FT measurement is recommended to diagnose MH. Given the limitations of previous studies, we conducted a prospective cross-sectional study, using a reliable FT assay, to determine the prevalence and risk factors of MH in asymptomatic men (no AIDS event), < 50 years old, treated with cART with HIV-RNA ≤ 50 copies/mL. FT was measured twice in the morning. MH was defined as an average serum FT < 70 pg/mL, calculated with the Vermeulen equation. Sociodemographic, anthropometric, bone-densitometric, hormonal, immunovirological, metabolic and therapeutic parameters were collected. The International Index of Erectile Function-5 (IIEF-5) score was used to evaluate erectile function.
Results: We included 250 patients, median age 43 years (IQR 36-47). Median time since HIV diagnosis was 8 years (IQR: 4-13) and median CD4 cell count was 623/mm^3 (IQR: 493-764). The average FT was low (< 70 pg/mL) in 20 patients (8.4%) and SHBG was increased in 119 patients (48%). At inclusion, 236(94.4%), 116(46.4%), 98(39.2%), 54(21.6%) patients were treated by a combination containing NRTI, NNRTI, PI or INSTI respectively. Patients who received no NRTI had a longer median time since HIV diagnosis and more lines of treatment. In multivariate analysis, parameters associated with MH were: an age > 43 years (ORa 3.08, 95% CI 0.98-9.64; p=0.05), a percentage of total fat > 19% (ORa 3.01, CI 95% 1.02-8.84; p=0.05), to receive efavirenz (ORa 4.67, CI 95% 1.55-14.11; p< 0.01) and a nadir of CD4 cell count > 200/mm3 (ORa 0.32, CI 95% 0.11-0.94; p=0.04), to receive nucleoside reverse transcriptase inhibitors (NRTI) (ORa 0.18, CI 95% 0.04-0.94; p=0.04).
Conclusions: In this study, the prevalence of MH is twice the rate reported in the general population of the same age. The three thresholds - the age of 43, 19% total body fat and taking efavirenz - might help to identify patients at increased risk.

WEPEB0516

Increased risk of overweightness and obesity after HCV clearance in patients co-infected with HIV and hepatitis C virus (HCV) (ANRS CO13-HEPAVIH cohort)

Presenting author email: issifou.yaya@inserm.fr

Background: Chronic infection with hepatitis C virus (HCV) in people living with HIV is often associated with systemic inflammation and comorbidities. Although curing HCV can decrease the burden of some comorbidities, overweightness and obesity are important clinical proxies of increased risk of diabetes and other metabolic disorders and constitute an emerging issue in this population. This study aimed to estimate the evolution of overweightness and obesity in HIV-HCV co-infected

patients enrolled in a multicenter prospective cohort, and also the impact of both HCV clearance and time-dependent behavioral factors on patients' body mass index (BMI).
Methods: This longitudinal study used data from the French multicenter cohort ANRS C013-HEPAVIH, which included clinical (medical records updated during follow-up) and socio-behavioral (annual self-administered questionnaires) characteristics. The study sample included patients who completed at least one self-administered questionnaire during follow-up. The outcome „overweightness or obesity" was defined as a BMI ≥ 25 kg/m^2 (annual measures). A mixed logistic regression model helped identify clinical and socio-behavioral factors associated with the outcome in this population.
Results: The analysis included 1,046 patients aged 19 to 80 years old. The prevalence of overweightness and obesity was 18% at cohort enrolment, and 27% in those still followed-up after five years (n=312). In the multivariable analysis, adjusted for both fixed (gender, antiretroviral therapy (ART) duration at cohort enrolment) and time-dependent (time of follow-up in years, HCV clearance, cannabis use) variables, the interaction between follow-up time and HCV clearance post interferon-based treatment was significant, showing an increased risk of overweightness and obesity over time after clearance, with an adjusted odds ratio [95% confidence interval] of 1.74 [1.00 - 3.02] per year.
ART duration at enrolment (0.91 [0.87 - 0.96] per year), female gender (0.42 [0.25-0.71]) and cannabis use (0.22 [0.08 - 0.61]) were independently negatively associated with overweightness and obesity.
Conclusions: Our results suggest that after HCV clearance, HIV-infected patients are at risk of overweightness and obesity. This risk is 50% and 80% lower in women and cannabis users, respectively. Sustained monitoring of HIV-HCV co-infected patients, even after clearance, is needed to control the risk of overweightness and metabolic disorders.

WEPEB0517

Factors influencing time to viral suppression of HIV patients on antiretroviral therapy in a resource-limited setting of Rakai district, Uganda

D.S. Kigozi[1], G. Nakigozi[2], T. Lutalo[1], G. Kigozi[2], F. Nalugoda[2], D. Sserwadda[3], R. Grey[4], M. Wewer[4], S. Leynold[5]
[1]VRakai Health Sciences Program, Data Management and Biostatistics, Kampala, Uganda, [2]Rakai Health Sciences Program, Principal Investigator, Kampala, Uganda, [3]Makerere University School of Public Health, Executive Director, Kampala, Uganda, [4]Johns Hopkins Bloomberg School of Public Health, Executive Director, Baltimore, United States, [5]National Institute Allergy and Infectious Diseases, Scientific Administrator, Kampala, Uganda

Background: The objectives of the study were to determine factors influencing patients' response to antiretroviral treatment by modeling time from start of treatment to viral suppression for patients enrolled in rural Rakai district, Uganda, the average time in months to viral suppression, the effect of different types of regimens, the influence of other co-infections like Hepatitis B and Tuberculosis, the initial levels of CD4, the effect of some demographic factors and how opportunistic infections affect the time to viral suppression.
Methods: We used secondary data from viral load results and other clinical tests from Rakai district of Uganda, We determined time from the start of medication to viral suppression using clinical dates among 1,954 non-hospitalized patients on ART and at least 10 years from 2006 to 2011. Using the Shared Frailty regression model, we assessed factors influencing time to viral suppression, including viral load test results, Initial CD4 count, Hepatitis B and TB co-infections while controlling for demographics (Age at start of medication, Sex), and Risk factors. We also used the Kaplan-Meier curves to compare the survival curves for the time to viral suppression between groups and the Log Rank tests as a procedure to compare the curves.
Results: The average time to viral suppression was 8.9 months with a standard deviation of 6.7 and a range of 65.3. Patients with lower CD4 levels took a longer time to viral suppression. Additionally the rate of recovery for female patients is 0.4 time that of men. RR=0.4, (95% CI, 0.2 - 0.8; P = 0.01). Patients treated of more concomitant infections experienced a shorter time to viral suppression. For example, patients treated of five co-infections had 0.1 times a recovery rate compared to those treated of none. RR=0.1, (95% CI, 0.0 - 0.3; P = 0.00). On the other hand, Hepatitis B, TB, age groups, alcohol and the most commonly used drug combinations were not statistically significant to estimate time to viral suppression.
Conclusions: Like in the developed world (H. Irene, 2013), early linkage to care and treatment of more side infections were associated with faster time to viral suppression..

HIV and the dual burden of malnutrition in Senegal, 1994-2012

N.A. Benzekri[1], P.S. Sow[2], M. Seydi[2], N.B. Kiviat[3], S.E. Hawes[4], G.S. Gottlieb[5]
[1]University of Washington, Medicine/Infectious Diseases, Seattle, United States, [2]Centre Hospitalier Universitaire de Fann, Maladies Infectieuses, Dakar, Senegal, [3]University of Washington, Pathology, Seattle, United States, [4]University of Washington, Epidemiology, Global Health, Seattle, United States, [5]University of Washington, Medicine/Infectious Diseases, Global Health, Seattle, United States
Presenting author email: benzekri@uw.edu

Background: Both undernutrition and overnutrition are associated with negative health outcomes among people living with HIV (PLHIV). The aims of this study were to determine the nutritional status of HIV-positive versus HIV-negative adults, to identify differences in the nutrition transition according to HIV status, and to identify predictors of nutritional status among PLHIV.
Methods: We conducted a retrospective study using data from individuals enrolled in previous studies in outpatient clinics in Senegal from 1994-2012. Undernutrition was defined as BMI < 18.5 and obesity as BMI ≥30.0. Logistic regression was used to identify predictors of nutritional status.
Results: We analyzed data from 2448 adults, 1772 were women (72%) and 1471 (60%) were HIV-1 and/or HIV-2 positive. Among PLHIV, the median CD4 count was 282; 24% were on ART. The prevalence of undernutrition among PLHIV decreased from 52% in 1994-1999 to 37% in 2006-2012 and in HIV-negative persons undernutrition decreased from 23% to 5%. The prevalence of obesity among PLHIV increased from 3% in 1994-1999 to 5% in 2006-2012, while among HIV-negative individuals obesity increased from 6% to 22%.
Women had substantially greater odds of obesity (OR 11.4, 95% CI 4.1-31.6; p<0.01), while men had greater odds of undernutrition (OR 3.2, 95% CI 2.6-5.0; p<0.01).
Among HIV-positive women, undernutrition was associated with WHO stage 3 or 4 (OR 3.4; p<0.01), CD4 count <200, (OR 2.4; p<0.01), and lack of education (OR 1.4; p=0.04). Obesity was associated with age>35 (OR 4.0; p<0.01), commercial sex work (OR 3.5; p<0.01) and alcohol use (OR 2.2; p<0.01).
Among HIV-positive men, the strongest predictors of undernutrition were WHO stage 3 or 4 (OR 3.2; p<0.01), CD4 count <200, (OR 2.2; p<0.01) and lack of ART (OR 6.3; p<0.01).
Conclusions: We discovered that both HIV-positive and HIV-negative individuals in Senegal are suffering from a dual burden of malnutrition. Importantly, we found that HIV-positive women are at substantial risk of obesity and would likely benefit from targeted nutrition programs.
Our study highlights an urgent need for the integration of nutrition interventions into HIV programs in Senegal and sub-Saharan Africa.

WEPEB0519

Does the non-alcoholic fatty liver disease (NAFLD) score predict liver fibrosis progression after hepatitis C virus (HCV) treatment in human immunodeficiency virus (HIV)-HCV co-infected patients?

N. Kronfli[1], R. Nitulescu[1], S. Walmsley[2], C. Cooper[3], S. Haider[4], J. Gill[5], M.-L. Vachon[6], M. Klein[1], on behalf of the Canadian Co-Infection Cohort Investigators
[1]McGill University Health Centre, Montreal, Canada, [2]Toronto General Research Institute, Toronto, Canada, [3]Ottawa Hospital Research Institute, Ottawa, Canada, [4]McMaster University, Hamilton, Canada, [5]University of Calgary, Calgary, Canada, [6]Universite de Laval, Laval, Canada
Presenting author email: nadine.kronfli@medportal.ca

Background: Steatosis secondary to NAFLD is associated with progression of liver fibrosis in chronic HCV. We aimed to determine the role of the NAFLD score in hepatic fibrosis progression following HCV treatment in co-infected patients.
Methods: The Canadian Co-infection Cohort is a prospective multicentre cohort of 1,693 co-infected patients from 19 sites in Canada. Liver fibrosis progression (regression) was defined as an increase (decrease) of at least one Metavir stage from pre-treatment as determined by FibroScan or aspartate aminotransferase-to-platelet ratio index (APRI). A multivariate logistic model assessed the association of the NAFLD score (which integrates age, body mass index, hyperglycemia, liver transferases, platelet count and serum albumin) with the odds of liver fibrosis regression. A linear model estimated the relationship between the NAFLD score and the percentage change in APRI (the best available proxy for fibrosis) post-treatment.
Results: Overall, 229 participants (185 men, 44 women) with a median age of 49 years; HCV duration 14 years; baseline APRI 1.0 were included. Of the 245 treatment courses, 71% achieved sustained virologic response (SVR). Between 6 and 24 months post-treatment (median 1.4 years), 5% progressed, 25% regressed and 70% remained stable. In the logistic model, the NAFLD score had no effect on fibrosis

regression; however, SVR and pre-treatment APRI were associated with regression (Table 1). In the linear model, the NAFLD score was associated with increases in APRI post-treatment.
Conclusions: SVR was strongly associated with fibrosis regression post-treatment. A high pre-treatment APRI was predictive of recovery, indicating reduction in inflammation or the greater potential for change. After controlling for confounders, a higher NAFLD score appeared to be associated with increases in APRI post-treatment. Management of fatty liver disease following treatment is essential to achieve optimal liver outcomes after cure. Further validation of the NAFLD score in this population is required.

	Odds of liver fibrosis regression*		Percentage change in APRI post-treatment†	
Variable	Odds ratio	95% C.I.	Coefficient	95% C.I.
SVR status indicator post-treatment	3.74	(1.49 ; 10.21)	-0.80	(-0.97 ; -0.62)
Log of pre-treatment NAFLD score	0.47	(0.03 ; 6.70)	1.12	(0.56 ; 1.69)
Log of pre-treatment APRI score	6.23	(3.48 ; 12.05)	-0.58	(-0.69 ;-0.47)
DAA-based treatment indicator	0.88	(0.38 ; 2.02)	-0.10	(-0.28 ; 0.07)
Genotype 3 indicator	0.91	(0.32 ; 2.46)	-0.06	(-0.30 ; 0.17)
HCV duration (per 5 years) at initiation	1.05	(0.83 ; 1.33)	0.04	(-0.01 ; 0.08)
CD4 count (per 100 units) at initiation	1.04	(0.92 ; 1.16)	-0.00	(-0.03 ; 0.02)
Lipodystrophy prior to treatment	0.52	(0.14 ; 1.71)	0.06	(-0.18 ; 0.31)
Waist circumference (cm) at initiation	1.01	(0.97 ; 1.04)	-0.00	(-0.01 ; 0.00)

* The dependent variable for this model was a binary indicator for fibrosis regression, based on Metavir stage
† The dependent variable for this model was the natural log of the percentage change in APRI from pre-treatment to post-treatment
C.I. = Confidence Interval

Occult liver cirrhosis diagnosed by transient elastography is frequent and under-monitored in HIV-infected patients: results of a large-scale screening program

A. Benmassaoud, T. Pembroke, B. Lebouche, P. Ghali, M. Deschenes, M. Klein, G. Sebastiani
McGill University Health Centre, Medicine, Montreal, Canada
Presenting author email: amine.benmassaoud@mail.mcgill.ca

Background: People living with HIV are at increased risk for liver cirrhosis and liver-related death. Unfortunately, the diagnosis of compensated cirrhosis at a preclinical stage is challenging due to the lack of any physical, laboratory and imaging findings. Therefore, we evaluated the prevalence, predictors and evolution of preclinical compensated cirrhosis, defined as occult cirrhosis (OC), diagnosed by liver stiffness measurement (LSM) on transient elastography (TE).
Methods: Unselected HIV-infected patients underwent a TE examination as part of a routine screening program for liver disease. Patients were classified as:
1) OC (LSM ≥13 kPa and absence of any clinical sign of cirrhosis, including no thrombocytopenia, nor signs of advanced liver disease on ultrasound);
2) clinically evident compensated cirrhosis (LSM ≥ 13kPa with any of the previous signs);
3) non-cirrhotic patients (LSM < 13kPa). Predictors of occult cirrhosis were investigated through multivariable logistic regression analysis.
Results: 749 HIV-infected patients were included. In our cohort, the mean age was 50.3 ± 10.6 years, 77.3% were men, the mean CD4 count was 593 ± 266 cell/mm^3, and 90% were on antiretrovirals. HIV/HCV co-infected individuals comprised 22% of our cohort. Overall, liver cirrhosis was present in 11.1% of cases. OC represented 4.4% of the whole patient population and 36.7% of patients with liver cirrhosis. After adjustments, HIV/HCV co-infection (aOR = 7.0, 95% CI 2.28-21.6; p=0.001), longer duration of HIV infection (aOR=1.01, 95% CI 1.0-1.17; p=0.04) and higher BMI (aOR=1.14, 95% CI 1.05-1.24; p=0.002) were factors independently associated with OC. Over a median follow-up period of 21.9 months (interquartile range 12.0-34.8), 6.1% of patients developed hepatocellular carcinoma or liver decompensation. Importantly, patients with OC had fewer ultrasounds and gastroscopies, than patients with clinically evident compensated cirrhosis (see Table).

	Non-cirrhotic	Occult cirrhotics	Clinically evident cirrhotics	p-value
Ultrasound (n ± SD)	1.27 ± 1.23	1.93 ± 1.82	3.10 ± 1.53	0.005
Gastroscopy (n ± SD)	0.16 ± 0.47	0.33 ± 0.73	1.17 ± 1.43	0.007
Surveillance of cirrhosis	NA	11%	45.7%	0.01

[Characteristics of cirrhosis surveillance]

Conclusions: OC is frequent in HIV-infected patients. Importantly, our study shows that HIV patients with OC are under-monitored as compared to those with clinically evident compensated cirrhosis which can lead to the under-diagnosis of cirrhosis complications. Screening HIV-infected patients by TE may prompt initiation of appropriate surveillance and interventions for an otherwise unrecognized condition.

WEPEB0521

Hepatotoxicity in HIV+ postpartum women initiating efavirenz-containing regimens

D. Bhattacharya[1], A. Gupta[2], C. Tierney[3], S. Huang[3], M. Peters[4], T. Chipato[5], F. Martinson[6], D. Dula[7], K. George[8], N. Chaktoura[9], K. Klingman[9], D. Gnanashanmugam[9], J. Currier[1], M.G. Fowler[2]

Presenting author email: debikab@mednet.ucla.edu

Background: Recently hepatotoxicity in HIV+ pregnant African women initiating efavirenz (EFV), was reported. We assessed the incidence and association of hepatotoxicity i.e. liver enzyme elevation (LEE) in postpartum (PP) women initiating EFV in the PROMISE study.
Methods: In PROMISE 1077BF/FF, HIV+ antiretroviral treatment (ART) naïve pregnant women with CD4≥350 and ALT≤ 2.5 ULN were assigned to antepartum (AP) and PP ART strategies to assess HIV vertical transmission, safety, and maternal disease progression. Sites participated between 4/2011-9/2016. In July 2015, based on the START study, participants were recommended to initiate ART, including EFV. LEE was defined as grade 2 (2.6 - 5.0), grade 3 (5.1 - 10.0), or grade 4 (> 10.0) x ULN ALT elevation. Cox proportional hazards models (ratio (HR), 95% confidence interval (CI)) were run for each covariate and entered in a multivariable model. Covariates included age, BMI, ALT, prior ALT elevation, HBsAg, ART regimen prior to EFV, CD4, country, EFV initiation date, time from delivery to EFV initiation, receipt of EFV prior to delivery, NRTI in regimen, and AP and PP randomized assignments.
Results: Among 3575 women, 2318 (65%) initiated EFV, 2267 (98%) PP. At EFV initiation median age was 29.2 yrs and median CD4 was 625, 62% were not on ARVs, 3% had prior ALT elevation and HBsAg+ was 4% (82/2318). After EFV, 7.3% (170/2318) and 2.5% (59/2318) had ≥grade 2 and ≥ grade 3 LEE PP, respectively; with an incidence of ≥ 3 LEE of 2.2 (95% CI 1.9-2.5) per 100-person years. Most were asymptomatic. In multivariable analysis, older age but not CD4 or HBsAg, was significantly associated with increased risk of grade 3/4 LEE PP after EFV initiation (HR per 5 years 1.35 CI (1.06-1.71) and per 50 cells higher 1.04 (0.986,1.086)), other covariates p≥ 0.14. Events occurred between 1-132 wks PP: 2 maternal deaths associated with LEE occurred at 16 and 25 weeks after EFV-ART.
Conclusions: Greater than 7% of PP women initiating EFV had grade 2 or greater LEE. Late-occurring and asymptomatic hepatotoxicity after EFV occurred. The risk of hepatotoxicity underscores the importance of laboratory monitoring for maternal LEE in ART treatment/PMTCT programs.

WEPEB0522

Incidence of hepatotoxicity among HIV-positive pregnant women initiating efavirenz-based ART through Option B+ in Malawi

B. Harrington[1,2], J. Phulusa[2], C. Melhado[2,3], M. Ngongondo[2], M. John[2], B. Mthiko[2], M. Hosseinipour[2], S4 Study (Safety, Suppression, Second-line, Survival)
[1]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [2]UNC Project Malawi, Lilongwe, Malawi, [3]Tufts University, Boston, United States
Presenting author email: bryna_harrington@med.unc.edu

Background: Under Option B+, pregnant women initiate ART with tenofovir/lamivudine/efavirenz (TDF/3TC/EFV) without routine liver enzyme monitoring. Previous studies show conflicting results on whether pregnant women have increased risk for hepatotoxicity on EFV-based regimens. With the expansion of Option B+, evidence on hepatotoxicity incidence and timing is necessary for clinical management and patient well-being.
Methods: HIV positive ART-naïve pregnant women attending a public antenatal clinic in Lilongwe, Malawi in 2015-2016 joined a prospective cohort study. All initiated TDF/3TC/EFV through Option B+. Lab values from the first 6 months on ART (enrollment, months 3 and 6) were evaluated for DAIDS Grade 1 or higher alanine aminotransferase (ALT, ≥50 IU/L). We compared differences in ALT elevations by low CD4 count (< 250cells/μL) and WHO Stages ≥2 with Fisher's exact tests.
Results: At enrollment of 299 women, median age was 26 (range 17-40), median CD4 count was 352 cells/μL (range 11-1099), and 95% were in WHO Stage 1. Elevated ALT prevalence was 0.3% at baseline, 0.4% at month 3, and 7.2% at month 6. The 6-month incidence of elevated ALT was 7.9%. Only 3 women (1.1%) had DAIDS Grade 3 or 4 ALT levels; all 3 were postpartum and not taking other hepatotoxic medications. Of those 3 women, one stayed on TDF/3TC/EFV with resolved ALT levels, one switched to a non-EFV regimen, and one died of fulminant hepatitis despite ART discontinuation (presenting total bilirubin=8.2mg/dL, ALT=7; confirmation bilirubin=18.7, ALT=1937). Low CD4 count was not associated with developing hepatotoxicity (p=0.62). A higher proportion of women in WHO Stages ≥2 developed elevated ALT (13.3%) compared to women in Stage 1 (6.7%), but the association was not significant (p=0.28). Viral hepatitis co-infection status was not available.
Conclusions: A small proportion of women who initiated EFV-based ART during pregnancy developed elevated ALT within 6 months of ART initiation, but all toxicities Grade ≥3 occurred postpartum. Neither low CD4 count nor WHO Stage was associated with hepatotoxicity. Our results do not support routine laboratory monitoring in this population; symptom monitoring is likely reasonable under a public health approach. Further follow-up will elucidate postpartum EFV hepatotoxicity timing among Option B+ women.

WEPEB0523

Liver transplantation for HIV-infected patients with hepatocellular carcinoma (HCC)

A. Dalla Pria[1,2], O. Adeyemi[3], C. Citti[4], D. Pinato[5], M. Ventura-Cots[6], H. Platt[7], M. Merli[8], B. Minguez[6], R. Sharma[5], S. Marcus[9], M. Nelson[1], M. Bower[1], V. Mazzaferro[10], N. Bräu[11,12], Liver Cancer in HIV Study Group
[1]Chelsea & Westminster Hospital, London, United Kingdom, [2]Imperial College, London, United Kingdom, [3]CORE Center & Rush Medical College, Chicago, United States, [4]Kaiser Permanente Los Angeles Medical Center, Los Angeles, United States, [5]Imperial College, Department of Surgery and Cancer, London, United Kingdom, [6]Hospital Universitario Vall d'Hebron, Barcelona, Spain, [7]Merck, Sharp & Dohme Corp, Kenilworth, United States, [8]San Raffaele Hospital, Milan, Italy, [9]James J. Peters VA Medical Center, Bronx, United States, [10]Istituto Tumori, Milan, Italy, [11]James J. Peters Veterans Affairs Medical Center, Bronx, United States, [12]Mount Sinai School of Medicine, New York, United States

Background: In selected patients with HCC, orthotopic liver transplantation (OLT) is a treatment option with high reported survival rates. Yet, OLT is not available to most HIV-infected patients. This study reports the experience of HIV-infected patients with HCC who underwent OLT.
Methods: HIV-infected patients with HCC were retrospectively identified from 1995-2014 in 47 centers in North and South America, Europe, and Australia. Among a total of 392 patients, 37 subjects with OLT were compared to 124 with other curative therapy (radiofrequency ablation, 58; surgical resection, 54; percutaneous ethanol injection, 12).
Results: Compared to 124 patients with other curative therapy, 37 patients with OLT were younger (50.3 vs. 53.4 years, p=0.038) and had higher Child-Turcotte-Pugh scores (6.8 vs. 5.8, p=0.015), but had similar etiology of HCC (HCV 76%, HBV 22%), frequency of alcohol abuse (19% vs. 22%, p=0.69) and control of HIV infection with HIV RNA < 400 copies/mL in 88% vs.82% (p=0.43) and median CD4+ cell count of 322 vs. 425 per mm3 (p=0.37). OLT patients more frequently had multiple tumors (46% vs. 22%, p=0.004), but frequency of early Barcelona-Clínic-Liver-Cancer (BCLC) stages A&B was similar (76% vs. 71%, p=0.58). Five-year survival in all patients was significantly higher for OLT (85%) compared to RFA (73%), resection (51%) and PEI (14%, p< 0.001, log rank). Survival at 5 years was higher for OLT compared to the other curative treatments, both in BCLC stage A (92% vs. 57%, p=0.006) and BCLC stage B (100% vs. 59%, p=0.044), but not in stages C&D (5-yr, 57% vs. 0%; 3-yr, 76% vs. 49%; p=0.31). Among patients with OLT, 5-year survival was superior in those with HBV vs. HCV infection (100% vs. 85%, p=0.013), but it was similar between BCLC stage A and B (92% vs. 100%, p=0.68) and in those who met Milan criteria (n=28, 78%) and those who did not (n=9, 100%).
Conclusions: For HIV-infected patients with HCC, OLT is a therapeutic option with high survival rates which are superior to radiofrequency ablation and surgical resection. The 5-year survival of 85% compares favorably to reported 5-year survival rates of HIV-negative patients with HCC undergoing OLT of 75-80%.

Bordeaux, ISPED, Centre INSERM U1219-Bordeaux Population Health, Bordeaux, France, [6]INSERM, ISPED, Centre INSERM U1219- Bordeaux Population Health, Bordeaux, France, [7]CHU de Bordeaux, Pole de Sante Publique, Bordeaux, France, [8]Service de Médecine Interne, Hôpital Saint-André, Centre Hospitalier Universitaire de Bordeaux Université de Bordeaux, Bordeaux, France, [9]Hôpital Foch, Service de Médecine Interne, Suresnes, France, [10]Service des Maladies Infectieuses et Tropicales, AP-HP, Hôpital Bichat Claude Bernard, Paris, France, [11]Université Paris Descartes, Paris, France, [12]Service Maladies Infectieuses et Tropicales, AP-HP, Hôpital Cochin, Paris, France
Presenting author email: melinabtu@gmail.com

Background: Alcohol consumption has a strong dose-response relationship with advanced liver fibrosis in patients co-infected with HIV and hepatitis C virus (HCV). In recent years, coffee intake has been shown to modulate both the effect of ethanol on serum gamma-glutamyl transferase (GGT) activities in alcohol consumers and the risk of alcoholic cirrhosis in patients with chronic diseases. In the context of HIV-HCV co-infection, elevated coffee intake (≥ 3 cups/day) was found to be associated with reduced levels of liver enzymes and lower risk of insulin resistance. This study aimed to analyze whether elevated coffee intake modifies the effect of alcohol consumption on advanced liver fibrosis among co-infected patients.
Methods: We used clinical/biological (medical follow-up) and socio-behavioral data (annual self-administered questionnaires) collected during a five-year follow-up in the French national cohort ANRS CO13-HEPAVIH. Patients with decompensated cirrhosis or history of liver transplant were excluded from the analyses. Hazardous alcohol consumption was defined according to the standard AUDIT-C cut-off values (score ≥4 for men or ≥3 for women). Advanced liver fibrosis was defined at each visit as a FIB-4 value > 3.25. Mixed logistic regression models were used to analyze the interaction between elevated coffee intake (≥ 3 cups/day) and alcohol consumption and its effect on advanced liver fibrosis, after adjustment for statistically significant (p< 0.05) clinical (body mass index, CD4 T-cell count, HCV treatment and ART status) and socio-behavioral (chocolate consumption, employment status, having children) factors.
Results: A total of 1,019 patients, accounting for 2,566 visits, were included in the analyses. At first visit, 34.4% of patients reported hazardous alcohol consumption and 27.5% elevated coffee intake. In the multivariable analysis, elevated coffee consumption was significantly associated with lower risk of advanced liver fibrosis, irrespective of the level of alcohol consumption (AOR [95% CI]: 0.46[0.27; 0.77], p=0.0035 for non-hazardous drinking, 0.37[0.19; 0.74], p=0.0049 for hazardous drinking, ref= non-hazardous drinking and low coffee consumption).
Conclusions: Elevated coffee intake modulates the effect of alcohol consumption on liver fibrosis in HIV-HCV co-infected patients. This confirms the need to systematically take into account coffee intake in the evaluation of liver fibrosis progression in this population.

Drug related problems and polypharmacy are common among people living with HIV/AIDS

E. Kara[1], A.C. Inkaya[2], N. Ozdemir[1], K. Tecen[1], D. Aydin Hakli[3], A. Bayraktar-Ekincioglu[1], K. Demirkan[1], S. Unal[2]
[1]Hacettepe University Faculty of Pharmacy, Department of Clinical Pharmacy, Ankara, Turkey, [2]Hacettepe University Faculty of Medicine, Department of Infectious Disease, Ankara, Turkey, [3]Hacettepe University Faculty of Medicine, Department of Biostatistics, Ankara, Turkey
Presenting author email: sunal@hacettepe.edu.tr

Background: Although recent advances in antiretroviral therapy have led to simplified regimens resulting in reduced pill burden, polypharmacy still continues to be a challenge for people living with HIV/AIDS (PLWHA). Determination of DRPs may pave the way to properly manage drug related adverse effects in PLWHA and may in turn improve medical care and costs.
We conducted a study to investigate the incidence of DRPs and polypharmacy in a cohort of PLWHA under treatment.
Methods: A prospective study was performed between September 1, 2015 and September 1, 2016 at Hacettepe University Hospitals Infectious Diseases Outpatient Clinic after the ethical committee approval. Pharmaceutical Care Network Europe Foundation version 6.2 (PCNE V 6.2) classification system was used to classify DRPs, causes, interventions and results of interventions. Chi square, Mann Whitney U and logistic regression tests were used in statistical analysis.
Results: One hundred eighty-one patients were included to the study. The mean age of the study group was 40.4 and 26% were older than 50. Fifty-nine (32.6%) had at least one comorbid condition and 12 (6.6%) had three or more comorbidities. The prevalence of polypharmacy in patients with comorbidity was 66.1% whereas, 12.1% in patients without comorbidity (p< 0.005). DRPs were common in PLWHA receiving polypharmacy (38.9% vs 18.9%) (p< 0.005). Based on PCNE classification, the most common DRPs were ´effect of drug treatment not optimal´ (36.2%) and ´adverse drug event (non-allergic)´ (20.7%). Most common reasons for DRPs were inappropriate drug (20.7%), synergistic/preventive drug required and not given (17.2%), inappropriate combination of drugs, or drugs and food (13.8%) and drug not taken/administered at all (13.8%). DRPs were more prominent with advanced age (46 vs 37 years, p< 0.005), longer duration of antiretroviral therapy (45 vs 27 months, p=0.014), and lower education level (p=0.013). Patients receiving intensive ART (>3 ART drug) had more DRPs in the logistic regression model (OR:8.299, %95 CI: 1,924 - 35.803).
Conclusions: This study shows that DRPs are common PLWHA under treatment. Attending physicians should especially take into account DRPs in older and heavily treated patients. Multidisciplinary team including clinical pharmacists is needed to address DRPs in high risk patients.

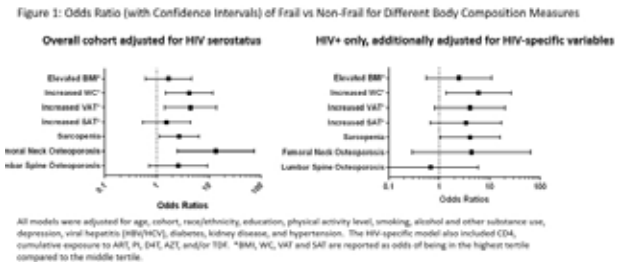
Abdominal obesity, sarcopenia, and osteoporosis are strongly associated with frailty in the MACS cohort

K.L. Hawkins[1], L. Zhang[2], D. Ng[2], K.N. Althoff[2], F.J. Palella[3], L.A. Kingsley[4], L.P. Jacobson[2], J.B. Margolick[2], J.E. Lake[5], T.T. Brown[6], K.M. Erlandson[1]
[1]University of Colorado, Aurora, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Northwestern University Feinberg School of Medicine, Chicago, United States, [4]University of Pittsburgh, Pittsburgh, United States, [5]University of Texas, Houston, United States, [6]Johns Hopkins School of Medicine, Baltimore, United States
Presenting author email: kellie.hawkins@ucdenver.edu

Background: Frailty is more prevalent in HIV-infected (HIV+) adults than in similar HIV-uninfected (HIV-) adults; concurrently, abnormalities in anatomic fat distribution, muscle function/mass, and bone mineral density (BMD) are common among HIV+.
However, the relationships between frailty and fat distribution, sarcopenia, and osteoporosis in older, HIV+ adults are poorly understood.
Methods: HIV+ and HIV- men (50-69 years) in the Multicenter AIDS Cohort Study Bone Strength Substudy were evaluated for frailty (Fried's phenotype) and body composition, including body mass index (BMI), waist circumference (WC), computed tomography-obtained abdominal visceral (VAT) and subcutaneous (SAT) fat volumes, and dual-energy X-ray absorptiometry-obtained appendicular skeletal muscle index (ASMI) and BMD (normal/osteopenia/osteoporosis). BMI, WC, VAT, and SAT were analyzed in tertiles. Baumgartner's definition of sarcopenia (ASMI ≤ 7.26 kg/m^2) was used. Multivariate multinomial logistic regression models determined associations of frailty with body composition.
Results: Of 399 (199 HIV+ and 200 HIV-) men, median age was 60.1 vs 60.0 years and frailty prevalence was 16.1% vs 8.0%, respectively. HIV serostatus was associated with a 2.43 higher odds of frailty (p=0.01). Overall, factors associated with increased odds of frailty included: higher WC, higher VAT, sarcopenia, and femoral neck osteoporosis (figure). In models restricted to HIV+ men and further adjusted for HIV-specific factors, similar trends were observed though some associations lost significance due to reduced sample size (figure). VAT and WC were positively correlated (r=0.63 overall, r=0.56 HIV+, both p<0.0001).



[Figure 1.]

Conclusions: Frailty in HIV+ and HIV- men was strongly associated with measures of visceral abdominal obesity and sarcopenia, but not with BMI or SAT. The association of frailty with WC and the correlations between WC and VAT suggests that, when VAT measurement is not available, WC may serve as surrogate for VAT. Measures to prevent or reverse central obesity and muscle loss may reduce the risk of frailty if these associations are causal.

Evolving disease burden at end of life among HIV-infected patients in the southeastern US, 1996-2015

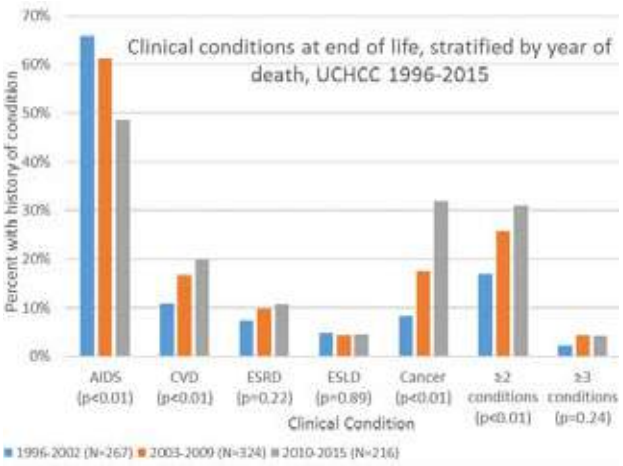
T. Davy-Méndez, J.J. Eron, O. Zakharova, A. Heine, C. Farel, S. Napravnik
University of North Carolina at Chapel Hill, Chapel Hill, United States
Presenting author email: tdavy@med.unc.edu

Background: Mortality rates among persons living with HIV (PLWH) have been decreasing. However, little is known about trends in disease burden among HIV-infected patients at the end of life.
Methods: We included patients in the UNC CFAR HIV Clinical Cohort (UCHCC) who died between 1996 and 2015 and had a clinic or laboratory visit < 2 years before death. Analyses were stratified by year of death (1996-2002, 2003-2009, 2010-2015) and patient demographic and clinical characteristics at end of life were contrasted across time using ANOVA and Cochrane-Armitage trend tests. Adjudicated conditions included history of: any AIDS-defining condition, stroke or myocardial infarction (cardiovascular disease, CVD), end-stage renal disease (ESRD), end-stage liver disease (ESLD), and any non-AIDS-defining cancer.
Results: Of 807 deceased patients, 28% were female, 29% men who have sex with men (MSM), and 70% African American (Table).

Characteristic	Total sample (N=807)	Death year 1996-2002 (N=267)	Death year 2003-2009 (N=324)	Death year 2010-2015 (N=216)	p-value
Female, N (%)	223 (28%)	73 (27%)	100 (31%)	58 (27%)	0.47
African American race, N (%)	568 (70%)	195 (73%)	229 (71%)	144 (67%)	0.13
MSM, N (%)	234 (29%)	65 (24%)	97 (30%)	72 (33%)	0.03
HIV RNA<400 copies/mL at death, N (%)	331 (41%)	61 (23%)	125 (39%)	145 (67%)	<0.01
Nadir CD4 count, median cells/mm3 (IQR)	39 (9, 148)	16 (9, 90)	38 (9, 139)	86 (23, 190)	<0.01
CD4 count at death, median cells/mm3 (IQR)	124 (24, 326)	36 (11, 166)	143 (25, 305)	264 (86, 536)	<0.01
Age at death, median years (IQR)	47 (40, 54)	43 (38, 50)	47 (40, 52)	52 (45, 58)	<0.01
Time on ART, median years (IQR)	7 (3, 11)	4 (2, 6)	8 (4, 11)	11 (6, 16)	<0.01

[Clinical and demog. characteristics at end of life]

Most patients (94%) were ART experienced, with median 7 years of ART use (IQR 3, 11). The proportion of MSM and virally suppressed patients increased over time, as did nadir CD4, proximal CD4, age, and ART duration (all p<0.05). Prevalence of AIDS decreased (66 to 49%), while CVD and cancer increased (11 to 20%, and 8 to 32%, respectively) (Figure, all p<0.01). Having 2 or more conditions was also more common in more recent years (from 17 to 31%, p<0.01).



[Clinical conditions at end of life, by death year]

Conclusions: The burden of clinical AIDS at end of life decreased over the study period, while CVD, cancer, and multiple morbidity increased. These findings underscore the need for routine health screening in PLWH.

Presenting author email: mhentzien@chu-reims.fr

Background: As HIV population is ageing, there is growing interest for specific prognostic tools in aged people living with HIV (PLHIV). The objective was to develop a multivariable prognostic index for 5-years overall mortality integrating classical HIV biomarkers and comorbidities in PLHIV aged 60 or older.
Methods: It was a prospective multicenter cohort study in the Dat'AIDS cohort that involves 12 French hospitals. All HIV-1 infected patients aged 60 years or more actively followed on 1st January 2008 were included. Sociodemographic data, CD4 cell count, CD4 nadir, HIV viral load, history of comorbidities, hepatitis co-infections and laboratory parameters at baseline were considered as potential prognostic variables. The outcome was five-years all-causes mortality. A multivariable Cox model was constructed and a mortality index was derived.
Results: A total of 1415 patients were included. Most patients were male (77.2%) and mean age was 65.7±5.5 years. During the five years of follow-up (6225 patient-years), 154 (10.9%) patients died. Main comorbidities were decreased eGFR (21.1%), diabetes (14.2%), and cardiovascular diseases (12.2%). We derived a score comprising the following predictors: Age (65 - 74: 1 point; ≥75: 8 points), CD4 cell count (200 - 349: 3 points; < 200: 6 points), non-HIV related cancer (6 points), cardiovascular disease (8 points), estimated glomerular filtration rate (30-59 ml/mn/1.73m^2: 5 points; < 30ml/mn/1.73m^2: 16 points), cirrhosis (13 points), low body mass index (10 points), anemia (6 points). Observed score was 7.0 ± 8.0 and ranged from 0 to 45. It allowed to define 4 risks groups for mortality: low risk (0-3 points), moderate risk(4-13 points), high risk (14-19 points) and very high risk (>19 points; 5-year survival probability 0.95 (95%CI [0.93 - 0.97]), 0.90 (95%CI [0.87 - 0.92]), 0.77 (95%CI [0.68 - 0.84]) and 0.54 (95%CI [0.43 - 0.63]) respectively). That score showed good discrimination (c-statistic=0.76) and calibration.
Conclusions: We propose a multivariable prognostic score for mortality among PLHIV aged 60 or over, that will be a predominant population in the future years in western populations. It would be a useful tool for research and for risk assessment by the clinician. External validation is required.

Slowing the premature aging process: the benefits of viral control and smoking cessation on leukocyte telomere length (LTL)

A.Y.Y. Hsieh[1,2], C. Van Ommen[3], E. Kimmel[2], M.C.M. Murray[4,5,6], N. Pick[4,5,6], A. Alimenti[7,8], J. Brophy[9], F. Kakkar[10], A. Bitnun[11], H.C.F. Côté[1,2,5], and the CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA)

[1]University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada, [2]Centre for Blood Research, Vancouver, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada, [4]Oak Tree Clinic, BC Women's Hospital, Vancouver, Canada, [5]Women's Health Research Institute, Vancouver, Canada, [6]University of British Columbia, Department of Medicine, Division of Infectious Disease, Vancouver, Canada, [7]Children's and Women's Health Centre of BC, Vancouver, Canada, [8]University of British Columbia, Department of Pediatrics, Vancouver, Canada, [9]University of Ottawa, Department of Pediatrics, Children's Hospital of Eastern Ontario, Ottawa, Canada, [10]Université de Montréal, Department of Pediatrics, Centre Hospitalier Universitaire Sainte-Justine, Montréal, Canada, [11]University of Toronto, Department of Pediatrics, Hospital for Sick Children, Toronto, Canada
Presenting author email: helene.cote@ubc.ca

Background: Telomeres shorten over lifespan, and shorter leukocyte telomere length (LTL) is a marker of cellular aging associated with age-related physical morbidities, cognitive aging, and mortality. HIV infection and smoking are both associated with LTL cross-sectionally, but their influence on LTL over time is unclear. This study investigated the relative contribution of HIV and smoking on LTL dynamics in people living with HIV.
Methods: All non-pregnant girls and women ≥12 years old enrolled in the CARMA cohort with available blood specimens were included. For those with >1 sampling ≥1 year apart, the latest specimens were included in longitudinal sub-analyses. LTL was measured by multiplex qPCR. Possible predictors including age, ethnicity, smoking (current, past, never), HIV/viral load (VL) status (HIV-, HIV+/detectable VL, HIV+/undetectable VL), peak VL, and Hepatitis C virus status were considered for inclusion in multivariable models.
Results: LTL was obtained for 287 HIV+ and 211 HIV- participants aged 12-78 years, including 199 HIV+ and 49 HIV- with two specimens 1.0-7.9 years apart. In a cross-sectional multivariable regression, shorter LTL was associated with older age (ß=-0.35, p< 0.0001), current smoking (ß=-0.18, p=0.001) vs. never, and HIV+/detectable VL (ß=-0.13, p=0.004), but not HIV+/undetectable VL (ß=-0.06, p=0.17) vs. HIV-, after adjusting for ethnicity (n=450, R^2=0.25). These results persisted in sensitivity analyses that either excluded ethnicity, restricted ethnicity to the largest group, or restricted age to ≥16 for consideration of smoking status. Longitudinally, LTL attrition rates were greater with current smoking (ß=-0.20, p=0.004) vs. never, but not associated with baseline HIV/VL status, after adjusting for baseline LTL (n=246, R^2=0.11). HIV+ participants with detectable VL who became undetectable at follow-up were more likely to show an increase in LTL and vice-versa (n=57, Fisher's exact test, p=0.043).
Conclusions: These analyses highlight the negative impact of current smoking on LTL, with an effect size larger than even uncontrolled HIV infection. These data suggest that LTL is better preserved in controlled HIV, and stress the importance of smoking cessation and controlling viremia to curb cellular aging.

WEPEB0530

Mutlimorbidity prevalence in South Brazilian HIV cohort (SoBrHIV) and comparison with non-HIV controls: a cross-sectional study

R. Aguiar[1], H. Kluck[2], E. Sprinz[3]

[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]School of Medicine - Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [3]Hospital de Clinicas de Porto Alegre - Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil
Presenting author email: eduardo.sprinz@gmail.com

Background: HIV has become a chronic disease with the use of cART, and life expectancy is quite similar to general population. However, as HIV population ages, non-AIDS related comorbidities are increasingly being reported, which directly interferes with the clinical management of the patient and further enhances morbimortality. The objective of our study was to describe disease burden in a South Brazilian HIV cohort (SoBrHIV) and compare with general population.
Methods: In a cross sectional study, HIV patients (n=78) over 50 years of age and a control group matched by age, race and sex were randomly selected at the Hospital de Clínicas de Porto Alegre Outpatient clinic, in a ratio of 1:1. Prevalence of multimorbidity (defined as the presence of at least 2 non-AIDS related comorbidities)

and individual non-infectious comorbidities were compared using chi-square test. The mean number of chronic diseases was compared using t student or non-parametrical tests. The study was approved by local ethical committee.
Results: The groups were comparable, median age was 57 years, 75% were from Caucasian ethnicity and 57% were men. Prevalence of renal, bone and hepatic disease, as well as multimorbidity, was higher in the HIV group. (Table 1).

	HIV	Non-HIV	p value
Osteopenia/osteoporosis	51.3%	10.4%	0.0001
Hypertension	66.7%	75.3%	0.235
Diabetes Mellitus	24.4%	27.3%	0.679
Cardiovascular disease	8,9%	12,7%	0.4
Renal disease	17.9%	9.1%	0.107
Hepatic disease	17.9%	6.5%	0.03
Lipid abnormalities	85.9%	81.6%	0.467
Multimorbidity (presence of at least 2 non-AIDS comorbidities)	85.9%	76.6%	0.139

[Prevalence of non-AIDS comorbidities]

The mean number of comorbidities was also higher, even when comparing with individuals about 10 years older in the control group. (table 2)

Mean nº of comorbidities	HIV	Non-HIV	p value
Total	2.88	2.31	0.003
51-55 years	2.81	1.84	0.001
56-60 years	2.83	2.62	0.601
61-65 years	2.76	2.44	0.426
>65 years	3.36	3.00	0.369

[Mean number of comorbidities across ages]

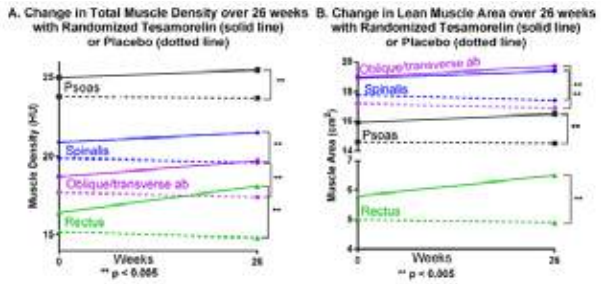
Conclusions: This is the first time that a high level of comorbidities is shown in a low/middle income country. Moreover, multimorbidity occurred more often and at younger ages in HIV patients. These initial results are extremely important. They imply that the world will need to build up a more comprehensive care of HIV individuals in order to better deal with their ageing.

WEPEB0531

The growth hormone releasing hormone analogue, tesamorelin, decreases muscle fat and increases muscle area in HIV-infected adults

K. Erlandson[1], S. Adrian[1], A. Scherzinger[1], A. Sanyal[2], J. Lake[3], J. Falutz[4], M. Dubé[5], T. Stanley[6,7], S. Grinspoon[6,7], J.-C. Mamputu[8], C. Marsolais[8], T. Brown[2]
[1]University of Colorado, Aurora, United States, [2]Johns Hopkins University, Baltimore, United States, [3]University of Texas Health Sciences Center, Houston, United States, [4]McGill University, Montreal, Canada, [5]University of Southern California, Keck School of Medicine, Los Angeles, United States, [6]Massachusetts General Hospital, Boston, United States, [7]Harvard Medical School, Boston, United States, [8]Theratechnologies, Montreal, Canada
Presenting author email: kristine.erlandson@ucdenver.edu

Background: HIV-infected adults have faster physical function decline with aging and a greater amount of muscle fat compared to HIV-uninfected controls. Muscle fat correlates with visceral adipose tissue (VAT) quantity, and is associated with physical function impairment and falls in older populations. Tesamorelin, a growth hormone-releasing hormone analogue, is effective in decreasing VAT in some HIV-infected patients. We hypothesized that tesamorelin would also decrease skeletal muscle fat.
Methods: Participants were selected from two completed, randomized (2:1) trials of tesamorelin vs placebo for the treatment of excess abdominal fat in HIV-infected patients with lipodystrophy. In tesamorelin responders (defined as VAT decrease of ≥8% and observed in ~70% receiving tesamorelin), and participants in the placebo arm, abdominal (L4-5) computed tomography scans at week 0 and 26 were re-analyzed. Between arm differences were compared for trunk muscle density and area (both total muscle and lean component [excluded intermuscular fat with < 30 Hounsfield units]).
Results: Of 193 tesamorelin responders and 148 persons randomized to placebo, participants were mostly male (87%) and Caucasian (83%). Groups were not significantly different (p>0.10) at baseline in regards to sex, race/ethnicity, age, body mass index, use of lipid-lowering therapy, testosterone use, CD4 T-cell count or HIV-1 viral load, ART regimen, or time since HIV diagnosis. Tesamorelin was associated with significantly greater improvements in total muscle density (less fat), and lean muscle area of the trunk muscle after 26 weeks compared to placebo (Figure; p<0.005). Lean muscle density of the oblique/transverse abdominal and rectus, and total psoas muscle area also increased significantly more in the tesamorelin vs placebo arm (p<0.005).



[Figure]

Conclusions: In HIV-infected adults with excess abdominal fat who have a clinical response to tesamorelin, trunk muscle fat decreased and lean muscle area increased over 26 weeks. The impact of these changes on physical function and long-term durability should be investigated.

Impact of the method of measurement (Southern Blot vs qPCR) in the analysis of factors associated with telomere length in HIV-infected patients

R. Montejano[1], N. Stella Ascariz[2], S. Monge[3], J.I. Bernardino[1], I. Pérez-Valero[1], M. Montes[1], J. Mingorance[2], L. Pintado-Berninches[4], R. Perona[4], J.R. Arribas[1]
[1]Hospital Universitario La Paz-IdiPAZ, HIV Unit, Internal Medicine Service, Madrid, Spain, [2]Hospital Universitario La Paz-IdiPAZ, Microbiology Service, Madrid, Spain, [3]Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]Instituto de Investigaciones Biomédicas CSIC/UAM, IdiPAZ, Biomarkers and new Therapies and CIBER de Enfermedades Raras (CIBERER), Madrid, Spain
Presenting author email: rocio.montejano@idipaz.es

Background: Southern blot has been traditionally used to asses telomere length (TL). Because its complexity, qPCR is used as an alternative (Cawthon RM.2009, Elbers CC et al.2014). We have compared both methods in the study of factors associated to TL in HIV-infected patients.
Methods: Cross-sectional study of HIV-infected patients with suppressed virological replication (HIV RNA < 50 copies/mL for ≥1 year). TL was measured in peripheral blood mononuclear cells using qPCR and Southern. Relative TL was determined by qPCR and run each sample in triplicate. Southern was done using TeloTAGGG™ TL Assay. TeloTool (Gohring J.2014) was used to process Southern images. Multivariate generalized linear models with Gaussian family and log link were used to identify variables independently associated with TL.
